'3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:26-57
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:21-22:25-57
1 row in set (0.01 sec)
    
```

- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set [, timeout] [, channel])`

Wait until the slave SQL thread has executed all of the transactions whose global transaction identifiers are contained in *gtid\_set* (see [Section 17.1.3.1, “GTID Concepts”](#), for a definition of “GTID sets”), or until *timeout* seconds have elapsed, whichever occurs first. *timeout* is optional; the default timeout is 0 seconds, in which case the function waits until all of the transactions in the GTID set have been executed.

For more information, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

```

mysql> SELECT WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
-> 5
    
```

The return value is the number of transactional events that were executed. If GTID-based replication is not active (that is, if the value of the `gtid_mode` variable is `OFF`), then this value is undefined and thus `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` returns `NULL`. If the slave is not running then this function also returns `NULL`.

The `channel` option, added in MySQL 5.7.6, enables you to choose which replication channel the function applies to. If no `channel` is set and no channels other than the default replication channel exist, the function applies to the default replication channel as found in versions of MySQL prior to 5.7.6. If you are using multiple replication channels you must specify a `channel` as otherwise it is not known which replication channel the function should act on. See [Section 17.2.3, “Replication Channels”](#) for more information on replication channels.

- `WAIT_FOR_EXECUTED_GTID_SET(gtid_set[, timeout])`

Introduced in MySQL 5.7.5, `WAIT_FOR_EXECUTED_GTID_SET()` is similar to `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` in that it waits until a server has executed all of the transactions whose global transaction identifiers are contained in `gtid_set`, or until `timeout` seconds have elapsed, whichever occurs first. Unlike `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`, `WAIT_FOR_EXECUTED_GTID_SET()` does not take into account whether the slave is running or not, and an error is returned if GTID-based replication is not enabled.

In addition, `WAIT_FOR_EXECUTED_GTID_SET()` returns only the state of the query, where 0 represents success, 1 represents timeout, and any other failures return the error message.

## 12.18 MySQL Enterprise Encryption Functions

### Note

MySQL Enterprise Encryption is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <http://www.mysql.com/products/>.

As of MySQL 5.7.9, MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

Enterprise Encryption supports the RSA, DSA, and DH cryptographic algorithms.

Enterprise Encryption is supplied as a user-defined function (UDF) library, from which individual functions can be installed individually.

### 12.18.1 Enterprise Encryption Installation

Enterprise Encryption functions are located in a user-defined function (UDF) library file installed in the plugin directory (the directory named by the `plugin_dir` system variable). The UDF library base name is `openssl_udf` and the suffix is platform dependent. For example, the file name on Linux or Windows is `openssl_udf.so` or `openssl_udf.dll`, respectively.

To install functions from the library file, use the `CREATE FUNCTION` statement. To load all functions from the library, use this set of statements (adjust the file name suffix as necessary):

```
CREATE FUNCTION asymmetric_decrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_derive RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_encrypt RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_sign RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION asymmetric_verify RETURNS INTEGER
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_priv_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_asymmetric_pub_key RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_dh_parameters RETURNS STRING
  SONAME 'openssl_udf.so';
CREATE FUNCTION create_digest RETURNS STRING
  SONAME 'openssl_udf.so';
```

Once installed, UDFs remain installed across server restarts. To unload UDFs, use the [DROP FUNCTION](#) statement. For example, to unload the key-generation functions, do this:

```
DROP FUNCTION create_asymmetric_priv_key;
DROP FUNCTION create_asymmetric_pub_key;
```

In the [CREATE FUNCTION](#) and [DROP FUNCTION](#) statements, the function names must be specified in lowercase. This differs from their use at function invocation time, for which you can use any lettercase.

The [CREATE FUNCTION](#) and [DROP FUNCTION](#) statements require the [INSERT](#) and [DROP](#) privilege, respectively, for the `mysql` database.

## 12.18.2 Enterprise Encryption Usage and Examples

To use Enterprise Encryption in applications, invoke the functions that are appropriate for the operations you wish to perform. This section demonstrates how to carry out some representative tasks.

**Task:** Create a private/public key pair using RSA encryption.

```
-- Encryption algorithm; can be 'DSA' or 'DH' instead
SET @algo = 'RSA';
-- Minimum key length in bits; make larger for stronger keys
SET @key_len = 1024;

-- Create private key
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY(@algo, @key_len);
-- Derive corresponding public key from private key, using same algorithm
SET @pub = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv);
```

Now you can use the key pair to encrypt and decrypt data, sign and verify data, or generate symmetric keys.

**Task:** Use the private key to encrypt data and the public key to decrypt it. This requires that the members of the key pair be RSA keys.

```
SET @ciphertext = ASYMMETRIC_ENCRYPT(@algo, 'My secret text', @priv);
SET @cleartext = ASYMMETRIC_DECRYPT(@algo, @ciphertext, @pub);
```

Conversely, you can encrypt using the public key and decrypt using the private key.

```
SET @ciphertext = ASYMMETRIC_ENCRYPT(@algo, 'My secret text', @pub);
SET @cleartext = ASYMMETRIC_DECRYPT(@algo, @ciphertext, @priv);
```

In either case, the algorithm specified for the encryption and decryption functions must match that used to generate the keys.

Task: Generate a digest from a string.

```
-- Digest type; can be 'SHA256', 'SHA384', or 'SHA512' instead
SET @dig_type = 'SHA224';

-- Generate digest string
SET @dig = CREATE_DIGEST(@dig_type, 'My text to digest');
```

Task: Use the digest with a key pair to sign data, then verify that the signature matches the digest.

```
-- Encryption algorithm; could be 'DSA' instead; keys must
-- have been created using same algorithm
SET @algo = 'RSA';

-- Generate signature for digest and verify signature against digest
SET @sig = ASYMMETRIC_SIGN(@algo, @dig, @priv, @dig_type);
-- Verify signature against digest
SET @verf = ASYMMETRIC_VERIFY(@algo, @dig, @sig, @pub, @dig_type);
```

Task: Create a symmetric key. This requires DH private/public keys as inputs, created using a shared symmetric secret. Create the secret by passing the key length to `CREATE_DH_PARAMETERS()`, then pass the secret as the “key length” to `CREATE_ASYMMETRIC_PRIV_KEY()`.

```
-- Generate DH shared symmetric secret
SET @dhp = CREATE_DH_PARAMETERS(1024);
-- Generate DH key pairs
SET @algo = 'DH';
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY(@algo, @dhp);
SET @pub1 = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv1);
SET @priv2 = CREATE_ASYMMETRIC_PRIV_KEY(@algo, @dhp);
SET @pub2 = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv2);

-- Generate symmetric key using public key of first party,
-- private key of second party
SET @sym1 = ASYMMETRIC_DERIVE(@pub1, @priv2);

-- Or use public key of second party, private key of first party
SET @sym2 = ASYMMETRIC_DERIVE(@pub2, @priv1);
```

Key string values can be created at runtime and stored into a variable or table using `SET`, `SELECT`, or `INSERT`:

```
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024);
SELECT CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024) INTO @priv2;
INSERT INTO t (key_col) VALUES(CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024));
```

Key string values stored in files can be read using the `LOAD_FILE()` function by users who have the `FILE` privilege.

Digest and signature strings can be handled similarly.

## 12.18.3 Enterprise Encryption Function Reference

Table 12.23 MySQL Enterprise Encryption Functions

Name	Description
<code>ASYMMETRIC_DECRYPT()</code>	Decrypt ciphertext using private or public key
<code>ASYMMETRIC_DERIVE()</code>	Derive symmetric key from asymmetric keys
<code>ASYMMETRIC_ENCRYPT()</code>	Encrypt cleartext using private or public key
<code>ASYMMETRIC_SIGN()</code>	Generate signature from digest
<code>ASYMMETRIC_VERIFY()</code>	Verify that signature matches digest

Name	Description
<code>CREATE_ASYMMETRIC_PRIV_KEY()</code>	Create private key
<code>CREATE_ASYMMETRIC_PUB_KEY()</code>	Create public key
<code>CREATE_DH_PARAMETERS()</code>	Generate shared DH secret
<code>CREATE_DIGEST()</code>	Generate digest from string

## 12.18.4 Enterprise Encryption Function Descriptions

Enterprise Encryption functions have these general characteristics:

- For arguments of the wrong type or an incorrect number of arguments, each function returns an error.
- If the arguments are not suitable to permit a function to perform the requested operation, it returns `NULL` or 0 as appropriate. This occurs, for example, if a function does not support a specified algorithm, a key length is too short or long, or a string expected to be a key string in PEM format is not a valid key.
- The underlying SSL library takes care of randomness initialization.

Several of the functions take an encryption algorithm argument. The following table summarizes the supported algorithms by function.

**Table 12.24 Supported Algorithms by Function**

Function	Supported Algorithms
<code>ASYMMETRIC_DECRYPT()</code>	RSA
<code>ASYMMETRIC_DERIVE()</code>	DH
<code>ASYMMETRIC_ENCRYPT()</code>	RSA
<code>ASYMMETRIC_SIGN()</code>	RSA, DSA
<code>ASYMMETRIC_VERIFY()</code>	RSA, DSA
<code>CREATE_ASYMMETRIC_PRIV_KEY()</code>	RSA, DSA, DH
<code>CREATE_ASYMMETRIC_PUB_KEY()</code>	RSA, DSA, DH

### Note

Although you can create keys using any of the RSA, DSA, or DH encryption algorithms, other functions that take key arguments might accept only certain types of keys. For example, `ASYMMETRIC_ENCRYPT()` and `ASYMMETRIC_DECRYPT()` accept only RSA keys.

The following descriptions describe the calling sequences for Enterprise Encryption functions. For additional examples and discussion, see [Section 12.18.2, “Enterprise Encryption Usage and Examples”](#).

- `ASYMMETRIC_DECRYPT(algorithm, crypt_str, key_str)`

Decrypts an encrypted string using the given algorithm and key string, and returns the resulting cleartext as a binary string. If decryption fails, the result is `NULL`.

*key\_str* must be a valid key string in PEM format. For successful decryption, it must be the public or private key string corresponding to the private or public key string used with `ASYMMETRIC_ENCRYPT()` to produce the encrypted string. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA'

For a usage example, see the description of `ASYMMETRIC_ENCRYPT()`.

- `ASYMMETRIC_DERIVE(pub_key_str, priv_key_str)`

Derives a symmetric key using the private key of one party and the public key of another, and returns the resulting key as a binary string. If key derivation fails, the result is `NULL`.

`pub_key_str` and `priv_key_str` must be valid key strings in PEM format. They must be created using the DH algorithm.

Suppose that you have two pairs of public and private keys:

```
SET @dhp = CREATE_DH_PARAMETERS(1024);
SET @priv1 = CREATE_ASYMMETRIC_PRIV_KEY('DH', @dhp);
SET @pub1 = CREATE_ASYMMETRIC_PUB_KEY('DH', @priv1);
SET @priv2 = CREATE_ASYMMETRIC_PRIV_KEY('DH', @dhp);
SET @pub2 = CREATE_ASYMMETRIC_PUB_KEY('DH', @priv2);
```

Suppose further that you use the private key from one pair and the public key from the other pair to create a symmetric key string. Then this symmetric key identity relationship holds:

```
ASYMMETRIC_DERIVE(@pub1, @priv2) = ASYMMETRIC_DERIVE(@pub2, @priv1)
```

- `ASYMMETRIC_ENCRYPT(algorithm, str, key_str)`

Encrypts a string using the given algorithm and key string, and returns the resulting ciphertext as a binary string. If encryption fails, the result is `NULL`.

The `str` length cannot be greater than the `key_str` length – 11, in bytes

`key_str` must be a valid key string in PEM format. `algorithm` indicates the encryption algorithm used to create the key.

Supported `algorithm` values: `'RSA'`

To encrypt a string, pass a private or public key string to `ASYMMETRIC_ENCRYPT()`. To recover the original unencrypted string, pass the encrypted string to `ASYMMETRIC_DECRYPT()`, along with the public or private key string corresponding to the private or public key string used for encryption.

```
-- Generate private/public key pair
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY('RSA', 1024);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY('RSA', @priv);

-- Encrypt using private key, decrypt using public key
SET @ciphertext = ASYMMETRIC_ENCRYPT('RSA', 'The quick brown fox', @priv);
SET @cleartext = ASYMMETRIC_DECRYPT('RSA', @ciphertext, @pub);

-- Encrypt using public key, decrypt using private key
SET @ciphertext = ASYMMETRIC_ENCRYPT('RSA', 'The quick brown fox', @pub);
SET @cleartext = ASYMMETRIC_DECRYPT('RSA', @ciphertext, @priv);
```

Suppose that:

```
SET @s = a string to be encrypted
SET @priv = a valid private RSA key string in PEM format
SET @pub = the corresponding public RSA key string in PEM format
```

Then these identity relationships hold:

```
ASYMMETRIC_DECRYPT('RSA', ASYMMETRIC_ENCRYPT('RSA', @s, @priv), @pub) = @s
ASYMMETRIC_DECRYPT('RSA', ASYMMETRIC_ENCRYPT('RSA', @s, @pub), @priv) = @s
```

- `ASYMMETRIC_SIGN(algorithm, digest_str, priv_key_str, digest_type)`

Signs a digest string using a private key string, and returns the signature as a binary string. If signing fails, the result is `NULL`.

`digest_str` is the digest string. It can be generated by calling `CREATE_DIGEST()`. `digest_type` indicates the digest algorithm used to generate the digest string.

`priv_key_str` is the private key string to use for signing the digest string. It must be a valid key string in PEM format. `algorithm` indicates the encryption algorithm used to create the key.

Supported `algorithm` values: 'RSA', 'DSA'

Supported `digest_type` values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

For a usage example, see the description of `ASYMMETRIC_VERIFY()`.

- `ASYMMETRIC_VERIFY(algorithm, digest_str, sig_str, pub_key_str, digest_type)`

Verifies whether the signature string matches the digest string, and returns 1 or 0 to indicate whether verification succeeded or failed.

`digest_str` is the digest string. It can be generated by calling `CREATE_DIGEST()`. `digest_type` indicates the digest algorithm used to generate the digest string.

`sig_str` is the signature string. It can be generated by calling `ASYMMETRIC_SIGN()`.

`pub_key_str` is the public key string of the signer. It corresponds to the private key passed to `ASYMMETRIC_SIGN()` to generate the signature string and must be a valid key string in PEM format. `algorithm` indicates the encryption algorithm used to create the key.

Supported `algorithm` values: 'RSA', 'DSA'

Supported `digest_type` values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```
-- Set the encryption algorithm and digest type
SET @algo = 'RSA';
SET @dig_type = 'SHA224';

-- Create private/public key pair
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY(@algo, 1024);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY(@algo, @priv);

-- Generate digest from string
SET @dig = CREATE_DIGEST(@dig_type, 'The quick brown fox');

-- Generate signature for digest and verify signature against digest
SET @sig = ASYMMETRIC_SIGN(@algo, @dig, @priv, @dig_type);
SET @verf = ASYMMETRIC_VERIFY(@algo, @dig, @sig, @pub, @dig_type);
```

- `CREATE_ASYMMETRIC_PRIV_KEY(algorithm, {key_len|dh_secret})`

Creates a private key using the given algorithm and key length or DH secret, and returns the key as a binary string in PEM format. If key generation fails, the result is `NULL`.

Supported `algorithm` values: 'RSA', 'DSA', 'DH'

Supported `key_len` values: The minimum key length in bits is 1024. The maximum key length depends on the algorithm: 16,384 for RSA and 10,000 for DSA. These lengths are constraints imposed by OpenSSL.

For DH keys, pass a shared DH secret instead of a key length. To create the secret, pass the key length to `CREATE_DH_PARAMETERS()`.

This example creates a 2,048-bit DSA private key, then derives a public key from the private key:

```
SET @priv = CREATE_ASYMMETRIC_PRIV_KEY('DSA', 2048);
SET @pub = CREATE_ASYMMETRIC_PUB_KEY('DSA', @priv);
```

For an example showing DH key generation, see the description of `ASYMMETRIC_DERIVE()`.

Some general considerations in choosing key lengths and encryption algorithms:

- The strength of encryption for private and public keys increases with the key size, but the time for key generation increases as well.
- Generation of DH keys takes much longer than RSA or RSA keys.
- Asymmetric encryption functions are slower than symmetric functions. If performance is an important factor and the functions are to be used very frequently, you are better off using symmetric encryption. For example, consider using `AES_ENCRYPT()` and `AES_DECRYPT()`.
- `CREATE_ASYMMETRIC_PUB_KEY(algorithm, priv_key_str)`

Derives a public key from the given private key using the given algorithm, and returns the key as a binary string in PEM format. If key derivation fails, the result is `NULL`.

*priv\_key\_str* must be a valid key string in PEM format. *algorithm* indicates the encryption algorithm used to create the key.

Supported *algorithm* values: 'RSA', 'DSA', 'DH'

For a usage example, see the description of `CREATE_ASYMMETRIC_PRIV_KEY()`.

- `CREATE_DH_PARAMETERS(key_len)`

Creates a shared secret for generating a DH private/public key pair and returns a binary string that can be passed to `CREATE_ASYMMETRIC_PRIV_KEY()`. If secret generation fails, the result is null.

Supported *key\_len* values: The minimum and maximum key lengths in bits are 1024 and 10,000. These lengths are constraints imposed by OpenSSL.

For an example showing how to use the return value for generating symmetric keys, see the description of `ASYMMETRIC_DERIVE()`.

```
SET @dhp = CREATE_DH_PARAMETERS(1024);
```

- `CREATE_DIGEST(digest_type, str)`

Creates a digest from the given string using the given digest type, and returns the digest as a binary string. If digest generation fails, the result is `NULL`.

Supported *digest\_type* values: 'SHA224', 'SHA256', 'SHA384', 'SHA512'

```
SET @dig = CREATE_DIGEST('SHA512', 'The quick brown fox');
```

The resulting digest string is suitable for use with `ASYMMETRIC_SIGN()` and `ASYMMETRIC_VERIFY()`.

## 12.19 Miscellaneous Functions

**Table 12.25 Miscellaneous Functions**

Name	Description
<code>ANY_VALUE()</code>	Suppress <code>ONLY_FULL_GROUP_BY</code> value rejection
<code>DEFAULT()</code>	Return the default value for a table column
<code>GET_LOCK()</code>	Get a named lock
<code>INET_ATON()</code>	Return the numeric value of an IP address
<code>INET_NTOA()</code>	Return the IP address from a numeric value
<code>INET6_ATON()</code>	Return the numeric value of an IPv6 address
<code>INET6_NTOA()</code>	Return the IPv6 address from a numeric value
<code>IS_FREE_LOCK()</code>	Checks whether the named lock is free
<code>IS_IPV4_COMPAT()</code>	Return true if argument is an IPv4-compatible address
<code>IS_IPV4_MAPPED()</code>	Return true if argument is an IPv4-mapped address
<code>IS_IPV4()</code>	Return true if argument is an IPv4 address
<code>IS_IPV6()</code>	Return true if argument is an IPv6 address
<code>IS_USED_LOCK()</code>	Checks whether the named lock is in use. Return connection identifier if true.
<code>MASTER_POS_WAIT()</code>	Block until the slave has read and applied all updates up to the specified position
<code>NAME_CONST()</code>	Causes the column to have the given name
<code>RAND()</code>	Return a random floating-point value
<code>RELEASE_ALL_LOCKS()</code>	Releases all current named locks
<code>RELEASE_LOCK()</code>	Releases the named lock
<code>SLEEP()</code>	Sleep for a number of seconds
<code>UUID_SHORT()</code>	Return an integer-valued universal identifier
<code>UUID()</code>	Return a Universal Unique Identifier (UUID)
<code>VALUES()</code>	Defines the values to be used during an INSERT

- `ANY_VALUE(arg)`

This function is useful for `GROUP BY` queries when the `ONLY_FULL_GROUP_BY` SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the `ONLY_FULL_GROUP_BY` SQL mode.

For example, if `name` is a nonindexed column, the following query fails with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP
BY clause and contains nonaggregated column 'mydb.t.address' which
is not functionally dependent on columns in GROUP BY clause; this
is incompatible with sql_mode=only_full_group_by
```

The failure occurs because `address` is a nonaggregated column that is neither named among `GROUP BY` columns nor functionally dependent on them. As a result, the `address` value for rows within each `name` group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

- Alter the table to make `name` a primary key or a unique `NOT NULL` column. This enables MySQL to determine that `address` is functionally dependent on `name`; that is, `address` is uniquely determined by `name`. (This technique is inapplicable if `NULL` must be permitted as a valid `name` value.)
- Use `ANY_VALUE()` to refer to `address`:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. `ANY_VALUE()` is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.

- Disable `ONLY_FULL_GROUP_BY`. This is equivalent to using `ANY_VALUE()` with `ONLY_FULL_GROUP_BY` enabled, as described in the previous item.

`ANY_VALUE()` is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with `ONLY_FULL_GROUP_BY` enabled:

```
SELECT age FROM t GROUP BY age-1;
```

To cause MySQL to accept the query, use `ANY_VALUE()`:

```
SELECT ANY_VALUE(age) FROM t GROUP BY age-1;
```

`ANY_VALUE()` can be used for queries that refer to aggregate functions in the absence of a `GROUP BY` clause:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'mydb.t.name'; this
is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is indeterminate which `name` value to choose for the group. `ANY_VALUE()` tells MySQL to accept the query:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a `GROUP BY` column. For example, an application may enforce uniqueness of one column with respect to another. In this case, using `ANY_VALUE()` for the effectively functionally dependent column may make sense.

For additional discussion, see [Section 12.20.3, “MySQL Handling of GROUP BY”](#).

- `DEFAULT(col_name)`

Returns the default value for a table column. An error results if the column has no default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- `FORMAT(X,D)`

Formats the number *x* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 12.5, “String Functions”](#).

- `GET_LOCK(str,timeout)`

Tries to obtain a lock with a name given by the string *str*, using a timeout of *timeout* seconds. A negative *timeout* value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

Returns `1` if the lock was obtained successfully, `0` if the attempt timed out (for example, because another client has previously locked the name), or `NULL` if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Lock release may also occur with another call to `GET_LOCK()`:

- Before 5.7.5, only a single simultaneous lock can be acquired and `GET_LOCK()` releases any existing lock.
- In MySQL 5.7.5, `GET_LOCK()` was reimplemented using the metadata locking (MDL) subsystem and its capabilities were extended. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks. It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

As a result of the MDL reimplementation, locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER_LEVEL_LOCK` and the `OBJECT_NAME` column indicates the lock name. Also, the capability of acquiring multiple locks introduces the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

The difference in lock acquisition behavior as of MySQL 5.7.5 can be seen by the following example. Suppose that you execute these statements:

```
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

In MySQL 5.7.5 or later, the second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return `1` (success). Before MySQL 5.7.5, the second `GET_LOCK()` releases the first lock ('lock1') and the second `RELEASE_LOCK()` returns `NULL` (failure) because there is no 'lock1' to release.

MySQL 5.7.5 and later enforces a maximum length on lock names of 64 characters. Previously, no limit was enforced.

Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined. Applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

### Caution

With the capability of acquiring multiple named locks in MySQL 5.7.5, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure will still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent will not be satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of user-defined functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see [Section 24.3.1, “The Locking Service”](#).

- `INET_ATON(expr)`

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_ATON('10.0.5.9');
-> 167773449
```

For this example, the return value is calculated as  $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$ .

`INET_ATON()` may or may not return a non-`NULL` result for short-form IP addresses (such as `'127.1'` as a representation of `'127.0.0.1'`). Because of this, `INET_ATON()` should not be used for such addresses.

### Note

To store values generated by `INET_ATON()`, use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See [Section 11.2.6, “Out-of-Range and Overflow Handling”](#).

- `INET_NTOA(expr)`

Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a nonbinary string in the connection character set. `INET_NTOA()` returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

- `INET6_ATON(expr)`

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the `VARBINARY` data type: `VARBINARY(16)` for IPv6 addresses and `VARBINARY(4)` for IPv4 addresses. If the argument is not a valid address, `INET6_ATON()` returns `NULL`.

The following examples use `HEX()` to display the `INET6_ATON()` result in printable form:

```
mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'FDFE00000000000005A55CAFFFEFA9089'
mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
-> '0A000509'
```

`INET6_ATON()` observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.
- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `192.168.1.0/24`.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `192.168.1` are rejected. A trailing port number is not permitted, as in `192.168.1.2:8080`. Hexadecimal numbers in address components are not permitted, as in `192.0xa0.1.2`. Octal numbers are not supported: `192.168.010.1` is treated as `192.168.10.1`, not `192.168.8.1`. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address *expr* represented in numeric form as an `INT` value to an IPv6 address represented in numeric form as a `VARBINARY` value, use this expression:

```
INET6_ATON(INET_NTOA(expr))
```

For example:

```
mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
-> '0A000509'
```

- `INET6_NTOA(expr)`

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a nonbinary string in the connection character set. If the argument is not a valid address, `INET6_NTOA()` returns `NULL`.

`INET6_NTOA()` has these properties:

- It does not use operating system functions to perform conversions, thus the output string is platform independent.
- The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

```
CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
```

The resulting table would have this definition:

```
CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
```

- The return string uses lowercase letters for IPv6 addresses.

```
mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:feffa:9089'));
-> 'fdfe::5a55:caff:feffa:9089'
mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
-> '10.0.5.9'

mysql> SELECT INET6_NTOA(UNHEX('FDFE0000000000005A55CAFFFEFFA9089'));
-> 'fdfe::5a55:caff:feffa:9089'
mysql> SELECT INET6_NTOA(UNHEX('0A000509'));
-> '10.0.5.9'
```

- `IS_FREE_LOCK(str)`

Checks whether the lock named *str* is free to use (that is, not locked). Returns `1` if the lock is free (no one is using the lock), `0` if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `IS_IPV4(expr)`

Returns `1` if the argument is a valid IPv4 address specified as a string, `0` otherwise.

```
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
-> 1, 0
```

For a given argument, if `IS_IPV4()` returns `1`, `INET_ATON()` (and `INET6_ATON()`) will return non-`NULL`. The converse statement is not true: In some cases, `INET_ATON()` returns non-`NULL` when `IS_IPV4()` returns `0`.

As implied by the preceding remarks, `IS_IPV4()` is more strict than `INET_ATON()` about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use `INET6_ATON()` to convert IPv4 addresses to internal form and check for a `NULL` result (which indicates an invalid address). `INET6_ATON()` is equally strong as `IS_IPV4()` about checking IPv4 addresses.

- `IS_IPV4_COMPAT(expr)`

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns `1` if the argument is a valid IPv4-compatible IPv6 address, `0` otherwise. IPv4-compatible addresses have the form `::ipv4_address`.

```
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
-> 0
```

The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, `192.168.0.1` has this raw hexadecimal value:

```
mysql> SELECT HEX(INET6_ATON('192.168.0.1'));
-> 'C0A80001'
```

Expressed in IPv4-compatible form, `::192.168.0.1` is equivalent to `::c0a8:0001` or (without leading zeros) `::c0a8:1`

```
mysql> SELECT
```

```
-> IS_IPV4_COMPAT(INET6_ATON('::192.168.0.1')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')),
-> IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1
```

- `IS_IPV4_MAPPED(expr)`

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form `::ffff:ipv4_address`.

```
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
```

As with `IS_IPV4_COMPAT()` the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

```
mysql> SELECT
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:192.168.0.1')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
```

- `IS_IPV6(expr)`

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

```
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` will return non-NULL.

- `IS_USED_LOCK(str)`

Checks whether the lock named *str* is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `MASTER_POS_WAIT(log_name, log_pos [, timeout] [, channel_name])`

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns `NULL` if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the slave SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the slave is past the specified position, the function returns immediately.

If a *timeout* value is specified, `MASTER_POS_WAIT()` stops waiting when *timeout* seconds have elapsed. *timeout* must be greater than 0; a zero or negative *timeout* means no timeout.

The optional *channel* added in MySQL 5.7.6 enables you to choose which replication channel the function applies to. See [Section 17.2.3, "Replication Channels"](#) for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `NAME_CONST(name, value)`

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in [Section 19.7, “Binary Logging of Stored Programs”](#). You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+-----+
| myname |
+-----+
|      14 |
+-----+
1 row in set (0.00 sec)
```

See [Section 13.2.9, “SELECT Syntax”](#), for more information about column aliases.

- `RELEASE_ALL_LOCKS()`

Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

This function was added in MySQL 5.7.5.

- `RELEASE_LOCK(str)`

Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()`. See [Section 13.2.3, “DO Syntax”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `SLEEP(duration)`

Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. If `SLEEP()` is interrupted, it returns 1. The duration may have a fractional part. If the argument is `NULL` or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `UUID()`

Returns a Universal Unique Identifier (UUID) generated according to “DCE 1.1: Remote Procedure Call” (Appendix A) CAE (Common Applications Environment) Specifications published by The Open Group in October 1997 (Document Number C706, <http://www.opengroup.org/public/pubs/catalog/c706.htm>).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

A UUID is a 128-bit number represented by a `utf8` string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from a timestamp.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host computer has no Ethernet card, or we do not know how to find the hardware address of an interface on your operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-0040f4311e29'
```

#### Warning

Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

#### Note

`UUID()` does not work with statement-based replication.

- `UUID_SHORT()`

Returns a “short” universal identifier as a 64-bit unsigned integer (rather than a string-form 128-bit identifier as returned by the `UUID()` function).

The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The `server_id` of the current host is unique among your set of master and slave servers
- `server_id` is between 0 and 255
- You do not set back your system time for your server between `mysqld` restarts
- You do not invoke `UUID_SHORT()` on average more than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
```

```
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

Note that `UUID_SHORT()` does not work with statement-based replication.

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See [Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

## 12.20 Functions and Modifiers for Use with GROUP BY Clauses

### 12.20.1 GROUP BY (Aggregate) Functions

Table 12.26 Aggregate (`GROUP BY`) Functions

Name	Description
<code>AVG()</code>	Return the average value of the argument
<code>BIT_AND()</code>	Return bitwise AND
<code>BIT_OR()</code>	Return bitwise OR
<code>BIT_XOR()</code>	Return bitwise XOR
<code>COUNT(DISTINCT)</code>	Return the count of a number of different values
<code>COUNT()</code>	Return a count of the number of rows returned
<code>GROUP_CONCAT()</code>	Return a concatenated string
<code>MAX()</code>	Return the maximum value
<code>MIN()</code>	Return the minimum value
<code>STD()</code>	Return the population standard deviation
<code>STDDEV_POP()</code>	Return the population standard deviation
<code>STDDEV_SAMP()</code>	Return the sample standard deviation
<code>STDDEV()</code>	Return the population standard deviation
<code>SUM()</code>	Return the sum
<code>VAR_POP()</code>	Return the population standard variance
<code>VAR_SAMP()</code>	Return the sample variance
<code>VARIANCE()</code>	Return the population standard variance

This section describes group (aggregate) functions that operate on sets of values. Unless otherwise stated, group functions ignore `NULL` values.

If you use a group function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows. For more information, see [Section 12.20.3, “MySQL Handling of GROUP BY”](#).

For numeric arguments, the variance and standard deviation functions return a `DOUBLE` value. The `SUM()` and `AVG()` functions return a `DECIMAL` value for exact-value arguments (integer or `DECIMAL`), and a `DOUBLE` value for approximate-value arguments (`FLOAT` or `DOUBLE`).

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;  
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` or `ENUM` values, the cast operation causes the underlying numeric value to be used.

- `AVG([DISTINCT] expr)`

Returns the average value of *expr*. The `DISTINCT` option can be used to return the average of the distinct values of *expr*.

`AVG()` returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, AVG(test_score)  
-> FROM student  
-> GROUP BY student_name;
```

- `BIT_AND(expr)`

Returns the bitwise `AND` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns `18446744073709551615` if there were no matching rows. (This is the value of an unsigned `BIGINT` value with all bits set to 1.)

- `BIT_OR(expr)`

Returns the bitwise `OR` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns `0` if there were no matching rows.

- `BIT_XOR(expr)`

Returns the bitwise `XOR` of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns `0` if there were no matching rows.

- `COUNT(expr)`

Returns a count of the number of non-`NULL` values of *expr* in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value.

`COUNT()` returns `0` if there were no matching rows.

```
mysql> SELECT student.student_name, COUNT(*)  
-> FROM student, course  
-> WHERE student.student_id=course.student_id  
-> GROUP BY student_name;
```

`COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain `NULL` values.

`COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization applies only to `MyISAM` tables only, because an exact row count is stored for this storage engine and can be accessed very quickly. For transactional storage engines such as `InnoDB`, storing an exact row count is more problematic because multiple transactions may be occurring, each of which may affect the count.

- `COUNT(DISTINCT expr, [expr...])`

Returns a count of the number of rows with different non-`NULL` `expr` values.

`COUNT(DISTINCT)` returns 0 if there were no matching rows.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain `NULL` by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.

- `GROUP_CONCAT(expr)`

This function returns a string result with the concatenated non-`NULL` values from a group. It returns `NULL` if there are no non-`NULL` values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
              [ASC | DESC] [,col_name ...]]
             [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
->        GROUP_CONCAT(test_score)
->        FROM student
->        GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
->        GROUP_CONCAT(DISTINCT test_score
->                      ORDER BY test_score DESC SEPARATOR ' ')
->        FROM student
->        GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the `DISTINCT` clause. To sort values in the result, use the `ORDER BY` clause. To sort in reverse order, add the `DESC` (descending) keyword to the name of the column you are sorting by in the `ORDER BY` clause. The default is ascending order; this may be specified explicitly using the `ASC` keyword. The default separator between values in a group is comma (`,`). To specify a separator explicitly, use `SEPARATOR` followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify `SEPARATOR ''`.

The result is truncated to the maximum length that is given by the `group_concat_max_len` system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of `max_allowed_packet`. The

syntax to change the value of `group_concat_max_len` at runtime is as follows, where `val` is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is `TEXT` or `BLOB` unless `group_concat_max_len` is less than or equal to 512, in which case the result type is `VARCHAR` or `VARBINARY`.

See also `CONCAT()` and `CONCAT_WS()`: [Section 12.5, “String Functions”](#).

- `MAX([DISTINCT] expr)`

Returns the maximum value of `expr`. `MAX()` may take a string argument; in such cases, it returns the maximum string value. See [Section 8.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the maximum of the distinct values of `expr`, however, this produces the same result as omitting `DISTINCT`.

`MAX()` returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
->      FROM student
->      GROUP BY student_name;
```

For `MAX()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `MIN([DISTINCT] expr)`

Returns the minimum value of `expr`. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See [Section 8.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the minimum of the distinct values of `expr`, however, this produces the same result as omitting `DISTINCT`.

`MIN()` returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
->      FROM student
->      GROUP BY student_name;
```

For `MIN()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `STD(expr)`

Returns the population standard deviation of `expr`. This is an extension to standard SQL. The standard SQL function `STDDEV_POP()` can be used instead.

This function returns `NULL` if there were no matching rows.

- `STDDEV(expr)`

Returns the population standard deviation of `expr`. This function is provided for compatibility with Oracle. The standard SQL function `STDDEV_POP()` can be used instead.

This function returns `NULL` if there were no matching rows.

- `STDDEV_POP(expr)`

Returns the population standard deviation of *expr* (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

`STDDEV_POP()` returns `NULL` if there were no matching rows.

- `STDDEV_SAMP(expr)`

Returns the sample standard deviation of *expr* (the square root of `VAR_SAMP()`).

`STDDEV_SAMP()` returns `NULL` if there were no matching rows.

- `SUM([DISTINCT] expr)`

Returns the sum of *expr*. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of *expr*.

`SUM()` returns `NULL` if there were no matching rows.

- `VAR_POP(expr)`

Returns the population standard variance of *expr*. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()`, which is equivalent but is not standard SQL.

`VAR_POP()` returns `NULL` if there were no matching rows.

- `VAR_SAMP(expr)`

Returns the sample variance of *expr*. That is, the denominator is the number of rows minus one.

`VAR_SAMP()` returns `NULL` if there were no matching rows.

- `VARIANCE(expr)`

Returns the population standard variance of *expr*. This is an extension to standard SQL. The standard SQL function `VAR_POP()` can be used instead.

`VARIANCE()` returns `NULL` if there were no matching rows.

## 12.20.2 GROUP BY Modifiers

The `GROUP BY` clause permits a `WITH ROLLUP` modifier that causes extra rows to be added to the summary output. These rows represent higher-level (or super-aggregate) summary operations. `ROLLUP` thus enables you to answer questions at multiple levels of analysis with a single query. It can be used, for example, to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a table named `sales` has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```
CREATE TABLE sales
(
  year      INT NOT NULL,
  country  VARCHAR(20) NOT NULL,
  product  VARCHAR(32) NOT NULL,
  profit   INT
);
```

The table's contents can be summarized per year with a simple `GROUP BY` like this:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year;
+-----+-----+
```

year	SUM(profit)
2000	4525
2001	3010

This output shows the total profit for each year, but if you also want to determine the total profit summed over all years, you must add up the individual values yourself or run an additional query.

Or you can use `ROLLUP`, which provides both levels of analysis with a single query. Adding a `WITH ROLLUP` modifier to the `GROUP BY` clause causes the query to produce another row that shows the grand total over all year values:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year WITH ROLLUP;
```

year	SUM(profit)
2000	4525
2001	3010
NULL	7535

The grand total super-aggregate line is identified by the value `NULL` in the `year` column.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a “break” (change in value) in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary on the `sales` table based on `year`, `country`, and `product` might look like this:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product;
```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	India	Calculator	150
2000	India	Computer	1200
2000	USA	Calculator	75
2000	USA	Computer	1500
2001	Finland	Phone	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250

The output indicates summary values only at the year/country/product level of analysis. When `ROLLUP` is added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP;
```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200
2000	India	NULL	1350
2000	USA	Calculator	75
2000	USA	Computer	1500

2000	USA	NULL	1575
2000	NULL	NULL	4525
2001	Finland	Phone	10
2001	Finland	NULL	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250
2001	USA	NULL	3000
2001	NULL	NULL	3010
NULL	NULL	NULL	7535

For this query, adding `ROLLUP` causes the output to include summary information at four levels of analysis, not just one. Here is how to interpret the `ROLLUP` output:

- Following each set of product rows for a given year and country, an extra summary row is produced showing the total for all products. These rows have the `product` column set to `NULL`.
- Following each set of rows for a given year, an extra summary row is produced showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`.
- Finally, following all other rows, an extra summary row is produced showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

## Other Considerations When using ROLLUP

The following items list some behaviors specific to the MySQL implementation of `ROLLUP`.

When you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` are mutually exclusive. However, you still have some control over sort order. `GROUP BY` in MySQL implicitly sorts results, and you can use explicit `ASC` and `DESC` keywords with columns named in the `GROUP BY` list to specify sort order for individual columns. (The higher-level summary rows added by `ROLLUP` still appear after the rows from which they are calculated, regardless of the sort order.)

Implicit `GROUP BY` sorting in MySQL 5.7 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. You can work around the restriction that prevents using `ROLLUP` with `ORDER BY` by placing the `ROLLUP` clause within a subquery. For example:

```
mysql> SELECT * FROM (SELECT year, country, SUM(profit) FROM sales GROUP BY year WITH ROLLUP)
-> derived_t1 ORDER BY year;
```

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP
-> LIMIT 5;
```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because you have less context for understanding the super-aggregate rows.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has changed value. For any column in the result set with a name that is a lexical match to any of those names, its value is set to `NULL`. (If you specify grouping columns by column number, the server identifies which columns to set to `NULL` by number.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you cannot test them as `NULL` values within the query itself. For example, you cannot add `HAVING product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

On the other hand, the `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface.

MySQL permits a column that does not appear in the `GROUP BY` list to be named in the select list. In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are indeterminate:

```
mysql> SELECT year, country, SUM(profit)
-> FROM sales GROUP BY year WITH ROLLUP;
```

year	country	SUM(profit)
2000	India	4525
2001	USA	3010
NULL	USA	7535

This behavior occurs if the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause. For more information about nonaggregated columns and `GROUP BY`, see [Section 12.20.3, “MySQL Handling of GROUP BY”](#).

### 12.20.3 MySQL Handling of GROUP BY

SQL92 and earlier does not permit queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on (uniquely determined by) `GROUP BY` columns. For example, this query is illegal in standard SQL92 because the nonaggregated `name` column in the select list does not appear in the `GROUP BY`:

```
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
```

For the query to be legal in SQL92, the `name` column must be omitted from the select list or named in the `GROUP BY` clause.

SQL99 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on `GROUP BY` columns: If such a relationship exists between `name` and `custid`, the query is legal. This would be the case, for example, were `custid` a primary key of `customers`.

MySQL 5.7.5 and up implements detection of functional dependence. If the `ONLY_FULL_GROUP_BY` SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on them. (Before 5.7.5, MySQL does not detect functional dependency and `ONLY_FULL_GROUP_BY` is not enabled by default. For a description of pre-5.7.5 behavior, see the [MySQL 5.6 Reference Manual](#).)

If `ONLY_FULL_GROUP_BY` is disabled, a MySQL extension to the standard SQL use of `GROUP BY` permits the select list, `HAVING` condition, or `ORDER BY` list to refer to nonaggregated columns even if the columns are not functionally dependent on `GROUP BY` columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are indeterminate, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an `ORDER BY` clause. Result set sorting occurs after values have been chosen, and `ORDER BY` does not affect which value within each group the server chooses. Disabling `ONLY_FULL_GROUP_BY` is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the `GROUP BY` are the same for each group.

You can achieve the same effect without disabling `ONLY_FULL_GROUP_BY` by using `ANY_VALUE()` to refer to the nonaggregated column.

The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with `ONLY_FULL_GROUP_BY` enabled because the nonaggregated `address` column in the select list is not named in the `GROUP BY` clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if `name` is a primary key of `t` or is a unique `NOT NULL` column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if `name` is a primary key, its value determines the value of `address` because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of `address` value in a group and no need to reject the query.

The query is invalid if `name` is not a primary key of `t` or a unique `NOT NULL` column. In this case, no functional dependency can be inferred and an error occurs:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP
BY clause and contains nonaggregated column 'mydb.t.address' which
is not functionally dependent on columns in GROUP BY clause; this
is incompatible with sql_mode=only_full_group_by
```

If you know that, *for a given data set*, each `name` value in fact uniquely determines the `address` value, `address` is effectively functionally dependent on `name`. To tell MySQL to accept the query, you can use the `ANY_VALUE()` function:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

Alternatively, disable `ONLY_FULL_GROUP_BY`.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see [Section 12.20.4, "Detection of Functional Dependence"](#).

If a query has aggregate functions and no `GROUP BY` clause, it cannot have nonaggregated columns in the select list, `HAVING` condition, or `ORDER BY` list with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'mydb.t.name'; this
is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is indeterminate which `name` value to choose for the group. Here, too, `ANY_VALUE()` can be used, if it is immaterial which `name` value MySQL chooses:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

In MySQL 5.7.5 and up, `ONLY_FULL_GROUP_BY` also affects handling of queries that use `DISTINCT` and `ORDER BY`. Consider the case of a table `t` with three columns `c1`, `c2`, and `c3` that contains these rows:

```
c1 c2 c3
1  2  A
3  4  B
1  2  C
```

Suppose that we execute the following query, expecting the results to be ordered by `c3`:

```
SELECT DISTINCT c1, c2 FROM t ORDER BY c3;
```

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of `c3`, which in turn influences ordering and makes it arbitrary as well. To prevent this problem, a query that has `DISTINCT` and `ORDER BY` is rejected as invalid if any `ORDER BY` expression does not satisfy at least one of these conditions:

- The expression is equal to one in the select list
- All columns referenced by the expression and belonging to the query's selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. For example, the following query returns `name` values that occur only once in table `orders`:

```
SELECT name, COUNT(name) FROM orders
      GROUP BY name
      HAVING COUNT(name) = 1;
```

The MySQL extension permits the use of an alias in the `HAVING` clause for the aggregated column:

```
SELECT name, COUNT(name) AS c FROM orders
      GROUP BY name
      HAVING c = 1;
```

#### Note

Before MySQL 5.7.5, enabling `ONLY_FULL_GROUP_BY` disables this extension, thus requiring the `HAVING` clause to be written using unaliased expressions.

Standard SQL does not permit expressions in `GROUP BY` clauses, so a statement such as this is invalid:

```
SELECT id, FLOOR(value/100)
      FROM tbl_name
      GROUP BY id, FLOOR(value/100);
```

MySQL extends standard SQL to permit expressions in `GROUP BY` clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in `GROUP BY` clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

In some cases, you can use `MIN()` and `MAX()` to obtain a specific column value even if it is not unique. If the `sort` column contains integers no larger than 6 digits, the following query gives the value of `column` from the row containing the smallest `sort` value:

```
SUBSTR(MIN(CONCAT(LPAD(sort,6,'0'),column)),7)
```

See [Section 3.6.4, “The Rows Holding the Group-wise Maximum of a Certain Column”](#).

## 12.20.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:

```
{X} -> {Y}
```

Understand this as “*X* uniquely determines *Y*,” which also means that *Y* is functionally dependent on *X*.

The examples use the `world` database, which can be downloaded from the [MySQL Documentation page](#). You can find details on how to install the database on the same page.

### Functional Dependencies Derived from Keys

The following query selects, for each country, a count of spoken languages:

```
SELECT co.Name, COUNT(*)
FROM CountryLanguage cl, Country co
WHERE cl.CountryCode = co.Code
GROUP BY co.Code;
```

`co.Code` is a primary key of `co`, so all columns of `co` are functionally dependent on it, as expressed using this notation:

```
{co.Code} -> {co.*}
```

Thus, `co.name` is functionally dependent on `GROUP BY` columns and the query is valid.

A `UNIQUE` index over a `NOT NULL` column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a `UNIQUE` index that permits `NULL` values because it permits multiple `NULL` values and in that case uniqueness is lost.)

### Functional Dependencies Derived from Multiple-Column Keys and from Equalities

This query selects, for each country, a list of all spoken languages and how many people speak them:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population / 100.0 AS SpokenBy
FROM CountryLanguage cl, Country co
WHERE cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

The pair (`cl.CountryCode`, `cl.Language`) is a two-column composite primary key of `cl`, so that column pair uniquely determines all columns of `cl`:

```
{cl.CountryCode, cl.Language} -> {cl.*}
```

Moreover, because of the equality in the `WHERE` clause:

```
{cl.CountryCode} -> {co.Code}
```

And, because `co.Code` is primary key of `co`:

```
{co.Code} -> {co.*}
```

“Uniquely determines” relationships are transitive, therefore:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

As a result, the query is valid.

As with the previous example, a `UNIQUE` key over `NOT NULL` columns could be used instead of a primary key.

An `INNER JOIN` condition can be used instead of `WHERE`. The same functional dependencies apply:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population/100.0 AS SpokenBy
FROM CountryLanguage cl INNER JOIN Country co
ON cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

## Functional Dependency Special Cases

Whereas an equality test in a `WHERE` condition or `INNER JOIN` condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of `CountryLanguage` without a corresponding row in `Country`. Consider the same query as in the previous example, but with a `LEFT JOIN`:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population/100.0 AS SpokenBy
FROM CountryLanguage cl LEFT JOIN Country co
ON cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of `cl.CountryCode`, the value of `co.Code` in the join result is either found in a matching row (determined by `cl.CountryCode`) or is `NULL`-complemented if there is no match (also determined by `cl.CountryCode`). In each case, this relationship applies:

```
{cl.CountryCode} -> {co.Code}
```

`cl.CountryCode` is itself functionally dependent on `{cl.CountryCode, cl.Language}` which is a primary key.

If in the join result `co.Code` is `NULL`-complemented, `co.Name` is as well. If `co.Code` is not `NULL`-complemented, then because `co.Code` is a primary key, it determines `co.Name`. Therefore, in all cases:

```
{co.Code} -> {co.Name}
```

Which yields:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population/100.0 AS SpokenBy
FROM Country co LEFT JOIN CountryLanguage cl
ON cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

Now this relationship does *not* apply:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

Indeed, all `NULL`-complemented rows made for `cl` will be put into a single group (they have both `GROUP BY` columns equal to `NULL`), and inside this group the value of `co.Name` can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the `LEFT JOIN`. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.

## Functional Dependencies and Views

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

```
CREATE VIEW Country2 AS
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM Country AS co JOIN CountryLanguage AS cl
ON cl.CountryCode = co.Code
WHERE cl.isOfficial = 'T'
GROUP BY co.Code;
```

This definition is valid because:

```
{co.Code} -> {co.*}
```

In the view result, the first selected column is `co.Code`, which is also the group column and thus determines all other selected expressions:

```
{Country2.Code} -> {Country2.*}
```

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they have, by joining the view with the `City` table:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM Country2 AS co2 JOIN City ci
ON ci.CountryCode = co2.Code
GROUP BY co2.Code;
```

This query is valid because, as seen previously:

```
{co2.Code} -> {co2.*}
```

MySQL is able to discover a functional dependency in the result of a view and use that to validate a query which uses the view. The same would be true if `Country2` were a derived table, as in:

```

SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM
(
  SELECT co.Code, UPPER(co.Name) AS UpperName,
  COUNT(cl.Language) AS OfficialLanguages
  FROM Country AS co JOIN CountryLanguage AS cl
  ON cl.CountryCode=co.Code
  WHERE cl.isOfficial='T'
  GROUP BY co.Code
) AS co2
JOIN City ci ON ci.CountryCode = co2.Code
GROUP BY co2.Code;

```

## Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality based, view based) to validate more complex queries.

## 12.21 Precision Math

MySQL 5.7 provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that is merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND( )` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see [Section 5.1.7, “Server SQL Modes”](#).

### 12.21.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and `DECIMAL` types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

## 12.21.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms) in MySQL 5.7, with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of `DECIMAL` columns

The declaration syntax for a `DECIMAL` column is `DECIMAL(M,D)`. The ranges of values for the arguments in MySQL 5.7 are as follows:

- `M` is the maximum number of digits (the precision). It has a range of 1 to 65.
- `D` is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than `M`.

The maximum value of 65 for `M` means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before.

Values for `DECIMAL` columns in MySQL 5.7 are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1–2	1
3–4	2
5–6	3
7–9	4

For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

`DECIMAL` columns in MySQL 5.7 do not store a leading `+` character or `-` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored.

`DECIMAL` columns in MySQL 5.7 do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column permits at most  $M - D$  digits to the left of the decimal point.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly*  $M$  digits. For `DECIMAL(M,D)`, the standard requires a precision of at least  $M$  digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly  $M$  digits.

For a full explanation of the internal format of `DECIMAL` values, see the file `strings/decimal.c` in a MySQL source distribution. The format is explained (with an example) in the `decimal2bin()` function.

### 12.21.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 5.1.7, “Server SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in [Section 12.21.4, “Rounding Behavior”](#).

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of `NULL` and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

sql_mode Value	Result
' ' (Default)	No warning, no error; <code>i</code> is set to <code>NULL</code> .
strict	No warning, no error; <code>i</code> is set to <code>NULL</code> .
<code>ERROR_FOR_DIVISION_BY_ZERO</code>	Warning, no error; <code>i</code> is set to <code>NULL</code> .
strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code>	Error condition; no row is inserted.

## 12.21.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
```

```
| 3 | 2 |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SELECT d FROM t;
+-----+
| d      |
+-----+
| 3      |
| 3      |
+-----+
```

## 12.21.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL 5.7. These examples demonstrate the principles described in [Section 12.21.3, “Expression Handling”](#), and [Section 12.21.4, “Rounding Behavior”](#).

**Example 1.** Numbers are used with their exact value as given when possible:

```
mysql> SELECT (.1 + .2) = .3;
+-----+
| (.1 + .2) = .3 |
+-----+
| 1 |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT (.1E0 + .2E0) = .3E0;
+-----+
| (.1E0 + .2E0) = .3E0 |
+-----+
| 0 |
+-----+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```

+-----+-----+
| d      | f      |
+-----+-----+
| 1.0000 | 0.999999999999991 |
+-----+-----+

```

**Example 2.** Multiplication is performed with the scale required by standard SQL. That is, for two numbers  $X1$  and  $X2$  that have scale  $S1$  and  $S2$ , the scale of the result is  $S1 + S2$ :

```

mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+

```

**Example 3.** Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half away from zero” rule. Values with a fractional part of .5 or greater are rounded away from zero to the nearest integer, as shown here:

```

mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+-----+
| 3          | -3          |
+-----+-----+

```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```

mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+-----+
| 2            | -2            |
+-----+-----+

```

**Example 4.** In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127  |
+-----+
1 row in set (0.00 sec)

```

However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

**Example 5:** In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| NULL  |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

**Example 6.** Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as `DECIMAL`:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double              | NO   |     | 0       |       |
+-----+-----+-----+-----+-----+-----+
```

```
2 rows in set (0.01 sec)
```

**Example 7.** If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
```

Field	Type	Null	Key	Default	Extra
AVG(i)	decimal(14,4)	YES		NULL	
AVG(d)	decimal(14,4)	YES		NULL	
AVG(f)	double	YES		NULL	

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

This chapter describes the syntax for the [SQL](#) statements supported by MySQL.

## 13.1 Data Definition Statements

### 13.1.1 ALTER DATABASE Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
```

[ALTER DATABASE](#) enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use [ALTER DATABASE](#), you need the [ALTER](#) privilege on the database. [ALTER SCHEMA](#) is a synonym for [ALTER DATABASE](#).

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

### National Language Characteristics

The [CHARACTER SET](#) clause changes the default database character set. The [COLLATE](#) clause changes the default database collation. [Section 10.1, “Character Set Support”](#), discusses character set and collation names.

You can see what character sets and collations are available using, respectively, the [SHOW CHARACTER SET](#) and [SHOW COLLATION](#) statements. See [Section 13.7.5.3, “SHOW CHARACTER SET Syntax”](#), and [Section 13.7.5.4, “SHOW COLLATION Syntax”](#), for more information.

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 13.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)

## Upgrading from Versions Older than MySQL 5.1

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see [Section 9.2.3, “Mapping of Identifiers to File Names”](#)). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by `mysqlcheck` (as invoked by `mysql_upgrade`).

For example, if a database in MySQL 5.0 has the name `a-b-c`, the name contains instances of the `-` (dash) character. In MySQL 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and later, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql150#a-b-c`, and you must refer to the name using the `#mysql150#` prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql150#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql150#` prefix.

### Note

The `UPGRADE DATA DIRECTORY NAME` clause is deprecated in MySQL 5.7.6 and will be removed in a future version of MySQL. If it is necessary to convert MySQL 5.0 database or table names, a workaround is to upgrade a MySQL 5.0 installation to MySQL 5.1 before upgrading to a more recent release.

## 13.1.2 ALTER EVENT Syntax

```
ALTER
  [DEFINER = { user | CURRENT_USER }]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION [NOT] PRESERVE]
  [RENAME TO new_event_name]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  [DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See [Section 13.1.9, “CREATE EVENT Syntax”](#).)

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
>     ON SCHEDULE
>     EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
ON SCHEDULE
  EVERY 6 HOUR
COMMENT 'A sample comment.'
DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
ON SCHEDULE
  EVERY 12 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER EVENT myevent
ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO
  TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
  RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

#### Note

There is no `RENAME EVENT` statement.

The value `DISABLE ON SLAVE` is used on a replication slave instead of `ENABLE` or `DISABLE` to indicate an event that was created on the master and replicated to the slave, but that is not executed on the slave. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See [Section 17.4.1.12, “Replication of Invoked Features”](#), for more information.

### 13.1.3 ALTER FUNCTION Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

### 13.1.4 ALTER PROCEDURE Syntax

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 19.2.2, “Stored Routines and MySQL Privileges”](#).

### 13.1.5 ALTER SERVER Syntax

```
ALTER SERVER server_name
  OPTIONS (option [, option] ...)
```

Alters the server information for *server\_name*, adjusting any of the options permitted in the [CREATE SERVER](#) statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the [SUPER](#) privilege.

For example, to update the [USER](#) option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

[ALTER SERVER](#) does not cause an automatic commit.

In MySQL 5.7, [ALTER SERVER](#) is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.7.1, `gtid_next` must be set to [AUTOMATIC](#) before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

## 13.1.6 ALTER TABLE Syntax

```
ALTER [IGNORE] TABLE tbl_name
  [alter_specification [, alter_specification] ...]
  [partition_options]

alter_specification:
  table_options
| ADD [COLUMN] col_name column_definition
  [FIRST | AFTER col_name ]
| ADD [COLUMN] (col_name column_definition,...)
| ADD {INDEX|KEY} [index_name]
  [index_type] (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]] PRIMARY KEY
  [index_type] (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]]
  UNIQUE [INDEX|KEY] [index_name]
  [index_type] (index_col_name,...) [index_option] ...
| ADD FULLTEXT [INDEX|KEY] [index_name]
  (index_col_name,...) [index_option] ...
| ADD SPATIAL [INDEX|KEY] [index_name]
  (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]]
  FOREIGN KEY [index_name] (index_col_name,...)
  reference_definition
| ALGORITHM [=] {DEFAULT|INPLACE|COPY}
| ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}

```

**ALTER TABLE** changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

Following the table name, specify the alterations to be made. If none are given, **ALTER TABLE** does nothing.

The syntax for many of the permissible alterations is similar to clauses of the **CREATE TABLE** statement. See [Section 13.1.14, “CREATE TABLE Syntax”](#), for more information.

*table\_options* signifies table options of the kind that can be used in the **CREATE TABLE** statement, such as **ENGINE**, **AUTO\_INCREMENT**, **AVG\_ROW\_LENGTH**, **MAX\_ROWS**, or **ROW\_FORMAT**. For a list of all table options and a description of each, see [Section 13.1.14, “CREATE TABLE Syntax”](#). However, **ALTER TABLE** ignores the **DATA DIRECTORY** and **INDEX DIRECTORY** table options.

*partition\_options* signifies options that can be used with partitioned tables for repartitioning, for adding, dropping, discarding, importing, merging, and splitting partitions, and for performing partitioning maintenance. It is possible for an **ALTER TABLE** statement to contain a **PARTITION BY** or **REMOVE PARTITIONING** clause in an addition to other alter specifications, but the **PARTITION BY** or **REMOVE PARTITIONING** clause must be specified last after any other specifications. The **ADD PARTITION**, **DROP PARTITION**, **DISCARD PARTITION**, **IMPORT PARTITION**, **COALESCE PARTITION**, **REORGANIZE PARTITION**, **EXCHANGE PARTITION**, **ANALYZE PARTITION**, **CHECK PARTITION**, and **REPAIR PARTITION** options cannot be combined with other alter specifications in a single **ALTER TABLE**, since the options just listed act on individual partitions. For more information about partition options, see [Section 13.1.14, “CREATE TABLE Syntax”](#), and [Section 13.1.6.1, “ALTER TABLE Partition Operations”](#). For information about and examples of **ALTER TABLE ... EXCHANGE PARTITION** statements, see [Section 18.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

Prior to MySQL 5.7.6, partitioned **InnoDB** tables used the generic **ha\_partition** partitioning handler employed by **MyISAM** and other storage engines not supplying their own partitioning handlers; in MySQL 5.7.6 and later, such tables are created using the **InnoDB** storage engine's own (or “native”) partitioning handler. Beginning with MySQL 5.7.9, you can upgrade an **InnoDB** table that was created

in MySQL 5.7.6 or earlier (that is, created using `ha_partition`) to the `InnoDB` native partition handler using `ALTER TABLE ... UPGRADE PARTITIONING`. (Bug #76734, Bug #20727344) This version of `ALTER TABLE` does not accept any other options and can be used only on a single table at a time.

#### Note

You can also use `mysql_upgrade` in MySQL 5.7.9 or later to upgrade older partitioned `InnoDB` tables to the native partitioning handler.

Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. These warnings can be displayed with `SHOW WARNINGS`. See [Section 13.7.5.40, “SHOW WARNINGS Syntax”](#).

For information on troubleshooting `ALTER TABLE`, see [Section B.5.6.1, “Problems with ALTER TABLE”](#).

## Storage, Performance, and Concurrency Considerations

In most cases, `ALTER TABLE` makes a temporary copy of the original table. MySQL waits for other operations that are modifying the table, then proceeds. It incorporates the alteration into the copy, deletes the original table, and renames the new one. While `ALTER TABLE` is executing, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table that begin after the `ALTER TABLE` operation begins are stalled until the new table is ready, then are automatically redirected to the new table without any failed updates. The temporary copy of the original table is created in the database directory of the new table. This can differ from the database directory of the original table for `ALTER TABLE` operations that rename the table to a different database.

The exception referred to earlier is that `ALTER TABLE` blocks reads (not just writes) at the point where it is ready to install a new version of the table `.frm` file, discard the old file, and clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads (and writes).

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

For some operations, an in-place `ALTER TABLE` is possible that does not require a temporary table:

- For `ALTER TABLE tbl_name RENAME TO new_tbl_name` without any other options, MySQL simply renames any files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See [Section 13.1.28, “RENAME TABLE Syntax”](#).) Any privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
- Alterations that modify only table metadata and not table data are immediate because the server only needs to alter the table `.frm` file, not touch table contents. The following changes are fast alterations that can be made this way:
  - Renaming a column.
  - Changing the default value of a column.
  - Changing the definition of an `ENUM` or `SET` column by adding new enumeration or set members to the *end* of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a `SET` column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this will require a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
- `ALTER TABLE` with `DISCARD ... PARTITION ... TABLESPACE` or `IMPORT ... PARTITION ... TABLESPACE` do not create any temporary tables or temporary partition files.

`ALTER TABLE` with `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REBUILD PARTITION`, or `REORGANIZE PARTITION` does not create any temporary tables (except when used with `NDB` tables); however, these operations can and do create temporary partition files.

`ADD` or `DROP` operations for `RANGE` or `LIST` partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for `HASH` or `KEY` partitions copy data between all partitions, unless `LINEAR HASH` or `LINEAR KEY` was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

- Renaming an index.
- Adding or dropping an index, for `InnoDB`.

You can force an `ALTER TABLE` operation that would otherwise not require a table copy to use the temporary table method (as supported in MySQL 5.0) by setting the `old_alter_table` system variable to `ON`, or specifying `ALGORITHM=COPY` as one of the *alter\_specification* clauses. If there is a conflict between the `old_alter_table` setting and an `ALGORITHM` clause with a value other than `DEFAULT`, the `ALGORITHM` clause takes precedence. (`ALGORITHM = DEFAULT` is the same as specifying no `ALGORITHM` clause at all.)

Specifying `ALGORITHM=INPLACE` makes the operation use the in-place technique for clauses and storage engines that support it, and fail with an error otherwise, thus avoiding a lengthy table copy if you try altering a table that uses a different storage engine than you expect. See [Section 14.10, “InnoDB and Online DDL”](#) for information about online DDL for `InnoDB` tables.

As of MySQL 5.7.4, `ALTER TABLE` upgrades MySQL 5.5 temporal columns to 5.6 format for `ADD COLUMN`, `CHANGE COLUMN`, `MODIFY COLUMN`, `ADD INDEX`, and `FORCE` operations. This conversion cannot be done using the `INPLACE` algorithm because the table must be rebuilt, so specifying `ALGORITHM=INPLACE` in these cases results in an error. Specify `ALGORITHM=COPY` if necessary.

Starting with MySQL 5.7.6, an `ALTER TABLE` operation on a multicolumn index used to partition a table by `KEY` cannot be performed online when the operation would change the order of the columns. In such cases, you must use a copying `ALTER TABLE` instead. (Bug #17896265)

You can control the level of concurrent reading and writing of the table while it is being altered, using the `LOCK` clause. Specifying a non-default value for this clause lets you require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available. The parameters for the `LOCK` clause are:

- `LOCK = DEFAULT`

Maximum level of concurrency for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- `LOCK = NONE`

If supported, permit concurrent reads and writes. Otherwise, return an error message.

- `LOCK = SHARED`

If supported, permit concurrent reads but block writes. Note that writes will be blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation. If concurrent reads are not supported, return an error message.

- `LOCK = EXCLUSIVE`

Enforce exclusive access. This will be done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation.

The `WITHOUT VALIDATION` and `WITH VALIDATION` clauses affect whether `ALTER TABLE` performs an in-place operation for `VIRTUAL` generated column modifications. See [ALTER TABLE and Generated Columns](#).

You can also use `ALTER TABLE tbl_name FORCE` to perform a “null” alter operation that rebuilds the table. Previously the `FORCE` option was recognized but ignored. As of MySQL 5.7.4, [online DDL](#) support is provided for the `FORCE` option. For more information, see [Section 14.10.1, “Overview of Online DDL”](#).

## Usage Notes

- To use `ALTER TABLE`, you need `ALTER`, `CREATE`, and `INSERT` privileges for the table. Renaming a table requires `ALTER` and `DROP` on the old table, `ALTER`, `CREATE`, and `INSERT` on the new table.
- `IGNORE` is a MySQL extension to standard SQL. It controls how `ALTER TABLE` works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If `IGNORE` is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If `IGNORE` is specified, only one row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.

As of MySQL 5.7.4, the `IGNORE` clause for `ALTER TABLE` is removed and its use produces an error.

- `table_option` signifies a table option of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, `AVG_ROW_LENGTH`, `MAX_ROWS`, `ROW_FORMAT`, and `TABLESPACE`. For a list of all table options and a description of each, see [Section 13.1.14, “CREATE TABLE Syntax”](#). However, `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.
- For example, to convert a table to be an `InnoDB` table, use this statement:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

See [Section 14.5.4, “Converting Tables from MyISAM to InnoDB”](#) for considerations when switching tables to the `InnoDB` storage engine.

When you specify an `ENGINE` clause, `ALTER TABLE` rebuilds the table. This is true even if the table already has the specified storage engine.

Running `ALTER TABLE tbl_name ENGINE=INNODB` on an existing `InnoDB` table performs a “null” `ALTER TABLE` operation, which can be used to defragment an `InnoDB` table, as described in [Section 14.9.4, “Defragmenting a Table”](#). Running `ALTER TABLE tbl_name FORCE` on an `InnoDB` table performs the same function.

As of MySQL 5.7.4, both `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use [online DDL \(ALGORITHM=COPY\)](#). For more information, see [Section 14.10.1, “Overview of Online DDL”](#).

The outcome of attempting to change a table's storage engine is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.7, “Server SQL Modes”](#).

To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.

- To change the value of the `AUTO_INCREMENT` counter to be used for new rows, do this:

```
ALTER TABLE t2 AUTO_INCREMENT = value;
```

You cannot reset the counter to a value less than or equal to the value that is currently in use. For both [InnoDB](#) and [MyISAM](#), if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum `AUTO_INCREMENT` column value plus one.

- As of MySQL 5.7.6, you can use `ALTER TABLE` with the `TABLESPACE` option to move non-partitioned [InnoDB](#) tables between existing [general tablespaces](#), a [file-per-table](#) tablespaces, and the [system tablespace](#). See [Moving Non-Partitioned Tables Between Tablespaces Using ALTER TABLE](#).

For partitioned tables, `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` only modifies the table's default tablespace. It does not move partitions from one tablespace to another. To move table partitions, you must move each partition using an `ALTER TABLE tbl_name REORGANIZE PARTITION` statement. See [Moving Table Partitions Between Tablespaces Using ALTER TABLE](#).

`ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

`ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

The `DATA DIRECTORY` clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with `ALTER TABLE ... TABLESPACE`, and is ignored if specified.

For more information about the capabilities and limitations of the `TABLESPACE` option, see [CREATE TABLE](#).

- You can issue multiple `ADD`, `ALTER`, `DROP`, and `CHANGE` clauses in a single `ALTER TABLE` statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per `ALTER TABLE` statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- `CHANGE col_name`, `DROP col_name`, and `DROP INDEX` are MySQL extensions to standard SQL.
- The word `COLUMN` is optional and can be omitted.
- `column_definition` clauses use the same syntax for `ADD` and `CHANGE` as for `CREATE TABLE`. See [Section 13.1.14, "CREATE TABLE Syntax"](#).
- You can rename a column using a `CHANGE old_col_name new_col_name column_definition` clause. To do so, specify the old and new column names and the definition that the column currently has. For example, to rename an `INTEGER` column from `a` to `b`, you can do this:

```
ALTER TABLE t1 CHANGE a b INTEGER;
```

To change a column's type but not the name, `CHANGE` syntax still requires an old and new column name, even if they are the same. For example:

```
ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
```

You can also use `MODIFY` to change a column's type without renaming it:

```
ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
```

`MODIFY` is an extension to `ALTER TABLE` for Oracle compatibility.

When you use `CHANGE` or `MODIFY`, *column\_definition* must include the data type and all attributes that should apply to the new column, other than index attributes such as `PRIMARY KEY` or `UNIQUE`. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

The resulting column will be defined as `BIGINT`, but will not include the attributes `UNSIGNED DEFAULT 1 COMMENT 'my column'`. To retain them, the statement should be:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

- When you change a data type using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.

### Warning

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see [Section 5.1.7, “Server SQL Modes”](#)).

- To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last. You can also use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations to reorder columns within a table.
- `ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in [Section 11.7, “Data Type Default Values”](#).
- `DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See [Section 13.1.21, “DROP INDEX Syntax”](#). If you are unsure of the index name, use `SHOW INDEX FROM tbl_name`.
- If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
- If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use `DROP TABLE` instead.
- `DROP PRIMARY KEY` drops the [primary key](#). If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for `InnoDB` tables, see [Section 8.3.2, “Using Primary Keys”](#).

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

- Some storage engines permit you to specify an index type when creating an index. The syntax for the *index\_type* specifier is `USING type_name`. For details about `USING`, see [Section 13.1.11, “CREATE INDEX Syntax”](#). The preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

*index\_option* values specify additional options for an index. `USING` is one such option. For details about permissible *index\_option* values, see [Section 13.1.11, “CREATE INDEX Syntax”](#).

- `RENAME INDEX old_index_name TO new_index_name` renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. *old\_index\_name* must be the name of an existing index in the table that is not dropped by the same `ALTER TABLE` statement. *new\_index\_name* is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be `PRIMARY`.
- After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See [Section 13.7.5.22, “SHOW INDEX Syntax”](#).
- `ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you are mostly to query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

#### Note

The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for `InnoDB` tables because `InnoDB` always orders table rows according to the [clustered index](#).

#### Note

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

- If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For `MyISAM` tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. `MyISAM` does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

- In MySQL 5.7, the server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. It also prohibits changes to the data type of such columns that may be unsafe. For example, changing `VARCHAR(20)` to `VARCHAR(30)` is permitted, but changing it to `VARCHAR(1024)` is not because that alters the number of length bytes required to store individual values. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward.
- The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` storage engine, which implements `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See [Section 14.5.6, “InnoDB and FOREIGN KEY Constraints”](#). For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by

all storage engines. See [Section 13.1.14, “CREATE TABLE Syntax”](#). The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See [Section 1.8.2, “MySQL Differences from Standard SQL”](#).

For `ALTER TABLE`, unlike `CREATE TABLE, ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (...)
```

### Important

The inline [REFERENCES](#) specifications where the references are defined as part of the column specification are silently ignored. MySQL only accepts [REFERENCES](#) clauses defined as part of a separate [FOREIGN KEY](#) specification.

### Note

Partitioned [InnoDB](#) tables do not support foreign keys. See [Section 18.6.2, “Partitioning Limitations Relating to Storage Engines”](#), for more information.

- MySQL supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

For more information, see [Section 14.5.6, “InnoDB and FOREIGN KEY Constraints”](#).

- Prior to MySQL 5.6.6, adding and dropping a foreign key in the same `ALTER TABLE` statement may be problematic in some cases and is therefore unsupported. Separate statements should be used for each operation. As of MySQL 5.6.6, adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but remains unsupported for `ALTER TABLE ... ALGORITHM=COPY`.
- For an [InnoDB](#) table that is created with its own [file-per-table](#) tablespace in an `.ibd` file, that file can be discarded and imported. To discard the `.ibd` file, use this statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

This deletes the current file-per-table `.ibd` file, so be sure that you have a backup first. Attempting to modify the table contents while the tablespace file is discarded results in an error. You can perform the DDL operations listed in [Section 14.10, “InnoDB and Online DDL”](#) while the tablespace file is discarded.

To import the backup `.ibd` file back into the table, copy it into the database directory, and then issue this statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

The tablespace file need not necessarily have been created on the server into which it is imported later. In MySQL 5.7, importing a tablespace file from another server works if the both servers have GA (General Availability) status and their versions are within the same series. Otherwise, the file must have been created on the server into which it is imported.

### Note

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data.

`ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a [general tablespace](#).

See [Section 14.4.4, “InnoDB File-Per-Table Tablespaces”](#).

- To change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no `COLLATE` clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of `VARCHAR` or one of the `TEXT` types, `CONVERT TO CHARACTER SET` will change the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a `TEXT` column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a `latin1 TEXT` column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to `utf8`, each character might require up to three bytes, for a maximum possible length of  $3 \times 65,535 = 196,605$  bytes. That length will not fit in a `TEXT` column's length bytes, so MySQL will convert the data type to `MEDIUMTEXT`, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a `VARCHAR` column might be converted to `MEDIUMTEXT`.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer will have a character set and a subsequent `CONVERT TO` operation will not apply to them.

If `charset_name` is `DEFAULT`, the database character set is used.

### Warning

The `CONVERT TO` operation converts column values between the character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

With the `mysql_info()` C API function, you can find out how many rows were copied by `ALTER TABLE`, and (when `IGNORE` is used) how many rows were deleted due to duplication of unique key values. See [Section 23.8.7.36, “mysql\\_info\(\)”](#).

## ALTER TABLE and Generated Columns

`ALTER TABLE` operations permitted for generated columns are `ADD`, `MODIFY`, and `CHANGE`.

- Generated columns can be added.
- The data type and expression of generated columns can be modified.
- Generated columns can be renamed or dropped, if no other column refers to them.
- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.
- Nongenerated columns can be altered to stored but not virtual generated columns.
- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.
- `ADD COLUMN` is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.
- `ADD COLUMN` and `DROP COLUMN` are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in combination with other `ALTER TABLE` operations.
- As of MySQL 5.7.8, `InnoDB` supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see [Secondary Indexes and Virtual Generated Columns](#).
- When a `VIRTUAL` generated column is added to a table or modified, it is not ensured that data being calculated by the generated column expression will not be out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. As of MySQL 5.7.9, to permit control over whether validation occurs for such columns, `ALTER TABLE` supports `WITHOUT VALIDATION` and `WITH VALIDATION` clauses:
  - With `WITHOUT VALIDATION` (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.
  - With `WITH VALIDATION`, `ALTER TABLE` copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.

`WITHOUT VALIDATION` and `WITH VALIDATION` are permitted only with `ADD COLUMN`, `CHANGE COLUMN`, and `MODIFY COLUMN` operations. An `ER_WRONG_USAGE` error occurs otherwise.

- As of MySQL 5.7.10, if expression evaluation causes truncation or provides incorrect input to a function, the `ALTER TABLE` statement terminates with an error and the DDL operation is rejected.

### 13.1.6.1 ALTER TABLE Partition Operations

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, for adding, dropping, discarding, importing, merging, and splitting partitions, and for performing partitioning maintenance.

- Simply using a `partition_options` clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the `partition_options`. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the `partition_options` clause for `CREATE TABLE` (see Section 13.1.14, “CREATE TABLE Syntax”, for more detailed information), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
);
```

This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
  PARTITION BY HASH(id)
  PARTITIONS 8;
```

MySQL 5.7.1 and later supports an `ALGORITHM` option with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

To upgrade a `KEY` partitioned table that was created in MySQL 5.1, first execute `SHOW CREATE TABLE` and note the exact columns and number of partitions shown. Now execute an `ALTER TABLE` statement using exactly the same column list and number of partitions as in the `CREATE TABLE` statement, while adding `ALGORITHM=2` immediately following the `PARTITION BY` keywords. (You should also include the `LINEAR` keyword if it was used for the original table definition.) An example from a session in the `mysql` client is shown here:

```
mysql> SHOW CREATE TABLE p\G
***** 1. row *****
      Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)
```

```
mysql> ALTER TABLE p PARTITION BY LINEAR KEY ALGORITHM=2 (id) PARTITIONS 32;
Query OK, 0 rows affected (5.34 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE p\G
***** 1. row *****
      Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)
```

Downgrading a table created using the default key-hashing used in MySQL 5.5 and later to enable its use by a MySQL 5.1 server is similar, except in this case you should use `ALGORITHM=1` to force the table's partitions to be rebuilt using the MySQL 5.1 key-hashing functions. It is recommended that you not do this except when necessary for compatibility with a MySQL 5.1 server, as the improved `KEY` hashing functions used by default in MySQL 5.5 and later provide fixes for a number of issues found in the older implementation.

#### Note

A table upgraded by means of `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY ...` can no longer be used by a MySQL 5.1 server. (Such a table would need to be downgraded with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY ...` before it could be used again by a MySQL 5.1 server.)

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Section 18.6.1, "Partitioning Keys, Primary Keys, and Unique Keys"](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See [Section 13.1.14, "CREATE TABLE Syntax"](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`ADD PARTITION` can also be used with the `TABLESPACE` clause to add a new partition to an existing general tablespace, to a file-per-table tablespace, or to the system tablespace.

```
ALTER TABLE t1 ADD PARTITION (PARTITION p4 VALUES LESS THAN (2015) TABLESPACE = `ts1`);
```

```
ALTER TABLE t1 ADD PARTITION (PARTITION p4 VALUES LESS THAN (2015) TABLESPACE = `innodb_file_per_tabl
```

```
ALTER TABLE t1 ADD PARTITION (PARTITION p4 VALUES LESS THAN (2015) TABLESPACE = `innodb_system`);
```

### Note

If the `TABLESPACE = tablespace_name` option is not defined, the `ALTER TABLE ... ADD PARTITION` operation adds the partition to the table's default tablespace, which can be specified at the table level during `CREATE TABLE` or `ALTER TABLE`.

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see below). Any data that was stored in the dropped partitions named in the `partition_names` list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

In MySQL 5.7.4, `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` options extend the [Transportable Tablespace](#) feature to individual InnoDB table partitions. Each InnoDB table partition has its own tablespace file (`.idb` file). The [Transportable Tablespace](#) feature makes it easy to copy the tablespaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a comma-separated list of one or more partition names. For example:

```
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

```
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

As of MySQL 5.7.4, the [Transportable Tablespace](#) feature also supports copying or restoring partitioned InnoDB tables (all partitions at once). For additional information about the [Transportable Tablespace](#) feature, see [Section 14.4.6, "Copying File-Per-Table Tablespaces to Another Server"](#). For usage examples, see [Section 14.4.6.1, "Transportable Tablespace Examples"](#).

Renames of partitioned tables are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation makes a copy of the partition's data..

In MySQL 5.7, it is possible to delete rows from selected partitions using the `TRUNCATE PARTITION` option. This option takes a comma-separated list of one or more partition names. For example, consider the table `t1` as defined here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2003),
  PARTITION p4 VALUES LESS THAN (2007)
```

```
);
```

To delete all rows from partition `p0`, you can use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex `WHERE` conditions if done with `DELETE` statements. For example, this statement deletes all rows from partitions `p1` and `p3`:

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent `DELETE` statement is shown here:

```
DELETE FROM t1 WHERE
  (year_col >= 1991 AND year_col < 1995)
  OR
  (year_col >= 2003 AND year_col < 2007);
```

You can also use the `ALL` keyword in place of the list of partition names; in this case, the statement acts on all partitions in the table.

`TRUNCATE PARTITION` merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

#### Note

Prior to MySQL 5.7.2, `TRUNCATE PARTITION` did not work with subpartitions (Bug #14028340, Bug #65184).

You can verify that the rows were dropped by checking the `INFORMATION_SCHEMA.PARTITIONS` table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
  FROM INFORMATION_SCHEMA.PARTITIONS
 WHERE TABLE_NAME = 't1';
```

`TRUNCATE PARTITION` is supported only for partitioned tables that use the `MyISAM`, `InnoDB`, or `MEMORY` storage engine. It also works on `BLACKHOLE` tables (but has no effect). It is not supported for `ARCHIVE` tables.

`COALESCE PARTITION` can be used with a table that is partitioned by `HASH` or `KEY` to reduce the number of partitions by *number*. Suppose that you have created table `t2` using the following definition:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

You can reduce the number of partitions used by `t2` from 6 to 4 using the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use [REORGANIZE PARTITION](#). This statement can be used in several ways:

- To merge a set of partitions into a single partition. This can be done by naming several partitions in the *partition\_names* list and supplying a single definition for *partition\_definition*.
- To split an existing partition into several partitions. You can accomplish this by naming a single partition for *partition\_names* and providing multiple *partition\_definitions*.
- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.
- To move a partition from one tablespace to another. For an example, see [Moving Table Partitions Between Tablespaces Using ALTER TABLE](#).

#### Note

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see [Section 18.3.1, “Management of RANGE and LIST Partitions”](#).

- In MySQL 5.7, it is possible to exchange a table partition or subpartition with a table using the `ALTER TABLE ... EXCHANGE PARTITION` statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

For usage information and examples, see [Section 18.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

- Several additional options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; see [Section 13.7.2, “Table Maintenance Statements”](#) for more information). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a *partition\_names* clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. You can also use the `ALL` keyword in place of *partition\_names*, in which case the statement acts on all partitions in the table. For more information and examples, see [Section 18.3.4, “Maintenance of Partitions”](#).

Some MySQL storage engines, such as `InnoDB`, do not support per-partition optimization. For a partitioned table using such a storage engine, `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822)

To work around this problem, use the statements `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not permitted for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.
- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning.

In MySQL 5.7, when `ALTER TABLE ... EXCHANGE PARTITION` or `ALTER TABLE ... TRUNCATE PARTITION` is run against a partitioned table that uses `MyISAM` (or another storage engine that makes use of table-level locking), only those partitions that are actually read from are locked. (This does not apply to partitioned tables using a storage engine that employs row-level locking, such as `InnoDB`.) See [Section 18.6.4, "Partitioning and Locking"](#).

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see [Section 13.1.6.1, "ALTER TABLE Partition Operations"](#).

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

Prior to MySQL 5.7.2, `ANALYZE`, `CHECK`, `OPTIMIZE`, `REPAIR`, and `TRUNCATE` operations were not supported for subpartitions. (Bug #14028340, Bug #65184)

`REBUILD` operations are currently unsupported for subpartitions. In MySQL 5.7.2, 5.7.3, and 5.7.4, the `REBUILD` keyword was accepted with subpartition names as valid syntax in `ALTER TABLE` statements, even though it had no effect. In MySQL 5.7.5, `REBUILD` is expressly disallowed with subpartitions, and causes `ALTER TABLE` to fail with an error if so used. (Bug #19075411, Bug #73130)

`CHECK PARTITION` and `REPAIR PARTITION` operations fail when the partition to be checked or repaired contains any duplicate key errors.

MySQL 5.7.2 and 5.7.3 allowed alternative behavior that could be invoked using `ALTER IGNORE TABLE` with the corresponding options (Bug #16900947), which caused the statement to behave as follows:

- `ALTER IGNORE TABLE ... REPAIR PARTITION` removed from the partition all rows that could not be moved due to the presence of duplicate keys.
- `ALTER IGNORE TABLE ... CHECK PARTITION` wrote out the contents of all columns in the partitioning expression for each row in the partition in which a duplicate key violation was found.

This is no longer possible in MySQL 5.7.4 and later, where the `IGNORE` keyword is no longer allowed (see [ALTER IGNORE TABLE](#)).

For more information about these statements, see [Section 18.3.4, “Maintenance of Partitions”](#).

### 13.1.6.2 ALTER TABLE Examples

Begin with a table `t1` that is created as shown here:

```
CREATE TABLE t1 (a INTEGER,b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,  
ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option. See [Section 5.1.4, “Server System Variables”](#).

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which

the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

### Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

## 13.1.7 ALTER VIEW Syntax

```
ALTER
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` and the effect is the same as for `CREATE OR REPLACE VIEW`. See [Section 13.1.17, “CREATE VIEW Syntax”](#). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is permitted only to the definer or users with the `SUPER` privilege.

## 13.1.8 CREATE DATABASE Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
  [create_specification] ...
```

```
create_specification:
  [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
```

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the `CREATE` privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

An error occurs if the database exists and you did not specify `IF NOT EXISTS`.

In MySQL 5.7, `CREATE DATABASE` is not permitted within a session that has an active `LOCK TABLES` statement.

*create\_specification* options specify database characteristics. Database characteristics are stored in the `db.opt` file in the database directory. The `CHARACTER SET` clause specifies the default database character set. The `COLLATE` clause specifies the default database collation. [Section 10.1, “Character Set Support”](#), discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for permissible database names are given in [Section 9.2, “Schema Object Names”](#). If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

You can also use the `mysqladmin` program to create databases. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

### 13.1.9 CREATE EVENT Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  DO event_body;

schedule:
  AT timestamp [+ INTERVAL interval] ...
  | EVERY interval
  [STARTS timestamp [+ INTERVAL interval] ...]
  [ENDS timestamp [+ INTERVAL interval] ...]

interval:
  quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
            WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
            DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see [Section 19.4.2, “Event Scheduler Configuration”](#).

`CREATE EVENT` requires the `EVENT` privilege for the schema in which the event is to be created. It might also require the `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in a database schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
```

```
DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 9.2, “Schema Object Names”](#).

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create an event with a nonexistent `DEFINER` account, an error occurs at event execution time if the account does not exist.

For more information about event security, see [Section 19.6, “Access Control for Stored Programs and Views”](#).

Within an event, the `CURRENT_USER()` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see [Section 6.3.16, “SQL-Based MySQL Account Activity Auditing”](#).

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `event_body` defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
-> ON SCHEDULE AT '2006-02-10 23:59:00'
-> DO INSERT INTO test.totals VALUES (NOW());
```

```
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
PRESERVE is set. The event was dropped immediately after
creation.
```

`CREATE EVENT` statements which are themselves invalid—for whatever reason—fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the `DATE_ADD()` function (see [Section 12.7, “Date and Time Functions”](#)). The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an *interval* as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

An `EVERY` clause may contain an optional `STARTS` clause. `STARTS` is followed by a *timestamp* value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a *timestamp* value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored

functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the `mysql.event` table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see [Section 19.4.4, “Event Metadata”](#). See also [Section 13.7.5.18, “SHOW EVENTS Syntax”](#), and [Section 20.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the `DISABLE` keyword. Alternatively, you can use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see [Section 13.1.2, “ALTER EVENT Syntax”](#)).

A third value may also appear in place of `ENABLE` or `DISABLE`; `DISABLE ON SLAVE` is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See [Section 17.4.1.12, “Replication of Invoked Features”](#).

You may supply a comment for an event using a `COMMENT` clause. `comment` may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See [Section C.1, “Restrictions on Stored Programs”](#).) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
  EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
  DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, *regardless of the current server SQL mode when the event begins executing*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

#### Note

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
delimiter |

CREATE EVENT e_daily
  ON SCHEDULE
    EVERY 1 DAY
  COMMENT 'Saves total number of sessions then clears the table each day'
  DO
    BEGIN
      INSERT INTO site_activity.totals (time, total)
        SELECT CURRENT_TIMESTAMP, COUNT(*)
          FROM site_activity.sessions;
      DELETE FROM site_activity.sessions;
    END |

delimiter ;
```

This example uses the `delimiter` command to change the statement delimiter. See [Section 19.1, “Defining Stored Programs”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |

CREATE EVENT e
  ON SCHEDULE
    EVERY 5 SECOND
  DO
    BEGIN
      DECLARE v INTEGER;
      DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

      SET v = 0;

      WHILE v < 5 DO
        INSERT INTO t1 VALUES (0);
        UPDATE t2 SET s1 = s1 + 1;
        SET v = v + 1;
      END WHILE;
    END |

delimiter ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```
CREATE EVENT e_call_myproc
  ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
  DO CALL myproc(5, 27);
```

If an event's definer has the `SUPER` privilege, the event can read and write global variables. As granting this privilege entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see [Section 19.2.1, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

### 13.1.10 CREATE FUNCTION Syntax

The `CREATE FUNCTION` statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see [Section 13.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).
- For information about creating user-defined functions, see [Section 13.7.3.1, “CREATE FUNCTION Syntax for User-Defined Functions”](#).

### 13.1.11 CREATE INDEX Syntax

```
CREATE [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
  [index_type]
  ON tbl_name (index_col_name,...)
  [index_option]
  [algorithm_option | lock_option] ...

index_col_name:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH}

index_option:
  KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'

algorithm_option:
  ALGORITHM [=] {DEFAULT|INPLACE|COPY}

lock_option:
  LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See [Section 13.1.6, “ALTER TABLE Syntax”](#). `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See [Section 13.1.14, “CREATE TABLE Syntax”](#). This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. `CREATE INDEX` enables you to add indexes to existing tables.

A column list of the form `(col1,col2,...)` creates a multiple-column index. Index key values are formed by concatenating the values of the given columns.

Indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns.
- `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given.
- Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first *length* bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns.
- For spatial columns, prefix values cannot be given, as described later in this section.

The statement shown here creates an index using the first 10 characters of the `name` column:

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, this index should not be much slower than an index created from the entire `name` column. Also, using column prefixes for indexes can make

the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for `InnoDB` tables or 3072 bytes if the `innodb_large_prefix` option is enabled. For `MyISAM` tables, the prefix limit is 1000 bytes.

#### Note

Prefix limits are measured in bytes, whereas the prefix length in `CREATE INDEX` statements is interpreted as number of characters for nonbinary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multibyte character set.

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix.

`FULLTEXT` indexes are supported only for `InnoDB` and `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation.

The `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` storage engines support spatial columns such as (`POINT` and `GEOMETRY`). ([Section 11.5, “Extensions for Spatial Data”](#), describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes are available according to the following rules.

Spatial indexes (created using `SPATIAL INDEX`) have these characteristics:

- Available only for `MyISAM` and (as of MySQL 5.7.5) `InnoDB` tables. Specifying `SPATIAL INDEX` for other storage engines results in an error.
- Indexed columns must be `NOT NULL`.
- In MySQL 5.7, column prefix lengths are prohibited. The full width of each column is indexed.

Characteristics of nonspatial indexes (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`):

- Permitted for any storage engine that supports spatial columns except `ARCHIVE`.
- Columns can be `NULL` unless the index is a primary key.
- For each spatial column in a non-`SPATIAL` index except `POINT` columns, a column prefix length must be specified. (This is the same requirement as for indexed `BLOB` columns.) The prefix length is given in bytes.
- The index type for a non-`SPATIAL` index depends on the storage engine. Currently, B-tree is used.

In MySQL 5.7:

- You can add an index on a column that can have `NULL` values only if you are using the `InnoDB`, `MyISAM`, or `MEMORY` storage engine.
- You can add an index on a `BLOB` or `TEXT` column only if you are using the `InnoDB` or `MyISAM` storage engine.
- When the `innodb_stats_persistent` setting is enabled, run the `ANALYZE TABLE` statement for an `InnoDB` table after creating an index on that table.

As of MySQL 5.7.8, `InnoDB` supports secondary indexes on virtual columns. For more information, see [Secondary Indexes and Virtual Generated Columns](#).

An *index\_col\_name* specification can end with `ASC` or `DESC`. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

Following the index column list, index options can be given. An *index\_option* value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`

Optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary.

#### Note

`KEY_BLOCK_SIZE` is only supported at the table level for `InnoDB`. See [Section 13.1.14, “CREATE TABLE Syntax”](#).

- *index\_type*

Some storage engines permit you to specify an index type when creating an index. The permissible index type values supported by different storage engines are shown in the following table. Where multiple index types are listed, the first one is the default when no index type specifier is given.

Storage Engine	Permissible Index Types
InnoDB	BTREE
MyISAM	BTREE
MEMORY/HEAP	HASH, BTREE
NDB	HASH, BTREE (see note in text)

Example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

The *index\_type* clause cannot be used together with `SPATIAL INDEX`.

If you specify an index type that is not valid for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes `RTREE` as a type name, but currently this cannot be specified for any storage engine.

Use of this option before the `ON tbl_name` clause is deprecated; support for use of the option in this position will be removed in a future MySQL release. If an *index\_type* option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

- `WITH_PARSER parser_name`

This option can be used only with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. Prior to MySQL 5.7.3, only `MyISAM` supported full-text parser plugins. As of MySQL 5.7.3, both `InnoDB` and `MyISAM` support full-text parser plugins. See [Section 24.2.3.2, “Full-Text Parser Plugins”](#) and [Section 24.2.4.4, “Writing Full-Text Parser Plugins”](#) for more information.

- `COMMENT 'string'`

Index definitions can include an optional comment of up to 1024 characters.

As of MySQL 5.7.6, the `MERGE_THRESHOLD` for index pages can be configured for individual indexes using the `index_option COMMENT` clause of the `CREATE INDEX` statement. For example:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

If the page-full percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value.

`MERGE_THRESHOLD` can also be defined at the index level and table level using `CREATE TABLE` and `ALTER TABLE` statements. For more information, see [Section 14.3.12, “Configuring the Merge Threshold for Index Pages”](#).

`ALGORITHM` and `LOCK` clauses may be given. These influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 13.1.6, “ALTER TABLE Syntax”](#)

## 13.1.12 CREATE PROCEDURE and CREATE FUNCTION Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  PROCEDURE sp_name ([proc_parameter[,...]])
  [characteristic ...] routine_body

CREATE
  [DEFINER = { user | CURRENT_USER }]
  FUNCTION sp_name ([func_parameter[,...]])
  RETURNS type
  [characteristic ...] routine_body

proc_parameter:
  [ IN | OUT | INOUT ] param_name type

func_parameter:
  param_name type

type:
  Any valid MySQL data type

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }

routine_body:
  Valid SQL routine statement
```

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name . sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support UDFs (user-defined functions). See [Section 24.4, “Adding New Functions to MySQL”](#). A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see [Section 13.2.1, “CALL Syntax”](#)). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

`CREATE PROCEDURE` and `CREATE FUNCTION` require the `CREATE ROUTINE` privilege. They might also require the `SUPER` privilege, depending on the `DEFINER` value, as described later in this section. If binary logging is enabled, `CREATE FUNCTION` might require the `SUPER` privilege, as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

By default, MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 19.2.2, “Stored Routines and MySQL Privileges”](#).

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

#### Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

Routine parameters cannot be referenced in statements prepared within the routine; see [Section C.1, “Restrictions on Stored Programs”](#).

The following example shows a simple stored procedure that uses an `OUT` parameter:

```
mysql> delimiter //

mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a    |
```

```
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See [Section 19.1, “Defining Stored Programs”](#).

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
      -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by the `CHARACTER SET` attribute.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in [Section 13.6, “MySQL Compound-Statement Syntax”](#).

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see [Section C.1, “Restrictions on Stored Programs”](#).

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 13.2.1, “CALL Syntax”](#).

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, *regardless of the current server SQL mode when the routine begins executing*.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See [Section 19.7, “Binary Logging of Stored Programs”](#).

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.
- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have

the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a routine with a nonexistent `DEFINER` account, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about stored routine security, see [Section 19.6, “Access Control for Stored Programs and Views”](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. For information about user auditing within stored routines, see [Section 6.3.16, “SQL-Based MySQL Account Activity Auditing”](#).

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.

- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if there is a `CHARACTER SET` attribute in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

If `CHARACTER SET` and `COLLATE` attributes are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide explicit `CHARACTER SET` and `COLLATE` attributes for character data parameters.

If you change the database default character set or collation, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see [Section 10.1.3.2, “Database Character Set and Collation”](#).

### 13.1.13 CREATE SERVER Syntax

```
CREATE SERVER server_name
  FOREIGN DATA WRAPPER wrapper_name
  OPTIONS (option [, option] ...)
```

*option*:

```
{ HOST character-literal
  | DATABASE character-literal
  | USER character-literal
  | PASSWORD character-literal
  | SOCKET character-literal
  | OWNER character-literal
  | PORT numeric-literal }
```

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The `wrapper_name` should be `mysql`, and may be quoted with single quotation marks. Other values for `wrapper_name` are not currently supported.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

#### Note

The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a [FEDERATED](#) table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see [Section 15.8, “The FEDERATED Storage Engine”](#).

`CREATE SERVER` causes an automatic commit.

In MySQL 5.7, `CREATE SERVER` is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

### 13.1.14 CREATE TABLE Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  (create_definition,...)
  [table_options]
  [partition_options]

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  [(create_definition,...)]
  [table_options]
  [partition_options]
  select_statement

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
  { LIKE old_tbl_name | (LIKE old_tbl_name) }
```

*create\_definition*:

```

select_statement:
[IGNORE | REPLACE] [AS] SELECT ... (Some valid select statement)

```

**CREATE TABLE** creates a table with the given name. You must have the **CREATE** privilege for the table.

Rules for permissible table names are given in [Section 9.2, “Schema Object Names”](#). By default, the table is created in the default database, using the **InnoDB** storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

The table name can be specified as *db\_name.tbl\_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

## Cloning or Copying a Table

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see [Section 13.1.14.1, “CREATE TABLE ... LIKE Syntax”](#).

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl;
```

For more information, see [Section 13.1.14.2, “CREATE TABLE ... SELECT Syntax”](#).

## Temporary Tables

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only to the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.) To create temporary tables, you must have the `CREATE TEMPORARY TABLES` privilege.

### Note

`CREATE TABLE` does not automatically commit the current active transaction if you use the `TEMPORARY` keyword.

### Note

`TEMPORARY` tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any `TEMPORARY` tables created within that database. Also, you can create a `TEMPORARY` table in a nonexistent database if you qualify the table name with the database name in the `CREATE TABLE` statement. In this case, all subsequent references to the table must be qualified with the database name.

## Existing Table with Same Name

The keywords `IF NOT EXISTS` prevent an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

## Physical Representation

MySQL represents each table by an `.frm` table format (definition) file in the database directory. The storage engine for the table might create other files as well.

For `InnoDB` tables, the file storage is controlled by the `innodb_file_per_table` configuration option. When this option is turned off, all `InnoDB` tables and indexes are stored in the `system tablespace`, represented by one or more `.ibd` files. For each `InnoDB` table created when this option is turned on, the table data and all associated indexes are stored in a `.ibd` file located inside the database directory.

For `MyISAM` tables, the storage engine creates data and index files. Thus, for each `MyISAM` table `tbl_name`, there are three disk files.

File	Purpose
<code>tbl_name.frm</code>	Table format (definition) file

File	Purpose
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

[Chapter 15, \*Alternative Storage Engines\*](#), describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

## Data Types and Attributes for Columns

`data_type` represents the data type in a column definition. `spatial_type` represents a spatial data type. The data type syntax shown is representative only. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see [Chapter 11, \*Data Types\*](#), and [Section 11.5, “Extensions for Spatial Data”](#). Beginning with MySQL 5.7.8, a `JSON` data type is also supported for table columns; see [Section 11.6, “The JSON Data Type”](#), for more information.

Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. `DEFAULT` does not apply to the `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` types.

- If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.
- An integer or floating-point column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See [Section 12.14, “Information Functions”](#), and [Section 23.8.7.38, “mysql\\_insert\\_id\(\)”](#).

If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store `0` in `AUTO_INCREMENT` columns as `0` without generating a new sequence value. See [Section 5.1.7, “Server SQL Modes”](#).

### Note

There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains `0`.

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See [Section 3.6.9, “Using AUTO\\_INCREMENT”](#).

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to `0`. See [Section 5.1.4, “Server System Variables”](#).

For information about `InnoDB` and `AUTO_INCREMENT`, see [Section 14.5.5, “AUTO\\_INCREMENT Handling in InnoDB”](#). For information about `AUTO_INCREMENT` and MySQL Replication, see [Section 17.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- Character data types ([CHAR](#), [VARCHAR](#), [TEXT](#)) can include [CHARACTER SET](#) and [COLLATE](#) attributes to specify the character set and collation for the column. For details, see [Section 10.1, “Character Set Support”](#). [CHARSET](#) is a synonym for [CHARACTER SET](#). Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.7 interprets length specifications in character column definitions in characters. Lengths for [BINARY](#) and [VARBINARY](#) are in bytes.

- The [DEFAULT](#) clause specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as [NOW\(\)](#) or [CURRENT\\_DATE](#). The exception is that you can specify [CURRENT\\_TIMESTAMP](#) as the default for a [TIMESTAMP](#) or [DATETIME](#) column. See [Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

If a column definition includes no explicit [DEFAULT](#) value, MySQL determines the default value as described in [Section 11.7, “Data Type Default Values”](#).

[BLOB](#), [TEXT](#), and [JSON](#) columns cannot be assigned a default value.

If the [NO\\_ZERO\\_DATE](#) or [NO\\_ZERO\\_IN\\_DATE](#) SQL mode is enabled and a date-valued default is not correct according to that mode, [CREATE TABLE](#) produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with [NO\\_ZERO\\_IN\\_DATE](#) enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

- A comment for a column can be specified with the [COMMENT](#) option, up to 1024 characters long. The comment is displayed by the [SHOW CREATE TABLE](#) and [SHOW FULL COLUMNS](#) statements.
- [COLUMN\\_FORMAT](#) is used by MySQL Cluster to determine a column's storage format. This option currently has no effect on columns of tables using storage engines other than [NDB](#). In MySQL 5.7 and later, [COLUMN\\_FORMAT](#) is silently ignored.
- [KEY](#) is normally a synonym for [INDEX](#). The key attribute [PRIMARY KEY](#) can also be specified as just [KEY](#) when given in a column definition. This was implemented for compatibility with other database systems.
- A [UNIQUE](#) index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a [UNIQUE](#) index permits multiple [NULL](#) values for columns that can contain [NULL](#).
- A [PRIMARY KEY](#) is a unique index where all key columns must be defined as [NOT NULL](#). If they are not explicitly declared as [NOT NULL](#), MySQL declares them so implicitly (and silently). A table can have only one [PRIMARY KEY](#). The name of a [PRIMARY KEY](#) is always [PRIMARY](#), which thus cannot be used as the name for any other kind of index.

If you do not have a [PRIMARY KEY](#) and an application asks for the [PRIMARY KEY](#) in your tables, MySQL returns the first [UNIQUE](#) index that has no [NULL](#) columns as the [PRIMARY KEY](#).

In [InnoDB](#) tables, keep the [PRIMARY KEY](#) short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See [Section 14.2.7, “InnoDB Table and Index Structures”](#).)

- In the created table, a [PRIMARY KEY](#) is placed first, followed by all [UNIQUE](#) indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated [UNIQUE](#) keys.
- A [PRIMARY KEY](#) can be a multiple-column index. However, you cannot create a multiple-column index using the [PRIMARY KEY](#) key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate [PRIMARY KEY\(index\\_col\\_name, ...\)](#) clause.

- If a [PRIMARY KEY](#) or [UNIQUE](#) index consists of only one column that has an integer type, you can also refer to the column as `_rowid` in `SELECT` statements.
- In MySQL, the name of a [PRIMARY KEY](#) is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2`, `_3`, ...) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See [Section 13.7.5.22, “SHOW INDEX Syntax”](#).
- Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`.

Example:

```
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for `USING` is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and will be removed in a future MySQL release.

`index_option` values specify additional options for an index. `USING` is one such option. The `WITH PARSER` option can only be used with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. Prior to MySQL 5.7.3, only `MyISAM` supported full-text parser plugins. As of MySQL 5.7.3, both `InnoDB` and `MyISAM` support full-text parser plugins. If you have a `MyISAM` table with an associated full-text parser plugin, you can convert the table to `InnoDB` using `ALTER TABLE`.

For more information about permissible `index_option` values, see [Section 13.1.11, “CREATE INDEX Syntax”](#). For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

- In MySQL 5.7, only the `InnoDB`, `MyISAM`, and `MEMORY` storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.
- For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first `length` bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. See [Section 8.3.4, “Column Indexes”](#).

Only the `InnoDB` and `MyISAM` storage engines support indexing on `BLOB` and `TEXT` columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 767 bytes long for `InnoDB` tables or 3072 bytes if the `innodb_large_prefix` option is enabled. For `MyISAM` tables, the prefix limit is 1000 bytes.

#### Note

Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters for nonbinary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multibyte character set.

- An *index\_col\_name* specification can end with `ASC` or `DESC`. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.
- When you use `ORDER BY` or `GROUP BY` on a column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.
- You can create special `FULLTEXT` indexes, which are used for full-text searches. Only the `InnoDB` and `MyISAM` storage engines support `FULLTEXT` indexes. They can be created only from `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation. A `WITH PARSER` clause can be specified as an *index\_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for `FULLTEXT` indexes. Prior to MySQL 5.7.3, only `MyISAM` supported full-text parser plugins. As of MySQL 5.7.3, both `InnoDB` and `MyISAM` support full-text parser plugins. See [Section 24.2.3.2, “Full-Text Parser Plugins”](#) and [Section 24.2.4.4, “Writing Full-Text Parser Plugins”](#) for more information.
- You can create `SPATIAL` indexes on spatial data types. Spatial types are supported only for `MyISAM` and (as of MySQL 5.7.5) `InnoDB` tables, and indexed columns must be declared as `NOT NULL`. See [Section 11.5, “Extensions for Spatial Data”](#).
- `JSON` columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the `JSON` column. See [Secondary Indexes and Virtual Generated Columns](#), for a detailed example.
- In MySQL 5.7, index definitions can include an optional comment of up to 1024 characters.
- `InnoDB` tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both `ON DELETE` and `ON UPDATE` actions on foreign keys. For more detailed information and examples, see [Section 13.1.14.3, “Using FOREIGN KEY Constraints”](#). For information specific to foreign keys in `InnoDB`, see [Section 14.5.6, “InnoDB and FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 1.8.2.3, “Foreign Key Differences”](#).

### Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. `InnoDB` essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, `InnoDB` does not enforce any requirement that the referenced columns be declared `UNIQUE` or `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You

are advised to use foreign keys that reference only keys that are both [UNIQUE](#) (or [PRIMARY](#)) and [NOT NULL](#).

MySQL parses but ignores “inline [REFERENCES](#) specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts [REFERENCES](#) clauses only when specified as part of a separate [FOREIGN KEY](#) specification.

#### Note

Partitioned tables employing the [InnoDB](#) storage engine do not support foreign keys. See [Section 18.6, “Restrictions and Limitations on Partitioning”](#), for more information.

- There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

## CREATE TABLE and Generated Columns

As of MySQL 5.7.6, [CREATE TABLE](#) supports the specification of generated columns. Values of a generated column are computed from an expression included in the column definition.

The following simple example shows a table that stores the lengths of the sides of right triangles in the [sidea](#) and [sideb](#) columns, and computes the length of the hypotenuse in [sidec](#) (the square root of the sums of the squares of the other sides):

```
CREATE TABLE triangle (
  sidea DOUBLE,
  sideb DOUBLE,
  sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb))
);
INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);
```

Selecting from the table yields this result:

```
mysql> SELECT * FROM triangle;
+-----+-----+-----+
| sidea | sideb | sidec |
+-----+-----+-----+
|      1 |      1 | 1.4142135623730951 |
|      3 |      4 | 5 |
|      6 |      8 | 10 |
+-----+-----+-----+
```

Any application that uses the [triangle](#) table has access to the hypotenuse values without having to specify the expression that calculates them.

Generated column definitions have this syntax:

```
col_name data_type [GENERATED ALWAYS] AS (expression)
  [VIRTUAL | STORED] [UNIQUE [KEY]] [COMMENT comment]
  [[NOT] NULL] [[PRIMARY] KEY]
```

[AS \(expression\)](#) indicates that the column is generated and defines the expression used to compute column values. [AS](#) may be preceded by [GENERATED ALWAYS](#) to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The [VIRTUAL](#) or [STORED](#) keyword indicates how column values are stored, which has implications for column use:

- **VIRTUAL**: Column values are not stored, but are evaluated when rows are read, immediately after any **BEFORE** triggers. A virtual column takes no storage.

Prior to MySQL 5.7.8, virtual columns cannot be indexed. As of MySQL 5.7.8, **InnoDB** supports secondary indexes on virtual columns. See [Secondary Indexes and Virtual Generated Columns](#).

- **STORED**: Column values are evaluated and stored when rows are inserted or updated. A stored column does require storage space and can be indexed.

The default is **VIRTUAL** if neither keyword is specified.

It is permitted to mix **VIRTUAL** and **STORED** columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be **NULL**, or provide a comment. (Note that the order of these attributes differs from their order in nongenerated column definitions.)

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that fail this definition: `CONNECTION_ID()`, `CURRENT_USER()`, `NOW()`.
- Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.
- A generated column definition can refer to other generated columns, but only those occurring earlier in the table definition. A generated column definition can refer to any base (nongenerated) column in the table whether its definition occurs earlier or later.
- The **AUTO\_INCREMENT** attribute cannot be used in a generated column definition.
- An **AUTO\_INCREMENT** column cannot be used as a base column in a generated column definition.
- As of MySQL 5.7.10, if expression evaluation causes truncation or provides incorrect input to a function, the **CREATE TABLE** statement terminates with an error and the DDL operation is rejected.

If the expression evaluates to a data type that differs from the declared column type, coercion to the declared type occurs according to the usual MySQL type-conversion rules. See [Section 12.2, “Type Conversion in Expression Evaluation”](#).

#### Note

If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For **CREATE TABLE ... LIKE**, the destination table preserves generated column information from the original table.

For **CREATE TABLE ... SELECT**, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The **SELECT** part of the statement cannot assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See [Creating Partitioned Tables](#).

Foreign keys on a **STORED** generated column cannot use **ON DELETE SET NULL**, **ON UPDATE SET NULL**, or **ON UPDATE CASCADE**.

A **VIRTUAL** generated column cannot be referenced as a part of a foreign key constraint.

Triggers cannot use `NEW.col_name` or use `OLD.col_name` to refer to generated columns.

For `INSERT`, `REPLACE`, and `UPDATE`, if a generated column is inserted into, replaced, or updated explicitly, the only permitted value is `DEFAULT`.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`.

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.
- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.
- Generated columns can simulate functional indexes: Use a stored column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as `JSON` columns; see [Secondary Indexes and Virtual Generated Columns](#) for a detailed example.

The disadvantage of such an approach is that values are stored twice; once as the value of the generated column and once in the index.

- If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does not refer to the column directly by name. For details, see [Section 8.3.9, “Optimizer Use of Generated Column Indexes”](#).

Example:

Suppose that a table `t1` contains `first_name` and `last_name` columns and that applications frequently construct the full name using an expression like this:

```
SELECT CONCAT(first_name, ' ', last_name) AS full_name FROM t1;
```

One way to avoid writing out the expression is to create a view `v1` on `t1`, which simplifies applications by enabling them to select `full_name` directly without using an expression:

```
CREATE VIEW v1 AS
SELECT *, CONCAT(first_name, ' ', last_name) AS full_name FROM t1;

SELECT full_name FROM v1;
```

A generated column also enables applications to select `full_name` directly without the need to define a view:

```
CREATE TABLE t1 (
  first_name VARCHAR(10),
  last_name VARCHAR(10),
  full_name VARCHAR(255) AS (CONCAT(first_name, ' ', last_name))
);

SELECT full_name FROM t1;
```

## Secondary Indexes and Virtual Generated Columns

As of MySQL 5.7.8, `InnoDB` supports secondary indexes on virtual generated columns. Other index types are not supported.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and non-virtual generated columns. Secondary indexes on virtual columns may be defined as [UNIQUE](#).

When a secondary index is created on a virtual generated column, generated column values are materialized in the records of the index. If the index is a [covering index](#) (one that includes all the columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during [INSERT](#) and [UPDATE](#) operations. Even with additional write costs, secondary indexes on virtual columns may be preferable to [STORED](#) generated columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column's row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for [COMPACT](#) and [REDUNDANT](#) row formats, and 3072 bytes for [DYNAMIC](#) and [COMPRESSED](#) row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

A secondary index on a virtual column cannot be used as the index for a foreign key.

Secondary indexes are not supported on virtual columns that have a base column that is referenced in a foreign key constraint and uses [ON DELETE CASCADE](#), [ON DELETE SET NULL](#), [ON UPDATE CASCADE](#), or [ON UPDATE SET NULL](#).

As noted elsewhere, [JSON](#) columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:

```
mysql> CREATE TABLE jemp (
->   c JSON,
->   g INT GENERATED ALWAYS AS (JSON_EXTRACT(c, '$.id')),
->   INDEX i (g)
-> );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO jemp (c) VALUES
>   ('{"id": "1", "name": "Fred"}'), ('{"id": "2", "name": "Wilma"}'),
>   ('{"id": "3", "name": "Barney"}'), ('{"id": "4", "name": "Betty"}');
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT JSON_UNQUOTE(JSON_EXTRACT(c, '$.name')) AS name
>   FROM jemp WHERE g > 2;
+-----+
| name |
+-----+
| Barney |
| Betty |
+-----+
2 rows in set (0.00 sec)

mysql> EXPLAIN SELECT JSON_UNQUOTE(JSON_EXTRACT(c, '$.name')) AS name
>   FROM jemp WHERE g > 2\G
***** 1. row *****
      id: 1
select_type: SIMPLE
      table: jemp
  partitions: NULL
      type: range
```

```

possible_keys: i
  key: i
  key_len: 5
  ref: NULL
  rows: 2
  filtered: 100.00
  Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
  Level: Note
  Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`, '$.name'))
AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2)
1 row in set (0.00 sec)

```

(We have wrapped the output from the last statement in this example to fit the viewing area. See [Section 8.3.9, “Optimizer Use of Generated Column Indexes”](#), for the statements used to create and populate the table just shown.)

In MySQL 5.7.9 and later, you can use `->` as shorthand for `JSON_EXTRACT()` to access a value by path from a `JSON` column value. See [Searching and Modifying JSON Values](#), for information about the `JSON` path syntax supported by MySQL.

When you use `EXPLAIN` on a statement containing one or more expressions that use the `->` operator, they are translated into the equivalent expressions using `JSON_EXTRACT()` instead, as shown here in the output from `SHOW WARNINGS` immediately following this `EXPLAIN` statement:

```

mysql> EXPLAIN SELECT c->"$.name"
  > FROM jemp WHERE g > 2\G ORDER BY c->"$.name"
***** 1. row *****
  id: 1
  select_type: SIMPLE
  table: jemp
  partitions: NULL
  type: range
possible_keys: i
  key: i
  key_len: 5
  ref: NULL
  rows: 2
  filtered: 100.00
  Extra: Using where; Using filesort
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
  Level: Note
  Code: 1003
Message: /* select#1 */ select json_extract(`test`.`jemp`.`c`, '$.name') AS
`c->"$.name"` from `test`.`jemp` where (`test`.`jemp`.`g` > 2) order by
json_extract(`test`.`jemp`.`c`, '$.name')
1 row in set (0.00 sec)

```

See the descriptions for the `->` operator and `JSON_EXTRACT()` function ([Section 12.16.3, “Functions That Search JSON Values”](#)) for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as `GEOMETRY` columns.

## Storage Engines

The `ENGINE` table option specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name `'DEFAULT'` is recognized but ignored.

Storage Engine	Description
InnoDB	Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See <a href="#">Chapter 14, The InnoDB Storage Engine</a> , and in particular <a href="#">Section 14.1.1, “InnoDB as the Default MySQL Storage Engine”</a> if you have MySQL experience but are new to InnoDB.
MyISAM	The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See <a href="#">Section 15.2, “The MyISAM Storage Engine”</a> .
MEMORY	The data for this storage engine is stored only in memory. See <a href="#">Section 15.3, “The MEMORY Storage Engine”</a> .
CSV	Tables that store rows in comma-separated values format. See <a href="#">Section 15.4, “The CSV Storage Engine”</a> .
ARCHIVE	The archiving storage engine. See <a href="#">Section 15.5, “The ARCHIVE Storage Engine”</a> .
EXAMPLE	An example engine. See <a href="#">Section 15.9, “The EXAMPLE Storage Engine”</a> .
FEDERATED	Storage engine that accesses remote tables. See <a href="#">Section 15.8, “The FEDERATED Storage Engine”</a> .
HEAP	This is a synonym for MEMORY.
MERGE	A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See <a href="#">Section 15.7, “The MERGE Storage Engine”</a> .

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is MyISAM. For example, if a table definition includes the `ENGINE=INNODB` option but the MySQL server does not support INNODB tables, the table is created as a MyISAM table. This makes it possible to have a replication setup where you have transactional tables on the master but tables created on the slave are nontransactional (to get more speed). In MySQL 5.7, a warning occurs if the storage engine specification is not honored.

Engine substitution can be controlled by the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.7, “Server SQL Modes”](#).

#### Note

The older `TYPE` option that was synonymous with `ENGINE` was removed in MySQL 5.5. *When upgrading to MySQL 5.5 or later, you must convert existing applications that rely on `TYPE` to use `ENGINE` instead.*

## Optimizing Performance

The other table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- `AUTO_INCREMENT`

The initial `AUTO_INCREMENT` value for the table. In MySQL 5.7, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value. The value cannot be set lower than the maximum value currently in the column.

- `AVG_ROW_LENGTH`

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a [MyISAM](#) table, MySQL uses the product of the [MAX\\_ROWS](#) and [AVG\\_ROW\\_LENGTH](#) options to decide how big the resulting table is. If you don't specify either option, the maximum size for [MyISAM](#) data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the [myisam\\_data\\_pointer\\_size](#) system variable. (See [Section 5.1.4, "Server System Variables"](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- [\[DEFAULT\] CHARACTER SET](#)

Specify a default character set for the table. [CHARSET](#) is a synonym for [CHARACTER SET](#). If the character set name is [DEFAULT](#), the database character set is used.

- [CHECKSUM](#)

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The [CHECKSUM TABLE](#) statement reports the checksum. ([MyISAM](#) only.)

- [\[DEFAULT\] COLLATE](#)

Specify a default collation for the table.

- [COMMENT](#)

A comment for the table, up to 2048 characters long.

As of MySQL 5.7.6, the [MERGE\\_THRESHOLD](#) for index pages can be configured for a table's indexes using the [table\\_option COMMENT](#) clause of the [CREATE TABLE](#) statement. For example:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
) COMMENT='MERGE_THRESHOLD=45';
```

If the page-full percentage for an index page falls below the [MERGE\\_THRESHOLD](#) value when a row is deleted or when a row is shortened by an update operation, [InnoDB](#) attempts to merge the index page with a neighboring index page. The default [MERGE\\_THRESHOLD](#) value is 50, which is the previously hardcoded value.

[MERGE\\_THRESHOLD](#) can also be defined for a table's indexes using the [ALTER TABLE table\\_option COMMENT](#) clause. [MERGE\\_THRESHOLD](#) can be defined for individual indexes using [CREATE INDEX](#), or by using the [index\\_option COMMENT](#) clause with [CREATE TABLE](#) or [ALTER TABLE](#). For more information, see [Section 14.3.12, "Configuring the Merge Threshold for Index Pages"](#).

- [COMPRESSION](#)

The compression algorithm used for page level compression for [InnoDB](#) tables. Supported values include [Zlib](#), [LZ4](#), and [None](#). The [COMPRESSION](#) attribute was introduced with the transparent page compression feature in MySQL 5.7.8. Page compression is only supported with [InnoDB](#) tables that reside in [file\\_per\\_table](#) tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see [Section 14.6.2, "InnoDB Page Compression"](#).

- [CONNECTION](#)

The connection string for a [FEDERATED](#) table.

**Note**

Older versions of MySQL used a [COMMENT](#) option for the connection string.

- [DATA DIRECTORY, INDEX DIRECTORY](#)

For [InnoDB](#), the [DATA DIRECTORY='directory'](#) option allows you to create [InnoDB](#) file-per-table tablespaces outside the MySQL data directory. Within the directory that you specify, MySQL creates a subdirectory corresponding to the database name, and within that a [.ibd](#) file for the table. The [innodb\\_file\\_per\\_table](#) configuration option must be enabled to use the [DATA DIRECTORY](#) option with [InnoDB](#). The full directory path must be specified. See [Section 14.4.5, “Creating a File-Per-Table Tablespace Outside the Data Directory”](#) for more information.

When creating [MyISAM](#) tables, you can use the [DATA DIRECTORY='directory'](#) clause, the [INDEX DIRECTORY='directory'](#) clause, or both. They specify where to put a [MyISAM](#) table's data file and index file, respectively. Unlike [InnoDB](#) tables, MySQL does not create subdirectories that correspond to the database name when creating a [MyISAM](#) table with a [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) option. Files are created in the directory that is specified.

**Important**

Table-level [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the [--skip-symbolic-links](#) option. Your operating system must also have a working, thread-safe [realpath\(\)](#) call. See [Section 8.12.4.2, “Using Symbolic Links for MyISAM Tables on Unix”](#), for more complete information.

If a [MyISAM](#) table is created with no [DATA DIRECTORY](#) option, the [.MYD](#) file is created in the database directory. By default, if [MyISAM](#) finds an existing [.MYD](#) file in this case, it overwrites it. The same applies to [.MYI](#) files for tables created with no [INDEX DIRECTORY](#) option. To suppress this behavior, start the server with the [--keep\\_files\\_on\\_create](#) option, in which case [MyISAM](#) will not overwrite existing files and returns an error instead.

If a [MyISAM](#) table is created with a [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) option and an existing [.MYD](#) or [.MYI](#) file is found, [MyISAM](#) always returns an error. It will not overwrite a file in the specified directory.

**Important**

You cannot use path names that contain the MySQL data directory with [DATA DIRECTORY](#) or [INDEX DIRECTORY](#). This includes partitioned tables and individual table partitions. (See Bug #32167.)

- [DELAY\\_KEY\\_WRITE](#)

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the [delay\\_key\\_write](#) system variable in [Section 5.1.4, “Server System Variables”](#). ([MyISAM](#) only.)

- [INSERT\\_METHOD](#)

If you want to insert data into a [MERGE](#) table, you must specify with [INSERT\\_METHOD](#) the table into which the row should be inserted. [INSERT\\_METHOD](#) is an option useful for [MERGE](#) tables only. Use a value of [FIRST](#) or [LAST](#) to have inserts go to the first or last table, or a value of [NO](#) to prevent inserts. See [Section 15.7, “The MERGE Storage Engine”](#).

- [KEY\\_BLOCK\\_SIZE](#)

For [compressed](#) InnoDB tables, optionally specifies the size in kilobytes to use for [pages](#). Possible [KEY\\_BLOCK\\_SIZE](#) values include 0, 1, 2, 4, 8, and 16. The [KEY\\_BLOCK\\_SIZE](#) value is treated as a hint; a different size could be used by InnoDB if necessary. A value of 0 represents the default compressed page size, which is half of the [innodb\\_page\\_size](#) value. The [KEY\\_BLOCK\\_SIZE](#) can only be less than or equal to the [innodb\\_page\\_size](#) value. If you specify a value greater than the [innodb\\_page\\_size](#) value, the value is ignored, a warning is issued, and [KEY\\_BLOCK\\_SIZE](#) is set to half of the [innodb\\_page\\_size](#) value. If [innodb\\_strict\\_mode=ON](#), specifying an invalid [KEY\\_BLOCK\\_SIZE](#) value returns an error. See [Section 14.6, “InnoDB Table and Page Compression”](#) for usage details.

**Note**

Support for 32k and 64k pages sizes was added in MySQL 5.7.6 but these page sizes are not supported with [ROW\\_FORMAT=COMPRESSED](#). For more information, refer to the [innodb\\_page\\_size](#) documentation.

Individual index definitions can specify a [KEY\\_BLOCK\\_SIZE](#) value of their own to override the table value.

**Note**

Oracle recommends enabling [innodb\\_strict\\_mode](#) when using the [KEY\\_BLOCK\\_SIZE](#) clause for InnoDB tables.

- [MAX\\_ROWS](#)

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

The maximum [MAX\\_ROWS](#) value is 4294967295; larger values are truncated to this limit.

- [MIN\\_ROWS](#)

The minimum number of rows you plan to store in the table. The [MEMORY](#) storage engine uses this option as a hint about memory use.

- [PACK\\_KEYS](#)

[PACK\\_KEYS](#) takes effect only with [MyISAM](#) tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to [DEFAULT](#) tells the storage engine to pack only long [CHAR](#), [VARCHAR](#), [BINARY](#), or [VARBINARY](#) columns.

If you do not use [PACK\\_KEYS](#), the default is to pack strings, but not numbers. If you use [PACK\\_KEYS=1](#), numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes [storage\\_size\\_for\\_key + pointer\\_size](#) (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if

the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- `PASSWORD`

This option is unused. If you have a need to scramble your `.frm` files and make them unusable to any other MySQL server, please contact our sales department.

- `ROW_FORMAT`

Defines the physical format in which the rows are stored. The choices differ depending on the storage engine used for the table.

For `InnoDB` tables:

- In MySQL 5.7.8 and earlier, rows are stored in `COMPACT` format by default. As of MySQL 5.7.9, the default row format is defined by `innodb_default_row_format`, which has a default setting of `DYNAMIC`. The default row format is used when the `ROW_FORMAT` option is not defined or when `ROW_FORMAT=DEFAULT` is used.

If the `ROW_FORMAT` option is not defined, or if `ROW_FORMAT=DEFAULT` is used, operations that rebuild a table also silently change the row format of the table to the default defined by `innodb_default_row_format`. For more information, see [Section 14.8.2, “Specifying the Row Format for a Table”](#).

- For more efficient `InnoDB` storage of data types, especially `BLOB` types, use the `DYNAMIC`. See [Section 14.8.3, “DYNAMIC and COMPRESSED Row Formats”](#) for requirements associated with the `DYNAMIC` row format.
- To enable compression for `InnoDB` tables, specify `ROW_FORMAT=COMPRESSED`. See [Section 14.6, “InnoDB Table and Page Compression”](#) for requirements associated with the `COMPRESSED` row format.
- The row format used in older versions of MySQL can still be requested by specifying the `REDUNDANT` row format.
- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.
- `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, `InnoDB` issues a warning and assumes `ROW_FORMAT=COMPACT`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, which is the default as of MySQL 5.7.7, `InnoDB` returns an error.
- For additional information about `InnoDB` row formats, see [Section 14.8, “InnoDB Row Storage and Row Formats”](#).

For `MyISAM` tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See [Section 15.2.3, “MyISAM Table Storage Formats”](#).

#### Note

When executing a `CREATE TABLE` statement, if you specify a row format that is not supported by the storage engine that is used for the table, the table is created using that storage engine's default row format. The information reported in this column in response to `SHOW TABLE STATUS` is the actual row format used. This may differ from the value in the `Create_options` column because the original `CREATE TABLE` definition is retained during creation.

- `STATS_AUTO_RECALC`

Specifies whether to automatically recalculate [persistent statistics](#) for an `InnoDB` table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_PERSISTENT`

Specifies whether to enable [persistent statistics](#) for an `InnoDB` table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_SAMPLE_PAGES`

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. For more information, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `TABLESPACE`

The `TABLESPACE` option may be used to create a table in an existing general tablespace, a file-per-table tablespace, or the system tablespace.

```
CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name
```

For information about general tablespaces, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

The `tablespace_name` is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character (“/”) is not permitted. Names beginning with “`innodb_`” are reserved for special use.

The `TABLESPACE` option may be used to assign `InnoDB` table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the system tablespace. `TABLESPACE` option support for table partitions and subpartitions was added in MySQL 5.7.8. All partitions must belong to the same storage engine.

A tablespace specified at the table level becomes the default tablespace for new partitions and subpartitions. The default tablespace may be overridden by specifying a tablespace at the partition or subpartition level in a `CREATE TABLE` or `ALTER TABLE` statement. The following example shows tablespaces defined at the table level and partition level.

```
mysql> CREATE TABLE t1 ( a INT NOT NULL, PRIMARY KEY (a))
-> ENGINE=InnoDB TABLESPACE ts1
-> PARTITION BY RANGE (a) PARTITIONS 3 (
-> PARTITION P1 VALUES LESS THAN (2),
-> PARTITION P2 VALUES LESS THAN (4) TABLESPACE ts2,
-> PARTITION P3 VALUES LESS THAN (6) TABLESPACE ts3);
```

For more information about the `TABLESPACE` option and partitioning, see [Section 14.4.9, “InnoDB General Tablespaces”](#)

To create a table in the system tablespace, specify `innodb_system` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system
```

Using the `TABLESPACE [=] innodb_system` option, you can place a table of any uncompressed row format in the system tablespace regardless of the `innodb_file_per_table` setting. For example, you can add a table with `ROW_FORMAT=DYNAMIC` to the system tablespace using the `TABLESPACE [=] innodb_system` option.

To create a table in a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
```

#### Note

If `innodb_file_per_table` is enabled, you need not specify `TABLESPACE=innodb_file_per_table` to create an InnoDB file-per-table tablespace. InnoDB tables are created in file-per-table tablespaces by default when `innodb_file_per_table` is enabled.

The `DATA DIRECTORY` clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the `TABLESPACE` option.

The `TABLESPACE` option is supported with `ALTER TABLE` and `ALTER TABLE ... REORGANIZE PARTITION` statements, which can be used to move tables and partitions from one tablespace to another, respectively. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

- `UNION`

`UNION` is used when you want to access a collection of identical `MyISAM` tables as one. This works only with `MERGE` tables. See [Section 15.7, “The MERGE Storage Engine”](#).

You must have `SELECT`, `UPDATE`, and `DELETE` privileges for the tables you map to a `MERGE` table.

#### Note

Formerly, all tables used had to be in the same database as the `MERGE` table itself. This restriction no longer applies.

## Creating Partitioned Tables

`partition_options` can be used to control partitioning of the table created with `CREATE TABLE`.

#### Important

Not all options shown in the syntax for `partition_options` at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 18, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

If used, a `partition_options` clause begins with `PARTITION BY`. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to `num`, where `num` is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.) The choices that are available for this function in MySQL 5.7 are shown in the following list:

- `HASH(expr)`: Hashes one or more columns to create a key for placing and locating rows. `expr` is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
  PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
  PARTITION BY HASH ( YEAR(col3) );
```

You may not use either [VALUES LESS THAN](#) or [VALUES IN](#) clauses with [PARTITION BY HASH](#).

[PARTITION BY HASH](#) uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 18.2.4, “HASH Partitioning”](#).

The [LINEAR](#) keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical [AND](#) operations. For discussion and examples of linear hashing, see [Section 18.2.4.1, “LINEAR HASH Partitioning”](#).

- [KEY\(\*column\\_list\*\)](#): This is similar to [HASH](#), except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column\_list* argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY KEY(col3)
  PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the [LINEAR](#) keyword. This has the same effect as with tables that are partitioned by [HASH](#). That is, the partition number is found using the [&](#) operator rather than the modulus (see [Section 18.2.4.1, “LINEAR HASH Partitioning”](#), and [Section 18.2.5, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
  PARTITION BY LINEAR KEY(col3)
  PARTITIONS 5;
```

The [ALGORITHM={1|2}](#) option is supported with [\[SUB\]PARTITION BY \[LINEAR\] KEY](#) beginning with MySQL 5.7.1. [ALGORITHM=1](#) causes the server to use the same key-hashing functions as MySQL 5.1; [ALGORITHM=2](#) means that the server employs the key-hashing functions implemented and used by default for new [KEY](#) partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using [ALGORITHM=2](#). This option is intended for use chiefly when upgrading or downgrading [\[LINEAR\] KEY](#) partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by [KEY](#) or [LINEAR KEY](#) on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see [Section 13.1.6.1, “ALTER TABLE Partition Operations”](#).

`mysqldump` in MySQL 5.7 (and later) writes this option encased in versioned comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50611 ALGORITHM = 1 */ /*!50100 ( )
  PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.7 server where you use tables that are partitioned or subpartitioned by [KEY](#) into a MySQL 5.6 server previous to version 5.6.11, be sure to consult [Changes Affecting Upgrades to MySQL 5.6](#), before proceeding. (The information found there also applies if you are loading a dump containing [KEY](#) partitioned or subpartitioned tables made from a MySQL 5.7—actually 5.6.11 or later—server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.6.11 and later, `ALGORITHM=1` is shown when necessary in the output of `SHOW CREATE TABLE` using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is always omitted from `SHOW CREATE TABLE` output, even if this option was specified when creating the original table.

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- `RANGE(expr)`: In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

#### Note

For tables partitioned by `RANGE`, `VALUES LESS THAN` must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 5.7, you can overcome this limitation in a table that is defined using `PARTITION BY RANGE COLUMNS`, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

Partition Number:	Years Range:
0	1990 and earlier
1	1991 to 1994
2	1995 to 1998
3	1999 to 2002
4	2003 to 2005
5	2006 and later

A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```
CREATE TABLE t1 (
  year_col INT,
  some_data INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2002),
  PARTITION p4 VALUES LESS THAN (2006),
  PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- `RANGE COLUMNS(column_list)`: This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND`

`b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...` You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```
CREATE TABLE rc (
  a INT NOT NULL,
  b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (10,5),
  PARTITION p1 VALUES LESS THAN (20,10),
  PARTITION p2 VALUES LESS THAN (MAXVALUE,15),
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see [Section 18.2.1, “RANGE Partitioning”](#), and [Section 18.4, “Partition Pruning”](#).

- `LIST(expr)`: This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify permissible values for each partition.

`VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

### Note

For tables partitioned by `LIST`, the value list used with `VALUES IN` must consist of integer values only. In MySQL 5.7, you can overcome this limitation using partitioning by `LIST COLUMNS`, which is described later in this section.

- `LIST COLUMNS(column_list)`: This variant on `LIST` facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as `WHERE a = 5 AND b = 5` or `WHERE a = 1 AND b = 10 AND c = 5`). It enables you to specify values in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES IN (value_list)` partition definition clause.

The rules governing regarding data types for the column list used in `LIST COLUMNS(column_list)` and the value list used in `VALUES IN(value_list)` are the same as those for the column list used in `RANGE COLUMNS(column_list)` and the value list used in `VALUES LESS THAN(value_list)`, respectively, except that in the `VALUES IN` clause, `MAXVALUE` is not permitted, and you may use `NULL`.

There is one important difference between the list of values used for `VALUES IN` with `PARTITION BY LIST COLUMNS` as opposed to when it is used with `PARTITION BY LIST`. When used with `PARTITION BY LIST COLUMNS`, each element in the `VALUES IN` clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the `COLUMNS` clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the `column_list` and in the elements making up the `value_list` is 16.

The table defined by the following `CREATE TABLE` statement provides an example of a table using `LIST COLUMNS` partitioning:

```
CREATE TABLE lc (
  a INT NULL,
  b INT NULL
)
PARTITION BY LIST COLUMNS(a,b) (
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
  PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- The number of partitions may optionally be specified with a `PARTITIONS num` clause, where *num* is the number of partitions. If both this clause *and* any `PARTITION` clauses are used, *num* must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

### Note

Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

- Rigorous checking of the value used in `PARTITIONS` or `SUBPARTITIONS` clauses is applied and this value must adhere to the following rules:
  - The value must be a positive, nonzero integer.
  - No leading zeros are permitted.
  - The value must be an integer literal, and cannot not be an expression. For example, `PARTITIONS 0.2E+01` is not permitted, even though `0.2E+01` evaluates to 2. (Bug #15890)

#### Note

The expression (*expr*) used in a `PARTITION BY` clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

Each partition may be individually defined using a *partition\_definition* clause. The individual parts making up this clause are as follows:

- `PARTITION partition_name`: This specifies a logical name for the partition.
- A `VALUES` clause: For range partitioning, each partition must include a `VALUES LESS THAN` clause; for list partitioning, you must specify a `VALUES IN` clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 18, Partitioning](#), for syntax examples.
- An optional `COMMENT` clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

The maximum length for a partition comment is 1024 characters.

- `DATA DIRECTORY` and `INDEX DIRECTORY` may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the *data\_dir* and the *index\_dir* must be absolute system path names. Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
  DATA DIRECTORY = '/var/appdata/95/data'
  INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
  DATA DIRECTORY = '/var/appdata/96/data'
  INDEX DIRECTORY = '/var/appdata/96/idx',
  PARTITION p2001 VALUES IN (1997, 2001, 2005)
  DATA DIRECTORY = '/var/appdata/97/data'
  INDEX DIRECTORY = '/var/appdata/97/idx',
  PARTITION p2002 VALUES IN (1998, 2002, 2006)
  DATA DIRECTORY = '/var/appdata/98/data'
  INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

`DATA DIRECTORY` and `INDEX DIRECTORY` behave in the same way as in the `CREATE TABLE` statement's *table\_option* clause as used for `MyISAM` tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions of `MyISAM` tables, and the `INDEX DIRECTORY` option is not supported for individual partitions or subpartitions of `InnoDB` tables. These options are ignored on Windows, except that a warning is generated. (Bug #30459)

**Note**

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` is in effect. (Bug #24633)

- `MAX_ROWS` and `MIN_ROWS` may be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.
- `TABLESPACE` may be used to assign InnoDB table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the system tablespace. `TABLESPACE` option support for table partitions and subpartitions was added in MySQL 5.7.8. All partitions must belong to the same storage engine. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).
- The partitioning handler accepts a `[STORAGE] ENGINE` option for both `PARTITION` and `SUBPARTITION`. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error `ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL`. We expect to lift this restriction on partitioning in a future MySQL release.
- The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See [Section 18.2.6, “Subpartitioning”](#).

Partitioning by generated columns is permitted. For example:

```
CREATE TABLE t1 (
  s1 INT,
  s2 INT AS (EXP(s1)) STORED
)
PARTITION BY LIST (s2) (
  PARTITION p1 VALUES IN (1)
);
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see [Section 18.6.3, “Partitioning Limitations Relating to Functions”](#)). The preceding example demonstrates this technique: `EXP()` cannot be used directly in the `PARTITION BY` clause, but a generated column defined using `EXP()` is permitted.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 13.1.6, “ALTER TABLE Syntax”](#). For more detailed descriptions and examples, see [Section 18.3, “Partition Management”](#).

**Important**

The original `CREATE TABLE` statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an `ALTER TABLE` statement, the original table options specified are retained. This enables you to change between InnoDB and MyISAM table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured (such as the

`ROW_FORMAT`), the active table definition (accessible through `DESCRIBE` or with `SHOW TABLE STATUS`) and the table creation string (accessible through `SHOW CREATE TABLE`) will report different values.

### 13.1.14.1 CREATE TABLE ... LIKE Syntax

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

#### Important

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

`CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE` and does not just copy the `.frm` file. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

### 13.1.14.2 CREATE TABLE ... SELECT Syntax

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,  
-> PRIMARY KEY (a), KEY(b))  
-> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
```

```

+----+
|  n  |
+----+
|  1  |
+----+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
|  m    |  n  |
+-----+-----+
| NULL |  1  |
+-----+-----+
1 row in set (0.00 sec)

```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Because the ordering of the rows in the underlying `SELECT` statements cannot always be determined, `CREATE TABLE ... IGNORE SELECT` and `CREATE TABLE ... REPLACE SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. See also [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

For `CREATE TABLE ... SELECT`, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The `SELECT` part of the statement cannot assign values to generated columns in the destination table.

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
SELECT artist.name, COUNT(work.artist_id) AS number_of_works
FROM artist LEFT JOIN work ON artist.id = work.artist_id
```

```
GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails.

### 13.1.14.3 Using FOREIGN KEY Constraints

MySQL supports foreign keys, which let you cross-reference related data across tables, and [foreign key constraints](#), which help keep this spread-out data consistent. The essential syntax for a foreign key constraint definition in a `CREATE TABLE` or `ALTER TABLE` statement looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (index_col_name, ...)
REFERENCES tbl_name (index_col_name,...)
[ON DELETE reference_option]
[ON UPDATE reference_option]

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION
```

`index_name` represents a foreign key ID. The `index_name` value is ignored if there is already an explicitly defined index on the child table that can support the foreign key. Otherwise, MySQL implicitly creates a foreign key index that is named according to the following rules:

- If defined, the `CONSTRAINT symbol` value is used. Otherwise, the `FOREIGN KEY index_name` value is used.
- If neither a `CONSTRAINT symbol` or `FOREIGN KEY index_name` is defined, the foreign key index name is generated using the name of the referencing foreign key column.

Foreign keys definitions are subject to the following conditions:

- Foreign key relationships involve a [parent table](#) that holds the central data values, and a [child table](#) with identical values pointing back to its parent. The `FOREIGN KEY` clause is specified in the child table. The parent and child tables must use the same storage engine. They must not be [TEMPORARY](#) tables.

In MySQL 5.7, creation of a foreign key constraint requires the `REFERENCES` privilege for the parent table as of 5.7.6.

- Corresponding columns in the foreign key and the referenced key must have similar data types. *The size and sign of integer types must be the same.* The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is described in [Section 13.1.6, "ALTER TABLE Syntax"](#).
- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the

referencing table automatically if it does not exist. This index might be silently dropped later, if you create another index that can be used to enforce the foreign key constraint. *index\_name*, if given, is used as described previously.

- **InnoDB** permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that **BLOB** and **TEXT** columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.
- If the **CONSTRAINT** *symbol* clause is given, the *symbol* value, if used, must be unique in the database. A duplicate *symbol* will result in an error similar to: `ERROR 1022 (2300): Can't write; duplicate key in table '#sql- 464_1'`. If the clause is not given, or a *symbol* is not included following the **CONSTRAINT** keyword, a name for the constraint is created automatically.
- **InnoDB** does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

## Referential Actions

This section describes how foreign keys help guarantee [referential integrity](#).

For storage engines supporting foreign keys, MySQL rejects any **INSERT** or **UPDATE** operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table.

When an **UPDATE** or **DELETE** operation affects a key value in the parent table that has matching rows in the child table, the result depends on the *referential action* specified using **ON UPDATE** and **ON DELETE** subclauses of the **FOREIGN KEY** clause. MySQL supports five options regarding the action to be taken, listed here:

- **CASCADE**: Delete or update the row from the parent table, and automatically delete or update the matching rows in the child table. Both **ON DELETE CASCADE** and **ON UPDATE CASCADE** are supported. Between two tables, do not define several **ON UPDATE CASCADE** clauses that act on the same column in the parent table or in the child table.

### Note

Cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table, and set the foreign key column or columns in the child table to **NULL**. Both **ON DELETE SET NULL** and **ON UPDATE SET NULL** clauses are supported.

If you specify a **SET NULL** action, *make sure that you have not declared the columns in the child table as **NOT NULL***.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying **RESTRICT** (or **NO ACTION**) is the same as omitting the **ON DELETE** or **ON UPDATE** clause.
- **NO ACTION**: A keyword from standard SQL. In MySQL, equivalent to **RESTRICT**. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and **NO ACTION** is a deferred check. In MySQL, foreign key constraints are checked immediately, so **NO ACTION** is the same as **RESTRICT**.
- **SET DEFAULT**: This action is recognized by the MySQL parser, but **InnoDB** rejects table definitions containing **ON DELETE SET DEFAULT** or **ON UPDATE SET DEFAULT** clauses.

For an `ON DELETE` or `ON UPDATE` that is not specified, the default action is always `RESTRICT`.

MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, “child table records” really refers to dependent records within the same table.

Foreign keys on a generated column cannot use `ON DELETE SET NULL`, `ON UPDATE SET NULL`, or `ON UPDATE CASCADE`.

## Examples of Foreign Key Clauses

Here is a simple example that relates `parent` and `child` tables through a single-column foreign key:

```
CREATE TABLE parent (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE child (
  id INT,
  parent_id INT,
  INDEX par_ind (parent_id),
  FOREIGN KEY (parent_id)
    REFERENCES parent(id)
    ON DELETE CASCADE
) ENGINE=INNODB;
```

A more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```
CREATE TABLE product (
  category INT NOT NULL, id INT NOT NULL,
  price DECIMAL,
  PRIMARY KEY(category, id)
) ENGINE=INNODB;

CREATE TABLE customer (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE product_order (
  no INT NOT NULL AUTO_INCREMENT,
  product_category INT NOT NULL,
  product_id INT NOT NULL,
  customer_id INT NOT NULL,

  PRIMARY KEY(no),
  INDEX (product_category, product_id),
  INDEX (customer_id),

  FOREIGN KEY (product_category, product_id)
    REFERENCES product(category, id)
    ON UPDATE CASCADE ON DELETE RESTRICT,

  FOREIGN KEY (customer_id)
    REFERENCES customer(id)
) ENGINE=INNODB;
```

## Adding foreign keys

You can add a new foreign key constraint to an existing table by using `ALTER TABLE`. The syntax relating to foreign keys for this statement is shown here:

```
ALTER TABLE tbl_name
  ADD [CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name, ...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, *remember to create the required indexes first*.

## Dropping Foreign Keys

You can also use `ALTER TABLE` to drop foreign keys, using the syntax shown here:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the `FOREIGN KEY` clause included a `CONSTRAINT` name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the `fk_symbol` value is generated internally when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use a `SHOW CREATE TABLE` statement, as shown here:

```
mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;
```

Prior to MySQL 5.6.6, adding and dropping a foreign key in the same `ALTER TABLE` statement may be problematic in some cases and is therefore unsupported. Separate statements should be used for each operation. As of MySQL 5.6.6, adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but remains unsupported for `ALTER TABLE ... ALGORITHM=COPY`.

In MySQL 5.7, the server prohibits changes to foreign key columns with the potential to cause loss of referential integrity. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward.

## Foreign Keys and Other MySQL Statements

Table and column identifiers in a `FOREIGN KEY ... REFERENCES ...` clause can be quoted within backticks (```). Alternatively, double quotation marks (`"`) can be used if the `ANSI_QUOTES` SQL mode is enabled. The setting of the `lower_case_table_names` system variable is also taken into account.

You can view a child table's foreign key definitions as part of the output of the `SHOW CREATE TABLE` statement:

```
SHOW CREATE TABLE tbl_name;
```

You can also obtain information about foreign keys by querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table.

You can find information about foreign keys used by InnoDB tables in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, also in the `INFORMATION_SCHEMA` database.

`mysqldump` produces correct definitions of tables in the dump file, including the foreign keys for child tables.

To make it easier to reload dump files for tables that have foreign key relationships, `mysqldump` automatically includes a statement in the dump output to set `foreign_key_checks` to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET foreign_key_checks = 0;
mysql> SOURCE dump_file_name;
mysql> SET foreign_key_checks = 1;
```

This enables you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `foreign_key_checks` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE` operations. However, even if `foreign_key_checks = 0`, MySQL does not permit the creation of a foreign key constraint where a column references a nonmatching column type. Also, if a table has foreign key constraints, `ALTER TABLE` cannot be used to alter the table to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

You cannot issue `DROP TABLE` for a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET foreign_key_checks = 0`. When you drop a table, any constraints that were defined in the statement used to create that table are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the correct column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns Error 1005 and refers to Error 150 in the error message, which means that a foreign key constraint was not correctly formed. Similarly, if an `ALTER TABLE` fails due to Error 150, this means that a foreign key definition would be incorrectly formed for the altered table.

For InnoDB tables, you can obtain a detailed explanation of the most recent InnoDB foreign key error in the MySQL Server, by checking the output of `SHOW ENGINE INNODB STATUS`.

### Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including InnoDB, recognizes or enforces the `MATCH` clause used in referential-integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. MySQL essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance reasons. However, the system does not enforce a requirement that

the referenced columns be [UNIQUE](#) or be declared [NOT NULL](#). The handling of foreign key references to nonunique keys or keys that contain [NULL](#) values is not well defined for operations such as [UPDATE](#) or [DELETE CASCADE](#). You are advised to use foreign keys that reference only [UNIQUE](#) (including [PRIMARY](#)) and [NOT NULL](#) keys.

Furthermore, MySQL parses but ignores “inline [REFERENCES](#) specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts [REFERENCES](#) clauses only when specified as part of a separate [FOREIGN KEY](#) specification. For storage engines that do not support foreign keys (such as [MyISAM](#)), MySQL Server parses and ignores foreign key specifications.

#### 13.1.14.4 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- Columns that are part of a [PRIMARY KEY](#) are made [NOT NULL](#) even if not declared that way.
- Trailing spaces are automatically deleted from [ENUM](#) and [SET](#) member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See [Section 11.10, “Using Data Types from Other Database Engines”](#).
- If you include a [USING](#) clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a [VARCHAR](#) column with a length specification greater than 65535 is converted to [TEXT](#), and a [VARBINARY](#) column with a length specification greater than 65535 is converted to [BLOB](#). Otherwise, an error occurs in either of these cases.
- Specifying the [CHARACTER SET binary](#) attribute for a character data type causes the column to be created as the corresponding binary data type: [CHAR](#) becomes [BINARY](#), [VARCHAR](#) becomes [VARBINARY](#), and [TEXT](#) becomes [BLOB](#). For the [ENUM](#) and [SET](#) data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a [DESCRIBE](#) or [SHOW CREATE TABLE](#) statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using `myisampack`. See [Section 15.2.3.3, “Compressed Table Characteristics”](#).

### 13.1.15 CREATE TABLESPACE Syntax

```
CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
  [FILE_BLOCK_SIZE = value]
  [ENGINE [=] engine_name]
```

This statement is used to create an `InnoDB` tablespace. An `InnoDB` tablespace created using `CREATE TABLESPACE` is referred to as *general tablespace*.

A general tablespace is a shared tablespace, similar to the system tablespace. It can hold multiple tables, and supports all table row formats. General tablespaces can also be created in a location relative to or independent of the MySQL data directory.

After creating an `InnoDB` general tablespace, you can use `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` to add tables to the tablespace.

For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

`CREATE TABLESPACE` is supported with `InnoDB` as of MySQL 5.7.6. In earlier releases, `CREATE TABLESPACE` supports `NDB`, which is the MySQL Cluster storage engine. `CREATE TABLESPACE` will support `NDB` in MySQL 5.7 when MySQL Cluster is branched from the MySQL 5.7 code base. The latest version of MySQL Cluster is based on MySQL 5.6.

#### Options

- **ADD DATAFILE:** Defines the name of the tablespace data file. A data file must be specified with the `CREATE TABLESPACE` statement, and the data file name must have a `.ibd` extension. An `InnoDB` general tablespace only supports a single data file.

To place the data file in a location outside of the MySQL data directory (`DATADIR`), include an absolute directory path or a path relative to the MySQL data directory. If you do not specify a path, the general tablespace is created in the MySQL data directory. As of MySQL 5.7.8, an `isl` file is created in the MySQL data directory when a general tablespace is created outside of the MySQL data directory.

To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the MySQL data directory is not supported. Also, when creating a general tablespace outside of the MySQL data directory, the directory must exist prior to creating the tablespace.

The `file_name`, including the path (optional), must be quoted with single or double quotation marks. File names (not counting the `.ibd` extension) and directory names must be at least one byte in length. Zero length file names and directory names are not supported.

- **FILE\_BLOCK\_SIZE:** Defines the block size of the tablespace data file. If you do not specify this option, `FILE_BLOCK_SIZE` defaults to `innodb_page_size`. The `FILE_BLOCK_SIZE` setting is only required if you will use the tablespace to store compressed `InnoDB` tables (`ROW_FORMAT=COMPRESSED`). In this case, you must define the tablespace `FILE_BLOCK_SIZE` when creating the tablespace.

If `FILE_BLOCK_SIZE` is equal `innodb_page_size`, the tablespace can only contain tables with an uncompressed row format (`COMPACT`, `REDUNDANT`, and `DYNAMIC` row formats). Tables with a `COMPRESSED` row format have a different physical page size than uncompressed tables. Therefore, compressed tables cannot coexist in the same tablespace as uncompressed tables.

For a general tablespace to contain compressed tables, `FILE_BLOCK_SIZE` must be specified, and the `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value. Also, the physical page size of the compressed table (`KEY_BLOCK_SIZE`) must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16K`, and `FILE_BLOCK_SIZE=8K`, the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

- `ENGINE`: Defines the storage engine which uses the tablespace, where `engine_name` is the name of the storage engine. Currently, only the InnoDB storage engine is supported. `ENGINE = InnoDB` must be defined as part of the `CREATE TABLESPACE` statement or InnoDB must be defined as the default storage engine (`default_storage_engine=InnoDB`).

## Notes

- `tablespace_name` is a case-sensitive identifier for the tablespace. It may be quoted or unquoted. The forward slash character (“/”) is not permitted. Names beginning with `innodb_` are either not permitted or are reserved for special use.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.
- As of MySQL 5.7.8, the `TABLESPACE` option may be used with `CREATE TABLE` or `ALTER TABLE` to assign InnoDB table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the system tablespace. `TABLESPACE` option support for table partitions and subpartitions was added in MySQL 5.7.8. All partitions must belong to the same storage engine. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).
- `innodb_file_per_table`, `innodb_file_format`, and `innodb_file_format_max` settings have no influence on `CREATE TABLESPACE` operations. `innodb_file_per_table` does not need to be enabled. General tablespaces support all table row formats regardless of file format settings. Likewise, general tablespaces support the addition of tables of any row format using `CREATE TABLE ... TABLESPACE`, regardless of file format settings.
- `innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules are strictly enforced independently of `innodb_strict_mode`. If `CREATE TABLESPACE` parameters are incorrect or incompatible, the operation fails regardless of the `innodb_strict_mode` setting. When a table is added to a general tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE`, `innodb_strict_mode` is ignored but the statement is evaluated as if `innodb_strict_mode` is enabled.
- Use `DROP TABLESPACE` to remove a general tablespace. All tables must be dropped from a general tablespace using `DROP TABLE` prior to dropping the tablespace.
- All parts of a table added to a general tablespace reside in the general tablespace, including indexes and BLOB pages.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace [.ibd data file](#) which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.
- A general tablespace is not associated with any database or schema.
- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- The server uses tablespace-level metadata locking for DDL that references general tablespaces. By comparison, the server uses table-level metadata locking for DDL that references file-per-table tablespaces.

- A generated or existing tablespace cannot be changed to a general tablespace.
- Tables stored in a general tablespace can only be opened in MySQL 5.7.6 or later due to the addition of new table flags.
- There is no conflict between general tablespace names and file-per-table tablespace names. The “/” character, which is present in file-per-table tablespace names, is not permitted in general tablespace names.
- General tablespaces created on Windows using a relative data file path cannot be opened on Unix-like systems. This limitation is removed in MySQL 5.7.8 (Bug #20555168).
- In MySQL 5.7.6 and MySQL 5.7.7, tables stored in general tablespaces may not open (due to a missing general tablespace file) after moving the MySQL data directory to a new location. This limitation is addressed in MySQL 5.7.8 with the introduction of `isl` files for general tablespaces created outside of the MySQL data directory (Bug #20563954).

## Examples

This example demonstrates creating a general tablespace and adding three uncompressed tables of different row formats.

```
mysql> CREATE TABLESPACE `ts1`
->     ADD DATAFILE 'ts1.ibd'
->     ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY)
->     TABLESPACE ts1
->     ROW_FORMAT=REDUNDANT;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY)
->     TABLESPACE ts1
->     ROW_FORMAT=COMPACT;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY)
->     TABLESPACE ts1
->     ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.00 sec)
```

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2`
->     ADD DATAFILE 'ts2.ibd'
->     FILE_BLOCK_SIZE = 8192
->     ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY)
->     TABLESPACE ts2
->     ROW_FORMAT=COMPRESSED
->     KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

## 13.1.16 CREATE TRIGGER Syntax

```
CREATE
[DEFINER = { user | CURRENT_USER }]
TRIGGER trigger_name
trigger_time trigger_event
```

```

ON tbl_name FOR EACH ROW
  [trigger_order]
  trigger_body

trigger_time: { BEFORE | AFTER }

trigger_event: { INSERT | UPDATE | DELETE }

trigger_order: { FOLLOWS | PRECEDES } other_trigger_name

```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named *tbl\_name*, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes `CREATE TRIGGER` syntax. For additional discussion, see [Section 19.3.1, “Trigger Syntax and Examples”](#).

`CREATE TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger. The statement might also require the `SUPER` privilege, depending on the `DEFINER` value, as described later in this section. If binary logging is enabled, `CREATE TRIGGER` might require the `SUPER` privilege, as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

*trigger\_time* is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

*trigger\_event* indicates the kind of operation that activates the trigger. These *trigger\_event* values are permitted:

- `INSERT`: The trigger activates whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- `UPDATE`: The trigger activates whenever a row is modified; for example, through `UPDATE` statements.
- `DELETE`: The trigger activates whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. `DROP TABLE` and `TRUNCATE TABLE` statements on the table do *not* activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

The *trigger\_event* does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger activates not only for `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

#### Note

Cascaded foreign key actions do not activate triggers.

As of MySQL 5.7.2, it is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a *trigger\_order* clause that indicates `FOLLOWS` or

`PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

Before MySQL 5.7.2, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_body` is the statement to execute when the trigger activates. To execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are permitted within stored routines. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#). Some statements are not permitted in triggers; see [Section C.1, “Restrictions on Stored Programs”](#).

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use `NEW.col_name` or use `OLD.col_name` to refer to generated columns. For information about generated columns, see [CREATE TABLE and Generated Columns](#).

MySQL stores the `sql_mode` system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, *regardless of the current server SQL mode when the trigger begins executing*.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a trigger with a nonexistent `DEFINER` account, it is not a good idea for such triggers to be activated until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
  - The `TRIGGER` privilege for the subject table.
  - The `SELECT` privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.
  - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.
- Whatever other privileges normally are required for the statements executed by the trigger.

For more information about trigger security, see [Section 19.6, “Access Control for Stored Programs and Views”](#).

Within a trigger body, the `CURRENT_USER()` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see [Section 6.3.16, “SQL-Based MySQL Account Activity Auditing”](#).

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in [Section 13.3.5.2, “LOCK TABLES and Triggers”](#).

For additional discussion of trigger use, see [Section 19.3.1, “Trigger Syntax and Examples”](#).

## 13.1.17 CREATE VIEW Syntax

```
CREATE
  [OR REPLACE]
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` is the same as `ALTER VIEW`.

The `select_statement` is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The `select_statement` can select from base tables or other views.

The view definition is “frozen” at creation time. Changes to the underlying tables afterward do not affect the view definition. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. `CREATE VIEW` might also require the `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional `column_list` clause can be given as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables.

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty  | price | value |
+-----+-----+-----+
| 3    | 50    | 150   |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- Before MySQL 5.7.7, the `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. After the view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

If you create a view and then change the query processing environment by changing system variables, that may affect the results you get from the view:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
```

```

Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc   |
+-----+
1 row in set (0.00 sec)

```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only valid `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a view with a nonexistent `DEFINER` account, an error occurs when the view is referenced if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about view security, see [Section 19.6, "Access Control for Stored Programs and Views"](#).

Within a view definition, `CURRENT_USER` returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view's invoker. For information about user auditing within views, see [Section 6.3.16, "SQL-Based MySQL Account Activity Auditing"](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT` privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function

invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.

- The user who references a view must have appropriate privileges to access it ([SELECT](#) to select from it, [INSERT](#) to insert into it, and so forth.)
- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view [DEFINER](#) account or invoker, depending on whether the [SQL SECURITY](#) characteristic is [DEFINER](#) or [INVOKER](#), respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function [SQL SECURITY](#) characteristic is [DEFINER](#) or [INVOKER](#). If the security characteristic is [DEFINER](#), the function runs with the privileges of the [DEFINER](#) account. If the characteristic is [INVOKER](#), the function runs with the privileges determined by the view's [SQL SECURITY](#) characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the [SQL SECURITY](#) values of the view `v` and the function `f()`.

The [DEFINER](#) and [SQL SECURITY](#) clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for [SQL SECURITY DEFINER](#). The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, [SELECT](#)) and may grant them. MySQL has no concept of a schema "owner", so MySQL adds a clause to identify the definer. The [DEFINER](#) clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default [DEFINER](#) value is the account of the view creator.

The optional [ALGORITHM](#) clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. [ALGORITHM](#) takes three values: [MERGE](#), [TEMPTABLE](#), or [UNDEFINED](#). For more information, see [Section 19.5.2, "View Processing Algorithms"](#).

Some views are updatable. That is, you can use them in statements such as [UPDATE](#), [DELETE](#), or [INSERT](#) to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is [DEFAULT](#). For information about generated columns, see [CREATE TABLE and Generated Columns](#).

The [WITH CHECK OPTION](#) clause can be given for an updatable view to prevent inserts or updates to rows except those for which the [WHERE](#) clause in the `select_statement` is true.

In a [WITH CHECK OPTION](#) clause for an updatable view, the [LOCAL](#) and [CASCADED](#) keywords determine the scope of check testing when the view is defined in terms of another view. The [LOCAL](#)

keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADDED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADDED`.

For more information about updatable views and the `WITH CHECK OPTION` clause, see [Section 19.5.3, “Updatable and Insertable Views”](#), and [Section 19.5.4, “The View WITH CHECK OPTION Clause”](#).

Views created before MySQL 5.7.3 containing `ORDER BY integer` can result in errors at view evaluation time. Consider these view definitions, which use `ORDER BY` with an ordinal number:

```
CREATE VIEW v1 AS SELECT x, y, z FROM t ORDER BY 2;
CREATE VIEW v2 AS SELECT x, 1, z FROM t ORDER BY 2;
```

In the first case, `ORDER BY 2` refers to a named column `y`. In the second case, it refers to a constant 1. For queries that select from either view fewer than 2 columns (the number named in the `ORDER BY` clause), an error occurs if the server evaluates the view using the MERGE algorithm. Examples:

```
mysql> SELECT x FROM v1;
ERROR 1054 (42S22): Unknown column '2' in 'order clause'
mysql> SELECT x FROM v2;
ERROR 1054 (42S22): Unknown column '2' in 'order clause'
```

As of MySQL 5.7.3, to handle view definitions like this, the server writes them differently into the `.frm` file that stores the view definition. This difference is visible with `SHOW CREATE VIEW`. Previously, the `.frm` file contained this for the `ORDER BY 2` clause:

```
For v1: ORDER BY 2
For v2: ORDER BY 2
```

As of 5.7.3, the `.frm` file contains this:

```
For v1: ORDER BY `t`.`y`
For v2: ORDER BY ''
```

That is, for `v1`, 2 is replaced by a reference to the name of the column referred to. For `v2`, 2 is replaced by a constant string expression (ordering by a constant has no effect, so ordering by any constant will do).

If you experience view-evaluation errors such as just described, drop and recreate the view so that the `.frm` file contains the updated view representation. Alternatively, for views like `v2` that order by a constant value, drop and recreate the view with no `ORDER BY` clause.

## 13.1.18 DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

### Important

When a database is dropped, user privileges on the database are *not* automatically dropped. See [Section 13.7.1.4, “GRANT Syntax”](#).

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the `DATABASE()` function returns `NULL`).

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions.

<code>.BAK</code>	<code>.DAT</code>	<code>.HSH</code>	<code>.MRG</code>
<code>.MYD</code>	<code>.MYI</code>	<code>.TRG</code>	<code>.TRN</code>
<code>.cfg</code>	<code>.db</code>	<code>.frm</code>	<code>.ibd</code>
<code>.ndb</code>	<code>.par</code>		

- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See [Temporary Tables](#).

You can also drop databases with `mysqladmin`. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

### 13.1.19 DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

### 13.1.20 DROP FUNCTION Syntax

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see [Section 13.1.22, “DROP PROCEDURE and DROP FUNCTION Syntax”](#).
- For information about dropping user-defined functions, see [Section 13.7.3.2, “DROP FUNCTION Syntax”](#).

### 13.1.21 DROP INDEX Syntax

```
DROP INDEX index_name ON tbl_name
    [algorithm_option | lock_option] ...
algorithm_option:
```

```
ALGORITHM [=] {DEFAULT|INPLACE|COPY}
```

*lock\_option*:

```
LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

`DROP INDEX` drops the index named *index\_name* from the table *tbl\_name*. This statement is mapped to an `ALTER TABLE` statement to drop the index. See [Section 13.1.6, “ALTER TABLE Syntax”](#).

To drop a primary key, the index name is always `PRIMARY`, which must be specified as a quoted identifier because `PRIMARY` is a reserved word:

```
DROP INDEX `PRIMARY` ON t;
```

`ALGORITHM` and `LOCK` clauses may be given. These influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 13.1.6, “ALTER TABLE Syntax”](#)

## 13.1.22 DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the `ALTER ROUTINE` privilege for the routine. (If the `automatic_sp_privileges` system variable is enabled, that privilege and `EXECUTE` are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See [Section 19.2.2, “Stored Routines and MySQL Privileges”](#).)

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

`DROP FUNCTION` is also used to drop user-defined functions (see [Section 13.7.3.2, “DROP FUNCTION Syntax”](#)).

## 13.1.23 DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named *server\_name*. The corresponding row in the `mysql.servers` table is deleted. This statement requires the `SUPER` privilege.

Dropping a server for a table does not affect any `FEDERATED` tables that used this connection information when they were created. See [Section 13.1.13, “CREATE SERVER Syntax”](#).

`DROP SERVER` does not cause an automatic commit.

In MySQL 5.7, `DROP SERVER` is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

## 13.1.24 DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
  tbl_name [, tbl_name] ...
  [RESTRICT | CASCADE]
```

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table. All table data and the table definition are *removed*, so *be careful* with this statement! If any of the tables named in the argument list do not exist, MySQL returns an error indicating by name which nonexisting tables it was unable to drop, but it also drops all of the tables in the list that do exist.

### Important

When a table is dropped, user privileges on the table are *not* automatically dropped. See [Section 13.7.1.4, “GRANT Syntax”](#).

For a partitioned table, `DROP TABLE` permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes partition definitions associated with the dropped table.

### Note

Prior to MySQL 5.7.6, `DROP TABLE` removes partition definitions (`.par`) files associated with the dropped table. As of MySQL 5.7.6, partition definition (`.par`) files are no longer created. Instead, partition definitions are stored in the internal data dictionary.

Use `IF EXISTS` to prevent an error from occurring for tables that do not exist. A `NOTE` is generated for each nonexistent table when using `IF EXISTS`. See [Section 13.7.5.40, “SHOW WARNINGS Syntax”](#).

`RESTRICT` and `CASCADE` are permitted to make porting easier. In MySQL 5.7, they do nothing.

### Note

`DROP TABLE` automatically commits the current active transaction, unless you use the `TEMPORARY` keyword.

The `TEMPORARY` keyword has the following effects:

- The statement drops only `TEMPORARY` tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A `TEMPORARY` table is visible only to the session that created it, so no check is necessary.)

Using `TEMPORARY` is a good way to ensure that you do not accidentally drop a non-`TEMPORARY` table.

## 13.1.25 DROP TABLESPACE Syntax

```
DROP TABLESPACE tablespace_name
[ENGINE [=] engine_name]
```

This statement is used to drop an `InnoDB` general tablespace that was created using `CREATE TABLESPACE` (see [Section 13.1.15, “CREATE TABLESPACE Syntax”](#)).

All tables must be dropped from the tablespace prior to a `DROP TABLESPACE` operation. If the tablespace is not empty, `DROP TABLESPACE` returns an error.

*tablespace\_name* is a case-sensitive identifier in MySQL.

**ENGINE:** Defines the storage engine that uses the tablespace, where *engine\_name* is the name of the storage engine. Currently, only the `InnoDB` storage engine is supported. You do not need to specify `ENGINE = InnoDB` if `InnoDB` is defined as the default storage engine (`default_storage_engine=InnoDB`).

`DROP TABLESPACE` is supported with `InnoDB` as of MySQL 5.7.6. In earlier releases, `DROP TABLESPACE` supports `NDB`, which is the MySQL Cluster storage engine. `DROP TABLESPACE` will

support [NDB](#) in MySQL 5.7 when MySQL Cluster is branched from the MySQL 5.7 code base. The latest version of MySQL Cluster is based on MySQL 5.6.

## Notes

- A general [InnoDB](#) tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.
- A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new [InnoDB](#) data. Space is not released back to the operating system as it is for file-per-table tablespaces.

## Example

This example demonstrates how to drop an [InnoDB](#) general tablespace. The general tablespace `ts1` is created with a single table. Before dropping the tablespace, the table must be dropped.

```
mysql> CREATE TABLESPACE `ts1`
->     ADD DATAFILE 'ts1.ibd'
->     ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY)
->     TABLESPACE ts10
->     ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)

mysql> DROP TABLE t1;
Query OK, 0 rows affected (0.01 sec)

mysql> DROP TABLESPACE ts1;
Query OK, 0 rows affected (0.01 sec)
```

## 13.1.26 DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the [TRIGGER](#) privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A [NOTE](#) is generated for a nonexistent trigger when using `IF EXISTS`. See [Section 13.7.5.40, “SHOW WARNINGS Syntax”](#).

Triggers for a table are also dropped if you drop the table.

## 13.1.27 DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
  view_name [, view_name] ...
  [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the [DROP](#) privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which nonexistent views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each nonexistent view. See [Section 13.7.5.40, "SHOW WARNINGS Syntax"](#).

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

### 13.1.28 RENAME TABLE Syntax

```
RENAME TABLE tbl_name TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables. The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running.

For example, a table named `old_table` can be renamed to `new_table` as shown here:

```
RENAME TABLE old_table TO new_table;
```

This statement is equivalent to the following `ALTER TABLE` statement:

```
ALTER TABLE old_table RENAME new_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
             new_table TO old_table,
             tmp_table TO new_table;
```

MySQL checks the destination table name before checking whether the source table exists. For example, if `new_table` already exists and `old_table` does not, the following statement fails as shown here:

```
mysql> SHOW TABLES;
+-----+
| Tables_in_mydb |
+-----+
| table_a        |
+-----+
1 row in set (0.00 sec)

mysql> RENAME TABLE table_b TO table_a;
ERROR 1050 (42S01): Table 'table_a' already exists
```

As long as two databases are on the same file system, you can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

You can use this method to move all tables from one database to a different one, in effect renaming the database. (MySQL has no single statement to perform this task.)

If there are any triggers associated with a table which is moved to a different database using `RENAME TABLE`, then the statement fails with the error `Trigger in wrong schema`.

Foreign keys that point to the renamed table are not automatically updated. In such cases, you must drop and re-create the foreign keys in order for them to function properly.

`RENAME TABLE` also works for views, as long as you do not try to rename a view into a different database.

Any privileges granted specifically for the renamed table or view are not migrated to the new name. They must be changed manually.

When you execute `RENAME TABLE`, you cannot have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

You cannot use `RENAME TABLE` to rename a `TEMPORARY` table. However, you can use `ALTER TABLE` with temporary tables.

Like `RENAME TABLE`, `ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used to perform the rename, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move the table files.

## 13.1.29 TRUNCATE TABLE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege.

Logically, `TRUNCATE TABLE` is similar to a `DELETE` statement that deletes all rows, or a sequence of `DROP TABLE` and `CREATE TABLE` statements. To achieve high performance, it bypasses the DML method of deleting data. Thus, it cannot be rolled back, it does not cause `ON DELETE` triggers to fire, and it cannot be performed for `InnoDB` tables with parent-child foreign key relationships.

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways in MySQL 5.7:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back.
- Truncation operations cannot be performed if the session holds an active table lock.
- `TRUNCATE TABLE` fails for an `InnoDB` table or `NDB` table if there are any `FOREIGN KEY` constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for `MyISAM` and `InnoDB`, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (`.par`) file is unaffected.

### Note

As of MySQL 5.7.6, partition definition (`.par`) files are no longer created. Instead, partition definitions are stored in the internal data dictionary.

- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using `InnoDB` and other transactional storage engines where the transaction isolation level does not permit statement-based logging (`READ COMMITTED` or `READ UNCOMMITTED`), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replication slaves using `InnoDB` in the manner described previously.

On a system with a large `InnoDB` buffer pool and `innodb_adaptive_hash_index` enabled, `TRUNCATE TABLE` operations may cause a temporary drop in system performance due to an LRU scan that occurs when removing an `InnoDB` table's adaptive hash index entries. The problem was addressed for `DROP TABLE` in MySQL 5.5.23 (Bug #13704145, Bug #64284) but remains a known issue for `TRUNCATE TABLE` (Bug #68184).

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. See [Section 21.9.14, “Performance Schema Summary Tables”](#).

## 13.2 Data Manipulation Statements

### 13.2.1 CALL Syntax

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.

Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
```

```
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.3-m3-log | 11 |
+-----+-----+
```

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholders can be used for `IN` parameters. For `OUT` and `INOUT` parameters, placeholder support is available as of MySQL 5.5.3. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.3-m3-log | 11 |
+-----+-----+
```

Before MySQL 5.5.3, placeholder support is not available for `OUT` or `INOUT` parameters. To work around this limitation for `OUT` and `INOUT` parameters, forego the use of placeholders; instead, refer to user variables in the `CALL` statement itself and do not specify them in the `EXECUTE` statement:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(@version, @increment)';
mysql> EXECUTE s;
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.0-m2-log | 11 |
+-----+-----+
```

To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). In MySQL 5.7, `CLIENT_MULTI_RESULTS` is enabled by default.

To process the result of a `CALL` statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 23.8.17, "C API Support for Multiple Statement Execution"](#).

For programs written in a language that provides a MySQL interface, there is no native method prior to MySQL 5.5.3 for directly retrieving the results of `OUT` or `INOUT` parameters from `CALL` statements. To get the parameter values, pass user-defined variables to the procedure in the `CALL` statement and then execute a `SELECT` statement to produce a result set containing the variable values. To handle an `INOUT` parameter, execute a statement prior to the `CALL` that sets the corresponding user variable to the value to be passed to the procedure.

The following example illustrates the technique (without error checking) for the stored procedure `p` described earlier that has an `OUT` parameter and an `INOUT` parameter:

```
mysql_query(mysql, "SET @increment = 10");
mysql_query(mysql, "CALL p(@version, @increment)");
mysql_query(mysql, "SELECT @version, @increment");
result = mysql_store_result(mysql);
row = mysql_fetch_row(result);
mysql_free_result(result);
```

After the preceding code executes, `row[0]` and `row[1]` contain the values of `@version` and `@increment`, respectively.

In MySQL 5.7, C programs can use the prepared-statement interface to execute `CALL` statements and access `OUT` and `INOUT` parameters. This is done by processing the result of a `CALL` statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see [Section 23.8.20, “C API Support for Prepared CALL Statements”](#). Languages that provide a MySQL interface can use prepared `CALL` statements to directly retrieve `OUT` and `INOUT` procedure parameters.

In MySQL 5.7, metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#).

## 13.2.2 DELETE Syntax

`DELETE` is a DML statement that removes rows from a table.

### Single-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
  [PARTITION (partition_name,...)]
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

The `DELETE` statement deletes rows from `tbl_name` and returns the number of deleted rows. To check the number of deleted rows, call the `ROW_COUNT()` function described in [Section 12.14, “Information Functions”](#).

### Main Clauses

The conditions in the optional `WHERE` clause identify which rows to delete. With no `WHERE` clause, all rows are deleted.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 13.2.9, “SELECT Syntax”](#).

If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

### Multiple-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name[.*] [, tbl_name[.*]] ...
  FROM table_references
  [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
```

```
FROM tbl_name[.*] [, tbl_name[.*]] ...  
USING table_references  
[WHERE where_condition]
```

## Privileges

You need the `DELETE` privilege on a table to delete rows from it. You need only the `SELECT` privilege for any columns that are only read, such as those named in the `WHERE` clause.

## Performance

When you do not need to know the number of deleted rows, the `TRUNCATE TABLE` statement is a faster way to empty a table than a `DELETE` statement with no `WHERE` clause. Unlike `DELETE`, `TRUNCATE TABLE` cannot be used within a transaction or if you have a lock on the table. See [Section 13.1.29, “TRUNCATE TABLE Syntax”](#) and [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#).

The speed of delete operations may also be affected by factors discussed in [Section 8.2.2.3, “Speed of DELETE Statements”](#).

To ensure that a given `DELETE` statement does not take too much time, the MySQL-specific `LIMIT row_count` clause for `DELETE` specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the `DELETE` statement until the number of affected rows is less than the `LIMIT` value.

## Subqueries

You cannot delete from a table and select from the same table in a subquery.

## Partitioned Tables

`DELETE` supports explicit partition selection using the `PARTITION` option, which takes a comma-separated list of the names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table `t` with a partition named `p0`, executing the statement `DELETE FROM t PARTITION (p0)` has the same effect on the table as executing `ALTER TABLE t TRUNCATE PARTITION (p0)`; in both cases, all rows in partition `p0` are dropped.

`PARTITION` can be used along with a `WHERE` condition, in which case the condition is tested only on rows in the listed partitions. For example, `DELETE FROM t PARTITION (p0) WHERE c < 5` deletes rows only from partition `p0` for which the condition `c < 5` is true; rows in any other partitions are not checked and thus not affected by the `DELETE`.

The `PARTITION` option can also be used in multiple-table `DELETE` statements. You can use up to one such option per table named in the `FROM` option.

See [Section 18.5, “Partition Selection”](#), for more information and examples.

## Auto-Increment Columns

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a `MyISAM` or `InnoDB` table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `autocommit` mode, the sequence starts over for all storage engines except `InnoDB` and `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, as discussed in [Section 14.5.5, “AUTO\\_INCREMENT Handling in InnoDB”](#).

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See [Section 3.6.9, “Using AUTO\\_INCREMENT”](#).

## Modifiers

The `DELETE` statement supports the following modifiers:

- If you specify `LOW_PRIORITY`, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- For `MyISAM` tables, if you use the `QUICK` keyword, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The `IGNORE` keyword causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

## Order of Deletion

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'  
ORDER BY timestamp_column LIMIT 1;
```

`ORDER BY` also helps to delete rows in an order required to avoid referential integrity violations.

## InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an `InnoDB` table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use `DELETE` at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use `RENAME TABLE` to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while `RENAME TABLE` executes, so the rename operation is not subject to concurrency problems. See [Section 13.1.28, “RENAME TABLE Syntax”](#).

## MyISAM Tables

In `MyISAM` tables, deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. To reclaim unused space and reduce file sizes, use the `OPTIMIZE TABLE` statement or the `myisamchk` utility to reorganize tables. `OPTIMIZE TABLE` is easier to use, but `myisamchk` is faster. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

The **QUICK** modifier affects whether index leaves are merged for delete operations. **DELETE QUICK** is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

**DELETE QUICK** is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of **QUICK** can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed **AUTO\_INCREMENT** column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using **DELETE QUICK**.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of **QUICK**. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use **DELETE** without **QUICK**, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use **OPTIMIZE TABLE**.

If you are going to delete many rows from a table, it might be faster to use **DELETE QUICK** followed by **OPTIMIZE TABLE**. This rebuilds the index rather than performing many index block merge operations.

## Multi-Table Deletes

You can specify multiple tables in a **DELETE** statement to delete rows from one or more tables depending on the condition in the **WHERE** clause. You cannot use **ORDER BY** or **LIMIT** in a multiple-table **DELETE**. The *table\_references* clause lists the tables involved in the join, as described in [Section 13.2.9.2, “JOIN Syntax”](#).

For the first multiple-table syntax, only matching rows from the tables listed before the **FROM** clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the **FROM** clause (before the **USING** clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables **t1** and **t2**.

The preceding examples use **INNER JOIN**, but multiple-table **DELETE** statements can use other types of join permitted in **SELECT** statements, such as **LEFT JOIN**. For example, to delete rows that exist in **t1** that have no match in **t2**, use a **LEFT JOIN**:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits **.\*** after each *tbl\_name* for compatibility with **Access**.

If you use a multiple-table **DELETE** statement involving **InnoDB** tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the **ON DELETE** capabilities that **InnoDB** provides to cause the other tables to be modified accordingly.

**Note**

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table **DELETE** should be declared only in the *table\_references* part of the statement. Elsewhere, alias references are permitted but not alias declarations.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;

DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

### 13.2.3 DO Syntax

```
DO expr [, expr] ...
```

**DO** executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT *expr*, ...**, but has the advantage that it is slightly faster when you do not care about the result.

**DO** is useful primarily with functions that have side effects, such as **RELEASE\_LOCK()**.

Example: This **SELECT** statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+-----+
| SLEEP(5) |
+-----+
|          0 |
+-----+
1 row in set (5.02 sec)
```

**DO**, on the other hand, pauses without producing a result set.:

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

**DO** only executes expressions. It cannot be used in all cases where **SELECT** can be used. For example, **DO id FROM t1** is invalid because it references a table.

As of MySQL 5.7.8, **DO** statement errors that previously were converted to warnings are returned as errors.

### 13.2.4 HANDLER Syntax

```

HANDLER tbl_name OPEN [ [AS] alias ]

HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
  [ WHERE where_condition ] [LIMIT ... ]

HANDLER tbl_name CLOSE

```

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for InnoDB and MyISAM tables.

The `HANDLER ... OPEN` statement opens a table, making it accessible using subsequent `HANDLER ... READ` statements. This table object is not shared by other sessions and is not closed until the session calls `HANDLER ... CLOSE` or the session terminates. If you open the table using an alias, further references to the open table with other `HANDLER` statements must use the alias rather than the table name.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```

HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...

```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier ``PRIMARY``:

```

HANDLER tbl_name READ `PRIMARY` ...

```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a MyISAM table data file. This statement works for InnoDB tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See [Section 13.2.9, "SELECT Syntax"](#).

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
  - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.

- There is no optimizer or query-checking overhead.
- The handler interface does not have to provide a consistent look of the data (for example, [dirty reads](#) are permitted), so the storage engine can use optimizations that [SELECT](#) does not normally permit.
- [HANDLER](#) makes it easier to port to MySQL applications that use a low-level [ISAM](#)-like interface. (See [Section 14.17, “InnoDB Integration with memcached”](#) for an alternative way to adapt applications that use the key-value store paradigm.)
- [HANDLER](#) enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with [SELECT](#). The [HANDLER](#) interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

[HANDLER](#) is a somewhat low-level statement. For example, it does not provide consistency. That is, [HANDLER ... OPEN](#) does *not* take a snapshot of the table, and does *not* lock the table. This means that after a [HANDLER ... OPEN](#) statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to [HANDLER ... NEXT](#) or [HANDLER ... PREV](#) scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes [FLUSH TABLES](#) or DDL statements on the handler's table.
- The session in which the handler is open executes non-[HANDLER](#) statements that use tables.

[TRUNCATE TABLE](#) for a table closes all handlers for the table that were opened with [HANDLER OPEN](#).

If a table is flushed with [FLUSH TABLES tbl\\_name WITH READ LOCK](#) was opened with [HANDLER](#), the handler is implicitly flushed and loses its position.

In previous versions of MySQL, [HANDLER](#) was not supported with partitioned tables. This limitation is removed beginning with MySQL 5.7.1.

## 13.2.5 INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  SET col_name={expr | DEFAULT}, ...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
```

```
[PARTITION (partition_name,...)]
[ (col_name,...)]
SELECT ...
[ ON DUPLICATE KEY UPDATE
  col_name=expr
  [, col_name=expr] ... ]
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in [Section 13.2.5.1, “INSERT ... SELECT Syntax”](#).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The `PARTITION` option takes a comma-separated list of the names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given `INSERT` statement do not match one of the partitions listed, the `INSERT` statement fails with the error `Found a row not matching the given partition set`. See [Section 18.5, “Partition Selection”](#), for more information and examples.

In MySQL 5.7, the `DELAYED` keyword is accepted but ignored by the server. See [Section 13.2.5.2, “INSERT DELAYED Syntax”](#), for the reasons for this.

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded. See [Section 13.2.8, “REPLACE Syntax”](#).

*tbl\_name* is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the `VALUES` list or the `SELECT` statement.
- If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.
- The `SET` clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 11.7, “Data Type Default Values”](#). See also [Section 1.8.3.3, “Constraints on Invalid Data”](#).

If you want an `INSERT` statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See [Section 5.1.7, “Server SQL Modes”](#).

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the `VALUES` list.

You can also use `DEFAULT(col_name)` as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression *expr* to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string '1999.0e-2' into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column results in the values 1999, 19.9921, 19.992100, and 1999 being inserted, respectively. The reason the value stored in the `INT` and `YEAR` columns is 1999 is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression *expr* can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, and either may be used whether there is a single values list or multiple lists.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` function (see Section 12.14, "Information Functions"), or the `mysql_affected_rows()` C API function (see Section 23.8.7.1, "mysql\_affected\_rows()").

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is `0` for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)
- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as `'10.34 a'` to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to `0`.
- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If a generated column is inserted into explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [CREATE TABLE and Generated Columns](#).

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See [Section 23.8.7.36, “mysql\\_info\(\)”](#).

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the SQL `LAST_INSERT_ID()` function. From within the C API, use the `mysql_insert_id()` function. However, you should note that the two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in [Section 12.14, “Information Functions”](#), and [Section 23.8.7.38, “mysql\\_insert\\_id\(\)”](#).

The `INSERT` statement supports the following modifiers:

- `INSERT DELAYED` was deprecated in MySQL 5.6, and is scheduled for eventual removal. In MySQL 5.7, the `DELAYED` keyword is accepted but ignored. Use `INSERT` (without `DELAYED`) instead. See [Section 13.2.5.2, “INSERT DELAYED Syntax”](#).
- If you use the `LOW_PRIORITY` keyword, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time.

#### Note

`LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See [Section 8.11.3, “Concurrent Inserts”](#).

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See [Section 8.11.3, “Concurrent Inserts”](#).

`LOW_PRIORITY` and `HIGH_PRIORITY` affect only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- If you use the `IGNORE` keyword, errors that occur while executing the `INSERT` statement are ignored. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row is discarded and no error occurs. Ignored errors generate warnings instead.

`IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error; however, when `INSERT IGNORE` is used, the insert operation fails silently for the row containing the unmatched value, but any rows that are matched are inserted. For an example, see [Section 18.2.2, “LIST Partitioning”](#).

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See [Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

Inserting into a table requires the `INSERT` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE` privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

In MySQL 5.7, an `INSERT` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions into which rows are actually inserted. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Section 18.6.4, “Partitioning and Locking”](#).

### 13.2.5.1 INSERT ... SELECT Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. (This was not possible in some older versions of MySQL.) However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into a table at the same time, MySQL creates a temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, it remains true that you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a

`TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement (see [Section B.5.6.2, “TEMPORARY Table Problems”](#)).

- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements.
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a `PARTITION` option following the name of the table. When `PARTITION` is used with the name of the source table in the `SELECT` portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When `PARTITION` is used with the name of the target table for the `INSERT` portion of the statement, then it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option, else the `INSERT ... SELECT` statement fails. For more information and examples, see [Section 18.5, “Partition Selection”](#).

In the values part of `ON DUPLICATE KEY UPDATE`, you can refer to columns in other tables, as long as you do not use `GROUP BY` in the `SELECT` part. One side effect is that you must qualify nonunique column names in the values part.

The order in which rows are returned by a `SELECT` statement with no `ORDER BY` clause is not determined. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the master and the slave; this can lead to inconsistencies between them. To prevent this from occurring, you should always write `INSERT ... SELECT` statements that are to be replicated as `INSERT ... SELECT ... ORDER BY column`. The choice of `column` does not matter as long as the same order for returning the rows is enforced on both the master and the slave. See also [Section 17.4.1.17, “Replication and LIMIT”](#).

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

In MySQL 5.7, an `INSERT ... SELECT` statement that acted on partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the target table; however, only those partitions that are actually read from the source table are locked. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) See [Section 18.6.4, “Partitioning and Locking”](#), for more information.

### 13.2.5.2 INSERT DELAYED Syntax

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as `MyISAM`), such that when a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

`DELAYED` inserts and replaces were deprecated in MySQL 5.6.6. In MySQL 5.7, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the insert as a nondelayed insert, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning (“INSERT DELAYED is no longer supported. The statement was converted to INSERT”). The `DELAYED` keyword is scheduled for removal in a future release.

### 13.2.5.3 INSERT ... ON DUPLICATE KEY UPDATE Syntax

If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, MySQL performs an `UPDATE` of the old row. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE table SET c=c+1 WHERE a=1;
```

(The effects are not identical for an `InnoDB` table where `a` is an auto-increment column. With an auto-increment column, an `INSERT` statement increases the auto-increment value but `UPDATE` does not.)

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

You can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... UPDATE` statements and returns `NULL` otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements for the master and the slave to diverge. Thus, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. In addition, an `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more

than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637) See also [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

In MySQL 5.7, an `INSERT ... ON DUPLICATE KEY UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks any partitions of the table in which a partitioning key column is updated. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) See [Section 18.6.4, “Partitioning and Locking”](#), for more information.

## 13.2.6 LOAD DATA INFILE Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[{FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number {LINES | ROWS}]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]
```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. `LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see [Section 8.2.2.1, “Speed of INSERT Statements”](#).

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The `character_set_filesystem` system variable controls the interpretation of the file name.

`LOAD DATA` supports explicit partition selection using the `PARTITION` option with a comma-separated list of one or more names of partitions, subpartitions, or both. When this option is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error `Found a row not matching the given partition set`. For more information, see [Section 18.5, “Partition Selection”](#).

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, `LOAD DATA` cannot prune any partition locks. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see [Section 18.6.4, “Partitioning and Locking”](#).

The server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not

affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

`LOAD DATA INFILE` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with `LOAD DATA INFILE`.

#### Note

It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. This option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

With row-based replication, `CONCURRENT` is replicated regardless of MySQL version. With statement-based replication `CONCURRENT` is not replicated prior to MySQL 5.5.1 (see Bug #34628). For more information, see [Section 17.4.1.18, “Replication and LOAD DATA INFILE”](#).

The `LOCAL` keyword affects expected location of the file and error handling, as described later. `LOCAL` works only if your server and your client both have been configured to permit it. For example, if `mysqld` was started with `--local-infile=0`, `LOCAL` does not work. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

The `LOCAL` keyword affects where the file is expected to be found:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.

When using `LOCAL` with `LOAD DATA`, a copy of the file is created in the server's temporary directory. This is *not* the directory determined by the value of `tmpdir` or `slave_load_tmpdir`, but rather the operating system's temporary directory, and is not configurable in the MySQL Server. (Typically the system temporary directory is `/tmp` on Linux systems and `C:\WINDOWS\TEMP` on Windows.) Lack of sufficient space for the copy in this directory can cause the `LOAD DATA LOCAL` statement to fail.

- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
  - If the file name is an absolute path name, the server uses it as given.
  - If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server's data directory.
  - If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

In the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement

reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

For security reasons, when reading text files located on the server, the files must either reside in the database directory or be readable by the user account used to run the server. Also, to use `LOAD DATA INFILE` on server files, you must have the `FILE` privilege. See [Section 6.2.1, “Privileges Provided by MySQL”](#). For non-`LOCAL` load operations, if the `secure_file_priv` system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

Using `LOCAL` is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE` privilege to load local files.

`LOCAL` also affects error handling:

- With `LOAD DATA INFILE`, data-interpretation and duplicate-key errors terminate the operation.
- With `LOAD DATA LOCAL INFILE`, data-interpretation and duplicate-key errors become warnings and the operation continues because the server has no way to stop transmission of the file in the middle of the operation. For duplicate-key errors, this is the same as if `IGNORE` is specified. `IGNORE` is explained further later in this section.

The `REPLACE` and `IGNORE` keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify `REPLACE`, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 13.2.8, “REPLACE Syntax”](#).
- If you specify `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).
- If you do not specify either option, the behavior depends on whether the `LOCAL` keyword is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

To ignore foreign key constraints during the load operation, issue a `SET foreign_key_checks = 0` statement before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA INFILE` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 8.2.2.1, “Speed of INSERT Statements”](#).

For both the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you specify no `FIELDS` or `LINES` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''
```

(Backslash is the MySQL escape character within strings in SQL statements, so to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences `'\t'` and `'\n'` specify tab and newline characters, respectively.)

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character “\” as escape sequences. For example, “\t”, “\n”, and “\\” signify tab, newline, and backslash, respectively. See the discussion of `FIELDS ESCAPED BY` later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use “\” to escape instances of tab, newline, or “\” that occur within field values.
- Write newlines at the ends of lines.

#### Note

If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be `("abc",1)` and `("def",2)`. The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA INFILE` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use `OPTIONALLY` before the `ENCLOSED BY` keywords.

Any of the field- or line-handling options can specify an empty string (' '). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (`SELECT ... INTO OUTFILE`), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a \", quote and comma","102.20"
```

If you specify `OPTIONALLY`, the `ENCLOSED BY` character is used only to enclose values from columns that have a string data type (such as `CHAR`, `BINARY`, `TEXT`, or `ENUM`):

```
1,"a string",100.20
```

```
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Occurrences of the **ENCLOSED BY** character within a field value are escaped by prefixing them with the **ESCAPED BY** character. Also note that if you specify an empty **ESCAPED BY** value, it is possible to inadvertently generate output that cannot be read properly by **LOAD DATA INFILE**. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the **ENCLOSED BY** character, if present, is stripped from the ends of field values. (This is true regardless of whether **OPTIONALLY** is specified; **OPTIONALLY** has no effect on input interpretation.) Occurrences of the **ENCLOSED BY** character preceded by the **ESCAPED BY** character are interpreted as part of the current field value.

If the field begins with the **ENCLOSED BY** character, instances of that character are recognized as terminating a field value only if followed by the field or line **TERMINATED BY** sequence. To avoid ambiguity, occurrences of the **ENCLOSED BY** character within a field value can be doubled and are interpreted as a single instance of the character. For example, if **ENCLOSED BY ' ''** is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss     -> The "BIG" boss
The ""BIG"" boss   -> The ""BIG"" boss
```

**FIELDS ESCAPED BY** controls how to read or write special characters:

- For input, if the **FIELDS ESCAPED BY** character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using “\” for the escape character). The rules for **NULL** handling are described later in this section.

Character	Escape Sequence
\0	An ASCII NUL (x'00') character
\b	A backspace character
\n	A newline (linefeed) character
\r	A carriage return character
\t	A tab character.
\z	ASCII 26 (Control+Z)
\N	NULL

For more information about “\”-escape syntax, see [Section 9.1.1, “String Literals”](#).

If the **FIELDS ESCAPED BY** character is empty, escape-sequence interpretation does not occur.

- For output, if the **FIELDS ESCAPED BY** character is not empty, it is used to prefix the following characters on output:
  - The **FIELDS ESCAPED BY** character
  - The **FIELDS [OPTIONALLY] ENCLOSED BY** character

- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII 0 (what is actually written following the escape character is ASCII “0”, not a zero-valued byte)

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is nonempty, lines are also terminated with `FIELDS TERMINATED BY`.
- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty ( ' ' ), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to ' '. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later.

#### Note

Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is “\”).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string 'NULL'.
- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.
- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 11.7, “Data Type Default Values”](#).

Some cases are not supported by `LOAD DATA INFILE`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '"' ENCLOSED BY '"'
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

The column list can contain either column names or user variables. With user variables, the `SET` clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 11.7, “Data Type Default Values”](#).

An empty field value is interpreted different from a missing field:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 11.3, “Date and Time Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if `sql_mode` is set to `TRADITIONAL`, conversion of an empty value or a value such as `'x'` for a numeric column results in an error, not conversion to 0. (With `LOCAL` or `IGNORE`, warnings occur rather than errors, even with a restrictive `sql_mode` value, and the row is inserted using the same closest-value behavior used for nonrestrictive SQL modes. This occurs because the server has no way to stop transmission of the file in the middle of the operation.)

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded using binary notation (for example, `b'011010'`). To work around this, specify the values as regular integers and use the `SET` clause to convert them so that MySQL performs a numeric type conversion and loads them into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
2
127
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
-> INTO TABLE bit_test (@var1) SET b = CAST(@var1 AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| bin(b+0) |
+-----+
| 10      |
| 1111111 |
+-----+
2 rows in set (0.00 sec)
```

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

When the `LOAD DATA INFILE` statement finishes, it returns an information string in the following format:

```
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see [Section 13.2.5, "INSERT Syntax"](#)), except that `LOAD DATA INFILE` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See [Section 13.7.5.40, "SHOW WARNINGS Syntax"](#).

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See [Section 23.8.7.36, "mysql\\_info\(\)"](#).

## 13.2.7 LOAD XML Syntax

```
LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
  [REPLACE | IGNORE]
  INTO TABLE [db_name.]tbl_name
  [CHARACTER SET charset_name]
  [ROWS IDENTIFIED BY '<tagname>']
  [IGNORE number {LINES | ROWS}]
  [(field_name_or_user_var,...)]
  [SET col_name = expr,...]
```

The `LOAD XML` statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

`LOAD XML` acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```
shell> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use `LOAD XML INFILE`. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
```

```
</row>
```

- Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

Prior to MySQL 5.7.9, `LOAD XML` did not handle empty XML elements in the form `<element/>` correctly. (Bug #67542, Bug #16171518)

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

- `LOW_PRIORITY` or `CONCURRENT`
- `LOCAL`
- `REPLACE` or `IGNORE`
- `CHARACTER SET`
- `SET`

See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#), for more information about these clauses.

`(field_name_or_user_var, ...)` is a comma-separated list of one or more XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with `@`. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first `number` rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```
USE test;

CREATE TABLE person (
  person_id INT NOT NULL PRIMARY KEY,
  fname VARCHAR(40) NULL,
  lname VARCHAR(40) NULL,
  created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```
<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
  <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
  <person><field name="person_id">5</field><field name="fname">Stoma</field>
  <field name="lname">Milu</field></person>
  <person><field name="person_id">6</field><field name="fname">Nirtam</field>
  <field name="lname">Sklöd</field></person>
```

```
<person person_id="7"><fname>Sungam</fname><lname>Dulbåd</lname></person>
<person person_id="8" fname="Sreref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```
mysql> LOAD XML LOCAL INFILE 'person.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';

Query OK, 8 rows affected (0.00 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likame | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
| 7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |
| 8 | Sreref | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read in using `LOAD XML`.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```
shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
<?xml version="1.0"?>

<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>

  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>
```

```

<row>
<field name="person_id">3</field>
<field name="fname">Likema</field>
<field name="lname">Örrtmons</field>
</row>

<row>
<field name="person_id">4</field>
<field name="fname">Slar</field>
<field name="lname">Manlanth</field>
</row>

<row>
<field name="person_id">5</field>
<field name="fname">Stoma</field>
<field name="lname">Nilu</field>
</row>

<row>
<field name="person_id">6</field>
<field name="fname">Nirtam</field>
<field name="lname">Sklöd</field>
</row>

<row>
<field name="person_id">7</field>
<field name="fname">Sungam</field>
<field name="lname">Dulbåd</field>
</row>

<row>
<field name="person_id">8</field>
<field name="fname">Sreraf</field>
<field name="lname">Encmelt</field>
</row>
</resultset>

```

### Note

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```

mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likema | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
| 7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |
| 8 | Sreraf | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)

```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

```
mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE person2\G
***** 1. row *****
      Table: person2
Create Table: CREATE TABLE `person2` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  PRIMARY KEY (`person_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+
| person_id | fname | lname |
+-----+-----+-----+
|          1 | Kapek | Sainnouine |
|          2 | Sajon | Rondela |
|          3 | Likema | Örrtmons |
|          4 | Slar | Manlanth |
|          5 | Stoma | Nilu |
|          6 | Nirtam | Sklöd |
|          7 | Sungam | Dulbåd |
|          8 | Sreraf | Encmelt |
+-----+-----+-----+
8 rows in set (0.00 sec)
```

The order in which the fields are given within each row of the XML file does not affect the operation of `LOAD XML`; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a `(field_name_or_user_var, ...)` list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```
mysql> CREATE TABLE individual (
->   individual_id INT NOT NULL PRIMARY KEY,
->   name1 VARCHAR(40) NULL,
->   name2 VARCHAR(40) NULL,
->   made TIMESTAMP
-> );
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
```

```
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```
mysql> LOAD XML INFILE '../bin/person-dump.xml'
-> INTO TABLE test.individual (@person_id, @fname, @lname, @created)
-> SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM individual;
+-----+-----+-----+-----+
| individual_id | name1 | name2 | made |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likema | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
| 7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |
| 8 | Srraf | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)
```

The names of the user variables *must* match those of the corresponding fields from the XML file, with the addition of the required `@` prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```
<?xml version="1.0"?>
<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>

  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
  </person>
</list>
```

You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql< TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql< SHOW CREATE TABLE person\G
***** 1. row *****
Table: person
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
```

```

`fname` varchar(40) DEFAULT NULL,
`lname` varchar(40) DEFAULT NULL,
`created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```

CREATE TABLE address (
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP
);

```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here;

```

mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

```

You can verify that the records were imported using a `SELECT` statement:

```

mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
|          1 | Robert | Jones | 2007-07-24 17:37:06 |
|          2 | Mary  | Smith | 2007-07-24 17:37:06 |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)

```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```

mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE address
-> ROWS IDENTIFIED BY '<address>';
Query OK, 3 rows affected (0.00 sec)
Records: 3 Deleted: 0 Skipped: 0 Warnings: 0

```

You can see that the data was imported using a `SELECT` statement such as this one:

```

mysql> SELECT * FROM address;
+-----+-----+-----+-----+-----+-----+
| address_id | person_id | street          | zip  | city          | created |
+-----+-----+-----+-----+-----+-----+
|          1 |          1 | Mill Creek Road | 45365 | Sidney        | 2007-07-24 17:37:37 |
|          2 |          1 | Main Street     | 28681 | Taylorsville  | 2007-07-24 17:37:37 |
|          3 |          2 | River Road      | 80239 | Denver        | 2007-07-24 17:37:37 |
+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)

```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

### Important

Revoking the `FILE` privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML INFILE` statement (as well as the `LOAD_FILE()` function; it does *not* prevent the user from executing `LOAD XML LOCAL INFILE`. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the `FILE` privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, any locks caused by `LOAD XML` perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see [Section 18.6.4, "Partitioning and Locking"](#).

## 13.2.8 REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
```

`REPLACE` works exactly like `INSERT`, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. See [Section 13.2.5, "INSERT Syntax"](#).

`REPLACE` is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL—that either inserts or *updates*—see [Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

`DELAYED` inserts and replaces were deprecated in MySQL 5.6.6. In MySQL 5.7, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the replace as a nondelayed replace, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning. (“REPLACE DELAYED is no longer supported. The statement was converted to REPLACE.”) The `DELAYED` keyword will be removed in a future release.

#### Note

`REPLACE` makes sense only if a table has a `PRIMARY KEY` or `UNIQUE` index. Otherwise, it becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

If a generated column is replaced explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [CREATE TABLE and Generated Columns](#).

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

`REPLACE` supports explicit partition selection using the `PARTITION` keyword with a comma-separated list of names of partitions, subpartitions, or both. As with `INSERT`, if it is not possible to insert the new row into any of these partitions or subpartitions, the `REPLACE` statement fails with the error `Found a row not matching the given partition set`. See [Section 18.5, “Partition Selection”](#), for more information.

The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
  - a. Delete from the table the conflicting row that has the duplicate key value
  - b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_xxx` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the master and the slave to diverge. For this reason, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using the `STATEMENT` binary logging mode, and are logged using the row-based format when using `MIXED` mode. See also [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see [Section 18.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```
CREATE TABLE test (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the `mysql` client, the result is as follows:

```
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+-----+-----+
| id | data | ts                |
+----+-----+-----+
|  1 | New  | 2014-08-20 18:47:42 |
+----+-----+-----+
1 row in set (0.00 sec)
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```
CREATE TABLE test2 (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id, ts)
);
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+----+-----+-----+
| id | data | ts                |
+----+-----+-----+
|  1 | Old  | 2014-08-20 18:47:00 |
|  1 | New  | 2014-08-20 18:47:42 |
+----+-----+-----+
```

```
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

In MySQL 5.7, a `REPLACE` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `REPLACE` statement's `WHERE` clause, as long as none of the table's partitioning columns are updated; otherwise the entire table is locked. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Section 18.6.4, “Partitioning and Locking”](#).

## 13.2.9 SELECT Syntax

```
SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [MAX_STATEMENT_TIME = N]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr ...]
  [FROM table_references
  [PARTITION partition_list]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
  [LIMIT {[offset,] row_count | row_count OFFSET offset}]
  [PROCEDURE procedure_name(argument_list)]
  [INTO OUTFILE 'file_name'
  [CHARACTER SET charset_name]
  export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name]]
  [FOR UPDATE | LOCK IN SHARE MODE]]
```

`SELECT` is used to retrieve rows selected from one or more tables, and can include `UNION` statements and subqueries. See [Section 13.2.9.3, “UNION Syntax”](#), and [Section 13.2.10, “Subquery Syntax”](#).

The most commonly used clauses of `SELECT` statements are these:

- Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.
- `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 13.2.9.2, “JOIN Syntax”](#).
- `SELECT` supports explicit partition selection using the `PARTITION` with a list of partitions or subpartitions (or both) following the name of the table in a `table_reference` (see [Section 13.2.9.2, “JOIN Syntax”](#)). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see [Section 18.5, “Partition Selection”](#).

`SELECT ... PARTITION` from tables using storage engines such as `MyISAM` that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the `PARTITION` option.

See [Section 18.6.4, “Partitioning and Locking”](#), for more information.

- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.

In the `WHERE` expression, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Section 9.5, “Expression Syntax”](#), and [Chapter 12, Functions and Operators](#).

`SELECT` can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
      -> 2
```

You are permitted to specify `DUAL` as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
      -> 2
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MySQL may ignore the clauses. MySQL does not require `FROM DUAL` if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a `HAVING` clause must come after any `GROUP BY` clause and before any `ORDER BY` clause. The exception is that the `INTO` clause can appear either as shown in the syntax description or immediately following the `select_expr` list. For more information about `INTO`, see [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).

The list of `select_expr` terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use `*`-shorthand:

- A select list consisting only of a single unqualified `*` can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```

- `tbl_name.*` can be used as a qualified shorthand to select all columns from the named table:

```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
```

- Use of an unqualified `*` with other items in the select list may produce a parse error. To avoid this problem, use a qualified `tbl_name.*` reference

```
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other `SELECT` clauses:

- A `select_expr` can be given an alias using `AS alias_name`. The alias is used as the expression's column name and can be used in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. For example:

```
SELECT CONCAT(last_name, ' ', first_name) AS full_name
      FROM mytable ORDER BY full_name;
```

The `AS` keyword is optional when aliasing a `select_expr` with an identifier. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ' ', first_name) full_name
      FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two `select_expr` expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See [Section B.5.4.4, “Problems with Column Aliases”](#).

- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 13.2.9.2, “JOIN Syntax”](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see [Section 8.9.4, “Index Hints”](#).

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 5.1.4, “Server System Variables”](#).

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference unless the reference would be ambiguous. See [Section 9.2.1, “Identifier Qualifiers”](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
  WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
  WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
  ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
  ORDER BY r, s;

SELECT college, region, seed FROM tournament
  ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

If `ORDER BY` occurs within a subquery and also is applied in the outer query, the outermost `ORDER BY` takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```
(SELECT ... ORDER BY a) ORDER BY a DESC;
```

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

Relying on implicit `GROUP BY` sorting in MySQL 5.7 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. `GROUP BY` sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.

- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in [Section 12.20, “Functions and Modifiers for Use with GROUP BY Clauses”](#).
- `GROUP BY` permits a `WITH ROLLUP` modifier. See [Section 12.20.2, “GROUP BY Modifiers”](#).
- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

```
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one *select\_expr* with the same name. This is an extension to standard SQL. Because MySQL also permits `GROUP BY` and `HAVING` to refer to *select\_expr* values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each *select\_expr*.

- MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the *select\_expr* values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the *select\_expr* values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as for `ORDER BY`.)
- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
  - Within prepared statements, `LIMIT` parameters can be specified using `?` placeholder markers.
  - Within stored programs, `LIMIT` parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5; # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a subquery and also is applied in the outer query, the outermost `LIMIT` takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see [Section 8.4.2.4, “Using PROCEDURE ANALYSE”](#), which describes `ANALYSE`, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.
- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See [Section 14.2.2.3, “Locking Reads \(SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE\)”](#).

In addition, you cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...` (If you attempt to do so, the statement is rejected with the error `Can't update table 'old_table' while 'new_table' is being created`.) This is a change in behavior from MySQL 5.5 and earlier, which permitted `CREATE TABLE ... SELECT` statements to make changes in tables other than the table being created.

Following the `SELECT` keyword, you can use a number of options that affect the operation of the statement. `HIGH_PRIORITY`, `MAX_STATEMENT_TIME`, `STRAIGHT_JOIN`, and options beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` options specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both options. `DISTINCTROW` is a synonym for `DISTINCT`.
- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `MAX_STATEMENT_TIME = N` sets a statement execution timeout of `N` milliseconds. If this option is absent or `N` is 0, the statement timeout established by the `max_statement_time` system variable applies.

#### Note

This option was added in MySQL 5.7.4. It was removed in MySQL 5.7.8 in preference to the `MAX_EXECUTION_TIME()` optimizer hint. See [Section 8.9.3, “Optimizer Hints”](#)

The `MAX_STATEMENT_TIME` option is applicable as follows:

- For statements with multiple `SELECT` keywords, such as unions or statements with subqueries, `MAX_STATEMENT_TIME` applies to the entire statement and must appear after the first `SELECT`.
- It applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.

- It does not apply to `SELECT` statements in stored programs; an error occurs.
- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See [Section 13.2.9.2, “JOIN Syntax”](#).

`STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by `EXPLAIN`. See [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#). This exception may not apply to `const` or `system` tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`).

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`, MySQL directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements. For `SQL_SMALL_RESULT`, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.
- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This option can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 12.14, “Information Functions”](#).
- The `SQL_CACHE` and `SQL_NO_CACHE` options affect caching of query results in the query cache (see [Section 8.10.3, “The MySQL Query Cache”](#)). `SQL_CACHE` tells MySQL to store the result in the query cache if it is cacheable and the value of the `query_cache_type` system variable is `2` or `DEMAND`. With `SQL_NO_CACHE`, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result.

For views, `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query. For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of a view referred to by the query.

These two options are mutually exclusive and an error occurs if they are both specified. Also, these options are not permitted in subqueries (including subqueries in the `FROM` clause), and `SELECT` statements in unions other than the first `SELECT`.

In MySQL 5.7, a `SELECT` from a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `SELECT` statement's `WHERE` clause. (This does not occur with storage engines such as `InnoDB` that employ row-level locking.) For more information, see [Section 18.6.4, “Partitioning and Locking”](#).

### 13.2.9.1 SELECT ... INTO Syntax

The `SELECT ... INTO` form of `SELECT` enables a query result to be stored in variables or written to a file:

- `SELECT ... INTO var_list` selects column values and stores them into variables.
- `SELECT ... INTO OUTFILE` writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.
- `SELECT ... INTO DUMPFILE` writes a single row to a file without any formatting.

The `SELECT` syntax description (see [Section 13.2.9, “SELECT Syntax”](#)) shows the `INTO` clause near the end of the statement. It is also possible to use `INTO` immediately following the `select_expr` list.

An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context.

The `INTO` clause can name a list of one or more variables, which can be user-defined variables, stored procedure or function parameters, or stored program local variables. (Within a prepared `SELECT ... INTO OUTFILE` statement, only user-defined variables are permitted; see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).)

The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

```
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See [Section 9.4, “User-Defined Variables”](#).

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some other host than the server host, you normally cannot use `SELECT ... INTO OUTFILE` since there is no way to write a path to the file relative to the server host's file system.

However, if the MySQL client software is installed on the remote machine, you can instead use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

It is also possible to create the resulting file on a different host other than the server host, if the location of the file on the remote host can be accessed using a network-mapped path on the server's file system. In this case, the presence of `mysql` (or some other MySQL client program) is not required on the target host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#), for information about the `FIELDS` and `LINES` clauses, including their default values and permissible values.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values

- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII “0”, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some paggers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.

#### Note

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see [Section 19.4.5, “Event Scheduler Status”](#).

### 13.2.9.2 JOIN Syntax

MySQL supports the following `JOIN` syntaxes for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references:
  escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference:
  table_reference
| { OJ table_reference }

table_reference:
  table_factor
| join_table

table_factor:
  tbl_name [PARTITION (partition_names)]
  [[AS] alias] [index_hint_list]
| table_subquery [AS] alias
| ( table_references )
```

```

join_table:
  table_reference [INNER | CROSS] JOIN table_factor [join_condition]
| table_reference STRAIGHT_JOIN table_factor
| table_reference STRAIGHT_JOIN table_factor ON conditional_expr
| table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
| table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
  ON conditional_expr
| USING (column_list)

index_hint_list:
  index_hint [, index_hint] ...

index_hint:
  USE {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
| IGNORE {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
| FORCE {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
  index_name [, index_name] ...

```

A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a [PARTITION](#) option, including a comma-separated list of partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions—in other words, any partitions or subpartitions not named in the list are ignored. For more information, see [Section 18.5, “Partition Selection”](#).

The syntax of *table\_factor* is extended in comparison with the SQL Standard. The latter accepts only *table\_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of *table\_reference* items as equivalent to an inner join. For example:

```

SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
    ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

is equivalent to:

```

SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
    ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

In MySQL, [JOIN](#), [CROSS JOIN](#), and [INNER JOIN](#) are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. [INNER JOIN](#) is used with an [ON](#) clause, [CROSS JOIN](#) is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins (see [Section 8.2.1.11, “Nested Join Optimization”](#)).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see [Section 8.9.4, “Index Hints”](#).

The following list describes general factors to take into account when writing joins.

- A table reference can be aliased using *tbl\_name AS alias\_name* or *tbl\_name alias\_name*:

```

SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary

```

```
FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- A *table\_subquery* is also known as a subquery in the `FROM` clause. Such subqueries *must* include an alias to give the subquery result a table name. A trivial example follows; see also [Section 13.2.10.8, “Subqueries in the FROM Clause”](#).

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- `INNER JOIN` and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than of `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The *conditional\_expr* used with `ON` is any conditional expression of the form that can be used in a `WHERE` clause. Generally, you should use the `ON` clause for conditions that specify how to join tables, and the `WHERE` clause to restrict which rows you want in the result set.
- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). This assumes that `right_tbl.id` is declared `NOT NULL`. See [Section 8.2.1.9, “LEFT JOIN and RIGHT JOIN Optimization”](#).

- The `USING(column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1,c2,c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.
- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.
- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

You can use other types of joins within `{ OJ ... }`, such as `INNER JOIN` or `RIGHT OUTER JOIN`. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- `STRAIGHT_JOIN` is similar to `JOIN`, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer puts the tables in the wrong order.

Some join examples:

```

SELECT * FROM table1, table2;

SELECT * FROM table1 INNER JOIN table2 ON table1.id=table2.id;

SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id;

SELECT * FROM table1 LEFT JOIN table2 USING (id);

SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id
LEFT JOIN table3 ON table2.id=table3.id;

```

### Join Processing Changes in MySQL 5.0.12

#### Note

Natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard. The goal was to align the syntax and semantics of MySQL with respect to `NATURAL JOIN` and `JOIN ... USING` according to SQL:2003. However, these changes in join processing can result in different output columns for some joins. Also, some queries that appeared to work correctly in older versions (prior to 5.0.12) must be rewritten to comply with the standard.

These changes have five main aspects:

- The way that MySQL determines the result columns of `NATURAL` or `USING` join operations (and thus the result of the entire `FROM` clause).
- Expansion of `SELECT *` and `SELECT tbl_name.*` into a list of selected columns.
- Resolution of column names in `NATURAL` or `USING` joins.
- Transformation of `NATURAL` or `USING` joins into `JOIN ... ON`.
- Resolution of column names in the `ON` condition of a `JOIN ... ON`.

The following list provides more detail about several effects of current join processing versus join processing in older versions. The term “previously” means “prior to MySQL 5.0.12.”

- The columns of a `NATURAL` join or a `USING` join may be different from previously. Specifically, redundant output columns no longer appear, and the order of columns for `SELECT *` expansion may be different from before.

Consider this set of statements:

```

CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);

```

Previously, the statements produced this output:

```

+-----+-----+-----+-----+
| i    | j    | k    | j    |
+-----+-----+-----+-----+
|  1   |  1   |  1   |  1   |
+-----+-----+-----+-----+
| i    | j    | k    | j    |
+-----+-----+-----+-----+
|  1   |  1   |  1   |  1   |
+-----+-----+-----+-----+

```

In the first `SELECT` statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second `SELECT` statement, column `j` is named in the `USING` clause and should appear only once in the output, not twice. But in both cases, the redundant column is not eliminated. Also, the order of the columns is not correct according to standard SQL.

Now the statements produce this output:

```
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
| 1     | 1     | 1     |
+-----+-----+-----+
```

The redundant column is eliminated and the column order is correct according to standard SQL:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN V1 IS NOT NULL THEN V1 ELSE V2 END)
```

If the join operation is any other join, the result columns of the join consists of the concatenation of all columns of the joined tables. This is the same as previously.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-`NULL` column if one of the two columns is always `NULL`. If neither or both columns are `NULL`, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a `JOIN`. Suppose that the tables `t1(a,b)` and `t2(a,c)` have the following contents:

```
t1    t2
----  ----
1 x   2 z
2 y   3 w
```

Then:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| 1     | x     | NULL  |
| 2     | y     | z     |
+-----+-----+-----+
```

Here column `a` contains the values of `t1.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
```

a	c	b
2	z	y
3	w	NULL

Here column `a` contains the values of `t2.a`.

Compare these results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
```

a	b	a	c
1	x	NULL	NULL
2	y	2	z

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
```

a	b	a	c
2	y	2	z
NULL	NULL	3	w

- Previously, a `USING` clause could be rewritten as an `ON` clause that compares corresponding columns. For example, the following two clauses were semantically identical:

```
a LEFT JOIN b USING (c1,c2,c3)
a LEFT JOIN b ON a.c1=b.c1 AND a.c2=b.c2 AND a.c3=b.c3
```

Now the two clauses no longer are quite the same:

- With respect to determining which rows satisfy the join condition, both joins remain semantically identical.
- With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the preceding `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1,b.c1), COALESCE(a.c2,b.c2), COALESCE(a.c3,b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1,b.c1)` is the same as either `a.c1` or `b.c1` because both columns will have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column will be omitted from the result.

- The evaluation of multi-way natural joins differs in a very important way that affects the result of `NATURAL` or `USING` joins and that can require query rewriting. Suppose that you have three tables `t1(a,b)`, `t2(c,b)`, and `t3(a,c)` that each have one row: `t1(1,2)`, `t2(10,2)`, and `t3(7,10)`. Suppose also that you have this `NATURAL JOIN` on the three tables:

```
SELECT ... FROM t1 NATURAL JOIN t2 NATURAL JOIN t3;
```

Previously, the left operand of the second join was considered to be `t2`, whereas it should be the nested join (`t1 NATURAL JOIN t2`). As a result, the columns of `t3` are checked for common columns only in `t2`, and, if `t3` has common columns with `t1`, these columns are not used as equi-join columns. Thus, previously, the preceding query was transformed to the following equi-join:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c;
```

That join is missing one more equi-join predicate (`t1.a = t3.a`). As a result, it produces one row, not the empty result that it should. The correct equivalent query is this:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c AND t1.a = t3.a;
```

If you require the same query result in current versions of MySQL as in older versions, rewrite the natural join as the first equi-join.

- Previously, the comma operator (`,`) and `JOIN` both had the same precedence, so the join expression `t1, t2 JOIN t3` was interpreted as `((t1, t2) JOIN t3)`. Now `JOIN` has higher precedence, so the expression is interpreted as `(t1, (t2 JOIN t3))`. This change affects statements that use an `ON` clause, because that clause can refer only to columns in the operands of the join, and the change in precedence changes interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
INSERT INTO t3 VALUES(1,1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

Previously, the `SELECT` was legal due to the implicit grouping of `t1, t2` as `(t1, t2)`. Now the `JOIN` takes precedence, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error. To allow the join to be processed, group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1, t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

Alternatively, avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

This change also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which now have higher precedence than the comma operator.

- Previously, the `ON` clause could refer to columns in tables named to its right. Now an `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
```

```
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

Previously, the `SELECT` statement was legal. Now the statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. The statement should be rewritten as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- Resolution of column names in `NATURAL` or `USING` joins is different than previously. For column names that are outside the `FROM` clause, MySQL now handles a superset of the queries compared to previously. That is, in cases when MySQL formerly issued an error that some column is ambiguous, the query now is handled correctly. This is due to the fact that MySQL now treats the common columns of `NATURAL` or `USING` joins as a single column, so when a query refers to such columns, the query compiler does not consider them as ambiguous.

Example:

```
SELECT * FROM t1 NATURAL JOIN t2 WHERE b > 1;
```

Previously, this query would produce an error `ERROR 1052 (23000): Column 'b' in where clause is ambiguous`. Now the query produces the correct result:

```
+-----+-----+-----+
| b    | c    | y    |
+-----+-----+-----+
| 4    | 2    | 3    |
+-----+-----+-----+
```

One extension of MySQL compared to the SQL:2003 standard is that MySQL enables you to qualify the common (coalesced) columns of `NATURAL` or `USING` joins (just as previously), while the standard disallows that.

### 13.2.9.3 UNION Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

`UNION` is used to combine the result from multiple `SELECT` statements into a single result set.

The column names from the first `SELECT` statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all of the `SELECT` statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
+-----+
| a              |
| bbbbbbbbbbbb  |
+-----+
```

The `SELECT` statements are normal select statements, but with the following restrictions:

- Only the last `SELECT` statement can use `INTO OUTFILE`. (However, the entire `UNION` result is written to the file.)

- `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`. If you specify it for the first `SELECT`, it has no effect. If you specify it for any subsequent `SELECT` statements, a syntax error results.

The default behavior for `UNION` is that duplicate rows are removed from the result. The optional `DISTINCT` keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

However, use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, the use of `ORDER BY` in this context is typically in conjunction with `LIMIT`, so that it is used to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

Use of an additional column also enables you to determine which `SELECT` each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

As of MySQL 5.7.5, `UNION` queries with an aggregate function in an `ORDER BY` clause are rejected with an `ER_AGGREGATE_ORDER_FOR_UNION` error. Example:

```
SELECT 1 AS foo UNION SELECT 2 ORDER BY MAX(1);
```

## 13.2.10 Subquery Syntax

A subquery is a `SELECT` statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1 ...` is the *outer query* (or *outer statement*), and `(SELECT column1 FROM t2)` is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
(SELECT COUNT(*) /* no hint */ FROM t2
WHERE NOT EXISTS
(SELECT * FROM t3
WHERE ROW(5*t2.s1,77)=
(SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
(SELECT * FROM t5) AS t5));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, joins, index hints, `UNION` constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: [SELECT](#), [INSERT](#), [UPDATE](#), [DELETE](#), [SET](#), or [DO](#).

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as [DELETE](#), [INSERT](#), [REPLACE](#), [UPDATE](#), and (because subqueries can be used in the [SET](#) clause) [LOAD DATA INFILE](#).

For information about how the optimizer handles subqueries, see [Section 8.2.1.18, "Subquery Optimization"](#). For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see [Section C.4, "Restrictions on Subqueries"](#).

### 13.2.10.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be [NULL](#), and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this [SELECT](#) returns a single value ( 'abcde' ) that has a data type of [CHAR](#), a length of 5, a character set and collation equal to the defaults in effect at [CREATE TABLE](#) time, and an indication that the value in the column can be [NULL](#). Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is [NULL](#). For the subquery just shown, if [t1](#) were empty, the result would be [NULL](#) even though [s2](#) is [NOT NULL](#).

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, [LIMIT](#) requires literal integer arguments, and [LOAD DATA INFILE](#) requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct ( [SELECT column1 FROM t1](#) ), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a [SELECT](#):

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is [2](#) because there is a row in [t2](#) containing a column [s1](#) that has a value of [2](#).

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

### 13.2.10.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where *comparison\_operator* is one of these operators:

```
= > < >= <= <> != <=>
```

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table *t1* for which the *column1* value is equal to a maximum value in table *t2*:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table *t1* containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See [Section 13.2.10.5, “Row Subqueries”](#).

### 13.2.10.3 Subqueries with ANY, IN, or SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where *comparison\_operator* is one of these operators:

```
= > < >= <= <> !=
```

The **ANY** keyword, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ANY** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table *t1* containing (10). The expression is **TRUE** if table *t2* contains (21,14,7) because there is a value 7 in *t2* that is less than 10. The expression is **FALSE** if table *t2* contains (20,10), or if table *t2* is empty. The expression is *unknown* (that is, **NULL**) if table *t2* contains (NULL,NULL,NULL).

When used with a subquery, the word **IN** is an alias for = **ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

`IN` and `= ANY` are not synonyms when used with an expression list. `IN` can take an expression list, but `= ANY` cannot. See [Section 12.3.2, “Comparison Functions and Operators”](#).

`NOT IN` is not an alias for `<> ANY`, but for `<> ALL`. See [Section 13.2.10.4, “Subqueries with ALL”](#).

The word `SOME` is an alias for `ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word `SOME` is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using `<> SOME` instead helps ensure that everyone understands the true meaning of the query.

### 13.2.10.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word `ALL`, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for `ALL` of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(-5, 0, +5)` because `10` is greater than all three values in `t2`. The expression is `FALSE` if table `t2` contains `(12, 6, NULL, -100)` because there is a single value `12` in table `t2` that is greater than `10`. The expression is *unknown* (that is, `NULL`) if table `t2` contains `(0, NULL, 1)`.

Finally, the expression is `TRUE` if table `t2` is empty. So, the following expression is `TRUE` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is `NULL` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is `NULL` when table `t2` is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing NULL values* and *empty tables* are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

`NOT IN` is an alias for `<> ALL`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

### 13.2.10.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
= > < >= <= <> != <=>
```

Here are two examples:

```
SELECT * FROM t1
  WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
  WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table `t2` contains a single row with `id = 10`, the subquery returns a single row. If this row has `col3` and `col4` values equal to the `col1` and `col2` values of any rows in `t1`, the `WHERE` expression is `TRUE` and each query returns those `t1` rows. If the `t2` row `col3` and `col4` values are not equal the `col1` and `col2` values of any `t1` row, the expression is `FALSE` and the query returns an empty result set. The expression is *unknown* (that is, `NULL`) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see [Section 12.3.2, “Comparison Functions and Operators”](#).

The expressions `(1,2)` and `ROW(1,2)` are sometimes called *row constructors*. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```
SELECT column1,column2,column3
  FROM t1
  WHERE (column1,column2,column3) IN
        (SELECT column1,column2,column3 FROM t2);
```

### 13.2.10.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
              WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in `Stores`”? But it is easier to say that a nested `NOT EXISTS` answers the question “is `x TRUE` for all `y`?”

### 13.2.10.7 Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
                    WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5,6)` is not equal to `(5,7)`), so the expression as a whole is `FALSE`.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
                  WHERE x.column1 = (SELECT column1 FROM t3
                                    WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

### 13.2.10.8 Subqueries in the FROM Clause

Subqueries are legal in a `SELECT` statement's `FROM` clause. The actual syntax is:

```
SELECT ... FROM (subquery) [AS] name ...
```

The `[AS] name` clause is mandatory, because every table in a `FROM` clause must have a name. Any columns in the `subquery` select list must have unique names.

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
  FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
 WHERE sb1 > 1;
```

Result: 2, '2', 4.0.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
  FROM (SELECT SUM(column1) AS sum_column1
        FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

Subqueries in the `FROM` clause can return a scalar, column, row, or table. Subqueries in the `FROM` clause cannot be correlated subqueries, unless used within the `ON` clause of a `JOIN` operation.

In MySQL 5.7, the optimizer determines information about derived tables in such a way that materialization of them does not occur for `EXPLAIN`. See [Optimizing Derived Tables and View References](#).

It is possible under certain circumstances to modify table data using `EXPLAIN SELECT`. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, created as shown here:

```
mysql> CREATE DATABASE d1;
Query OK, 1 row affected (0.00 sec)

mysql> USE d1;
Database changed

mysql> CREATE TABLE t1 (c1 INT);
Query OK, 0 rows affected (0.15 sec)

mysql> CREATE TABLE t2 (c1 INT);
Query OK, 0 rows affected (0.08 sec)
```

Now we create a stored function `f1` which modifies `t2`:

```
mysql> DELIMITER //
mysql> CREATE FUNCTION f1(p1 INT) RETURNS INT
mysql> BEGIN
mysql>     INSERT INTO t2 VALUES (p1);
mysql>     RETURN p1;
mysql> END //
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;
```

Referencing the function directly in an `EXPLAIN SELECT` does not have any effect on `t2`, as shown here:

```
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

```
mysql> EXPLAIN SELECT f1(5);
```

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	NULL	NULL	NULL	NULL	NULL	NULL	NULL	No tables used

1 row in set (0.00 sec)

```
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2;
```

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	PRIMARY	NULL	NULL	NULL	NULL	NULL	NULL	NULL	No tables used

1 row in set, 1 warning (0.00 sec)

```
mysql> SHOW WARNINGS;
```

Level	Code	Message
Note	1249	Select 2 was reduced during optimization

1 row in set (0.00 sec)

```
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well:

```
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | type | possible_keys | key | key_len | ref | rows | Extra |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | PRIMARY | a1 | system | NULL | NULL | NULL | NULL | 0 | const row not fou |
| 1 | PRIMARY | <derived2> | system | NULL | NULL | NULL | NULL | 1 | |
| 2 | DERIVED | NULL | NULL | NULL | NULL | NULL | NULL | NULL | No tables used |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+
| c1 |
+-----+
| 5 |
+-----+
1 row in set (0.00 sec)
```

This also means that an `EXPLAIN SELECT` statement such as the one shown here may take a long time to execute because the `BENCHMARK()` function is executed once for each row in `t1`:

```
EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));
```

### 13.2.10.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

```
ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"
```

This means that MySQL does not support statements of the following form:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

- Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See [Section 13.2.10.5, "Row Subqueries"](#).

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

### 13.2.10.10 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with:

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
  (SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (
  SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2
  WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See [Section 13.2.10.11, "Rewriting Subqueries as Joins"](#).
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1
WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.
- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.
- Use `= ANY` rather than `EXISTS`.
- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1
WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1
WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See [Section 12.14, “Information Functions”](#).

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <= } (uncorrelated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also [MySQL Internals: How MySQL Transforms Subqueries](#).

### 13.2.10.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
  FROM table1 LEFT JOIN table2 ON table1.id=table2.id
 WHERE table2.id IS NULL;
```

A `LEFT [OUTER] JOIN` can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table `DELETE` statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table `UPDATE` statements are also supported. See [Section 13.2.2, “DELETE Syntax”](#), and [Section 13.2.11, “UPDATE Syntax”](#).

## 13.2.11 UPDATE Syntax

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
  SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
  [WHERE where_condition]
  [ORDER BY ...]
```

```
[LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
  SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
  [WHERE where_condition]
```

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the `ORDER BY` clause is specified, the rows are updated in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, `UPDATE` updates rows in each table named in *table\_references* that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, `ORDER BY` and `LIMIT` cannot be used.

For partitioned tables, both the single-table and multiple-table forms of this statement support the use of a `PARTITION` option as part of a table reference. This option takes a list of one or more partitions or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that is not in any of these partitions or subpartitions is not updated, whether it satisfies the *where\_condition* or not.

#### Note

Unlike the case when using `PARTITION` with an `INSERT` or `REPLACE` statement, an otherwise valid `UPDATE ... PARTITION` statement is considered successful even if no rows in the listed partitions (or subpartitions) match the *where\_condition*.

See [Section 18.5, “Partition Selection”](#), for more information and examples.

*where\_condition* is an expression that evaluates to true for each row to be updated. For expression syntax, see [Section 9.5, “Expression Syntax”](#).

*table\_references* and *where\_condition* are specified as described in [Section 13.2.9, “SELECT Syntax”](#).

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

The `UPDATE` statement supports the following modifiers:

- With the `LOW_PRIORITY` keyword, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- With the `IGNORE` keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

`UPDATE IGNORE` statements, including those having an `ORDER BY` clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439) See [Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#), for more information.

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table `UPDATE` assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared `NOT NULL` by setting to `NULL`, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is `0` for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types. See [Section 11.7, “Data Type Default Values”](#).

If a generated column is updated explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [CREATE TABLE and Generated Columns](#).

`UPDATE` returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the `UPDATE`.

You can use `LIMIT row_count` to restrict the scope of the `UPDATE`. A `LIMIT` clause is a rows-matched restriction. The statement stops as soon as it has found `row_count` rows that satisfy the `WHERE` clause, whether or not they actually were changed.

If an `UPDATE` statement includes an `ORDER BY` clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an `ORDER BY` clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform `UPDATE` operations covering multiple tables. However, you cannot use `ORDER BY` or `LIMIT` with a multiple-table `UPDATE`. The `table_references` clause lists the tables involved in the join. Its syntax is described in [Section 13.2.9.2, “JOIN Syntax”](#). Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table `UPDATE` statements can use any type of join permitted in `SELECT` statements, such as `LEFT JOIN`.

If you use a multiple-table `UPDATE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/

child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the `ON UPDATE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly. See [Section 14.5.6, “InnoDB and FOREIGN KEY Constraints”](#).

You cannot update a table and select from the same table in a subquery.

In MySQL 5.7, an `UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `UPDATE` statement's `WHERE` clause, as long as none of the table's partitioning columns are updated. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Section 18.6.4, “Partitioning and Locking”](#).

## 13.3 MySQL Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#). XA transaction support enables MySQL to participate in distributed transactions as well. See [Section 13.3.7, “XA Transactions”](#).

### 13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Syntax

```
START TRANSACTION
    [transaction_characteristic [, transaction_characteristic] ...]

transaction_characteristic:
    WITH CONSISTENT SNAPSHOT
    | READ WRITE
    | READ ONLY

BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

These statements provide control over use of [transactions](#):

- `START TRANSACTION` or `BEGIN` start a new transaction.
- `COMMIT` commits the current transaction, making its changes permanent.
- `ROLLBACK` rolls back the current transaction, canceling its changes.
- `SET autocommit` disables or enables the default autocommit mode for the current session.

By default, MySQL runs with `autocommit` mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk to make it permanent. The change cannot be rolled back.

To disable autocommit mode implicitly for a single series of statements, use the `START TRANSACTION` statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With `START TRANSACTION`, `autocommit` remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The `autocommit` mode then reverts to its previous state.

`START TRANSACTION` permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

- The `WITH CONSISTENT SNAPSHOT` modifier starts a [consistent read](#) for storage engines that are capable of it. This applies only to `InnoDB`. The effect is the same as issuing a `START TRANSACTION` followed by a `SELECT` from any `InnoDB` table. See [Section 14.2.2.2, “Consistent Nonlocking Reads”](#). The `WITH CONSISTENT SNAPSHOT` modifier does not change the current transaction [isolation level](#), so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is `REPEATABLE READ`. For all other isolation levels, the `WITH CONSISTENT SNAPSHOT` clause is ignored. As of MySQL 5.7.2, a warning is generated when the `WITH CONSISTENT SNAPSHOT` clause is ignored.
- The `READ WRITE` and `READ ONLY` modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The `READ ONLY` restriction prevents the transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables.

MySQL enables extra optimizations for queries on `InnoDB` tables when the transaction is known to be read-only. Specifying `READ ONLY` ensures these optimizations are applied in cases where the read-only status cannot be determined automatically. See [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for more information.

If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see [Section 13.3.6, “SET TRANSACTION Syntax”](#).

If the `read_only` system variable is enabled, explicitly starting a transaction with `START TRANSACTION READ WRITE` requires the `SUPER` privilege.

### Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See [Chapter 23, Connectors and APIs](#), or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the `autocommit` variable to zero, changes to transaction-safe tables (such as those for `InnoDB` or `NDB`) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

`autocommit` is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the `autocommit` system variable at [Section 5.1.4, “Server System Variables”](#).

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that `BEGIN` does not.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

**Note**

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN . . . END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See [Section 5.1.4, “Server System Variables”](#).

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#), for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as `InnoDB`), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)
- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.
- If you issue a `ROLLBACK` statement after updating a nontransactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception:** Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that modifications to the nontransactional tables are replicated.) See [Section 5.2.4, “The Binary Log”](#).

You can change the isolation level or access mode for transactions with the `SET TRANSACTION` statement. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

**Note**

In MySQL 5.7, `BEGIN`, `COMMIT`, and `ROLLBACK` are not affected by `--replicate-do-db` or `--replicate-ignore-db` rules.

### 13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

### 13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a `COMMIT` before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction because it cannot be rolled back anyway. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- **Data definition language (DDL) statements that define or modify database objects.** `ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER SERVER`, `ALTER TABLE`, `ALTER VIEW`, `CREATE DATABASE`, `CREATE EVENT`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE SERVER`, `CREATE TABLE`, `CREATE TRIGGER`, `CREATE VIEW`, `DROP DATABASE`, `DROP EVENT`, `DROP INDEX`, `DROP PROCEDURE`, `DROP SERVER`, `DROP TABLE`, `DROP TRIGGER`, `DROP VIEW`, `INSTALL PLUGIN` (as of MySQL 5.7.6), `RENAME TABLE`, `TRUNCATE TABLE`, `UNINSTALL PLUGIN` (as of MySQL 5.7.6).

`ALTER FUNCTION`, `CREATE FUNCTION` and `DROP FUNCTION` also cause an implicit commit when used with stored functions, but not with user-defined functions. (`ALTER FUNCTION` can only be used with stored functions.)

`CREATE TABLE` and `DROP TABLE` statements do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `ALTER TABLE` and `CREATE INDEX`, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use `CREATE TEMPORARY TABLE` and then roll back the transaction, the table remains in existence.

The `CREATE TABLE` statement in `InnoDB` is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

`CREATE TABLE ... SELECT` causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for `CREATE TEMPORARY TABLE ... SELECT`.) This is to prevent an issue during replication where the table could be created on the master after a rollback, but fail to be recorded in the binary log, and therefore not replicated to the slave.

- **Statements that implicitly use or modify tables in the `mysql` database.** `ALTER USER`, `CREATE USER`, `DROP USER`, `GRANT`, `RENAME USER`, `REVOKE`, `SET PASSWORD`.
- **Transaction-control and locking statements.** `BEGIN`, `LOCK TABLES`, `SET autocommit = 1` (if the value is not already 1), `START TRANSACTION`, `UNLOCK TABLES`.

`UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES` to acquire nontransactional table locks. A commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

- **Data loading statements.** `LOAD DATA INFILE`. `LOAD DATA INFILE` causes an implicit commit only for tables using the `NDB` storage engine.
- **Administrative statements.** `ANALYZE TABLE`, `CACHE INDEX`, `CHECK TABLE`, `FLUSH`, `LOAD INDEX INTO CACHE`, `OPTIMIZE TABLE`, `REPAIR TABLE`, `RESET`.
- **Replication control statements.** `START SLAVE`, `STOP SLAVE`, `RESET SLAVE`, `CHANGE MASTER TO`.

### 13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does *not* release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

### 13.3.5 LOCK TABLES and UNLOCK TABLES Syntax

```

LOCK TABLES
  tbl_name [[AS] alias] lock_type
  [, tbl_name [[AS] alias] lock_type] ...

lock_type:
  READ [LOCAL]
  | [LOW_PRIORITY] WRITE

UNLOCK TABLES

```

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail later in this section.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked.

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in [Section 13.3.5.2, “LOCK TABLES and Triggers”](#).

`UNLOCK TABLES` explicitly releases any table locks held by the current session. `LOCK TABLES` implicitly releases any table locks held by the current session before acquiring new locks.

Another use for `UNLOCK TABLES` is to release the global read lock acquired with the `FLUSH TABLES WITH READ LOCK` statement, which enables you to lock all tables in all databases. See [Section 13.7.6.3, “FLUSH Syntax”](#). (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`. For sessions holding a `READ` lock, `DROP TABLE` and `TRUNCATE TABLE` operations are not permitted.

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is permitted (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

For information about other conditions on the use of `LOCK TABLES` and statements that cannot be used while `LOCK TABLES` is in effect, see [Section 13.3.5.3, “Table-Locking Restrictions and Conditions”](#)

### Rules for Lock Acquisition

To acquire table locks within the current session, use the `LOCK TABLES` statement. The following lock types are available:

`READ [LOCAL]` lock:

- The session that holds the lock can read the table (but not write it).
- Multiple sessions can acquire a `READ` lock for the table at the same time.
- Other sessions can read the table without explicitly acquiring a `READ` lock.
- The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See [Section 8.11.3, “Concurrent Inserts”](#).) However,

`READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For `InnoDB` tables, `READ LOCAL` is the same as `READ`.

`[LOW_PRIORITY] WRITE` lock:

- The session that holds the lock can read and write the table.
- Only the session that holds the lock can access the table. No other session can access it until the lock is released.
- Lock requests for the table by other sessions block while the `WRITE` lock is held.
- The `LOW_PRIORITY` modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use `WRITE` without `LOW_PRIORITY` instead.

If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+-----+
| COUNT(*) |
+-----+
|          3 |
+-----+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
```

```
mysql> SELECT * FROM t AS myalias;
```

**WRITE** locks normally have higher priority than **READ** locks to ensure that updates are processed as soon as possible. This means that if one session obtains a **READ** lock and then another session requests a **WRITE** lock, subsequent **READ** lock requests wait until the session that requested the **WRITE** lock has obtained the lock and released it.

**LOCK TABLES** acquires locks as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is to be locked with a read and a write lock, put the write lock request before the read lock request.
3. Lock one table at a time until the session gets all locks.

This policy ensures that table locking is deadlock free.

#### Note

**LOCK TABLES** or **UNLOCK TABLES**, when applied to a partitioned table, always locks or unlocks the entire table; these statements do not support partition lock pruning. See [Section 18.6.4, “Partitioning and Locking”](#).

#### Rules for Lock Release

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with **UNLOCK TABLES**.
- If a session issues a **LOCK TABLES** statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with **START TRANSACTION**), an implicit **UNLOCK TABLES** is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see [Section 13.3.5.1, “Interaction of Table Locking and Transactions”](#).)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks will no longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See [Section 23.8.16, “Controlling Automatic Reconnection Behavior”](#).

#### Note

If you use **ALTER TABLE** on a locked table, it may become unlocked. For example, if you attempt a second **ALTER TABLE** operation, the result may be an error `Table 'tbl_name' was not locked with LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

### 13.3.5.1 Interaction of Table Locking and Transactions

**LOCK TABLES** and **UNLOCK TABLES** interact with the use of transactions as follows:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.
- `UNLOCK TABLES` implicitly commits any active transaction, but only if `LOCK TABLES` has been used to acquire table locks. For example, in the following set of statements, `UNLOCK TABLES` releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ... ;
UNLOCK TABLES;
```

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.
- `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See [Section 13.7.6.3, “FLUSH Syntax”](#).
- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).
- The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as `InnoDB` tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

When you call `LOCK TABLES`, `InnoDB` internally takes its own table lock, and MySQL takes its own table lock. `InnoDB` releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then `InnoDB` releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. `InnoDB` does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.

### 13.3.5.2 LOCK TABLES and Triggers

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken at the same time as those acquired explicitly with the `LOCK TABLES` statement.
- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.
- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table's appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers will also be locked. Suppose that `t1` has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

- `t1` is locked for writing per the `WRITE` lock request.
- `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.
- `t3` is locked for reading because it is only read from within the trigger.
- `t4` is locked for writing because it might be updated within the trigger.

### 13.3.5.3 Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See [Section 13.7.6.4, “KILL Syntax”](#).

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

The following statements are prohibited while a `LOCK TABLES` statement is in effect: `CREATE TABLE`, `CREATE TABLE ... LIKE`, `CREATE VIEW`, `DROP VIEW`, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
```

If you want to explicitly place a `WRITE` lock on any of those tables with a `LOCK TABLES` statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single `UPDATE` statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of `MyISAM` tables, it is much faster to lock the tables you are going to use. Locking `MyISAM` tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until `UNLOCK TABLES` is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a [READ](#)-locked table (including the one holding the lock) and no session can access a [WRITE](#)-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use [LOCK TABLES](#) if you want to ensure that no other session modifies the tables between a [SELECT](#) and an [UPDATE](#). The example shown here requires [LOCK TABLES](#) to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without [LOCK TABLES](#), it is possible that another session might insert a new row in the `trans` table between execution of the [SELECT](#) and [UPDATE](#) statements.

You can avoid using [LOCK TABLES](#) in many cases by using relative updates ([UPDATE customer SET value=value+new\\_value](#)) or the [LAST\\_INSERT\\_ID\(\)](#) function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions [GET\\_LOCK\(\)](#) and [RELEASE\\_LOCK\(\)](#). These locks are saved in a hash table in the server and implemented with [pthread\\_mutex\\_lock\(\)](#) and [pthread\\_mutex\\_unlock\(\)](#) for high speed. See [Section 12.19, "Miscellaneous Functions"](#).

See [Section 8.11.1, "Internal Locking Methods"](#), for more information on locking policy.

### 13.3.6 SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION
  transaction_characteristic [, transaction_characteristic] ...

transaction_characteristic:
  ISOLATION LEVEL level
  | READ WRITE
  | READ ONLY

level:
  REPEATABLE READ
  | READ COMMITTED
  | READ UNCOMMITTED
  | SERIALIZABLE
```

This statement specifies [transaction](#) characteristics. It takes a list of one or more characteristic values separated by commas. These characteristics set the transaction [isolation level](#) or access mode. The isolation level is used for operations on [InnoDB](#) tables. The access mode may be specified as to whether transactions operate in read/write or read-only mode.

In addition, [SET TRANSACTION](#) can include an optional [GLOBAL](#) or [SESSION](#) keyword to indicate the scope of the statement.

#### Scope of Transaction Characteristics

You can set transaction characteristics globally, for the current session, or for the next transaction:

- With the [GLOBAL](#) keyword, the statement applies globally for all subsequent sessions. Existing sessions are unaffected.
- With the [SESSION](#) keyword, the statement applies to all subsequent transactions performed within the current session.

- Without any [SESSION](#) or [GLOBAL](#) keyword, the statement applies to the next (not started) transaction performed within the current session. Subsequent transactions revert to using the [SESSION](#) isolation level.

A global change to transaction characteristics requires the [SUPER](#) privilege. Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction.

`SET TRANSACTION` without `GLOBAL` or `SESSION` is not permitted while there is an active transaction:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed
while a transaction is in progress
```

To set the global default isolation level at server startup, use the `--transaction-isolation=level` option to `mysqld` on the command line or in an option file. Values of `level` for this option use dashes rather than spaces, so the permissible values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. For example, to set the default isolation level to `REPEATABLE READ`, use these lines in the `[mysqld]` section of an option file:

```
[mysqld]
transaction-isolation = REPEATABLE-READ
```

It is possible to check or set the global and session transaction isolation levels at runtime by using the `tx_isolation` system variable:

```
SELECT @@GLOBAL.tx_isolation, @@tx_isolation;
SET GLOBAL tx_isolation='REPEATABLE-READ';
SET SESSION tx_isolation='SERIALIZABLE';
```

Similarly, to set the transaction access mode at server startup or at runtime, use the `--transaction-read-only` option or `tx_read_only` system variable. By default, these are `OFF` (the mode is read/write) but can be set to `ON` for a default mode of read only.

Setting the global or session value of `tx_isolation` or `tx_read_only` is equivalent to setting the isolation level or access mode with `SET GLOBAL TRANSACTION` or `SET SESSION TRANSACTION`.

## Details and Usage of Isolation Levels

[InnoDB](#) supports each of the transaction isolation levels described here using different [locking](#) strategies. You can enforce a high degree of consistency with the default `REPEATABLE READ` level, for operations on crucial data where [ACID](#) compliance is important. Or you can relax the consistency rules with `READ COMMITTED` or even `READ UNCOMMITTED`, in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. `SERIALIZABLE` enforces even stricter rules than `REPEATABLE READ`, and is used mainly in specialized situations, such as with [XA](#) transactions and for troubleshooting issues with concurrency and [deadlocks](#).

For full information about how these isolation levels work with [InnoDB](#) transactions, see [Section 14.2.2, “The InnoDB Transaction Model and Locking”](#). In particular, for additional information about [InnoDB](#) record-level locks and how it uses them to execute various types of statements, see [Section 14.2.2.4, “InnoDB Record, Gap, and Next-Key Locks”](#) and [Section 14.2.2.7, “Locks Set by Different SQL Statements in InnoDB”](#).

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- `REPEATABLE READ`

This is the default isolation level for `InnoDB`. For `consistent reads`, there is an important difference from the `READ COMMITTED` isolation level: All consistent reads within the same transaction read the snapshot established by the first read. This convention means that if you issue several plain (nonlocking) `SELECT` statements within the same transaction, these `SELECT` statements are consistent also with respect to each other. See [Section 14.2.2.2, “Consistent Nonlocking Reads”](#).

For `locking reads` (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE`, and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition. For a unique index with a unique search condition, `InnoDB` locks only the index record found, not the `gap` before it. For other search conditions, `InnoDB` locks the index range scanned, using `gap locks` or `next-key locks` to block insertions by other sessions into the gaps covered by the range.

- `READ COMMITTED`

A somewhat Oracle-like isolation level with respect to consistent (nonlocking) reads: Each `consistent read`, even within the same transaction, sets and reads its own fresh `snapshot`. See [Section 14.2.2.2, “Consistent Nonlocking Reads”](#).

For `locking reads` (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE` statements, and `DELETE` statements, `InnoDB` locks only index records, not the `gaps` before them, and thus permits the free insertion of new records next to locked records.

#### Note

In MySQL 5.7, when `READ COMMITTED` isolation level is used, or the deprecated `innodb_locks_unsafe_for_binlog` system variable is enabled, there is no `InnoDB` gap locking except for foreign-key constraint checking and duplicate-key checking. Also, record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition.

If you use `READ COMMITTED` or enable `innodb_locks_unsafe_for_binlog`, you *must* use row-based binary logging.

- `READ UNCOMMITTED`

`SELECT` statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a `dirty read`. Otherwise, this isolation level works like `READ COMMITTED`.

- `SERIALIZABLE`

This level is like `REPEATABLE READ`, but `InnoDB` implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if `autocommit` is disabled. If `autocommit` is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

## Transaction Access Mode

The transaction access mode may be specified with `SET TRANSACTION`. By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using an access mode of `READ WRITE`.

If the transaction access mode is set to `READ ONLY`, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

The `READ WRITE` and `READ ONLY` access modes also may be specified for an individual transaction using the `START TRANSACTION` statement.

### 13.3.7 XA Transactions

Support for XA transactions is available for the `InnoDB` storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in [Section C.6, “Restrictions on XA Transactions”](#).

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also will work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (However, for a distributed transaction, you must use the `SERIALIZABLE` isolation level to achieve ACID properties. It is enough to use `REPEATABLE READ` for a nondistributed transaction, but not for a distributed transaction.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions

within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA MySQL enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

### 13.3.7.1 XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER [CONVERT XID]
```

For XA **START**, the **JOIN** and **RESUME** clauses are not supported.

For XA **END** the **SUSPEND [FOR MIGRATE]** clause is not supported.

Each XA statement begins with the **XA** keyword, and most of them require an *xid* value. An *xid* is an XA transaction identifier. It indicates which transaction the statement applies to. *xid* values are supplied by the client, or generated by the MySQL server. An *xid* value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

*gtrid* is a global transaction identifier, *bqual* is a branch qualifier, and *formatID* is a number that identifies the format used by the *gtrid* and *bqual* values. As indicated by the syntax, *bqual* and *formatID* are optional. The default *bqual* value is '' if not given. The default *formatID* value is 1 if not given.

*gtrid* and *bqual* must be string literals, each up to 64 bytes (not characters) long. *gtrid* and *bqual* can be specified in several ways. You can use a quoted string ('ab'), hex string (X'6162', 0x6162), or bit value (b'nnnn').

*formatID* is an unsigned integer.

The *gtrid* and *bqual* values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write *gtrid* and *bqual* as hex strings.

*xid* values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own *xid* values in a list of values returned by the XA RECOVER statement.

For XA START *xid* starts an XA transaction with the given *xid* value. Each XA transaction must have a unique *xid* value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the *gtrid* and *bqual* values. All following XA statements for the XA transaction must be specified using the same *xid* value as that given in the XA START statement. If you use any of those statements but specify an *xid* value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same *gtrid* value in the *xid* value. For this reason, *gtrid* values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The *bqual* part of the *xid* value must be different for each XA transaction within a global transaction. (The requirement that *bqual* values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The XA RECOVER statement returns information for those XA transactions on the MySQL server that are in the PREPARED state. (See Section 13.3.7.2, "XA Transaction States".) The output includes a row for each such XA transaction on the server, regardless of which client started it.

XA RECOVER output rows look like this (for an example *xid* value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|          7 |             3 |             3 | abcdef |
+-----+-----+-----+-----+
```

The output columns have the following meanings:

- *formatID* is the *formatID* part of the transaction *xid*
- *gtrid\_length* is the length in bytes of the *gtrid* part of the *xid*
- *bqual\_length* is the length in bytes of the *bqual* part of the *xid*
- *data* is the concatenation of the *gtrid* and *bqual* parts of the *xid*

XID values may contain nonprintable characters. As of MySQL 5.7.5, XA RECOVER permits an optional CONVERT XID clause so that clients can request XID values in hexadecimal.

### 13.3.7.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use XA START to start an XA transaction and put it in the ACTIVE state.

2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.
3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:
  - `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point will include the transaction's `xid` value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.
  - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The `xid` value will not be listed by `XA RECOVER` because the transaction terminates.
4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

## 13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. Statements are split into a group which controls master servers, a group which controls slave servers, and a group which can be applied to any replication servers.

### 13.4.1 SQL Statements for Controlling Master Servers

This section discusses statements for managing master replication servers. [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#), discusses statements for managing slave servers.

In addition to the statements described here, the following `SHOW` statements are used with master servers in replication. For information about these statements, see [Section 13.7.5, “SHOW Syntax”](#).

- `SHOW BINARY LOGS`
- `SHOW BINLOG EVENTS`
- `SHOW MASTER STATUS`
- `SHOW SLAVE HOSTS`

### 13.4.1.1 PURGE BINARY LOGS Syntax

```
PURGE { BINARY | MASTER } LOGS
      { TO 'log_name' | BEFORE datetime_expr }
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see [Section 5.2.4, “The Binary Log”](#)).

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2008-04-02 22:46:26';
```

The `BEFORE` variant's *datetime\_expr* argument should evaluate to a `DATETIME` value (a value in `'YYYY-MM-DD hh:mm:ss'` format).

This statement is safe to run while slaves are replicating. You need not stop them. If you have an active slave that currently is reading one of the log files you are trying to delete, this statement does nothing. In MySQL 5.7.2 and later, it fails with an error in such cases. (Bug #13727933) However, if a slave is not connected and you happen to purge one of the log files it has yet to read, the slave will be unable to replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the master server with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the slaves. This is the target file. If all the slaves are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.1.4, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

`PURGE BINARY LOGS TO` and `PURGE BINARY LOGS BEFORE` both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple

text file) manually to ensure that it lists only the binary log files that are actually present, then run again the `PURGE BINARY LOGS` statement that failed.

### 13.4.1.2 RESET MASTER Syntax

```
RESET MASTER
```

Deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

`RESET MASTER` also clears the values of the `gtid_purged` system variable as well as the global value of the `gtid_executed` system variable (but not its session value); that is, executing this statement sets each of these values to an empty string ( `' '` ). In MySQL 5.7.5 and later, this statement also clears the `mysql.gtid_executed` table (see [The mysql.gtid\\_executed Table](#)).

This statement is intended to be used only when the master is started for the first time.

#### Important

The effects of `RESET MASTER` differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET MASTER` removes *all* binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.
2. `RESET MASTER` is *not* intended to be used while any replication slaves are running. The behavior of `RESET MASTER` when used while slaves are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replication slaves are running.

See also [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

`RESET MASTER` can prove useful when you first set up the master and the slave, so that you can verify the setup as follows:

1. Start the master and slave, and start replication (see [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#)).
2. Execute a few test queries on the master.
3. Check that the queries were replicated to the slave.
4. When replication is running correctly, issue `STOP SLAVE` followed by `RESET SLAVE` on the slave, then verify that any unwanted data no longer exists on the slave.
5. Issue `RESET MASTER` on the master to clean up the test queries.

After verifying the setup and getting rid of any unwanted and log files generated by testing, you can start the slave and begin replicating.

### 13.4.1.3 SET sql\_log\_bin Syntax

```
SET sql_log_bin = {0|1}
```

The `sql_log_bin` variable controls whether logging to the binary log is done. The default value is 1 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SUPER` privilege to set this variable. Set this variable to 0 for a session to temporarily disable binary logging while making changes to the master which you do not want to replicate to the slave.

As of MySQL 5.5, `sql_log_bin` can be set as a global or session variable. Setting `sql_log_bin` globally is only detected when a new session is started. Any sessions previously running are not impacted when setting `sql_log_bin` globally.

### Warning

Incorrect use of `sql_log_bin` with a global scope means any changes made in an already running session are *still* being recorded to the binary log and therefore replicated. Exercise extreme caution using `sql_log_bin` with a global scope as the above situation could cause unexpected results including replication failure.

In MySQL 5.7, it is not possible to set `@session.sql_log_bin` within a transaction or subquery. (Bug #53437)

## 13.4.2 SQL Statements for Controlling Slave Servers

This section discusses statements for managing slave replication servers. [Section 13.4.1, “SQL Statements for Controlling Master Servers”](#), discusses statements for managing master servers.

In addition to the statements described here, `SHOW SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replication slaves. For information about these statements, see [Section 13.7.5.34, “SHOW SLAVE STATUS Syntax”](#), and [Section 13.7.5.32, “SHOW RELAYLOG EVENTS Syntax”](#).

### 13.4.2.1 CHANGE MASTER TO Syntax

```
CHANGE MASTER TO option [, option] ... [ channel_option ]
```

*option*:

```
MASTER_BIND = 'interface_name'
| MASTER_HOST = 'host_name'
| MASTER_USER = 'user_name'
| MASTER_PASSWORD = 'password'
| MASTER_PORT = port_num
| MASTER_CONNECT_RETRY = interval
| MASTER_RETRY_COUNT = count
| MASTER_DELAY = interval
| MASTER_HEARTBEAT_PERIOD = interval
| MASTER_LOG_FILE = 'master_log_name'
| MASTER_LOG_POS = master_log_pos
| MASTER_AUTO_POSITION = {0|1}
| RELAY_LOG_FILE = 'relay_log_name'
| RELAY_LOG_POS = relay_log_pos
| MASTER_SSL = {0|1}
| MASTER_SSL_CA = 'ca_file_name'
| MASTER_SSL_CAPATH = 'ca_directory_name'
| MASTER_SSL_CERT = 'cert_file_name'
| MASTER_SSL_CRL = 'crl_file_name'
| MASTER_SSL_CRLPATH = 'crl_directory_name'
| MASTER_SSL_KEY = 'key_file_name'
| MASTER_SSL_CIPHER = 'cipher_list'
| MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
| MASTER_TLS_VERSION = 'protocol_list'
| IGNORE_SERVER_IDS = (server_id_list)
```

*channel\_option*:

```
FOR CHANNEL channel
```

*server\_id\_list*:

```
[server_id [, server_id] ... ]
```

`CHANGE MASTER TO` changes the parameters that the slave server uses for connecting to the master server, for reading the master binary log, and reading the slave relay log. It also updates the contents of the master info and relay log info repositories (see [Section 17.2.4, “Replication Relay and Status Logs”](#)).

Prior to MySQL 5.7.4, the slave replication threads must be stopped, using `STOP SLAVE` if necessary, before issuing this statement. In MySQL 5.7.4 and later, you can issue `CHANGE MASTER TO` statements on a running slave without doing this, depending on the states of the slave SQL thread and slave I/O thread. The rules governing such use are provided later in this section.

When using a multi-threaded slave (in other words `slave_parallel_workers` is greater than 0), stopping the slave can cause “gaps” in the sequence of transactions that have been executed from the relay log, regardless of whether the slave was stopped intentionally or otherwise. When such gaps exist, issuing `CHANGE MASTER TO` fails. The solution in this situation is to issue `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` which ensures that the gaps are closed.

The optional `FOR CHANNEL channel` clause added in MySQL 5.7.6 enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a `FOR CHANNEL channel` clause applies the `CHANGE MASTER TO` statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called `channel2`:

```
CHANGE MASTER TO MASTER_NAME=host1, MASTER_PORT=3002 FOR CHANNEL channel2
```

When using multiple replication channels, if a `CHANGE MASTER TO` statement does not have a channel defined using a `FOR CHANNEL channel` clause an error is generated. See [Section 17.2.3, “Replication Channels”](#) for more information.

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change. For example, if the password to connect to your MySQL master has changed, issue this statement to tell the slave about the new password:

```
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
```

Similarly, incompatible options which have been set previously must be unset if other options depend on them. For example if `MASTER_LOG_FILE` and `MASTER_LOG_POS` have been set when using `AUTO_POSITION=0`, and you want to use GTID based replication with `AUTO_POSITION=1`, you must also unset `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

`MASTER_HOST`, `MASTER_USER`, `MASTER_PASSWORD`, and `MASTER_PORT` provide information to the slave about how to connect to its master:

- `MASTER_HOST` and `MASTER_PORT` are the host name (or IP address) of the master host and its TCP/IP port.

#### Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

If you specify the `MASTER_HOST` or `MASTER_PORT` option, the slave assumes that the master server is different from before (even if the option value is the same as its current value.) In this case, the old values for the master binary log file name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE= ''` and `MASTER_LOG_POS=4` are silently appended to it.

Setting `MASTER_HOST= ''` (that is, setting its value explicitly to an empty string) is *not* the same as not setting `MASTER_HOST` at all. Beginning with MySQL 5.5, trying to set `MASTER_HOST` to an empty string fails with an error. Previously, setting `MASTER_HOST` to an empty string caused `START SLAVE` subsequently to fail. (Bug #28796)

Values used for `MASTER_HOST` and other `CHANGE MASTER TO` options are checked for linefeed (`\n` or `0x0A`) characters; the presence of such characters in these values causes the statement to fail with `ER_MASTER_INFO`. (Bug #11758581, Bug #50801)

- `MASTER_USER` and `MASTER_PASSWORD` are the user name and password of the account to use for connecting to the master.

`MASTER_USER` cannot be made empty; setting `MASTER_USER = ''` or leaving it unset when setting a value for `MASTER_PASSWORD` causes an error (Bug #13427949).

The password used for a MySQL Replication slave account in a `CHANGE MASTER TO` statement is limited to 32 characters in length; prior to MySQL 5.7.5, if the password was longer, the statement succeeded, but any excess characters were silently truncated. In MySQL 5.7.5 and later, trying to use a password of more than 32 characters causes `CHANGE MASTER TO` to fail. (Bug #11752299, Bug #43439)

The text of a running `CHANGE MASTER TO` statement, including values for `MASTER_USER` and `MASTER_PASSWORD`, can be seen in the output of a concurrent `SHOW PROCESSLIST` statement. (The complete text of a `START SLAVE` statement is also visible to `SHOW PROCESSLIST`.)

The `MASTER_SSL_XXX` options provide information about using SSL for the connection. They correspond to the `--ssl-xxx` options described in [Section 6.3.12.5, “SSL Command Options”](#), and [Section 17.3.7, “Setting Up Replication Using SSL”](#). These options can be changed even on slaves that are compiled without SSL support. They are saved to the master info repository, but are ignored if the slave does not have SSL support enabled.

As of MySQL 5.7.3, the `MASTER_SSL=1` is prescriptive, not advisory. When given, the slave connection to the master must use SSL or the connection attempt fails. Before 5.7.3, an SSL connection is permitted but not required. This is analogous to the client-side meaning of the `--ssl` command-line option; see [Section 6.3.12.5, “SSL Command Options”](#).

The `MASTER_TLS_VERSION` option specifies the encryption protocols permitted by the master for slave connections. The value is like that for the `tls_version` system variable: A comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.3.12.2, “Secure Connection Protocols and Ciphers”](#). This option was added in MySQL 5.7.10.

`MASTER_CONNECT_RETRY` specifies how many seconds to wait between connect retries. The default is 60.

`MASTER_RETRY_COUNT` limits the *number* of reconnection attempts and updates the value of the `Master_Retry_Count` column in the output of `SHOW SLAVE STATUS`. The default value is  $24 * 3600 = 86400$ . `MASTER_RETRY_COUNT` is intended to replace the older `--master-retry-count` server option, and is now the preferred method for setting this limit. You are encouraged not to rely on `--master-retry-count` in new applications and, when upgrading to MySQL 5.7, to update any existing applications that rely on it, so that they use `CHANGE MASTER TO ... MASTER_RETRY_COUNT` instead.

`MASTER_DELAY` specifies how many seconds behind the master the slave must lag. An event received from the master is not executed until at least *interval* seconds later than its execution on the master. The default is 0. An error occurs if *interval* is not a nonnegative integer in the range from 0 to  $2^{31}-1$ . For more information, see [Section 17.3.9, “Delayed Replication”](#).

In MySQL 5.7.4 and later, a `CHANGE MASTER TO` statement employing the `MASTER_DELAY` option can be executed on a running slave when the slave SQL thread is stopped.

`MASTER_BIND` is for use on replication slaves having multiple network interfaces, and determines which of the slave's network interfaces is chosen for connecting to the master.

The address configured with this option, if any, can be seen in the `Master_Bind` column of the output from `SHOW SLAVE STATUS`. If you are using slave status log tables (server started with `--master-info-repository=TABLE`), the value can also be seen as the `Master_bind` column of the `mysql.slave_master_info` table.

`MASTER_HEARTBEAT_PERIOD` sets the interval in seconds between replication heartbeats. Whenever the master's binary log is updated with an event, the waiting period for the next heartbeat is reset. `interval` is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Heartbeats are sent by the master only if there are no unsent events in the binary log file for a period longer than `interval`.

Prior to MySQL 5.7.4, not including `MASTER_HEARTBEAT_PERIOD` caused `CHANGE MASTER TO` to reset the heartbeat period (`Slave_heartbeat_period`) to the default, and `Slave_received_heartbeats` to 0. (Bug #18185490)

If you are logging master connection information to tables, `MASTER_HEARTBEAT_PERIOD` can be seen as the value of the `Heartbeat` column of the `mysql.slave_master_info` table.

Setting `interval` to 0 disables heartbeats altogether. The default value for `interval` is equal to the value of `slave_net_timeout` divided by 2.

Setting `@@global.slave_net_timeout` to a value less than that of the current heartbeat interval results in a warning being issued. The effect of issuing `RESET SLAVE` on the heartbeat interval is to reset it to the default value.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. `RELAY_LOG_FILE` and `RELAY_LOG_POS` are the coordinates at which the slave SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you also cannot specify `MASTER_AUTO_POSITION = 1` (described later in this section). If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` is specified, the slave uses the last coordinates of the *slave SQL thread* before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

In MySQL 5.7.4 and later, a `CHANGE MASTER TO` statement employing `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or both options can be executed on a running slave when the slave SQL thread is stopped.

If `MASTER_AUTO_POSITION = 1` is used with `CHANGE MASTER TO`, the slave attempts to connect to the master using the GTID-based replication protocol. In MySQL 5.7.4 and later, this option can be employed by `CHANGE MASTER TO` only if both the slave SQL and slave I/O threads are stopped.

When using GTIDs, the slave tells the master which transactions it has already received, executed, or both. To compute this set, it reads the global value of `gtid_executed` and the value of the `Retrieved_gtid_set` column from `SHOW SLAVE STATUS`. Since the GTID of the last transmitted transaction is included in `Retrieved_gtid_set` even if the transaction was only partially transmitted, the last received GTID is subtracted from this set. Thus, the slave computes the following set:

```
UNION(@@global.gtid_executed, Retrieved_gtid_set - last_received_GTID)
```

This set is sent to the master as part of the initial handshake, and the master sends back all transactions that it has executed which are not part of the set. If any of these transactions have been already purged from the master's binary log, the master sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the slave, and replication does not start.

When GTID-based replication is employed, the coordinates represented by `MASTER_LOG_FILE` and `MASTER_LOG_POS` are not used, and global transaction identifiers are used instead. Thus the use of either or both of these options together with `MASTER_AUTO_POSITION` causes an error.

Beginning with MySQL 5.7.1, you can see whether replication is running with autopositioning enabled by checking the output of `SHOW SLAVE STATUS`. (Bug #15992220)

`gtid_mode` must also be enabled before issuing `CHANGE MASTER TO ... MASTER_AUTO_POSITION = 1`. Otherwise, the statement fails with an error.

To revert to the older file-based replication protocol after using GTIDs, you can issue a new `CHANGE MASTER TO` statement that specifies `MASTER_AUTO_POSITION = 0`, as well as at least one of `MASTER_LOG_FILE` or `MASTER_LOG_POS`.

Prior to MySQL 5.7.4, `CHANGE MASTER TO` deletes all relay log files and starts a new one, unless you specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. In that case, relay log files are kept; the `relay_log_purge` global variable is set silently to 0. In MySQL 5.7.4 and later, relay logs are preserved when neither the slave SQL thread nor the slave I/O thread is stopped; if both threads are stopped, all relay log files are deleted unless you at least one of `RELAY_LOG_FILE` or `RELAY_LOG_POS` is specified.

`RELAY_LOG_FILE` can use either an absolute or relative path, and uses the same base name as `MASTER_LOG_FILE`. (Bug #12190)

`IGNORE_SERVER_IDS` takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE MASTER TO` statement that you issue on server 4 to tell it to use server 2 as its master instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

If a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ( );
```

Prior to MySQL 5.7.5, `RESET SLAVE ALL` has no effect on the server ID list. In MySQL 5.7.5 and later, `RESET SLAVE ALL` clears `IGNORE_SERVER_IDS`. (Bug #18816897)

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

In MySQL 5.7, the master info repository and the output of `SHOW SLAVE STATUS` provide the list of servers that are currently ignored. For more information, see [Section 17.2.4.2, "Slave Status Logs"](#), and [Section 13.7.5.34, "SHOW SLAVE STATUS Syntax"](#).

In MySQL 5.7, invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the slave's state prior to execution.

In MySQL 5.7, `CHANGE MASTER TO` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, "Statements That Cause an Implicit Commit"](#).

In MySQL 5.7.4 and later, the strict requirement to execute `STOP SLAVE` prior to issuing any `CHANGE MASTER TO` statement (and `START SLAVE` afterward) is removed. Instead of depending on whether the slave is stopped, the behavior of `CHANGE MASTER TO` depends (in MySQL 5.7.4 and later) on the states of the slave SQL thread and slave I/O threads; which of these threads is stopped or running now determines the options that can or cannot be used with a `CHANGE MASTER TO` statement at a given point in time. The rules for making this determination are listed here:

- If the SQL thread is stopped, you can execute `CHANGE MASTER TO` using any combination that is otherwise allowed of `RELAY_LOG_FILE`, `RELAY_LOG_POS`, and `MASTER_DELAY` options, even if the

slave I/O thread is running. No other options may be used with this statement when the I/O thread is running.

- If the I/O thread is stopped, you can execute `CHANGE MASTER TO` using any of the options for this statement (in any allowed combination) *except* `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or `MASTER_DELAY`, even when the SQL thread is running. These three options may not be used when the I/O thread is running.
- Both the SQL thread and the I/O thread must be stopped before issuing a `CHANGE MASTER TO` statement that employs `MASTER_AUTO_POSITION = 1`.

You can check the current state of the slave SQL and I/O threads using `SHOW SLAVE STATUS`.

For more information, see [Section 17.3.6, “Switching Masters During Failover”](#).

If you are using statement-based replication and temporary tables, it is possible for a `CHANGE MASTER TO` statement following a `STOP SLAVE` statement to leave behind temporary tables on the slave. In MySQL 5.7.4 and later, a warning (`ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO`) is now issued whenever this occurs. You can avoid this in such cases by making sure that the value of the `Slave_open_temp_tables` system status variable is equal to 0 prior to executing such a `CHANGE MASTER TO` statement.

`CHANGE MASTER TO` is useful for setting up a slave when you have the snapshot of the master and have recorded the master binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the slave to synchronize it with the master, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the slave to specify the coordinates at which the slave should begin reading the master binary log.

The following example changes the master server the slave uses and establishes the master binary log coordinates from which the slave begins reading. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='big3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay log files that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

You can even use the second operation in a nonreplication setup with a standalone, nonslave server for recovery following a crash. Suppose that your server has crashed and you have restored it from a backup. You want to replay the server's own binary log files (not relay log files, but regular binary log files), named (for example) `myhost-bin.*`. First, make a backup copy of these binary log files in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary log. Use `SET GLOBAL relay_log_purge=0` for additional safety. Then start the server without the `--log-bin` option. Instead, use the `--replicate-same-server-id, --relay-log=myhost-bin` (to make the server believe that these regular binary log files are relay log files) and `--skip-slave-start` options. After the server starts, issue these statements:

```
CHANGE MASTER TO
  RELAY_LOG_FILE='myhost-bin.153',
  RELAY_LOG_POS=410,
  MASTER_HOST='some_dummy_string';
START SLAVE SQL_THREAD;
```

The server reads and executes its own binary log files, thus achieving crash recovery. Once the recovery is finished, run `STOP SLAVE`, shut down the server, clear the master info and relay log info repositories, and restart the server with its original options.

Specifying the `MASTER_HOST` option (even with a dummy value) is required to make the server think it is a slave.

The following table shows the maximum permissible length for the string-valued options.

Option	Maximum Length
<code>MASTER_HOST</code>	60
<code>MASTER_USER</code>	16
<code>MASTER_PASSWORD</code>	32
<code>MASTER_LOG_FILE</code>	255
<code>RELAY_LOG_FILE</code>	255
<code>MASTER_SSL_CA</code>	255
<code>MASTER_SSL_CAPATH</code>	255
<code>MASTER_SSL_CERT</code>	255
<code>MASTER_SSL_CRL</code>	255
<code>MASTER_SSL_CRLPATH</code>	255
<code>MASTER_SSL_KEY</code>	255
<code>MASTER_SSL_CIPHER</code>	511

### 13.4.2.2 CHANGE REPLICATION FILTER Syntax

```
CHANGE REPLICATION FILTER filter [, filter] [, ...]

filter:
  REPLICATE_DO_DB = (db_list)
  | REPLICATE_IGNORE_DB = (db_list)
  | REPLICATE_DO_TABLE = (tbl_list)
  | REPLICATE_IGNORE_TABLE = (tbl_list)
  | REPLICATE_WILD_DO_TABLE = (wild_tbl_list)
  | REPLICATE_WILD_IGNORE_TABLE = (wild_tbl_list)
  | REPLICATE_REWRITE_DB = (db_pair_list)

db_list:
  db_name [, db_name] [, ...]

tbl_list:
  db_name.table_name [, db_table_name] [, ...]

wild_tbl_list:
  'db_pattern.table_pattern' [, 'db_pattern.table_pattern'] [, ...]

db_pair_list:
  (db_pair) [, (db_pair)] [, ...]

db_pair:
  from_db, to_db
```

In MySQL 5.7.3 and later, `CHANGE REPLICATION FILTER` sets one or more replication filtering rules on the slave in the same way as starting the slave `mysqld` with replication filtering options

such as `--replicate-do-db` or `--replicate-wild-ignore-table`. Unlike the case with the server options, this statement does not require restarting the server to take effect, only that the slave SQL thread be stopped using `STOP SLAVE SQL_THREAD` first (and restarted with `START SLAVE SQL_THREAD` afterwards).

The following list shows the `CHANGE REPLICATION FILTER` options and how they relate to `--replicate-*` server options:

- `REPLICATE_DO_DB`: Include updates based on database name. Equivalent to `--replicate-do-db`.
- `REPLICATE_IGNORE_DB`: Exclude updates based on database name. Equivalent to `--replicate-ignore-db`.
- `REPLICATE_DO_TABLE`: Include updates based on table name. Equivalent to `--replicate-do-table`.
- `REPLICATE_IGNORE_TABLE`: Exclude updates based on table name. Equivalent to `--replicate-ignore-table`.
- `REPLICATE_WILD_DO_TABLE`: Include updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-do-table`.
- `REPLICATE_WILD_IGNORE_TABLE`: Exclude updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-ignore-table`.
- `REPLICATE_REWRITE_DB`: Perform updates on slave after substituting new name on slave for specified database on master. Equivalent to `--replicate-rewrite-db`.

The precise effects of `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` filters are dependent on whether statement-based or row-based replication is in effect. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#), for more information.

Multiple replication filtering rules can be created in a single `CHANGE REPLICATION FILTER` statement by separating the rules with commas, as shown here:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (d1), REPLICATE_IGNORE_DB = (d2);
```

Issuing the statement just shown is equivalent to starting the slave `mysqld` with the options `--replicate-do-db=d1 --replicate-ignore-db=d2`.

If the same filtering rule is specified multiple times, only the *last* such rule is actually used. For example, the two statements shown here have exactly the same effect, because the first `REPLICATE_DO_DB` rule in the first statement is ignored:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db1, db2), REPLICATE_DO_DB = (db3, db4);

CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db3, db4);
```

### Caution

This behavior differs from that of the `--replicate-*` filter options where specifying the same option multiple times causes the creation of multiple filter rules.

Names of tables and database not containing any special characters need not be quoted. Values used with `REPLICATION_WILD_TABLE` and `REPLICATION_WILD_IGNORE_TABLE` are string expressions,

possibly containing (special) wildcard characters, and so must be quoted. This is shown in the following example statements:

```
CHANGE REPLICATION FILTER
  REPLICATE_WILD_DO_TABLE = ('db1.old%');

CHANGE REPLICATION FILTER
  REPLICATE_WILD_IGNORE_TABLE = ('db1.new%', 'db2.new*');
```

Values used with `REPLICATE_REWRITE_DB` represent *pairs* of database names; each such value must be enclosed in parentheses. The following statement rewrites statements occurring on database `dbA` on the master to database `dbB` on the slave:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB = ((db1, db2));
```

The statement just shown contains two sets of parentheses, one enclosing the pair of database names, and the other enclosing the entire list. This is perhaps more easily seen in the following example, which creates two `rewrite-db` rules, one rewriting database `dbA` to `dbB`, and one rewriting database `dbC` to `dbD`:

```
CHANGE REPLICATION FILTER
  REPLICATE_REWRITE_DB = ((dbA, dbB), (dbC, dbD));
```

This statement leaves any existing replication filtering rules unchanged; to unset all filters of a given type, set the filter's value to an explicitly empty list, as shown in this example, which removes all existing `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` rules:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (), REPLICATE_IGNORE_DB = ();
```

Setting a filter to empty in this way removes all existing rules, does not create any new ones, and does not restore any rules set at `mysqld` startup using `--replicate-*` options on the command line or in the configuration file.

Values employed with `REPLICATE_WILD_DO_TABLE` and `REPLICATE_WILD_IGNORE_TABLE` must be in the format `db_name.tbl_name`. Prior to MySQL 5.7.5, this was not strictly enforced, although using nonconforming values with these options could lead to erroneous results (Bug #18095449).

For more information, see [Section 17.2.5, "How Servers Evaluate Replication Filtering Rules"](#).

### 13.4.2.3 MASTER\_POS\_WAIT() Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos [, timeout][, channel])
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See [Section 12.19, "Miscellaneous Functions"](#), for a full description.

### 13.4.2.4 RESET SLAVE Syntax

```
RESET SLAVE [ALL] [channel_option]

channel_option:
  FOR CHANNEL channel
```

`RESET SLAVE` makes the slave forget its replication position in the master's binary log. This statement is meant to be used for a clean start: It clears the master info and relay log info repositories, deletes

all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the `MASTER_DELAY` option to `CHANGE MASTER TO`. To use `RESET SLAVE`, the slave replication threads must be stopped (use `STOP SLAVE` if necessary).

#### Note

All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a `STOP SLAVE` statement or if the slave is highly loaded.)

The optional `FOR CHANNEL channel` clause added in MySQL 5.7.6 enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a `FOR CHANNEL channel` clause applies the `RESET SLAVE` statement to a specific replication channel. Combining a `FOR CHANNEL channel` clause with the `ALL` option deletes the specified channel. Issuing a `RESET SLAVE ALL` statement without a `FOR CHANNEL channel` clause when multiple replication channels exist deletes *all* replication channels and recreates only the default channel. See [Section 17.2.3, “Replication Channels”](#) for more information.

`RESET SLAVE` does not change any replication connection parameters such as master host, master port, master user, or master password, which are retained in memory. This means that `START SLAVE` can be issued without requiring a `CHANGE MASTER TO` statement following `RESET SLAVE`.

Connection parameters are reset by `RESET SLAVE ALL`. (`RESET SLAVE` followed by a restart of the slave `mysqld` also does this.)

In MySQL 5.7 `RESET SLAVE` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the slave.

Prior to MySQL 5.7.5, `RESET SLAVE` also had the effect of resetting both the heartbeat period (`Slave_heartbeat_period`) and `SSL_VERIFY_SERVER_CERT`. This issue is fixed in MySQL 5.7.5 and later. (Bug #18777899, Bug #18778485)

Prior to MySQL 5.7.5, `RESET SLAVE ALL` did not clear the `IGNORE_SERVER_IDS` list set by `CHANGE MASTER TO`. In MySQL 5.7.5 and later, the statement clears the list. (Bug #18816897)

### 13.4.2.5 SET GLOBAL `sql_slave_skip_counter` Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

This statement skips the next *N* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave threads are not running. Otherwise, it produces an error.

When using this statement, it is important to understand that the binary log is actually organized as a sequence of groups known as *event groups*. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

#### Note

A single transaction can contain changes to both transactional and nontransactional tables.

When you use `SET GLOBAL sql_slave_skip_counter` to skip events and the result is in the middle of a group, the slave continues to skip events until it reaches the end of the group. Execution then starts with the next event group.

### 13.4.2.6 START SLAVE Syntax

```
START SLAVE [thread_types] [until_option] [connection_options] [channel_option]

thread_types:
  [thread_type [, thread_type] ... ]

thread_type:
  IO_THREAD | SQL_THREAD

until_option:
  UNTIL {
    {SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS} = gtid_set
    | MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
    | RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
    | SQL_AFTER_MTS_GAPS }

connection_options:
  [USER='user_name'] [PASSWORD='user_pass'] [DEFAULT_AUTH='plugin_name'] [PLUGIN_DIR='plugin_dir']

channel_option:
  FOR CHANNEL channel

gtid_set:
  uuid_set [, uuid_set] ...
  | ''

uuid_set:
  uuid:interval[:interval]...

uuid:
  hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh

h:
  [0-9,A-F]

interval:
  n[-n]

  (n >= 1)
```

`START SLAVE` with no *thread\_type* options starts both of the slave threads. The I/O thread reads events from the master server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. `START SLAVE` requires the `SUPER` privilege.

If `START SLAVE` succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary log, or some other problem). `START SLAVE` does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with `SHOW SLAVE STATUS`.

In MySQL 5.7, `START SLAVE` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

Beginning with MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement (Bug #16062608).

The optional `FOR CHANNEL channel` clause added in MySQL 5.7.6 enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a `FOR CHANNEL channel` clause applies the `START SLAVE` statement to a specific replication channel. If a `START SLAVE` statement does not have a channel defined when using multiple

channels, this statement starts the specified threads for all channels. Beginning with MySQL 5.7.9, this statement is disallowed for the `group_replication_recovery` channel. See [Section 17.2.3, “Replication Channels”](#) for more information.

MySQL 5.7 supports pluggable user-password authentication with `START SLAVE` with the `USER`, `PASSWORD`, `DEFAULT_AUTH` and `PLUGIN_DIR` options, as described in the following list:

- `USER`: User name. Cannot be set to an empty or null string, or left unset if `PASSWORD` is used.
- `PASSWORD`: Password.
- `DEFAULT_AUTH`: Name of plugin; default is MySQL native authentication.
- `PLUGIN_DIR`: Location of plugin.

You cannot use the `SQL_THREAD` option when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

See [Section 6.3.8, “Pluggable Authentication”](#), for more information.

If an insecure connection is used with any these options, the server issues the warning `Sending passwords in plain text without SSL/TLS is extremely insecure`.

`START SLAVE ... UNTIL` supports two additional options for use with global transaction identifiers (GTIDs) (see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#)). Each of these takes a set of one or more global transaction identifiers `gtid_set` as an argument (see [GTID Sets](#), for more information).

When no `thread_type` is specified, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the slave SQL thread to process transactions until it has reached the *first* transaction whose GTID is listed in the `gtid_set`. `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the slave threads to process all transactions until the *last* transaction in the `gtid_set` has been processed by both threads. In other words, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the slave SQL thread to process all transactions occurring before the first GTID in the `gtid_set` is reached, and `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the slave threads to handle all transactions, including those whose GTIDs are found in `gtid_set`, until each has encountered a transaction whose GTID is not part of the set. `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` each support the `SQL_THREAD` and `IO_THREAD` options, although using `IO_THREAD` with them currently has no effect.

For example, `START SLAVE SQL_THREAD UNTIL SQL_BEFORE_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56` causes the slave SQL thread to process all transactions originating from the master whose `server_uuid` [2426] is `3E11FA47-71CA-11E1-9E33-C80AA9429562` until it encounters the transaction having sequence number 11; it then stops without processing this transaction. In other words, all transactions up to and including the transaction with sequence number 10 are processed. Executing `START SLAVE SQL_THREAD UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56`, on the other hand, would cause the slave SQL thread to obtain all transactions just mentioned from the master, including all of the transactions having the sequence numbers 11 through 56, and then to stop without processing any additional transactions; that is, the transaction having sequence number 56 would be the last transaction fetched by the slave SQL thread.

Prior to MySQL 5.7.3, `SQL_AFTER_GTIDS` did not stop the slave once the indicated transaction was completed, but waited until another GTID event was received (Bug #14767986).

When using a multi-threaded slave, there is a chance of gaps in the sequence of transactions that have been executed from the relay log in the following cases:

- killing the coordinator thread
- after an error occurs in the worker threads

- `mysqld` shuts down unexpectedly

Use the `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` statement to cause a multi-threaded slave's worker threads to only run until no more gaps are found in the relay log, and then to stop. This statement can take an `SQL_THREAD` option, but the effects of the statement remain unchanged. It has no effect on the slave I/O thread (and cannot be used with the `IO_THREAD` option).

Issuing `START SLAVE` on a multi-threaded slave with gaps in the sequence of transactions executed from the relay log generates a warning. In such a situation, the solution is to use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`, then issue `RESET SLAVE` to remove any remaining relay logs. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

To change a failed multi-threaded slave to single-threaded mode, you can issue the following series of statements, in the order shown:

```
START SLAVE UNTIL SQL_AFTER_MTS_GAPS;

SET @@GLOBAL.slave_parallel_workers = 0;

START SLAVE SQL_THREAD;
```

#### Note

It is possible to view the entire text of a running `START SLAVE ...` statement, including any `USER` or `PASSWORD` values used, in the output of `SHOW PROCESSLIST`. This is also true for the text of a running `CHANGE MASTER TO` statement, including any values it employs for `MASTER_USER` or `MASTER_PASSWORD`.

`START SLAVE` sends an acknowledgment to the user after both the I/O thread and the SQL thread have started. However, the I/O thread may not yet have connected. For this reason, a successful `START SLAVE` causes `SHOW SLAVE STATUS` to show `Slave_SQL_Running=Yes`, but this does not guarantee that `Slave_IO_Running=Yes` (because `Slave_IO_Running=Yes` only if the I/O thread is running *and connected*). For more information, see [Section 13.7.5.34, “SHOW SLAVE STATUS Syntax”](#), and [Section 17.1.7.1, “Checking Replication Status”](#).

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start. The `SQL_THREAD` option is disallowed when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

An `UNTIL` clause (*until\_option*, in the preceding grammar) may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary log, specified by the `MASTER_LOG_POS` and `MASTER_LOG_FILE` options, or a given point in the slave relay log, indicated with the `RELAY_LOG_POS` and `RELAY_LOG_FILE` options. When the SQL thread reaches the point specified, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued. You cannot use an `UNTIL` clause with the `IO_THREAD` option.

It is also possible with `START SLAVE UNTIL` to specify a stop point relative to a given GTID or set of GTIDs using one of the options `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`, as explained previously in this section. When using one of these options, you can specify `SQL_THREAD`, `IO_THREAD`, both of these, or neither of them. If you specify only `SQL_THREAD`, then only the slave SQL thread is affected by the statement; if only `IO_THREAD` is used, then only the slave I/O is affected. If both `SQL_THREAD` and `IO_THREAD` are used, or if neither of them is used, then both the SQL and I/O threads are affected by the statement.

The `UNTIL` clause is not supported for multi-threaded slaves except when also using `SQL_AFTER_MTS_GAPS`.

For an `UNTIL` clause, you must specify any one of the following:

- *Both* a log file name and a position in that file
- *Either* of `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`
- `SQL_AFTER_MTS_GAPS`

Do not mix master and relay log options. Do not mix log file options with GTID options.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

When specifying a log file and position, you can use the `IO_THREAD` option with `START SLAVE ... UNTIL` even though only the SQL thread is affected by this statement. The `IO_THREAD` option is ignored in such cases. The preceding restriction does not apply when using one of the GTID options (`SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`); the GTID options support both `SQL_THREAD` and `IO_THREAD`, as explained previously in this section.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate an event. For example, if an unwise `DROP TABLE` statement was executed on the master, you can use `UNTIL` to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master binary log or slave relay log, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

Prior to MySQL 5.7.5, the failure of this statement caused the slave heartbeat period to be reset. This issue is fixed in MySQL 5.7.5 and later. (Bug #18791604)

In very old versions of MySQL (before 4.0.5), this statement was called `SLAVE START`. In MySQL 5.7, that syntax produces an error.

### 13.4.2.7 STOP SLAVE Syntax

```
STOP SLAVE [thread_types]

thread_types:
  [thread_type [, thread_type]... ]

thread_type: IO_THREAD | SQL_THREAD

channel_option:
  FOR CHANNEL channel
```

Stops the slave threads. `STOP SLAVE` requires the `SUPER` privilege. Recommended best practice is to execute `STOP SLAVE` on the slave before stopping the slave server (see [Section 5.1.12, “The Server Shutdown Process”](#), for more information).

*When using the row-based logging format.* You should execute `STOP SLAVE` or `STOP SLAVE SQL_THREAD` on the slave prior to shutting down the slave server if you are replicating any tables that use a nontransactional storage engine (see the *Note* later in this section).

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped.

In MySQL 5.7, `STOP SLAVE` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

Beginning with MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement (Bug #16062608).

In MySQL 5.7.2 and later, you can control how long `STOP SLAVE` waits before timing out by setting the `rpl_stop_slave_timeout` system variable. This can be used to avoid deadlocks between `STOP SLAVE` and other slave SQL statements using different client connections to the slave. (Bug #16856735)

Prior to MySQL 5.7.4, it was necessary to issue this statement on a running slave prior to executing `CHANGE MASTER TO`. In MySQL 5.7.4 and later, this is no longer always the case; some `CHANGE MASTER TO` statements are now allowed while the slave is running, depending on the states of the slave SQL and I/O threads. However, using `STOP SLAVE` prior to executing `CHANGE MASTER TO` in such cases is still supported. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#), and [Section 17.3.6, “Switching Masters During Failover”](#), for more information.

The optional `FOR CHANNEL channel` clause added in MySQL 5.7.6 enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a `FOR CHANNEL channel` clause applies the `STOP SLAVE` statement to a specific replication channel. If a `STOP SLAVE` statement does not have a channel defined when using multiple channels, this statement stops the specified threads for all channels. Beginning with MySQL 5.7.9, this statement cannot be used with the `group_replication_recovery` channel. See [Section 17.2.3, “Replication Channels”](#) for more information.

*When using statement-based replication:* changing the master while it has open temporary tables is potentially unsafe. This is one of the reasons why statement-based replication of temporary tables is not recommended. You can find out whether there are any temporary tables on the slave by checking the value of `Slave_open_temp_tables`; when using statement-based replication, this value should be 0 before executing `CHANGE MASTER TO`. In MySQL 5.7.4 and later, if there are any temporary tables open on the slave, issuing a `CHANGE MASTER TO` statement after issuing a `STOP SLAVE` causes an `ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO` warning.

When using a multi-threaded slave (`slave_parallel_workers` is a nonzero value), any gaps in the sequence of transactions executed from the relay log are closed as part of stopping the worker threads. If the slave is stopped unexpectedly (for example due to an error in a worker thread, or another thread issuing `KILL`) while a `STOP SLAVE` statement is executing, the sequence of executed transactions from the relay log may become inconsistent. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

#### Note

In MySQL 5.7, `STOP SLAVE` waits until the current replication event group affecting one or more nontransactional tables has finished executing (if there is any such replication group), or until you issue a `KILL QUERY` or `KILL CONNECTION` statement. (Bug #319, Bug #38205)

## 13.4.3 SQL Statements for Controlling Group Replication

This section provides information about the statements used for controlling group replication.

### 13.4.3.1 START GROUP\_REPLICATION Syntax

```
START GROUP_REPLICATION
```

Starts group replication. Added in MySQL 5.7.6.

### 13.4.3.2 STOP GROUP\_REPLICATION Syntax

```
STOP GROUP_REPLICATION
```

Stops group replication. Added in MySQL 5.7.6.

## 13.5 SQL Syntax for Prepared Statements

MySQL 5.7 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as `WHERE` for queries and deletes, `SET` for updates, and `VALUES` for inserts.
- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

### Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the [MySQL C API client library](#) or [MySQL Connector/C](#) for C programs, [MySQL Connector/J](#) for Java programs, and [MySQL Connector/Net](#) for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See [Section 23.8.8, “C API Prepared Statements”](#). Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the [mysql\\_i extension](#), available in PHP 5.0 and later.

### Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that can send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library, as long as you connect to a server running MySQL 4.1 or higher.

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.
- To use prepared statements when you do not have access to a programming API that supports them.
- To interactively troubleshoot application issues with prepared statements.
- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

### PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see [Section 13.5.1, “PREPARE Syntax”](#)).
- `EXECUTE` executes a prepared statement (see [Section 13.5.2, “EXECUTE Syntax”](#)).

- `DEALLOCATE PREPARE` releases a prepared statement (see [Section 13.5.3, “DEALLOCATE PREPARE Syntax”](#)).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          5 |
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);

mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);

mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+----+
| a  |
+----+
|  4 |
|  8 |
| 11 |
| 32 |
| 80 |
+----+
mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

## SQL Syntax Allowed in Prepared Statements

The following SQL statements can be used as prepared statements:

```
ALTER TABLE
ALTER USER
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
COMMIT
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
RENAME TABLE
REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE | QUERY CACHE}
REVOKE
SELECT
SET
SHOW {WARNINGS | ERRORS}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
TRUNCATE TABLE
UNINSTALL PLUGIN
UPDATE
```

As of MySQL 5.7.2, for compliance with the SQL standard, which states that diagnostics statements are not preparable, MySQL does not support the following as prepared statements:

- `SHOW WARNINGS`, `SHOW COUNT(*) WARNINGS`
- `SHOW ERRORS`, `SHOW COUNT(*) ERRORS`
- Statements containing any reference to the `warning_count` or `error_count` system variable.

Other statements are not supported in MySQL 5.7.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in [Section C.1, “Restrictions on Stored Programs”](#).

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#).

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See [Section 13.2.9, “SELECT Syntax”](#).

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 5.7. See [Section 13.2.1, “CALL Syntax”](#), for

an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by “;” characters).

Prepared statements use the query cache under the conditions described in [Section 8.10.3.1, “How the Query Cache Operates”](#).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see [Section 13.2.1, “CALL Syntax”](#).

## 13.5.1 PREPARE Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a SQL statement and assigns it a name, *stmt\_name*, by which to refer to the statement later. The prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`. For examples, see [Section 13.5, “SQL Syntax for Prepared Statements”](#).

Statement names are not case sensitive. *preparable\_stmt* is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which has several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See [Section 23.8.16, “Controlling Automatic Reconnection Behavior”](#).

- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see [Section 9.4, “User-Defined Variables”](#).

## 13.5.2 EXECUTE Syntax

```
EXECUTE stmt_name
    [USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see [Section 13.5, “SQL Syntax for Prepared Statements”](#).

## 13.5.3 DEALLOCATE PREPARE Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the `DEALLOCATE PREPARE` statement or the end of the session, you might encounter the upper limit enforced by the `max_prepared_stmt_count` system variable.

For examples, see [Section 13.5, “SQL Syntax for Prepared Statements”](#).

## 13.6 MySQL Compound-Statement Syntax

This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see [Chapter 19, \*Stored Programs and Views\*](#)).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

### 13.6.1 BEGIN ... END Compound-Statement Syntax

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents

a list of one or more statements, each terminated by a semicolon (;) statement delimiter. The *statement\_list* itself is optional, so the empty compound statement (`BEGIN END`) is legal.

`BEGIN ... END` blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the ; statement delimiter. In the `mysql` command-line client, this is handled with the `delimiter` command. Changing the ; end-of-statement delimiter (for example, to //) permit ; to be used in a program body. For an example, see [Section 19.1, “Defining Stored Programs”](#).

A `BEGIN ... END` block can be labeled. See [Section 13.6.2, “Statement Label Syntax”](#).

The optional `[NOT] ATOMIC` clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

#### Note

Within all stored programs, the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

## 13.6.2 Statement Label Syntax

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]

[begin_label:] LOOP
    statement_list
END LOOP [end_label]

[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

Labels are permitted for `BEGIN ... END` blocks and for the `LOOP`, `REPEAT`, and `WHILE` statements. Label use for those statements follows these rules:

- *begin\_label* must be followed by a colon.
- *begin\_label* can be given without *end\_label*. If *end\_label* is present, it must be the same as *begin\_label*.
- *end\_label* cannot be given without *begin\_label*.
- Labels at the same nesting level must be distinct.
- Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an `ITERATE` or `LEAVE` statement. The following example uses those statements to continue iterating or terminate the loop:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
    label1: LOOP
        SET p1 = p1 + 1;
```

```
IF p1 < 10 THEN ITERATE labell; END IF;
LEAVE labell;
END LOOP labell;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#).

### 13.6.3 DECLARE Syntax

The `DECLARE` statement is used to define various items local to a program:

- Local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).
- Conditions and handlers. See [Section 13.6.7, “Condition Handling”](#).
- Cursors. See [Section 13.6.6, “Cursors”](#).

`DECLARE` is permitted only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

### 13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use `DECLARE` to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the `DECLARE` statement, as described in [Section 13.6.4.1, “Local Variable DECLARE Syntax”](#).
- Variables can be set directly with the `SET` statement. See [Section 13.7.4, “SET Syntax”](#).
- Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See [Section 13.2.9.1, “SELECT ... INTO Syntax”](#), and [Section 13.6.6, “Cursors”](#).

For information about the scope of local variables and how MySQL resolves ambiguous names, see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).

It is not permitted to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). In MySQL 5.7, this results in a syntax error.

#### 13.6.4.1 Local Variable DECLARE Syntax

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See [Section 13.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in [Section 9.2, “Schema Object Names”](#).

The scope of a local variable is the `BEGIN . . . END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

### 13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN . . . END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT . . . INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See [Section 13.5.1, “PREPARE Syntax”](#).

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT . . . INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname, id INTO newname, xid
  FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  DECLARE done TINYINT DEFAULT 0;
  DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

  OPEN cur1;
  read_loop: LOOP
    FETCH FROM cur1 INTO newname, xid;
    IF done THEN LEAVE read_loop; END IF;
    SELECT newname;
  END LOOP;
  CLOSE cur1;
END;
```

See also [Section C.1, “Restrictions on Stored Programs”](#).

## 13.6.5 Flow Control Statements

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs. It also supports `RETURN` within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

MySQL does not support `FOR` loops.

### 13.6.5.1 CASE Syntax

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

The `CASE` statement for stored programs implements a complex conditional construct.

#### Note

There is also a `CASE expression`, which differs from the `CASE statement` described here. See [Section 12.4, “Control Flow Functions”](#). The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

For the first syntax, `case_value` is an expression. This value is compared to the `when_value` expression in each `WHEN` clause until one of them is equal. When an equal `when_value` is found, the corresponding `THEN` clause `statement_list` executes. If no `when_value` is equal, the `ELSE` clause `statement_list` executes, if there is one.

This syntax cannot be used to test for equality with `NULL` because `NULL = NULL` is false. See [Section 3.3.4.6, “Working with NULL Values”](#).

For the second syntax, each `WHEN` clause `search_condition` expression is evaluated until one is true, at which point its corresponding `THEN` clause `statement_list` executes. If no `search_condition` is equal, the `ELSE` clause `statement_list` executes, if there is one.

If no `when_value` or `search_condition` matches the value tested and the `CASE` statement contains no `ELSE` clause, a `Case not found for CASE statement` error results.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN ... END` block, as shown in this example. (The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |
```

```

CREATE PROCEDURE p()
BEGIN
  DECLARE v INT DEFAULT 1;

  CASE v
    WHEN 2 THEN SELECT v;
    WHEN 3 THEN SELECT 0;
    ELSE
      BEGIN
        END;
      END CASE;
  END;
|

```

### 13.6.5.2 IF Syntax

```

IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF

```

The `IF` statement for stored programs implements a basic conditional construct.

#### Note

There is also an `IF()` function, which differs from the `IF statement` described here. See [Section 12.4, “Control Flow Functions”](#). The `IF` statement can have `THEN`, `ELSE`, and `ELSEIF` clauses, and it is terminated with `END IF`.

If the *search\_condition* evaluates to true, the corresponding `THEN` or `ELSEIF` clause *statement\_list* executes. If no *search\_condition* matches, the `ELSE` clause *statement\_list* executes.

Each *statement\_list* consists of one or more SQL statements; an empty *statement\_list* is not permitted.

An `IF ... END IF` block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```

DELIMITER //

CREATE FUNCTION SimpleCompare(n INT, m INT)
  RETURNS VARCHAR(20)

BEGIN
  DECLARE s VARCHAR(20);

  IF n > m THEN SET s = '>';
  ELSEIF n = m THEN SET s = '=';
  ELSE SET s = '<';
  END IF;

  SET s = CONCAT(n, ' ', s, ' ', m);

  RETURN s;
END //

DELIMITER ;

```

As with other flow-control constructs, `IF ... END IF` blocks may be nested within other flow-control constructs, including other `IF` statements. Each `IF` must be terminated by its own `END IF` followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```

DELIMITER //

CREATE FUNCTION VerboseCompare (n INT, m INT)
  RETURNS VARCHAR(50)

BEGIN
  DECLARE s VARCHAR(50);

  IF n = m THEN SET s = 'equals';
  ELSE
    IF n > m THEN SET s = 'greater';
    ELSE SET s = 'less';
    END IF;

    SET s = CONCAT('is ', s, ' than');
  END IF;

  SET s = CONCAT(n, ' ', s, ' ', m, '.');

  RETURN s;
END //

DELIMITER ;

```

In this example, the inner `IF` is evaluated only if `n` is not equal to `m`.

### 13.6.5.3 ITERATE Syntax

```
ITERATE label
```

`ITERATE` can appear only within `LOOP`, `REPEAT`, and `WHILE` statements. `ITERATE` means “start the loop again.”

For an example, see [Section 13.6.5.5, “LOOP Syntax”](#).

### 13.6.5.4 LEAVE Syntax

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, `LEAVE` exits the program.

`LEAVE` can be used within `BEGIN ... END` or loop constructs (`LOOP`, `REPEAT`, `WHILE`).

For an example, see [Section 13.6.5.5, “LOOP Syntax”](#).

### 13.6.5.5 LOOP Syntax

```

[begin_label:] LOOP
  statement_list
END LOOP [end_label]

```

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a `LEAVE` statement. Within a stored function, `RETURN` can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A `LOOP` statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```

CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN
      ITERATE label1;
    END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END;

```

### 13.6.5.6 REPEAT Syntax

```

[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]

```

The statement list within a `REPEAT` statement is repeated until the `search_condition` expression is true. Thus, a `REPEAT` always enters the loop at least once. `statement_list` consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter.

A `REPEAT` statement can be labeled. For the rules regarding label use, see [Section 13.6.2, "Statement Label Syntax"](#).

Example:

```

mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT
->     SET @x = @x + 1;
->     UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x   |
+-----+
| 1001 |
+-----+
1 row in set (0.00 sec)

```

### 13.6.5.7 RETURN Syntax

```

RETURN expr

```

The `RETURN` statement terminates execution of a stored function and returns the value `expr` to the function caller. There must be at least one `RETURN` statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The `LEAVE` statement can be used to exit a stored program of those types.

### 13.6.5.8 WHILE Syntax

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

The statement list within a **WHILE** statement is repeated as long as the *search\_condition* expression is true. *statement\_list* consists of one or more SQL statements, each terminated by a semicolon (;) statement delimiter.

A **WHILE** statement can be labeled. For the rules regarding label use, see [Section 13.6.2, "Statement Label Syntax"](#).

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
    DECLARE v1 INT DEFAULT 5;

    WHILE v1 > 0 DO
        ...
        SET v1 = v1 - 1;
    END WHILE;
END;
```

## 13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
    DECLARE done INT DEFAULT FALSE;
    DECLARE a CHAR(16);
    DECLARE b, c INT;
    DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
    DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
    DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

    OPEN cur1;
    OPEN cur2;

    read_loop: LOOP
        FETCH cur1 INTO a, b;
        FETCH cur2 INTO c;
        IF done THEN
            LEAVE read_loop;
        END IF;
        IF b < c THEN
            INSERT INTO test.t3 VALUES (a,b);
        ELSE
            INSERT INTO test.t3 VALUES (a,c);
        END IF;
    END LOOP;

    CLOSE cur1;
```

```
CLOSE cur2;  
END;
```

### 13.6.6.1 Cursor CLOSE Syntax

```
CLOSE cursor_name
```

This statement closes a previously opened cursor. For an example, see [Section 13.6.6, “Cursors”](#).

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the `BEGIN . . . END` block in which it was declared.

### 13.6.6.2 Cursor DECLARE Syntax

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a `SELECT` statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a `FETCH` statement. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

The `SELECT` statement cannot have an `INTO` clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see [Section 13.6.6, “Cursors”](#).

For information available through `SHOW` statements, it is possible in many cases to obtain equivalent information by using a cursor with an `INFORMATION_SCHEMA` table.

### 13.6.6.3 Cursor FETCH Syntax

```
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] . . .
```

This statement fetches the next row for the `SELECT` statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value `'02000'`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see [Section 13.6.6, “Cursors”](#).

### 13.6.6.4 Cursor OPEN Syntax

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see [Section 13.6.6, “Cursors”](#).

## 13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as

warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#). For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#).

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

### 13.6.7.1 DECLARE ... CONDITION Syntax

```
DECLARE condition_name CONDITION FOR condition_value
```

```
condition_value:
    mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
```

The `DECLARE ... CONDITION` statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent `DECLARE ... HANDLER` statement (see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#)).

Condition declarations must appear before cursor or handler declarations.

The *condition\_value* for `DECLARE ... CONDITION` can be a MySQL error code (a number) or an SQLSTATE value (a 5-character string literal). You should not use MySQL error code 0 or SQLSTATE values that begin with '00', because those indicate success rather than an error condition. For a list of MySQL error codes and SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know the meaning of MySQL error code 1051:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
  -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
  -- body of handler
END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
  -- body of handler
END;
```

Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

### 13.6.7.2 DECLARE ... HANDLER Syntax

```
DECLARE handler_action HANDLER
  FOR condition_value [, condition_value] ...
  statement

handler_action:
  CONTINUE
  | EXIT
  | UNDO

condition_value:
  mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
  | SQLEXCEPTION
```

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified *statement* executes. *statement* can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#)).

Handler declarations must appear after variable or condition declarations.

The *handler\_action* value indicates what action the handler takes after execution of the handler statement:

- `CONTINUE`: Execution of the current program continues.
- `EXIT`: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- `UNDO`: Not supported.

The *condition\_value* for `DECLARE ... HANDLER` indicates the specific condition or class of conditions that activates the handler:

- A MySQL error code (a number) or an SQLSTATE value (a 5-character string literal). You should not use MySQL error code 0 or SQLSTATE values that begin with `'00'`, because those indicate success rather than an error condition. For a list of MySQL error codes and SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).
- A condition name previously specified with `DECLARE ... CONDITION`. A condition name can be associated with a MySQL error code or SQLSTATE value. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#).
- `SQLWARNING` is shorthand for the class of SQLSTATE values that begin with `'01'`.
- `NOT FOUND` is shorthand for the class of SQLSTATE values that begin with `'02'`. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value `'02000'`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see [Section 13.6.6, “Cursors”](#). This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
- `SQLEXCEPTION` is shorthand for the class of SQLSTATE values that do not begin with `'00'`, `'01'`, or `'02'`.

For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For `SQLEXCEPTION` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For `SQLWARNING` conditions, the program continues executing, as if there were a `CONTINUE` handler.
- For `NOT FOUND` conditions, if the condition was raised normally, the action is `CONTINUE`. If it was raised by `SIGNAL` or `RESIGNAL`, the action is `EXIT`.

The following example uses a handler for `SQLSTATE '23000'`, which occurs for a duplicate-key error:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
->   SET @x = 1;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 2;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x   |
+-----+
| 3    |
+-----+
1 row in set (0.00 sec)
```

Notice that `@x` is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the `DECLARE . . . HANDLER` statement had not been present, MySQL would have taken the default action (`EXIT`) after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

To ignore a condition, declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use `ITERATE` or `LEAVE` to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the `REPEAT` block has a label of `retry`:

```
CREATE PROCEDURE p ()
```

```

BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      ITERATE retry;    # illegal
    END;
    IF i < 0 THEN
      LEAVE retry;      # legal
    END IF;
    SET i = i - 1;
  END;
  UNTIL FALSE END REPEAT;
END;

```

The `retry` label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an `EXIT` handler. If no block cleanup is required, the `BEGIN ... END` handler body can be empty:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

Otherwise, put the cleanup statements in the handler body:

```

DECLARE EXIT HANDLER FOR SQLWARNING
BEGIN
  block cleanup statements
END;

```

- To continue execution, set a status variable in a `CONTINUE` handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

```

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      SET done = TRUE;
    END;
    IF done OR i < 0 THEN
      LEAVE retry;
    END IF;
    SET i = i - 1;
  END;
  UNTIL FALSE END REPEAT;
END;

```

### 13.6.7.3 GET DIAGNOSTICS Syntax

```

GET [CURRENT | STACKED] DIAGNOSTICS
{
  statement_information_item
  [, statement_information_item] ...

```

```

| CONDITION condition_number
| condition_information_item
| [, condition_information_item] ...
}

statement_information_item:
    target = statement_information_item_name

condition_information_item:
    target = condition_information_item_name

statement_information_item_name:
    NUMBER
| ROW_COUNT

condition_information_item_name:
    CLASS_ORIGIN
| SUBCLASS_ORIGIN
| RETURNED_SQLSTATE
| MESSAGE_TEXT
| MYSQL_ERRNO
| CONSTRAINT_CATALOG
| CONSTRAINT_SCHEMA
| CONSTRAINT_NAME
| CATALOG_NAME
| SCHEMA_NAME
| TABLE_NAME
| COLUMN_NAME
| CURSOR_NAME

condition_number, target:
    (see following discussion)

```

SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`.

The keyword `CURRENT` means to retrieve information from the current diagnostics area. The keyword `STACKED` means to retrieve information from the second diagnostics area, which is available only if the current context is a condition handler. If neither keyword is given, the default is to use the current diagnostics area.

The `GET DIAGNOSTICS` statement is typically used in a handler within a stored program. It is a MySQL extension that `GET [CURRENT] DIAGNOSTICS` is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```

mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
mysql> GET DIAGNOSTICS CONDITION 1
-> @p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
mysql> SELECT @p1, @p2;
+-----+-----+
| @p1   | @p2                                     |
+-----+-----+
| 42S02 | Unknown table 'test.no_such_table'    |
+-----+-----+

```

This extension applies only to the current diagnostics area. It does not apply to the second diagnostics area because `GET STACKED DIAGNOSTICS` is permitted only if the current context is a condition handler. If that is not the case, a `GET STACKED DIAGNOSTICS` when handler not active error occurs.

For a description of the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#). Briefly, it contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

`GET DIAGNOSTICS` can obtain either statement or condition information, but not both in the same statement:

- To obtain statement information, retrieve the desired statement items into target variables. This instance of `GET DIAGNOSTICS` assigns the number of available conditions and the rows-affected count to the user variables `@p1` and `@p2`:

```
GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of `GET DIAGNOSTICS` assigns the SQLSTATE value and error message to the user variables `@p3` and `@p4`:

```
GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
```

The retrieval list specifies one or more `target = item_name` assignments, separated by commas. Each assignment names a target variable and either a `statement_information_item_name` or `condition_information_item_name` designator, depending on whether the statement retrieves statement or condition information.

Valid `target` designators for storing item information can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, or user-defined variables.

Valid `condition_number` designators can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by `GET DIAGNOSTICS`. For example:

```
mysql> GET DIAGNOSTICS CONDITION 1
  -> @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;
```

```
mysql> SELECT @p5, @p6;
+-----+-----+
| @p5   | @p6   |
+-----+-----+
|       |       |
+-----+-----+
```

In standard SQL, if there are multiple conditions, the first condition relates to the `SQLSTATE` value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see [Diagnostics Area Information Items](#).

Here is an example that uses `GET DIAGNOSTICS` and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses `GET DIAGNOSTICS` to get the rows-affected count. This shows that you can use `GET DIAGNOSTICS` multiple times to retrieve information about a statement as long as the current diagnostics area has not been cleared.

```
CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE rows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    GET DIAGNOSTICS CONDITION 1
      code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
  END;

  -- Perform the insert
  INSERT INTO t1 (int_col) VALUES(value);
  -- Check whether the insert was successful
  IF code = '00000' THEN
    GET DIAGNOSTICS rows = ROW_COUNT;
    SET result = CONCAT('insert succeeded, row count = ',rows);
  ELSE
    SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
  END IF;
  -- Say what happened
  SELECT result;
END;
```

Suppose that `t1.int_col` is an integer column that is declared as `NOT NULL`. The procedure produces these results when invoked to insert non-`NULL` and `NULL` values, respectively:

```
mysql> CALL do_insert(1);
+-----+-----+
| result                                     |
+-----+-----+
| insert succeeded, row count = 1 |
+-----+-----+

mysql> CALL do_insert(NULL);
```

```

+-----+
| result |
+-----+
| insert failed, error = 23000, message = Column 'int_col' cannot be null |
+-----+

```

When a condition handler activates, a push to the diagnostics area stack occurs:

- The first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it.
- `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current and stacked diagnostics areas.
- Initially, both diagnostics areas return the same result, so it is possible to get information from the current diagnostics area about the condition that activated the handler, *as long as you execute no statements within the handler that change its current diagnostics area*.
- However, statements executing within the handler can modify the current diagnostics area, clearing and setting its contents according to the normal rules (see [How the Diagnostics Area is Populated](#)).

A more reliable way to obtain information about the handler-activating condition is to use the stacked diagnostics area, which cannot be modified by statements executing within the handler except `RESIGNAL`. For information about when the current diagnostics area is set and cleared, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

The next example shows how `GET STACKED DIAGNOSTICS` can be used within a handler to obtain information about the handled exception, even after the current diagnostics area has been modified by handler statements.

Within a stored procedure `p()`, we attempt to insert two values into a table that contains a `TEXT NOT NULL` column. The first value is a non-`NULL` string and the second is `NULL`. The column prohibits `NULL` values, so the first insert succeeds but the second causes an exception. The procedure includes an exception handler that maps attempts to insert `NULL` into inserts of the empty string:

```

DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (c1 TEXT NOT NULL);
DROP PROCEDURE IF EXISTS p;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    -- Declare variables to hold diagnostics area information
    DECLARE errcount INT;
    DECLARE errno INT;
    DECLARE msg TEXT;
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        -- Here the current DA is nonempty because no prior statements
        -- executing within the handler have cleared it
        GET CURRENT DIAGNOSTICS CONDITION 1
            errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'current DA before mapped insert' AS op, errno, msg;
        GET STACKED DIAGNOSTICS CONDITION 1
            errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
        SELECT 'stacked DA before mapped insert' AS op, errno, msg;

        -- Map attempted NULL insert to empty string insert
        INSERT INTO t1 (c1) VALUES('');

        -- Here the current DA should be empty (if the INSERT succeeded),
        -- so check whether there are conditions before attempting to
        -- obtain condition information
        GET CURRENT DIAGNOSTICS errcount = NUMBER;
        IF errcount = 0
        THEN
            SELECT 'mapped insert succeeded, current DA is empty' AS op;

```

```

ELSE
  GET CURRENT DIAGNOSTICS CONDITION 1
  errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
  SELECT 'current DA after mapped insert' AS op, errno, msg;
END IF ;
GET STACKED DIAGNOSTICS CONDITION 1
  errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
  SELECT 'stacked DA after mapped insert' AS op, errno, msg;
END;
INSERT INTO t1 (c1) VALUES('string 1');
INSERT INTO t1 (c1) VALUES(NULL);
END;
//
delimiter ;
CALL p();
SELECT * FROM t1;

```

When the handler activates, a copy of the current diagnostics area is pushed to the diagnostics area stack. The handler first displays the contents of the current and stacked diagnostics areas, which are both the same initially:

```

+-----+-----+-----+
| op                | errno | msg                |
+-----+-----+-----+
| current DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

+-----+-----+-----+
| op                | errno | msg                |
+-----+-----+-----+
| stacked DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

```

Statements executing after the `GET DIAGNOSTICS` statements may reset the current diagnostics area. statements may reset the current diagnostics area. For example, the handler maps the `NULL` insert to an empty-string insert and displays the result. The new insert succeeds and clears the current diagnostics area, but the stacked diagnostics area remains unchanged and still contains information about the condition that activated the handler:

```

+-----+-----+-----+
| op                |
+-----+-----+-----+
| mapped insert succeeded, current DA is empty |
+-----+-----+-----+

+-----+-----+-----+
| op                | errno | msg                |
+-----+-----+-----+
| stacked DA after mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

```

When the condition handler ends, its current diagnostics area is popped from the stack and the stacked diagnostics area becomes the current diagnostics area in the stored procedure.

After the procedure returns, the table contains two rows. The empty row results from the attempt to insert `NULL` that was mapped to an empty-string insert:

```

+-----+
| c1    |
+-----+
| string 1 |
|      |
+-----+

```

In the preceding example, the first two `GET DIAGNOSTICS` statements within the condition handler that retrieve information from the current and stacked diagnostics areas return the same values. This will

not be the case if statements that reset the current diagnostics area execute earlier within the handler. Suppose that `p()` is rewritten to place the `DECLARE` statements within the handler definition rather than preceding it:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Declare variables to hold diagnostics area information
    DECLARE errcount INT;
    DECLARE errno INT;
    DECLARE msg TEXT;
    GET CURRENT DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;
    ...
  
```

In this case, the result is version dependent:

- Before MySQL 5.7.2, `DECLARE` does not change the current diagnostics area, so the first two `GET DIAGNOSTICS` statements return the same result, just as in the original version of `p()`.

In MySQL 5.7.2, work was done to ensure that all nondiagnostic statements populate the diagnostics area, per the SQL standard. `DECLARE` is one of them, so in 5.7.2 and up, `DECLARE` statements executing at the beginning of the handler clear the current diagnostics area and the `GET DIAGNOSTICS` statements produce different results:

```
+-----+-----+-----+
| op                | errno | msg |
+-----+-----+-----+
| current DA before mapped insert | NULL | NULL |
+-----+-----+-----+

+-----+-----+-----+
| op                | errno | msg |
+-----+-----+-----+
| stacked DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+
```

To avoid this issue within a condition handler when seeking to obtain information about the condition that activated the handler, be sure to access the stacked diagnostics area, not the current diagnostics area.

### 13.6.7.4 RESIGNAL Syntax

```
RESIGNAL [condition_value]
  [SET signal_information_item
  [, signal_information_item] ...]

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | condition_name

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name:
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
```

```

| CONSTRAINT_NAME
| CATALOG_NAME
| SCHEMA_NAME
| TABLE_NAME
| COLUMN_NAME
| CURSOR_NAME

```

*condition\_name*, *simple\_value\_specification*:  
(see following discussion)

**RESIGNAL** passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event.

**RESIGNAL** may change some or all information before passing it on. **RESIGNAL** is related to **SIGNAL**, but instead of originating a condition as **SIGNAL** does, **RESIGNAL** relays existing condition information, possibly after modifying it.

**RESIGNAL** makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. **RESIGNAL** also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No special privileges are required to execute the **RESIGNAL** statement.

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs.

To retrieve information from the diagnostics area, use the **GET DIAGNOSTICS** statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

For *condition\_value* and *signal\_information\_item*, the definitions and rules are the same for **RESIGNAL** as for **SIGNAL**. For example, the *condition\_value* can be an **SQLSTATE** value, and the value can indicate errors, warnings, or “not found.” For additional information, see [Section 13.6.7.5, “SIGNAL Syntax”](#).

The **RESIGNAL** statement takes *condition\_value* and **SET** clauses, both of which are optional. This leads to several possible uses:

- **RESIGNAL** alone:

```
RESIGNAL;
```

- **RESIGNAL** with new signal information:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

- **RESIGNAL** with a condition value and possibly new signal information:

```
RESIGNAL condition_value
  [SET signal_information_item [, signal_information_item] ...];
```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.
- A condition area contains condition information items, such as the **SQLSTATE** value, **MYSQL\_ERRNO**, or **MESSAGE\_TEXT**.

There is a stack of diagnostics areas. When a handler takes control, it pushes a diagnostics area to the top of the stack, so there are two diagnostics areas during handler execution:

- The first (current) diagnostics area, which starts as a copy of the last diagnostics area, but will be overwritten by the first statement in the handler that changes the current diagnostics area.
- The last (stacked) diagnostics area, which has the condition areas that were set up before the handler took control.

The maximum number of condition areas in a diagnostics area is determined by the value of the `max_error_count` system variable. See [Diagnostics Area-Related System Variables](#).

## RESIGNAL Alone

A simple `RESIGNAL` alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for `RESIGNAL` alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Suppose that the `DROP TABLE xx` statement fails. The diagnostics area stack looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

Then execution enters the `EXIT` handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. `BEGIN` is an exception, it does not clear, it does nothing. `SET` is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, if `@a = 0`, `RESIGNAL` pops the diagnostics area stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

And that is what the caller sees.

If `@a` is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been “handled”), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
```

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

## RESIGNAL with New Signal Information

`RESIGNAL` with a `SET` clause provides new signal information, so the statement means “pass on the error with changes”:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

As with `RESIGNAL` alone, the idea is to pop the diagnostics area stack so that the original information will go out. Unlike `RESIGNAL` alone, anything specified in the `SET` clause changes.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Remember from the previous discussion that `RESIGNAL` alone results in a diagnostics area stack like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

The `RESIGNAL SET MYSQL_ERRNO = 5` statement results in this stack instead, which is what the caller sees:

```
DA 1. ERROR 5 (42S02): Unknown table 'xx'
```

In other words, it changes the error number, and nothing else.

The `RESIGNAL` statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

## RESIGNAL with a Condition Value and Optional New Signal Information

`RESIGNAL` with a condition value means “push a condition into the current diagnostics area.” If the `SET` clause is present, it also changes the error information.

```
RESIGNAL condition_value
  [SET signal_information_item [, signal_information_item] ...];
```

This form of `RESIGNAL` restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack, which is the same as what a simple `RESIGNAL` alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;
```

This is similar to the previous example, and the effects are the same, except that if `RESIGNAL` happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The `RESIGNAL` statement includes a condition value (`SQLSTATE '45000'`), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

```
DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
      (condition 1) ERROR 5 (45000) Unknown table 'xx'
```

The result of `CALL p()` and `SHOW ERRORS` for this example is:

```
mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message                               |
+-----+-----+-----+
| Error | 1051 | Unknown table 'xx'                   |
| Error | 5    | Unknown table 'xx'                   |
+-----+-----+-----+
```

## RESIGNAL Requires Condition Handler Context

All forms of `RESIGNAL` require that the current context be a condition handler. Otherwise, `RESIGNAL` is illegal and a `RESIGNAL when handler not active` error occurs. For example:

```
mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active
```

Here is a more difficult example:

```
delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
  RESIGNAL;
```

```

RETURN 5;
END//
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
  SIGNAL SQLSTATE '55555';
END//
delimiter ;
CALL p();

```

`RESIGNAL` occurs within the stored function `f()`. Although `f()` itself is invoked within the context of the `EXIT` handler, execution within `f()` has its own context, which is not handler context. Thus, `RESIGNAL` within `f()` results in a “handler not active” error.

### 13.6.7.5 SIGNAL Syntax

```

SIGNAL condition_value
  [SET signal_information_item
  [, signal_information_item] ...]

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | condition_name

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name:
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME

condition_name, simple_value_specification:
  (see following discussion)

```

`SIGNAL` is the way to “return” an error. `SIGNAL` provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error’s characteristics (error number, `SQLSTATE` value, message). Without `SIGNAL`, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No special privileges are required to execute the `SIGNAL` statement.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

The *condition\_value* in a `SIGNAL` statement indicates the error value to be returned. It can be an `SQLSTATE` value (a 5-character string literal) or a *condition\_name* that refers to a named condition previously defined with `DECLARE ... CONDITION` (see [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#)).

An `SQLSTATE` value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in [Signal Condition Information Items](#). Some signal values cause statement termination; see [Effect of Signals on Handlers, Cursors, and Statements](#).

The `SQLSTATE` value for a `SIGNAL` statement should not start with `'00'` because such values indicate success and are not valid for signaling an error. This is true whether the `SQLSTATE` value is specified

directly in the `SIGNAL` statement or in a named condition referred to in the statement. If the value is invalid, a `Bad SQLSTATE` error occurs.

To signal a generic `SQLSTATE` value, use `'45000'`, which means “unhandled user-defined exception.”

The `SIGNAL` statement optionally includes a `SET` clause that contains multiple signal items, in a comma-separated list of `condition_information_item_name = simple_value_specification` assignments.

Each `condition_information_item_name` may be specified only once in the `SET` clause. Otherwise, a `Duplicate condition information item` error occurs.

Valid `simple_value_specification` designators can be specified using stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer.

For information about permissible `condition_information_item_name` values, see [Signal Condition Information Items](#).

The following procedure signals an error or warning depending on the value of `pval`, its input parameter:

```
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
    SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
    SET MESSAGE_TEXT = 'A warning occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
  END IF;
END;
```

If `pval` is 0, `p()` signals a warning because `SQLSTATE` values that begin with `'01'` are signals in the warning class. The warning does not terminate the procedure, and can be seen with `SHOW WARNINGS` after the procedure returns.

If `pval` is 1, `p()` signals an error and sets the `MESSAGE_TEXT` condition information item. The error terminates the procedure, and the text is returned with the error information.

If `pval` is 2, the same error is signaled, although the `SQLSTATE` value is specified using a named condition in this case.

If `pval` is anything else, `p()` first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and `p()` then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

`SIGNAL` is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the `mysql` client program, you can enter any of these statements at the prompt:

```
mysql> SIGNAL SQLSTATE '77777';
```

```
mysql> CREATE TRIGGER t_bi BEFORE INSERT ON t
-> FOR EACH ROW SIGNAL SQLSTATE '77777';
mysql> CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
-> DO SIGNAL SQLSTATE '77777';
```

`SIGNAL` executes according to the following rules:

If the `SIGNAL` statement indicates a particular `SQLSTATE` value, that value is used to signal the condition specified. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```

If the `SIGNAL` statement uses a named condition, the condition must be declared in some scope that applies to the `SIGNAL` statement, and must be defined using an `SQLSTATE` value, not a MySQL error number. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
  IF divisor = 0 THEN
    SIGNAL divide_by_zero;
  END IF;
END;
```

If the named condition does not exist in the scope of the `SIGNAL` statement, an `Undefined CONDITION` error occurs.

If `SIGNAL` refers to a named condition that is defined with a MySQL error number rather than an `SQLSTATE` value, a `SIGNAL/RESIGNAL can only use a CONDITION defined with SQLSTATE` error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
  END IF;
  SIGNAL my_error;
END;
```

If `divisor` is 0, the first `SIGNAL` statement executes. The innermost `my_error` condition declaration applies, raising `SQLSTATE '22012'`.

If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising `SQLSTATE '45000'`.

For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

Signals can be raised within exception handlers:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
    SET MESSAGE_TEXT = 'An error occurred';
  END;
  DROP TABLE no_such_table;
END;
```

`CALL p()` reaches the `DROP TABLE` statement. There is no table named `no_such_table`, so the error handler is activated. The error handler destroys the original error (“no such table”) and makes a new error with `SQLSTATE '99999'` and message `An error occurred`.

### Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a `SIGNAL` (or `RESIGNAL`) statement. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. For more information about these items see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

Item Name	Definition
CLASS_ORIGIN	VARCHAR(64)
SUBCLASS_ORIGIN	VARCHAR(64)
CONSTRAINT_CATALOG	VARCHAR(64)
CONSTRAINT_SCHEMA	VARCHAR(64)
CONSTRAINT_NAME	VARCHAR(64)
CATALOG_NAME	VARCHAR(64)
SCHEMA_NAME	VARCHAR(64)
TABLE_NAME	VARCHAR(64)
COLUMN_NAME	VARCHAR(64)
CURSOR_NAME	VARCHAR(64)
MESSAGE_TEXT	VARCHAR(128)
MYSQL_ERRNO	SMALLINT UNSIGNED

The character set for character items is UTF-8.

It is illegal to assign `NULL` to a condition information item in a `SIGNAL` statement.

A `SIGNAL` statement always specifies an `SQLSTATE` value, either directly, or indirectly by referring to a named condition defined with an `SQLSTATE` value. The first two characters of an `SQLSTATE` value are its class, and the class determines the default value for the condition information items:

- Class = '00' (success)

Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- Class = '01' (warning)

```
MESSAGE_TEXT = 'Unhandled user-defined warning condition';
MYSQL_ERRNO = ER_SIGNAL_WARN
```

- Class = '02' (not found)

```
MESSAGE_TEXT = 'Unhandled user-defined not found condition';
MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND
```

- Class > '02' (exception)

```
MESSAGE_TEXT = 'Unhandled user-defined exception condition';
MYSQL_ERRNO = ER_SIGNAL_EXCEPTION
```

For legal classes, the other condition information items are set as follows:

```
CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';
```

The error values that are accessible after `SIGNAL` executes are the `SQLSTATE` value raised by the `SIGNAL` statement and the `MESSAGE_TEXT` and `MYSQL_ERRNO` items. These values are available from the C API:

- `SQLSTATE` value: Call `mysql_sqlstate()`
- `MYSQL_ERRNO` value: Call `mysql_errno()`
- `MESSAGE_TEXT` value: Call `mysql_error()`

From SQL, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the `MYSQL_ERRNO` and `MESSAGE_TEXT` values in the `Code` and `Message` columns.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

## Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the `sql_mode` system variable; in particular, strict SQL mode does not matter. MySQL also ignores `IGNORE`: The intent of `SIGNAL` is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled `SQLSTATE` value has been defined with `DECLARE ... HANDLER`.

- Class = '00' (success)

Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- Class = '01' (warning)

The value of the `warning_count` system variable goes up. `SHOW WARNINGS` shows the signal. `SQLWARNING` handlers catch the signal. If the signal is unhandled in a function, statements do not end.

- Class = '02' (not found)

`NOT FOUND` handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a function, statements end.

- Class > '02' (exception)

`SQLEXCEPTION` handlers catch the signal. If the signal is unhandled in a function, statements end.

- Class = '40'

Treated as an ordinary exception.

Example:

```
mysql> delimiter //
mysql> CREATE FUNCTION f () RETURNS INT
-> BEGIN
->   SIGNAL SQLSTATE '01234'; -- signal a warning
->   RETURN 5;
-> END//
mysql> delimiter ;
mysql> CREATE TABLE t (s1 INT);
mysql> INSERT INTO t VALUES (f());
```

The result is that a row containing 5 is inserted into table `t`. The warning that is signaled can be viewed with `SHOW WARNINGS`.

### 13.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a `BEGIN ... END` block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers `H1` and `H2` are in scope for conditions raised by statements `stmt1` and `stmt2`. But neither `H1` nor `H2` are in scope for conditions raised in the body of `H1` or `H2`.

```
BEGIN -- outer block
  DECLARE EXIT HANDLER FOR ...; -- handler H1
  DECLARE EXIT HANDLER FOR ...; -- handler H2
  stmt1;
  stmt2;
END;
```

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler `H1` is in scope for `stmt1` in the inner block, but not for `stmt2` in the outer block:

```
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE EXIT HANDLER FOR ...; -- handler H1
    stmt1;
  END;
  stmt2;
END;
```

- A handler can be specific or general. A specific handler is for a MySQL error code, `SQLSTATE` value, or condition name. A general handler is for a condition in the `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` class. Condition specificity is related to condition precedence, as described later.

Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general `SQLWARNING` handler in an inner block. Or there might be handlers for a specific MySQL error code and the general `SQLWARNING` class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current `BEGIN ... END` block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an `SQLSTATE` value handler.

- An `SQLSTATE` value handler takes precedence over general `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` handlers.
- An `SQLEXCEPTION` handler takes precedence over an `SQLWARNING` handler.
- The precedence of `NOT FOUND` depends on how the condition is raised:
  - Normally, a condition in the `NOT FOUND` class can be handled by an `SQLWARNING` or `NOT FOUND` handler, with the `SQLWARNING` handler taking precedence if both are present. Normal occurrence of `NOT FOUND` takes place when a cursor used to fetch a set of rows reaches the end of the data set, or for instances of `SELECT ... INTO var_list` such that the `WHERE` clause finds no rows.
  - If a `NOT FOUND` condition is raised by a `SIGNAL` (or `RESIGNAL`) statement, the condition can be handled by a `NOT FOUND` handler but not an `SQLWARNING` handler.
- It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is indeterminate, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

- For `SQLEXCEPTION` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For `SQLWARNING` conditions, the program continues executing, as if there were a `CONTINUE` handler.
- For `NOT FOUND` conditions, if the condition was raised normally, the action is `CONTINUE`. If it was raised by `SIGNAL` or `RESIGNAL`, the action is `EXIT`.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific `SQLSTATE` value (`'42S02'`) that occurs for attempts to drop a nonexistent table, and one for the general `SQLEXCEPTION` class:

```
CREATE PROCEDURE p1()
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;

  DROP TABLE test.t;
END;
```

Both handlers are declared in the same block and have the same scope. However, `SQLSTATE` handlers take precedence over `SQLEXCEPTION` handlers, so if the table `t` is nonexistent, the `DROP TABLE` statement raises a condition that activates the `SQLSTATE` handler:

```
mysql> CALL p1();
+-----+
| msg          |
+-----+
| SQLSTATE handler was activated |
```

This procedure contains the same two handlers. But this time, the `DROP TABLE` statement and `SQLEXCEPTION` handler are in an inner block relative to the `SQLSTATE` handler:

```
CREATE PROCEDURE p2()
BEGIN -- outer block
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
        SELECT 'SQLSTATE handler was activated' AS msg;
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
            SELECT 'SQLEXCEPTION handler was activated' AS msg;

        DROP TABLE test.t; -- occurs within inner block
    END;
END;
```

In this case, the handler that is more local to where the condition occurs takes precedence. The `SQLEXCEPTION` handler activates, even though it is more general than the `SQLSTATE` handler:

```
mysql> CALL p2();
+-----+
| msg                |
+-----+
| SQLEXCEPTION handler was activated |
+-----+
```

In this procedure, one of the handlers is declared in a block inner to the scope of the `DROP TABLE` statement:

```
CREATE PROCEDURE p3()
BEGIN -- outer block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
        SELECT 'SQLEXCEPTION handler was activated' AS msg;
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
            SELECT 'SQLSTATE handler was activated' AS msg;
    END;

    DROP TABLE test.t; -- occurs within outer block
END;
```

Only the `SQLEXCEPTION` handler applies because the other one is not in scope for the condition raised by the `DROP TABLE`:

```
mysql> CALL p3();
+-----+
| msg                |
+-----+
| SQLEXCEPTION handler was activated |
+-----+
```

In this procedure, both handlers are declared in a block inner to the scope of the `DROP TABLE` statement:

```
CREATE PROCEDURE p4()
BEGIN -- outer block
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
            SELECT 'SQLEXCEPTION handler was activated' AS msg;
        DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
            SELECT 'SQLSTATE handler was activated' AS msg;
    END;

    DROP TABLE test.t;
END;
```

```
DROP TABLE test.t; -- occurs within outer block
END;
```

Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```
mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'
```

### 13.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution. MySQL supports the `STACKED` keyword as of MySQL 5.7. Before that, MySQL does not support `STACKED`; there is a single diagnostics area containing information from the most recent statement that wrote to it.

This section describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL, how statements clear and set the diagnostics area, and how diagnostics areas are pushed to and popped from the stack.

#### Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

#### Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be `NULL`. If a statement or condition item is not set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- `NUMBER`: An integer indicating the number of condition areas that have information.

- **ROW\_COUNT**: An integer indicating the number of rows affected by the statement. **ROW\_COUNT** has the same value as the **ROW\_COUNT( )** function (see [Section 12.14, “Information Functions”](#)).

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the **NUMBER** statement condition item. If **NUMBER** is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except **MYSQL\_ERRNO**, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a **SIGNAL** or **RESIGNAL** statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- **CLASS\_ORIGIN**: A string containing the class of the **RETURNED\_SQLSTATE** value. If the **RETURNED\_SQLSTATE** value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, **SQLSTATE**), **CLASS\_ORIGIN** is 'ISO 9075'. Otherwise, **CLASS\_ORIGIN** is 'MySQL'.
- **SUBCLASS\_ORIGIN**: A string containing the subclass of the **RETURNED\_SQLSTATE** value. If **CLASS\_ORIGIN** is 'ISO 9075' or **RETURNED\_SQLSTATE** ends with '000', **SUBCLASS\_ORIGIN** is 'ISO 9075'. Otherwise, **SUBCLASS\_ORIGIN** is 'MySQL'.
- **RETURNED\_SQLSTATE**: A string that indicates the **SQLSTATE** value for the condition.
- **MESSAGE\_TEXT**: A string that indicates the error message for the condition.
- **MYSQL\_ERRNO**: An integer that indicates the MySQL error code for the condition.
- **CONSTRAINT\_CATALOG**, **CONSTRAINT\_SCHEMA**, **CONSTRAINT\_NAME**: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.
- **CATALOG\_NAME**, **SCHEMA\_NAME**, **TABLE\_NAME**, **COLUMN\_NAME**: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.
- **CURSOR\_NAME**: A string that indicates the cursor name. This is always empty.

For the **RETURNED\_SQLSTATE**, **MESSAGE\_TEXT**, and **MYSQL\_ERRNO** values for particular errors, see [Section B.3, “Server Error Codes and Messages”](#).

If a **SIGNAL** (or **RESIGNAL**) statement populates the diagnostics area, its **SET** clause can assign to any condition information item except **RETURNED\_SQLSTATE** any value that is legal for the item data type. **SIGNAL** also sets the **RETURNED\_SQLSTATE** value, but not directly in its **SET** clause. That value comes from the **SIGNAL** statement **SQLSTATE** argument.

**SIGNAL** also sets statement information items. It sets **NUMBER** to 1. It sets **ROW\_COUNT** to -1 for errors and 0 otherwise.

## How the Diagnostics Area is Populated

Nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the **SIGNAL** and **RESIGNAL** statements. The diagnostics area can be examined with **GET DIAGNOSTICS** to extract specific items, or with **SHOW WARNINGS** or **SHOW ERRORS** to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements. (Before MySQL 5.7.2, the server clears the diagnostics area for nondiagnostic statements that use tables.) Diagnostic statements do not clear the diagnostics area (**SHOW WARNINGS**, **SHOW ERRORS**, **GET DIAGNOSTICS**).

- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by `GET DIAGNOSTICS` and `RESIGNAL` are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using `SHOW WARNINGS` to display information about conditions stored there.

This `DROP TABLE` statement clears the diagnostics area and populates it when the condition occurs:

```
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                               |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

This `SET` statement generates an error, so it clears and populates the diagnostics area:

```
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                               |
+-----+-----+-----+
| Error | 1193 | Unknown system variable 'x' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The previous `SET` statement produced a single condition, so 1 is the only valid condition number for `GET DIAGNOSTICS` at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                               |
+-----+-----+-----+
| Error | 1193 | Unknown system variable 'xx' |
| Error | 1753 | Invalid condition number      |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

Now there are two conditions in the diagnostics area, so the same `GET DIAGNOSTICS` statement succeeds:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @p;
+-----+
| @p   |
+-----+
| Invalid condition number |
+-----+
```

```
1 row in set (0.01 sec)
```

## How the Diagnostics Area Stack Works

When a push to the diagnostics area stack occurs, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Diagnostics areas are pushed to and popped from the stack under the following circumstances:

- Execution of a stored program

A push occurs before the program executes and a pop occurs afterward. If the stored program ends while handlers are executing, there can be more than one diagnostics area to pop; this occurs due to an exception for which there are no appropriate handlers or due to `RETURN` in the handler.

Any warning or error conditions occurring during stored program execution then are added to the current diagnostics area, except that, for triggers, only errors are added. When the stored program ends, the caller sees these conditions in its current diagnostics area.

- Execution of a condition handler within a stored program

When a push occurs as a result of condition handler activation, the stacked diagnostics area is the area that was current within the stored program prior to the push. The new now-current diagnostics area is the handler's current diagnostics area. `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current (handler) and stacked (stored program) diagnostics areas. Initially, they return the same result, but statements executing within the handler modify the current diagnostics area, clearing and setting its contents according to the normal rules (see [How the Diagnostics Area is Populated](#)). The stacked diagnostics area cannot be modified by statements executing within the handler except `RESIGNAL`.

If the handler executes successfully, the current (handler) diagnostics area is popped and the stacked (stored program) diagnostics area again becomes the current diagnostics area. Conditions added to the handler diagnostics area during handler execution are added to the current diagnostics area.

- Execution of `RESIGNAL`

The `RESIGNAL` statement passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored program. `RESIGNAL` may change some or all information before passing it on, modifying the diagnostics stack as described in [Section 13.6.7.4, "RESIGNAL Syntax"](#).

## Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- `max_error_count` controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by `RESIGNAL` are always added, with older conditions being discarded as necessary to make room.)
- `warning_count` indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, `NUMBER` and `warning_count` are the same. However, as the number of conditions generated exceeds `max_error_count`, the value of `warning_count` continues to rise whereas `NUMBER` remains capped at `max_error_count` because no additional conditions are stored in the diagnostics area.
- `error_count` indicates the number of errors that occurred. This value includes "not found" and exception conditions, but excludes warnings and notes. Like `warning_count`, its value can exceed `max_error_count`.
- If the `sql_notes` system variable is set to 0, notes are not stored and do not increment `warning_count`.

Example: If `max_error_count` is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, `NUMBER` is 10, `warning_count` is 20, and `error_count` is 12.

Changes to the value of `max_error_count` have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and `max_error_count` is set to 5, that has no immediate effect on the size or content of the diagnostics area.

## 13.7 Database Administration Statements

### 13.7.1 Account Management Statements

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in [Chapter 5, MySQL Server Administration](#), which you should consult for additional details.

#### Important

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. To ensure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you update to a new version of MySQL. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

When the `read_only` system variable is enabled, account-management statements require the `SUPER` privilege, in addition to any other required privileges. This is because they modify tables in the `mysql` database.

#### 13.7.1.1 ALTER USER Syntax

`ALTER USER` syntax for MySQL 5.7.6 and up:

```
ALTER USER [IF EXISTS]
    user_specification [, user_specification] ...
    [REQUIRE {NONE | ssl_option [[AND] ssl_option] ...}]
    [WITH resource_option [resource_option] ...]
    [password_option | lock_option] ...

ALTER USER [IF EXISTS]
    USER() IDENTIFIED BY 'auth_string'

user_specification:
    user [ auth_option ]

auth_option: {
    IDENTIFIED BY 'auth_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin BY 'auth_string'
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}

ssl_option: {
    SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'
}

resource_option: {
    MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
}
```

```

| MAX_USER_CONNECTIONS count
}

password_option: {
    PASSWORD EXPIRE
| PASSWORD EXPIRE DEFAULT
| PASSWORD EXPIRE NEVER
| PASSWORD EXPIRE INTERVAL N DAY
}

lock_option: {
    ACCOUNT LOCK
| ACCOUNT UNLOCK
}

```

**ALTER USER** syntax before MySQL 5.7.6:

```

ALTER USER user_specification [, user_specification] ...

user_specification:
    user password_option

password_option: {
    PASSWORD EXPIRE
| PASSWORD EXPIRE DEFAULT
| PASSWORD EXPIRE NEVER
| PASSWORD EXPIRE INTERVAL N DAY
}

```

The **ALTER USER** statement modifies MySQL accounts. It provides control over account password expiration. As of MySQL 5.7.6, it also provides control over authentication, SSL, and resource-limit properties, and account locking and unlocking.

To use **ALTER USER**, you must have the global **CREATE USER** privilege or the **UPDATE** privilege for the `mysql` database. When the `read_only` system variable is enabled, **ALTER USER** additionally requires the **SUPER** privilege.

An error occurs if you try to modify an account that does not exist.

As of MySQL 5.7.8, the **IF EXISTS** clause can be used, which causes the statement to produce a warning for each named account that does not exist, rather than an error.

**ALTER USER** modifies the `mysql.user` table row for each affected account according to the options specified in the statement. Unspecified properties retain their current values.

Example 1: Change an account's password and expire it. As a result, the user must connect with the named password and choose a new one at the next connection:

```

ALTER USER 'jeffrey'@'localhost'
    IDENTIFIED BY 'new_password' PASSWORD EXPIRE;

```

Example 2: Modify an account to use the `sha256_password` authentication plugin and the given password. Require that a new password be chosen every 180 days:

```

ALTER USER 'jeffrey'@'localhost'
    IDENTIFIED WITH sha256_password BY 'new_password'
    PASSWORD EXPIRE INTERVAL 180 DAY;

```

Example 3: Lock or unlock an account:

```

ALTER USER 'jeffrey'@'localhost' ACCOUNT LOCK;
ALTER USER 'jeffrey'@'localhost' ACCOUNT UNLOCK;

```

Example 4: Require an account to connect using SSL and establish a limit of 20 connections per hour:

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SSL WITH MAX_CONNECTIONS_PER_HOUR 20;
```

Because the capabilities of this statement were expanded considerably in MySQL 5.7.6, this section first describes current syntax, and then the more limited pre-5.7.6 syntax.

- [ALTER USER as of MySQL 5.7.6](#)
- [ALTER USER Before MySQL 5.7.6](#)

### Important

Under some circumstances, `ALTER USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

## ALTER USER as of MySQL 5.7.6

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). If you specify only the user name part of the account name, a host name part of `'%'` is used. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

For one syntax only, the account may be specified with the `USER()` function:

```
ALTER USER USER() IDENTIFIED BY 'auth_string';
```

This syntax enables changing your own password without naming your account literally.

Each *user\_specification* clause consists of an account name and an optional *auth\_option* value that specifies how the account authenticates. These values enable account authentication plugins and credentials (passwords) to be specified. Each *auth\_option* value applies *only* to the user named immediately preceding it.

Following the user specifications, the statement may include options for SSL, resource-limit, password-expiration, and locking properties. All these options are *global* to the statement and apply to *all* named users.

Example: This statement changes the password for `jeffrey` but leaves that for `jeanne` unchanged. For both accounts, connections are required to use SSL and each account can be used for a maximum of two simultaneous connections:

```
ALTER USER
  'jeffrey'@'localhost' IDENTIFIED BY 'new_password',
  'jeanne'@'localhost'
  REQUIRE SSL WITH MAX_USER_CONNECTIONS 2;
```

In the absence of a particular type of option, the account remains unchanged in that respect. For example, with no locking option, the locking state of the account is not changed.

### Authentication Options

An account name may be followed by an authentication option that specifies the account authentication plugin, credentials, or both:

- *auth\_plugin* names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` table.

- `'auth_string'` or `'hash_string'` specify account credentials, either as cleartext or hashed in the format expected by the authentication plugin, respectively. Credentials are stored in the `authentication_string` column of the `mysql.user` table.

`ALTER USER` permits these `auth_option` syntaxes:

- `IDENTIFIED BY 'auth_string'`

Sets the account authentication plugin to the default plugin, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin`

Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string (the credentials are associated with the old authentication plugin, not the new one), and stores the result in the `mysql.user` account row.

In addition, the password is marked expired. The user must choose a new one when next connecting.

- `IDENTIFIED WITH auth_plugin BY 'auth_string'`

Sets the account authentication plugin to `auth_plugin`, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin AS 'hash_string'`

Sets the account authentication plugin to `auth_plugin`, takes the hashed `'hash_string'` value as is, and stores the result in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise. For descriptions of each plugin, see [Section 6.3.9, “Authentication Plugins Available in MySQL”](#).

Example 1: Specify the password as cleartext; the default plugin is used:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'mypass';
```

Example 2: Specify the authentication plugin, along with a cleartext password value:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'mypass';
```

Example 3: Specify the authentication plugin, along with a hashed password value:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  AS '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

## SSL Options

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see [Section 6.3.12, “Using Secure Connections”](#).

To specify SSL-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `ssl_option` values.

`ALTER USER` permits these `ssl_option` values:

- **NONE**

Indicates that the account has no SSL or X509 requirements. Unencrypted connections are permitted if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files.

As of MySQL 5.7.3, a client need specify only the `--ssl` option to obtain an encrypted connection. The connection attempt fails if SSL is not available. Before MySQL 5.7.3, the client must specify either the `--ssl-ca` option, or all three of the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options.

- **SSL**

Tells the server to permit only SSL-encrypted connections for the account.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE SSL;
```

As of MySQL 5.7.3, a client need specify only the `--ssl` option to obtain an encrypted connection. The connection attempt fails if SSL is not available. Before MySQL 5.7.3, the client must specify the `--ssl-ca` option to authenticate the server certificate, and may additionally specify the `--ssl-key` and `--ssl-cert` options. If neither the `--ssl-ca` option nor `--ssl-capath` option is specified, the client does not authenticate the server certificate.

- **X509**

Requires that the client must have a valid certificate but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE X509;
```

To connect, the client must specify the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options. This is also true for **ISSUER** and **SUBJECT** because those **REQUIRE** options imply the requirements of **X509**.

- **ISSUER 'issuer'**

Places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA `'issuer'`. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

To connect, the client must specify the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options because **ISSUER** implies the requirements of **X509**.

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com';
```

#### Note

If MySQL is linked against a version of OpenSSL older than 0.9.6h, use **Email** rather than `emailAddress` in the `'issuer'` value.

- **SUBJECT 'subject'**

Places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject `subject`. If the client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

To connect, the client must specify the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options because `SUBJECT` implies the requirements of X509.

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the '*subject*' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

#### Note

Regarding `emailAddress`, see the note in the description of `REQUIRE ISSUER`.

- `CIPHER 'cipher'`

Requests a specific cipher method for connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause:

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The order of the options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

### Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.3.4, “Setting Account Resource Limits”](#). To do so, use a `WITH` clause that specifies one or more *resource\_option* values:

`ALTER USER` permits these *resource\_option* values:

- `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`,  
`MAX_CONNECTIONS_PER_HOUR count`

These options restrict the number of queries, updates, and connections to the server permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the `MAX_QUERIES_PER_HOUR` limit.) If *count* is 0 (the default), this means that there is no limitation for the account.

- `MAX_USER_CONNECTIONS count`

Restricts the maximum number of simultaneous connections to the server by the account. A nonzero *count* specifies the limit for the account explicitly. If *count* is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

Example:

```
ALTER USER 'jeffrey'@'localhost'
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

If a given resource limit is specified multiple times, the last instance takes precedence.

### Password-Expiration Options

`ALTER USER` supports several *password\_option* values for password expiration management, to either expire an account password or establish its password expiration *policy*. Policy options do not expire the password; instead, they determine how the server applies automatic expiration to the account (see [Section 6.3.6, “Password Expiration Policy”](#)).

`ALTER USER` permits these *password\_option* values:

- `PASSWORD EXPIRE`

Expires the account password.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

- `PASSWORD EXPIRE DEFAULT`

Sets the account so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

- `PASSWORD EXPIRE NEVER`

Disables password expiration for the account so that its password never expires.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

- `PASSWORD EXPIRE INTERVAL N DAY`

Sets the account password lifetime to *N* days. This statement requires the password to be changed every 180 days:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
```

If multiple password-expiration options are specified, the last one takes precedence.

A client session operates in restricted mode if the account password was expired manually or if the password is considered past its lifetime per the automatic expiration policy. In restricted mode, operations performed within the session result in an error until the user establishes a new account password. See [Section 6.3.6, “Password Expiration Policy”](#).

#### Note

It is possible to “reset” a password by setting it to its current value. As a matter of good policy, it is preferable to choose a different password.

### Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see [Section 6.3.11, “User Account Locking”](#).

If multiple account-locking options are specified, the last one takes precedence.

## ALTER USER Before MySQL 5.7.6

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). If you specify only the user name part of the account name, a host name part of `'%'` is used. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

Each *user\_specification* clause consists of an account name and a *password\_option* value that specifies the action to take for the account, to either expire an account password or establish its password expiration *policy*. Policy options do not expire the password; instead, they determine how the server applies automatic expiration to the account (see [Section 6.3.6, “Password Expiration Policy”](#)).

The *password\_option* values are as described earlier in this section. The `DEFAULT`, `NEVER`, and `INTERVAL` variants of `PASSWORD EXPIRE` are not available before MySQL 5.7.4.

Before MySQL 5.7.3, it was possible to use `ALTER USER` to expire the password for anonymous-user accounts. This is no longer permitted because an anonymous user cannot reset the account password to lift the expiration.

### 13.7.1.2 CREATE USER Syntax

`CREATE USER` syntax for MySQL 5.7.6 and up:

```
CREATE USER [IF NOT EXISTS]
    user_specification [, user_specification] ...
    [REQUIRE {NONE | ssl_option [[AND] ssl_option] ...}]
    [WITH resource_option [resource_option] ...]
    [password_option | lock_option] ...

user_specification:
    user [ auth_option ]

auth_option: {
    IDENTIFIED BY 'auth_string'
  | IDENTIFIED BY PASSWORD 'hash_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin BY 'auth_string'
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}

ssl_option: {
    SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'
}

resource_option: {
    MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
}

password_option: {
    PASSWORD EXPIRE
  | PASSWORD EXPIRE DEFAULT
  | PASSWORD EXPIRE NEVER
  | PASSWORD EXPIRE INTERVAL N DAY
}

lock_option: {
    ACCOUNT LOCK
  | ACCOUNT UNLOCK
}
```

}

**CREATE USER** syntax before MySQL 5.7.6:

```
CREATE USER user_specification [, user_specification] ...

user_specification:
  user [ auth_option ]

auth_option: {
  IDENTIFIED BY 'auth_string'
  | IDENTIFIED BY PASSWORD 'hash_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}
```

The **CREATE USER** statement creates new MySQL accounts. It enables account authentication properties to be established. As of MySQL 5.7.6, it is also possible to establish authentication, SSL, and resource-limit properties, account password expiration, and account locking and unlocking.

To use **CREATE USER**, you must have the global **CREATE USER** privilege or the **INSERT** privilege for the `mysql` database. When the `read_only` system variable is enabled, **CREATE USER** additionally requires the **SUPER** privilege.

An error occurs if you try to create an account that already exists.

As of MySQL 5.7.8, the **IF NOT EXISTS** clause can be used, which causes the statement to produce a warning for each named account that already exists, rather than an error.

For each account, **CREATE USER** creates a new row in the `mysql.user` table. The row reflects the properties specified in the statement. Unspecified properties are set to their default values.

Example 1: Create an account that uses the default authentication plugin and the given password. Mark the password expired so that the user must choose a new one at the first connection to the server:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example 2: Create an account that uses the `sha256_password` authentication plugin and the given password. Require that a new password be chosen every 180 days:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED WITH sha256_password BY 'new_password'
  PASSWORD EXPIRE INTERVAL 180 DAY;
```

Because the capabilities of this statement were expanded considerably in MySQL 5.7.6, this section first describes current syntax, and then the more limited pre-5.7.6 syntax.

- [CREATE USER as of MySQL 5.7.6](#)
- [CREATE USER Before MySQL 5.7.6](#)

### Important

Under some circumstances, **CREATE USER** may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

For additional information about setting passwords and authentication plugins, see [Section 6.3.5, “Assigning Account Passwords”](#), and [Section 6.3.8, “Pluggable Authentication”](#).

## CREATE USER as of MySQL 5.7.6

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

If you specify only the user name part of the account name, a host name part of `'%'` is used.

Each *user\_specification* clause consists of an account name and an optional *auth\_option* value that specifies how the account authenticates. These values enable account authentication plugins and credentials (passwords) to be specified. Each *auth\_option* value applies *only* to the user named immediately preceding it.

Following the user specifications, the statement may include options for SSL, resource-limit, password-expiration, and locking properties. All these options are *global* to the statement and apply to *all* named users.

Example: This statement creates two accounts, each with the default authentication plugin and named password. For both accounts, connections must be made using a valid X509 certificate and up to 60 queries per hour are permitted. Both accounts are locked initially, so effectively they are placeholders and cannot be used until an administrator unlocks them:

```
CREATE USER
  'jeffrey'@'localhost' IDENTIFIED BY 'new_password1',
  'jeanne'@'localhost' IDENTIFIED BY 'new_password2'
  REQUIRE X509 WITH MAX_QUERIES_PER_HOUR 60
  ACCOUNT LOCK;
```

For omitted options, these default values are used:

- Authentication: The authentication plugin defined by the `default_authentication_plugin` system variable, and empty credentials
- SSL: `NONE`
- Resource limits: Unlimited
- Password expiration: `PASSWORD EXPIRE DEFAULT`
- Account locking: `ACCOUNT UNLOCK`

### Authentication Options

An account name may be followed by an authentication option that specifies the account authentication plugin, credentials, or both:

- *auth\_plugin* names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` table.
- `'auth_string'` or `'hash_string'` specify account credentials, either as cleartext or hashed in the format expected by the authentication plugin, respectively. Credentials are stored in the `authentication_string` column of the `mysql.user` table.

`CREATE USER` permits these *auth\_option* syntaxes:

- `IDENTIFIED BY 'auth_string'`

Sets the account authentication plugin to the default plugin, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED BY PASSWORD 'hash_string'`

Sets the account authentication plugin to the default plugin, takes the hashed `'hash_string'` value as is, and stores the result in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

#### Note

This syntax is deprecated and will be removed in a future MySQL release.

- `IDENTIFIED WITH auth_plugin`

Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin BY 'auth_string'`

Sets the account authentication plugin to `auth_plugin`, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin AS 'hash_string'`

Sets the account authentication plugin to `auth_plugin`, takes the `'hash_string'` value as is, and stores the result in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise. For descriptions of each plugin, see [Section 6.3.9, “Authentication Plugins Available in MySQL”](#).

Example 1: Specify the password as cleartext; the default plugin is used:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'mypass';
```

Example 2: Specify the authentication plugin, along with a cleartext password value:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password BY 'mypass';
```

## SSL Options

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see [Section 6.3.12, “Using Secure Connections”](#).

To specify SSL-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `ssl_option` values:

`CREATE USER` permits these `ssl_option` values:

- `NONE`

Indicates that the account has no SSL or X509 requirements. Unencrypted connections are permitted if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files.

As of MySQL 5.7.3, a client need specify only the `--ssl` option to obtain an encrypted connection. The connection attempt fails if SSL is not available. Before MySQL 5.7.3, the client must specify either the `--ssl-ca` option, or all three of the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options.

- **SSL**

Tells the server to permit only SSL-encrypted connections for the account.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE SSL;
```

As of MySQL 5.7.3, a client need specify only the `--ssl` option to obtain an encrypted connection. The connection attempt fails if SSL is not available. Before MySQL 5.7.3, the client must specify the `--ssl-ca` option to authenticate the server certificate, and may additionally specify the `--ssl-key` and `--ssl-cert` options. If neither the `--ssl-ca` option nor `--ssl-capath` option is specified, the client does not authenticate the server certificate.

- **X509**

Requires that the client must have a valid certificate but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```

To connect, the client must specify the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options. This is also true for `ISSUER` and `SUBJECT` because those `REQUIRE` options imply the requirements of X509.

- **ISSUER 'issuer'**

Places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA `'issuer'`. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

To connect, the client must specify the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options because `ISSUER` implies the requirements of X509.

```
CREATE USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com';
```

#### Note

If MySQL is linked against a version of OpenSSL older than 0.9.6h, use `Email` rather than `emailAddress` in the `'issuer'` value.

- **SUBJECT 'subject'**

Places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject `subject`. If the client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

To connect, the client must specify the `--ssl-ca`, `--ssl-key`, and `--ssl-cert` options because `SUBJECT` implies the requirements of X509.

```
CREATE USER 'jeffrey'@'localhost'
```

```

REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
O=MySQL demo client certificate/
CN=client/emailAddress=client@example.com';

```

MySQL does a simple string comparison of the '*subject*' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

### Note

Regarding `emailAddress`, see the note in the description of `REQUIRE ISSUER`.

- `CIPHER 'cipher'`

Requests a specific cipher method for connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used.

```

CREATE USER 'jeffrey'@'localhost' REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';

```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause:

```

CREATE USER 'jeffrey'@'localhost'
REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
O=MySQL demo client certificate/
CN=client/emailAddress=client@example.com'
AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
O=MySQL/CN=CA/emailAddress=ca@example.com'
AND CIPHER 'EDH-RSA-DES-CBC3-SHA';

```

The order of the options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

### Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.3.4, “Setting Account Resource Limits”](#). To do so, use a `WITH` clause that specifies one or more `resource_option` values.

`CREATE USER` permits these `resource_option` values:

- `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`, `MAX_CONNECTIONS_PER_HOUR count`

These options restrict the number of queries, updates, and connections to the server permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the `MAX_QUERIES_PER_HOUR` limit.) If `count` is 0 (the default), this means that there is no limitation for the account.

- `MAX_USER_CONNECTIONS count`

Restricts the maximum number of simultaneous connections to the server by the account. A nonzero `count` specifies the limit for the account explicitly. If `count` is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

Example:

```

CREATE USER 'jeffrey'@'localhost'
WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;

```

If a given resource limit is specified multiple times, the last instance takes precedence.

### Password-Expiration Options

`CREATE USER` supports several *password\_option* values for password expiration management, to either expire an account password or establish its password expiration *policy*. Policy options do not expire the password; instead, they determine how the server applies automatic expiration to the account (see [Section 6.3.6, “Password Expiration Policy”](#)).

`CREATE USER` permits these *password\_option* values:

- `PASSWORD EXPIRE`

Expires the account password.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

- `PASSWORD EXPIRE DEFAULT`

Sets the account so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

- `PASSWORD EXPIRE NEVER`

Disables password expiration for the account so that its password never expires.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

- `PASSWORD EXPIRE INTERVAL N DAY`

Sets the account password lifetime to *N* days. This statement requires the password to be changed every 180 days:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
```

If multiple password-expiration options are specified, the last one takes precedence.

A client session operates in restricted mode if the account password was expired manually or if the password is considered past its lifetime per the automatic expiration policy. In restricted mode, operations performed within the session result in an error until the user establishes a new account password. See [Section 6.3.6, “Password Expiration Policy”](#).

### Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see [Section 6.3.11, “User Account Locking”](#).

If multiple account-locking options are specified, the last one takes precedence.

## CREATE USER Before MySQL 5.7.6

For each account, `CREATE USER` creates a new row in the `mysql.user` table with no privileges and assigns the account an authentication plugin and credentials (such as a password). If the statement specifies no credentials, the empty string is assigned.

Each *user\_specification* clause consists of an account name and information about how authentication occurs for clients that use the account.

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

If you specify only the user name part of the account name, a host name part of `'%'` is used.

The server assigns an authentication plugin and password to each account as follows, depending on whether the user specification clause includes `IDENTIFIED WITH` to specify a plugin or `IDENTIFIED BY` to specify a password:

- With `IDENTIFIED WITH`, the server assigns the specified plugin and the account has no password. If the optional `AS 'hash_string'` clause is also given, the string is stored as is in the `authentication_string` column (it is assumed to be already hashed in the format required by the plugin).
- With `IDENTIFIED BY`, the server assigns the plugin implicitly and assigns the specified password.
- With neither `IDENTIFIED WITH` nor `IDENTIFIED BY`, the server assigns the plugin implicitly and the account has no password.

If the account has no password, the credentials in the account's `mysql.user` table row remain empty, which is insecure. To set the password, use `SET PASSWORD`. See [Section 13.7.1.7, “SET PASSWORD Syntax”](#).

For implicit plugin assignment, the default plugin becomes the value of the `plugin` column in the account's `mysql.user` table row. The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise.

For client connections that use a given account, the server invokes the authentication plugin assigned to the account and the client must provide credentials as required by the authentication method that the plugin implements. If the server cannot find the plugin, either at account-creation time or connect time, an error occurs

If an account's `mysql.user` table row has a nonempty `plugin` column:

- The server authenticates client connection attempts using the named plugin.
- Changes to the account password using `SET PASSWORD` with `PASSWORD()` must be made with the `old_passwords` system variable set to the value required by the authentication plugin, so that `PASSWORD()` uses the appropriate password hashing method. If the plugin is `mysql_old_password`, the password can also be changed using `SET PASSWORD` with `OLD_PASSWORD()`, which uses pre-4.1 password hashing regardless of the value of `old_passwords`. (Use of `mysql_old_password` is not recommended. It is deprecated and support for it is removed in MySQL 5.7.5.)

If an account's `mysql.user` table row has an empty `plugin` column:

- As of MySQL 5.7.2, the server disables any account with an empty plugin until the DBA assigns a nonempty one. Before MySQL 5.7.2, the server authenticates client connection attempts using the `mysql_native_password` or `mysql_old_password` authentication plugin, depending on the hash format of the password stored in the `Password` column.
- Changes to the account password using `SET PASSWORD` can be made with `PASSWORD()`, with `old_passwords` set to 0 or 1 for 4.1 or pre-4.1 password hashing, respectively, or with `OLD_PASSWORD()`, which uses pre-4.1 password hashing regardless of the value of `old_passwords`.

`CREATE USER` examples:

- To specify an authentication plugin for an account, use `IDENTIFIED WITH auth_plugin`. The plugin name can be a quoted string literal or an unquoted name. `'auth_string'` is an optional

quoted string literal to pass to the plugin. The plugin interprets the meaning of the string, so its format is plugin specific and it is stored in the `authentication_string` column as given. (This value is meaningful only for plugins that use that column.) Consult the documentation for a given plugin for information about the authentication string values it accepts, if any.

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
```

The server assigns the given authentication plugin to the account but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To ensure that an account uses a specific authentication plugin and has a password with the corresponding hash format, specify the plugin explicitly with `IDENTIFIED WITH`, then use `SET PASSWORD` to set the password:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
SET old_passwords = 0;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
```

Changes to the account password using `SET PASSWORD` with `PASSWORD()` must be made with the `old_passwords` system variable set to the value required by the account's authentication plugin, so that `PASSWORD()` uses the appropriate password hashing method. Therefore, to use the `sha256_password` or `mysql_old_password` plugin instead, name that plugin in the `CREATE USER` statement and set `old_passwords` to 2 or 1, respectively, before using `SET PASSWORD`. (Use of `mysql_old_password` is not recommended. It is deprecated and support for it is removed in MySQL 5.7.5.)

- To specify a password for an account at account-creation time, use `IDENTIFIED BY` with the literal cleartext password value:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

The server assigns an authentication plugin to the account implicitly, as described previously, and assigns the given password. Clients must provide the given password when they connect.

If the implicitly assigned plugin is `mysql_native_password`, the `old_passwords` system variable must be set to 0. Otherwise, `CREATE USER` does not hash the password in the format required by the plugin and an error occurs:

```
mysql> SET old_passwords = 1;
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
ERROR 1827 (HY000): The password hash doesn't have the expected
format. Check if the correct password algorithm is being used with
the PASSWORD() function.

mysql> SET old_passwords = 0;
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
Query OK, 0 rows affected (0.00 sec)
```

- To avoid specifying the cleartext password if you know its hash value (the value that `PASSWORD()` would return for the password), specify the hash value preceded by the keyword `PASSWORD`:

```
CREATE USER 'jeffrey'@'localhost'
IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388827D2BA3A9B689';
```

The server assigns an authentication plugin to the account implicitly, as described previously, and assigns the given password. The password hash must be in the format required by the assigned plugin. Clients must provide the password when they connect.

- To enable the user to connect with no password, include no `IDENTIFIED BY` clause:

```
CREATE USER 'jeffrey'@'localhost';
```

The server assigns an authentication plugin to the account implicitly, as described previously, but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To avoid this, use `SET PASSWORD` to set the account password.

As mentioned previously, implicit plugin assignment depends on the default authentication plugin. Permitted values of `default_authentication_plugin` are `mysql_native_plugin` and `sha256_password`, but not `mysql_old_password`. This means it is not possible to set the default plugin so as to be able to create an account that uses `mysql_old_password` with `CREATE USER ... IDENTIFIED BY` syntax. To create an account that uses `mysql_old_password`, use `CREATE USER ... IDENTIFIED WITH` to name the plugin explicitly, then set the password:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_old_password;
SET old_passwords = 1;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
```

However, the preceding procedure is not recommended because `mysql_old_password` is deprecated and support for it is removed in MySQL 5.7.5.

### 13.7.1.3 DROP USER Syntax

```
DROP USER [IF EXISTS] user [, user] ...
```

The `DROP USER` statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables.

To use `DROP USER`, you must have the global `CREATE USER` privilege or the `DELETE` privilege for the `mysql` database. When the `read_only` system variable is enabled, `DROP USER` additionally requires the `SUPER` privilege.

An error occurs if you try to drop an account that does not exist.

As of MySQL 5.7.8, the `IF EXISTS` clause can be used, which causes the statement to produce a warning for each named account that does not exist, rather than an error.

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
DROP USER 'jeffrey'@'localhost';
```

If you specify only the user name part of the account name, a host name part of `'%'` is used.

#### Important

`DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

`DROP USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 19.6, “Access Control for Stored Programs and Views”](#).)

### 13.7.1.4 GRANT Syntax

```
GRANT
```

```

priv_type [(column_list)]
[, priv_type [(column_list)]] ...
ON [object_type] priv_level
TO user_specification [, user_specification] ...
[REQUIRE {NONE | ssl_option [[AND] ssl_option] ...}]
[WITH {GRANT OPTION | resource_option} ...]

GRANT PROXY ON user_specification
TO user_specification [, user_specification] ...
[WITH GRANT OPTION]

object_type: {
TABLE
| FUNCTION
| PROCEDURE
}

priv_level: {
*
| *.*
| db_name.*
| db_name.tbl_name
| tbl_name
| db_name.routine_name
}

user_specification:
user [ auth_option ]

auth_option: {      # Before MySQL 5.7.6
IDENTIFIED BY 'auth_string'
| IDENTIFIED BY PASSWORD 'hash_string'
| IDENTIFIED WITH auth_plugin
| IDENTIFIED WITH auth_plugin AS 'hash_string'
}

auth_option: {      # As of MySQL 5.7.6
IDENTIFIED BY 'auth_string'
| IDENTIFIED BY PASSWORD 'hash_string'
| IDENTIFIED WITH auth_plugin
| IDENTIFIED WITH auth_plugin BY 'auth_string'
| IDENTIFIED WITH auth_plugin AS 'hash_string'
}

ssl_option: {
SSL
| X509
| CIPHER 'cipher'
| ISSUER 'issuer'
| SUBJECT 'subject'
}

resource_option: {
| MAX_QUERIES_PER_HOUR count
| MAX_UPDATES_PER_HOUR count
| MAX_CONNECTIONS_PER_HOUR count
| MAX_USER_CONNECTIONS count
}

```

The [GRANT](#) statement grants privileges to MySQL user accounts.

To use [GRANT](#), you must have the [GRANT OPTION](#) privilege, and you must have the privileges that you are granting. When the `read_only` system variable is enabled, [GRANT](#) additionally requires the [SUPER](#) privilege.

The [REVOKE](#) statement is related to [GRANT](#) and enables administrators to remove account privileges. See [Section 13.7.1.6, “REVOKE Syntax”](#).

Normally, a database administrator first uses [CREATE USER](#) to create an account and define its nonprivilege characteristics such as its password, whether it uses secure connections, and limits on

access to server resources, then uses [GRANT](#) to define its privileges. [ALTER USER](#) may be used to change the nonprivilege characteristics of existing accounts. For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
ALTER USER 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
```

**Note**

Examples shown here include no [IDENTIFIED](#) clause. It is assumed that you establish passwords with [CREATE USER](#) at account-creation time to avoid creating insecure accounts.

**Note**

If an account named in a [GRANT](#) statement does not already exist, [GRANT](#) may create it under the conditions described later in the discussion of the [NO\\_AUTO\\_CREATE\\_USER](#) SQL mode. It is also possible to use [GRANT](#) to specify nonprivilege account characteristics such as whether it uses secure connections and limits on access to server resources.

However, use of [GRANT](#) to create accounts or define nonprivilege characteristics is deprecated as of MySQL 5.7.6. Instead, perform these tasks using [CREATE USER](#) or [ALTER USER](#).

From the `mysql` program, [GRANT](#) responds with `Query OK, 0 rows affected` when executed successfully. To determine what privileges result from the operation, use [SHOW GRANTS](#). See [Section 13.7.5.21, “SHOW GRANTS Syntax”](#).

There are several aspects to the [GRANT](#) statement, described under the following topics in this section:

- [Privileges Supported by MySQL](#)
- [Global Privileges](#)
- [Database Privileges](#)
- [Table Privileges](#)
- [Column Privileges](#)
- [Stored Routine Privileges](#)
- [Proxy User Privileges](#)
- [Account Names and Passwords](#)
- [Implicit Account Creation](#)
- [Other Account Characteristics](#)
- [MySQL and Standard SQL Versions of GRANT](#)

[GRANT](#) supports host names up to 60 characters long. Database, table, column, and routine names can be up to 64 characters. User names can be up to 32 characters (16 characters before MySQL 5.7.8).

**Warning**

*The permissible length for user names cannot be changed by altering the `mysql.user` table. Attempting to do so results in unpredictable behavior which*

may even make it impossible for users to log in to the MySQL server. You should never alter the structure of tables in the `mysql` database in any manner whatsoever except by means of the procedure described in [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

### Important

Under some circumstances, `GRANT` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

## Privileges Supported by MySQL

The following table summarizes the permissible `priv_type` privilege types that can be specified for the `GRANT` and `REVOKE` statements, and the levels at which each privilege can be granted. For additional information about these privileges, see [Section 6.2.1, “Privileges Provided by MySQL”](#).

**Table 13.1 Permissible Privileges for GRANT and REVOKE**

Privilege	Meaning and Grantable Levels
<code>ALL [PRIVILEGES]</code>	Grant all privileges at specified access level except <code>GRANT OPTION</code>
<code>ALTER</code>	Enable use of <code>ALTER TABLE</code> . Levels: Global, database, table.
<code>ALTER ROUTINE</code>	Enable stored routines to be altered or dropped. Levels: Global, database, procedure.
<code>CREATE</code>	Enable database and table creation. Levels: Global, database, table.
<code>CREATE ROUTINE</code>	Enable stored routine creation. Levels: Global, database.
<code>CREATE TABLESPACE</code>	Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.
<code>CREATE TEMPORARY TABLES</code>	Enable use of <code>CREATE TEMPORARY TABLE</code> . Levels: Global, database.
<code>CREATE USER</code>	Enable use of <code>CREATE USER</code> , <code>DROP USER</code> , <code>RENAME USER</code> , and <code>REVOKE ALL PRIVILEGES</code> . Level: Global.
<code>CREATE VIEW</code>	Enable views to be created or altered. Levels: Global, database, table.
<code>DELETE</code>	Enable use of <code>DELETE</code> . Level: Global, database, table.
<code>DROP</code>	Enable databases, tables, and views to be dropped. Levels: Global, database, table.
<code>EVENT</code>	Enable use of events for the Event Scheduler. Levels: Global, database.
<code>EXECUTE</code>	Enable the user to execute stored routines. Levels: Global, database, table.
<code>FILE</code>	Enable the user to cause the server to read or write files. Level: Global.
<code>GRANT OPTION</code>	Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, procedure, proxy.
<code>INDEX</code>	Enable indexes to be created or dropped. Levels: Global, database, table.
<code>INSERT</code>	Enable use of <code>INSERT</code> . Levels: Global, database, table, column.
<code>LOCK TABLES</code>	Enable use of <code>LOCK TABLES</code> on tables for which you have the <code>SELECT</code> privilege. Levels: Global, database.

Privilege	Meaning and Grantable Levels
PROCESS	Enable the user to see all processes with <code>SHOW PROCESSLIST</code> . Level: Global.
PROXY	Enable user proxying. Level: From user to user.
REFERENCES	Enable foreign key creation. Levels: Global, database, table, column.
RELOAD	Enable use of <code>FLUSH</code> operations. Level: Global.
REPLICATION CLIENT	Enable the user to ask where master or slave servers are. Level: Global.
REPLICATION SLAVE	Enable replication slaves to read binary log events from the master. Level: Global.
SELECT	Enable use of <code>SELECT</code> . Levels: Global, database, table, column.
SHOW DATABASES	Enable <code>SHOW DATABASES</code> to show all databases. Level: Global.
SHOW VIEW	Enable use of <code>SHOW CREATE VIEW</code> . Levels: Global, database, table.
SHUTDOWN	Enable use of <code>mysqladmin shutdown</code> . Level: Global.
SUPER	Enable use of other administrative operations such as <code>CHANGE MASTER TO</code> , <code>KILL</code> , <code>PURGE BINARY LOGS</code> , <code>SET GLOBAL</code> , and <code>mysqladmin debug</code> command. Level: Global.
TRIGGER	Enable trigger operations. Levels: Global, database, table.
UPDATE	Enable use of <code>UPDATE</code> . Levels: Global, database, table, column.
USAGE	Synonym for “no privileges”

A trigger is associated with a table, so to create or drop a trigger, you must have the `TRIGGER` privilege for the table, not the trigger.

In `GRANT` statements, the `ALL [PRIVILEGES]` or `PROXY` privilege must be named by itself and cannot be specified along with other privileges. `ALL [PRIVILEGES]` stands for all privileges available for the level at which privileges are to be granted except for the `GRANT OPTION` and `PROXY` privileges.

`USAGE` can be specified to create a user that has no privileges, or to specify the `REQUIRE` or `WITH` clauses for an account without changing its existing privileges. (However, use of `GRANT` to define nonprivilege characteristics is deprecated as of MySQL 5.7.6. Instead, perform this task using `CREATE USER` or `ALTER USER`.)

MySQL account information is stored in the tables of the `mysql` database. For additional details, consult [Section 6.2, “The MySQL Access Privilege System”](#), which discusses the `mysql` database and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting that variable.)

Privileges can be granted at several levels, depending on the syntax used for the `ON` clause. For `REVOKE`, the same `ON` syntax specifies which privileges to remove.

For the global, database, table, and routine levels, `GRANT ALL` assigns only the privileges that exist at the level you are granting. For example, `GRANT ALL ON db_name.*` is a database-level statement, so it does not grant any global-only privileges such as `FILE`. Granting `ALL` does not assign the `GRANT OPTION` or `PROXY` privilege.

The `object_type` clause, if present, should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

The privileges for a database, table, column, or routine are formed additively as the logical **OR** of the privileges at each of the privilege levels. For example, if a user has a global **SELECT** privilege, the privilege cannot be denied by an absence of the privilege at the database, table, or column level. Details of the privilege-checking procedure are presented in [Section 6.2.5, “Access Control, Stage 2: Request Verification”](#).

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the **CREATE** privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

### Important

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

## Global Privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use **ON \*.\*** syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The **CREATE TABLESPACE**, **CREATE USER**, **FILE**, **PROCESS**, **RELOAD**, **REPLICATION CLIENT**, **REPLICATION SLAVE**, **SHOW DATABASES**, **SHUTDOWN**, and **SUPER** privileges are administrative and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

MySQL stores global privileges in the `mysql.user` table.

## Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use **ON db\_name.\*** syntax:

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use **ON \*** syntax (rather than **ON \*.\***) and you have selected a default database, privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The **CREATE**, **DROP**, **EVENT**, **GRANT OPTION**, **LOCK TABLES**, and **REFERENCES** privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the `mysql.db` table.

## Table Privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use **ON db\_name.tbl\_name** syntax:

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify *tbl\_name* rather than *db\_name.tbl\_name*, the statement applies to *tbl\_name* in the default database. An error occurs if there is no default database.

The permissible *priv\_type* values at the table level are ALTER, CREATE VIEW, CREATE, DELETE, DROP, GRANT OPTION, INDEX, INSERT, REFERENCES, SELECT, SHOW VIEW, TRIGGER, and UPDATE.

MySQL stores table privileges in the `mysql.tables_priv` table.

## Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1,col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible *priv\_type* values for a column (that is, when you use a *column\_list* clause) are INSERT, REFERENCES, SELECT, and UPDATE.

MySQL stores column privileges in the `mysql.columns_priv` table.

## Stored Routine Privileges

The ALTER ROUTINE, CREATE ROUTINE, EXECUTE, and GRANT OPTION privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for CREATE ROUTINE, these privileges can be granted at the routine level for individual routines.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible *priv\_type* values at the routine level are ALTER ROUTINE, EXECUTE, and GRANT OPTION. CREATE ROUTINE is not a routine-level privilege because you must have this privilege to create a routine in the first place.

MySQL stores routine-level privileges in the `mysql.procs_priv` table.

## Proxy User Privileges

The PROXY privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user.

```
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When PROXY is granted, it must be the only privilege named in the GRANT statement, the REQUIRE clause cannot be given, and the only permitted WITH option is WITH GRANT OPTION.

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the PROXY privilege for the proxied user. For details and examples, see [Section 6.3.10, “Proxy Users”](#).

MySQL stores proxy privileges in the `mysql.proxies_priv` table.

## Account Names and Passwords

The *user\_specification* clause names a user and optionally provides authentication information such as a password.

The `user` value indicates the MySQL account to which the `GRANT` statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the `user` value in the form `user_name@host_name`. If a `user_name` or `host_name` value is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a `user_name` string containing special characters (such as “-”), or a `host_name` string containing special characters or wildcard characters (such as “%”); for example, `'test-user'@'%.com'`. Quote the user name and host name separately.

You can specify wildcards in the host name. For example, `user_name@'%.example.com'` applies to `user_name` for any host in the `example.com` domain, and `user_name@'192.168.1.%'` applies to `user_name` for any host in the `192.168.1` class C subnet.

The simple form `user_name` is a synonym for `user_name@'%'`.

*MySQL does not support wildcards in user names.* To refer to an anonymous user, specify an account with an empty user name with the `GRANT` statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user will be permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see [Section 6.2.3, “Specifying Account Names”](#).

To specify quoted values, quote database, table, column, and routine names as identifiers. Quote user names and host names as identifiers or as strings. Quote passwords as strings. For string-quoting and identifier-quoting guidelines, see [Section 9.1.1, “String Literals”](#), and [Section 9.2, “Schema Object Names”](#).

The “\_” and “%” wildcards are permitted when specifying database names in `GRANT` statements that grant privileges at the global or database levels. This means, for example, that if you want to use a “\_” character as part of a database name, you should specify it as “\\_” in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, `GRANT ... ON `foo\_bar`.* TO ...`

### Warning

If you permit anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `user_name@localhost`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see [Section 6.2.4, “Access Control, Stage 1: Connection Verification”](#).

To determine whether the preceding warning applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

To indicate how a user should authenticate when connecting to the server, the `user_specification` value may include an `IDENTIFIED` clause to specify an authentication plugin, a password, or both.

Syntax of the user specification is the same as for the `CREATE USER` statement. For details, see [Section 13.7.1.2, “CREATE USER Syntax”](#).

#### Note

Use of `GRANT` to define account authentication characteristics is deprecated as of MySQL 5.7.6. Instead, establish or change authentication characteristics using `CREATE USER` or `ALTER USER`. This `GRANT` capability will be removed in a future MySQL release.

When `IDENTIFIED BY` is present and you have the global grant privilege (`GRANT OPTION`), the password becomes the new password for the account, even if the account exists and already has a password. Without `IDENTIFIED BY`, the account password remains unchanged.

## Implicit Account Creation

If an account named in a `GRANT` statement does not exist, the action taken depends on the `NO_AUTO_CREATE_USER` SQL mode:

- If `NO_AUTO_CREATE_USER` is not enabled, `GRANT` creates the account. *This is very insecure unless you specify a nonempty password using `IDENTIFIED BY`.*
- If `NO_AUTO_CREATE_USER` is enabled, `GRANT` fails and does not create the account, unless you specify a nonempty password using `IDENTIFIED BY` or name an authentication plugin using `IDENTIFIED WITH`.

As of MySQL 5.7.2, if the account already exists, `IDENTIFIED WITH` is prohibited because it is intended only for use when creating new accounts.

## Other Account Characteristics

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see [Section 6.3.12, “Using Secure Connections”](#).

The optional `REQUIRE` clause specifies SSL-related options for a MySQL account. The syntax is the same as for the `CREATE USER` statement. For details, see [Section 13.7.1.2, “CREATE USER Syntax”](#).

#### Note

Use of `GRANT` to define account SSL characteristics is deprecated as of MySQL 5.7.6. Instead, establish or change SSL characteristics using `CREATE USER` or `ALTER USER`. This `GRANT` capability will be removed in a future MySQL release.

The optional `WITH` clause is used for these purposes:

- To enable a user to grant privileges to other users
- To specify resource limits for a user

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the `GRANT OPTION` privilege to an account without otherwise changing its privileges, do this:

```
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see [Section 6.2.1, “Privileges Provided by MySQL”](#).

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.3.4, “Setting Account Resource Limits”](#). To do so, use a `WITH` clause that specifies one or more `resource_option` values. Limits not specified retain their current values. The syntax is the same as for the `CREATE USER` statement. For details, see [Section 13.7.1.2, “CREATE USER Syntax”](#).

#### Note

Use of `GRANT` to define account resource limits is deprecated as of MySQL 5.7.6. Instead, establish or change resource limits using `CREATE USER` or `ALTER USER`. This `GRANT` capability will be removed in a future MySQL release.

## MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `UNDER` privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See [Section 13.7.1.3, “DROP USER Syntax”](#).
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with `DROP USER` or `REVOKE` statements.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) For information about strict SQL mode and implicit default values, see [Section 5.1.7, “Server SQL Modes”](#), and [Section 11.7, “Data Type Default Values”](#).

### 13.7.1.5 RENAME USER Syntax

```
RENAME USER old_user TO new_user
```

```
[, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use `RENAME USER`, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. When the `read_only` system variable is enabled, `RENAME USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

If you specify only the user name part of the account name, a host name part of `'%'` is used.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 19.6, “Access Control for Stored Programs and Views”](#).)

The privilege changes take effect as indicated in [Section 6.2.6, “When Privilege Changes Take Effect”](#).

### 13.7.1.6 REVOKE Syntax

```
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list))] ...
  ON [object_type] priv_level
  FROM user [, user] ...

REVOKE ALL PRIVILEGES, GRANT OPTION
  FROM user [, user] ...

REVOKE PROXY ON user
  FROM user [, user] ...
```

The `REVOKE` statement enables system administrators to revoke privileges from MySQL accounts.

When the `read_only` system variable is enabled, `REVOKE` requires the `SUPER` privilege in addition to any other required privileges described in the following discussion.

Each account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). For example:

```
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
```

If you specify only the user name part of the account name, a host name part of `'%'` is used.

For details on the levels at which privileges exist, the permissible `priv_type` and `priv_level` values, and the syntax for specifying users and passwords, see [Section 13.7.1.4, “GRANT Syntax”](#)

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database.

`REVOKE` removes privileges, but does not drop `mysql.user` table entries. To remove a user account entirely, use `DROP USER` (see [Section 13.7.1.3, “DROP USER Syntax”](#)) or `DELETE`.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

When successfully executed from the `mysql` program, `REVOKE` responds with `Query OK, 0 rows affected`. To determine what privileges result from the operation, use `SHOW GRANTS`. See [Section 13.7.5.21, “SHOW GRANTS Syntax”](#).

### 13.7.1.7 SET PASSWORD Syntax

`SET PASSWORD` syntax for MySQL 5.7.6 and up:

```
SET PASSWORD [FOR user] = password_option

password_option: {
  PASSWORD('auth_string')
  | 'auth_string'
}
```

`SET PASSWORD` syntax before MySQL 5.7.6:

```
SET PASSWORD [FOR user] = password_option

password_option: {
  PASSWORD('auth_string')
  | OLD_PASSWORD('auth_string')
  | 'hash_string'
}
```

The `'auth_string'` function argument is the cleartext (unencrypted) password.

The `'hash_string'` function argument is the encrypted password.

#### Note

`SET PASSWORD` is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release. `ALTER USER` is now the preferred statement for assigning passwords. For example:

```
ALTER USER user IDENTIFIED BY 'auth_string';
```

The `SET PASSWORD` statement assigns a password to a MySQL user account:

- With no `FOR user` clause, this statement sets the password for the current user:

```
SET PASSWORD = password_option;
```

Any client who connects to the server using a nonanonymous account can change the password for that account. To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```
SELECT CURRENT_USER();
```

- With a `FOR user` clause, this statement sets the password for the named account, which must exist:

```
SET PASSWORD FOR 'jeffrey'@'localhost' = password_option;
```

In this case, you must have the `UPDATE` privilege for the `mysql` database.

When the `read_only` system variable is enabled, `SET PASSWORD` requires the `SUPER` privilege in addition to any other required privileges.

If a `FOR user` clause is given, the account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). The `user` value should be given as `'user_name'@'host_name'`, where `'user_name'` and `'host_name'` are exactly as listed in the `User` and `Host` columns of the account's `mysql.user` table row. If you specify only a user name, a host name of `'%'` is used. For example, to set the password for an account with `User` and `Host` column values of `'bob'` and `'%.example.org'`, write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.example.org' = PASSWORD('cleartext password');
```

The password can be specified in these ways:

- Using the `PASSWORD()` function

The `'auth_string'` function argument is the cleartext (unencrypted) password. `PASSWORD()` hashes the password and returns the encrypted password string for storage in the `mysql.user` account row.

The `old_passwords` system variable value determines the hashing method used by `PASSWORD()`. If `SET PASSWORD` rejects the password as not being in the correct format, it may be necessary to change `old_passwords` to change the hashing method. For example, if the account uses the `mysql_native_password` plugin, the `old_passwords` value must be 0:

```
SET old_passwords = 0;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
```

If the `old_passwords` value differs from that required by the authentication plugin, the hashed password value returned by `PASSWORD()` is not acceptable for that plugin, and attempts to set the password produce an error. For example:

```
mysql> SET old_passwords = 1;
mysql> SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
ERROR 1372 (HY000): Password hash should be a 41-digit hexadecimal number
```

Permitted `old_passwords` values are described later in this section.

- Using the `OLD_PASSWORD()` function (permitted before MySQL 5.7.5 only):

The `'auth_string'` function argument is the cleartext (unencrypted) password. `OLD_PASSWORD()` hashes the password using pre-4.1 hashing and returns the encrypted password string for storage in the `mysql.user` account row. This hashing method is appropriate only for accounts that use the `mysql_old_password` authentication plugin.

#### Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them is removed

in MySQL 5.7.5. Consequently, `OLD_PASSWORD()` is deprecated and is removed in MySQL 5.7.5.

- Using a string without `PASSWORD()` or `OLD_PASSWORD()`

For this syntax, the meaning *differs in MySQL 5.7.6 and up from earlier versions*:

- As of MySQL 5.7.6, `SET PASSWORD` interprets the string as a cleartext string and hashes it appropriately for the account authentication plugin before storing it in the `mysql.user` account row.
- Before MySQL 5.7.6, `SET PASSWORD` interprets the string as a hashed password value to be stored directly. The string must be hashed in the format required by the account authentication plugin.

For more information about setting passwords, see [Section 6.3.5, “Assigning Account Passwords”](#)

The following table shows the permitted values of `old_passwords`, the password hashing method for each value, and which authentication plugins use passwords hashed with each method.

Value	Password Hashing Method	Associated Authentication Plugin
0	MySQL 4.1 native hashing	<code>mysql_native_password</code>
1	Pre-4.1 (“old”) hashing	<code>mysql_old_password</code>
2	SHA-256 hashing	<code>sha256_password</code>

#### Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them is removed in MySQL 5.7.5. Consequently, `old_passwords=1`, which causes `PASSWORD()` to generate pre-4.1 password hashes, is not permitted as of 5.7.5. For account upgrade instructions, see [Section 6.3.9.3, “Migrating Away from Pre-4.1 Password Hashing and the `mysql\_old\_password` Plugin”](#).

#### Important

Under some circumstances, `SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

If you are using MySQL Replication, be aware that, currently, a password used by a replication slave as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by the MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see [Bug #43439](#).)

## 13.7.2 Table Maintenance Statements

### 13.7.2.1 ANALYZE TABLE Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
    tbl_name [, tbl_name] ...
```

`ANALYZE TABLE` analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock for `InnoDB` and `MyISAM`. This statement works with `InnoDB`, `NDB`, and `MyISAM` tables. For `MyISAM` tables, this statement is equivalent to using `myisamchk --analyze`. This statement does not work with views.

For more information on how the analysis works within `InnoDB`, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#) and [Section 14.3.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#). Also see [Section 14.5.7, “Limits on InnoDB Tables”](#). In particular, when you enable the `innodb_stats_persistent` option, you must run `ANALYZE TABLE` after loading substantial data into an `InnoDB` table, or creating a new index for one.

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions; for more information, see [Section 13.1.6, “ALTER TABLE Syntax”](#), and [Section 18.3.4, “Maintenance of Partitions”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

`ANALYZE TABLE` returns a result set with the following columns.

Column	Value
Table	The table name
Op	Always <code>analyze</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
Msg_text	An informational message

You can check the stored key distribution with the `SHOW INDEX` statement. See [Section 13.7.5.22, “SHOW INDEX Syntax”](#).

If the table has not changed since the last `ANALYZE TABLE` statement, the table is not analyzed again.

By default, the server writes `ANALYZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

### 13.7.2.2 CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
```

```
option = {
  FOR UPGRADE
  | QUICK
  | FAST
  | MEDIUM
  | EXTENDED
  | CHANGED
}
```

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` works for `InnoDB`, `MyISAM`, `ARCHIVE`, and `CSV` tables. For `MyISAM` tables, the key statistics are updated as well.

To check a table, you must have some privilege for it.

`CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

`CHECK TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions; for more information, see [Section 13.1.6, “ALTER TABLE Syntax”](#), and [Section 18.3.4, “Maintenance of Partitions”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

`CHECK TABLE` ignores virtual generated columns that are not indexed.

## Output

`CHECK TABLE` returns a result set with the following columns.

Column	Value
Table	The table name
Op	Always <code>check</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
Msg_text	An informational message

The statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK`. If you don't get `OK`, or `Table is already up to date` for a `MyISAM` table, you should normally run a repair of the table. See [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#). `Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

## Checking Version Compatibility

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table's `.frm` file with the current MySQL version number. Marking the `.frm` file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

`FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables changed between MySQL 4.1 and 5.0.
- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.
- If your table was created by a different version of the MySQL server than the one you are currently running, `FOR UPGRADE` indicates that the table has an `.frm` file with an incompatible version. In this case, the result set returned by `CHECK TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Table upgrade required. Please do "REPAIR TABLE `tbl_name`" to fix it!`
- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about these changes and when `FOR UPGRADE` detects them, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#).

- The `YEAR(2)` data type is deprecated and support for it is removed in MySQL 5.7.5. For tables containing `YEAR(2)` columns, `CHECK TABLE` recommends `REPAIR TABLE`, which converts `YEAR(2)` to `YEAR(4)`.
- As of MySQL 5.7.2, trigger creation time is maintained. If run against a table that has triggers, `CHECK TABLE ... FOR UPGRADE` displays this warning for each trigger created before MySQL 5.7.2:

```
Trigger db_name.tbl_name.trigger_name does not have CREATED attribute.
```

The warning is informational only. No change is made to the trigger.

## Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use them or not.

Type	Meaning
<code>QUICK</code>	Do not scan the rows to check for incorrect links. Applies to <code>InnoDB</code> and <code>MyISAM</code> tables and views.
<code>FAST</code>	Check only tables that have not been closed properly. Applies only to <code>MyISAM</code> tables and views; ignored for <code>InnoDB</code> .
<code>CHANGED</code>	Check only tables that have been changed since the last check or that have not been closed properly. Applies only to <code>MyISAM</code> tables and views; ignored for <code>InnoDB</code> .
<code>MEDIUM</code>	Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Applies only to <code>MyISAM</code> tables and views; ignored for <code>InnoDB</code> .
<code>EXTENDED</code>	Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Applies only to <code>MyISAM</code> tables and views; ignored for <code>InnoDB</code> .

If none of the options `QUICK`, `MEDIUM`, or `EXTENDED` are specified, the default check type for dynamic-format `MyISAM` tables is `MEDIUM`. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is `MEDIUM` for static-format `MyISAM` tables, unless `CHANGED` or `FAST` is specified. In that case, the default is `QUICK`. The row scan is skipped for `CHANGED` and `FAST` because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

### Note

`CHECK TABLE` may change the table if the table is marked as “corrupted” or “not closed properly” but `CHECK TABLE` does not find any problems in the table. In this case, `CHECK TABLE` marks the table as okay.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from `cron`) if you want to check tables from time to time. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it is not preferred is when you suspect that you have found a bug in the `MyISAM` code.)

`EXTENDED` is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of `CHECK TABLE ... EXTENDED` might influence the execution plan generated by the query optimizer.

Some problems reported by `CHECK TABLE` cannot be corrected automatically:

- Found row where the `auto_increment` column has the value 0.

This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, execute an `UPDATE` statement to set the column to some value other than 0.

## InnoDB Details

The following notes apply to `InnoDB` tables:

- If `CHECK TABLE` encounters errors in `InnoDB` tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table.
- If `CHECK TABLE` encounters a corrupt page, the server exits to prevent error propagation (Bug #10132).
- If `CHECK TABLE` finds the wrong number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.
- `CHECK TABLE` surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for `BLOB` pointers.
- When an `InnoDB` table is stored in its own `.ibd` file in `file-per-table` mode, the first 3 pages of the `.ibd` contain header information rather than table or index data. The `CHECK TABLE` statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an `InnoDB .ibd` file, use the `innochecksum` command.
- When running `CHECK TABLE` on large `InnoDB` tables, other threads may be blocked during `CHECK TABLE` execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for `CHECK TABLE` operations. If `InnoDB` detects semaphore waits of 240 seconds or more it starts printing `InnoDB` monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, `InnoDB` will abort the process. To avoid the possibility of a semaphore wait timeout entirely, you can run `CHECK TABLE QUICK` instead of `CHECK TABLE`.
- `CHECK TABLE` functionality for `InnoDB SPATIAL` indexes is enhanced in MySQL 5.7.6. Enhancements include an R-tree validity check and a check to ensure that the R-tree row count matches the clustered index. Prior to these enhancements, minimal checks were performed on `InnoDB SPATIAL` indexes (introduced in MySQL 5.7.5).

- `CHECK TABLE` supports secondary indexes on virtual generated columns. `InnoDB` added support for secondary indexes on virtual generated columns in MySQL 5.7.8.

### 13.7.2.3 CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

`CHECKSUM TABLE` reports a `checksum` for the contents of a table. During the checksum operation, the table is locked with a read lock for `InnoDB` and `MyISAM`. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state. This statement requires the `SELECT` privilege for the table.

This statement is not supported for views. If you run `CHECKSUM TABLE` against a view, the `Checksum` value is always `NULL`, and a warning is returned.

### Performance Considerations

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the `EXTENDED` clause, with `InnoDB` and all other storage engines other than `MyISAM`, and with `MyISAM` tables not created with the `CHECKSUM=1` clause.

For `MyISAM` tables created with the `CHECKSUM=1` clause, `CHECKSUM TABLE` or `CHECKSUM TABLE ... QUICK` returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the `QUICK` method returns `NULL`. See [Section 13.1.14, “CREATE TABLE Syntax”](#) for the syntax of the `CHECKSUM` clause.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

#### Important

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by `CHECKSUM TABLE` is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

### 13.7.2.4 OPTIMIZE TABLE Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE  
tbl_name [, tbl_name] ...
```

Reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the `storage engine` used by that table. This statement does not work with views.

Use `OPTIMIZE TABLE` in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an `InnoDB` table that has its own `.ibd` file because it was created with the `innodb_file_per_table` option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.
- After doing substantial insert, update, or delete operations on columns that are part of a `FULLTEXT` index in an `InnoDB` table. Set the configuration option `innodb_optimize_fulltext_only=1` first. To keep the index maintenance period to a reasonable time, set the `innodb_ft_num_word_optimize` option to specify how many words to

update in the search index, and run a sequence of `OPTIMIZE TABLE` statements until the search index is fully updated.

- After deleting a large part of a `MyISAM` or `ARCHIVE` table, or making many changes to a `MyISAM` or `ARCHIVE` table with variable-length rows (tables that have `VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT` columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires `SELECT` and `INSERT` privileges for the table.

`OPTIMIZE TABLE` is also supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see [Section 18.3.4, “Maintenance of Partitions”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

`OPTIMIZE TABLE` works for `InnoDB`, `MyISAM`, and `ARCHIVE` tables.

By default, `OPTIMIZE TABLE` does *not* work for tables created using any other storage engine and returns a result indicating this lack of support. You can make `OPTIMIZE TABLE` work for other storage engines by starting `mysqld` with the `--skip-new` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

## InnoDB Details

For `InnoDB` tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE ... FORCE`, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of `OPTIMIZE TABLE` when you run it on an `InnoDB` table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
+-----+-----+-----+-----+
| Table      | Op       | Msg_type | Msg_text                                     |
+-----+-----+-----+-----+
| test.foo   | optimize | note     | Table does not support optimize, doing recreate + analyze instead |
| test.foo   | optimize | status   | OK                                          |
+-----+-----+-----+-----+
```

Prior to MySQL 5.7.4, `OPTIMIZE TABLE` does not use [online DDL \(ALGORITHM=INPLACE\)](#). Consequently, concurrent DML (`INSERT`, `UPDATE`, `DELETE`) is not permitted on a table while `OPTIMIZE TABLE` is running, i.e. the table is locked. Also, secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key.

As of 5.7.4, `OPTIMIZE TABLE` uses [online DDL \(ALGORITHM=INPLACE\)](#) for both regular and partitioned `InnoDB` tables. The table rebuild, triggered by `OPTIMIZE TABLE` and performed under the cover by `ALTER TABLE ... FORCE`, is now performed using [online DDL \(ALGORITHM=INPLACE\)](#) and only locks the table for a brief interval, which reduces downtime for concurrent DML operations.

`OPTIMIZE TABLE` continues to use `ALGORITHM=COPY` under the following conditions:

- When the `old_alter_table` system variable is turned ON.
- When the `mysqld --skip-new` option is enabled.

`OPTIMIZE TABLE` using [online DDL \(ALGORITHM=INPLACE\)](#) is not supported for `InnoDB` tables that contain `FULLTEXT` indexes. `ALGORITHM=COPY` must be used instead.

`InnoDB` stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as `MyISAM`) will. When considering whether or not to run `optimize`, consider the workload of transactions that your server will process:

- Some level of fragmentation is expected. InnoDB only fills pages 93% full, to leave room for updates without having to split pages.
- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.
- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See [Section 14.6.1.5, “How Compression Works for InnoDB Tables”](#) and [Section 14.8.1, “Overview of InnoDB Row Storage”](#).
- High-concurrency workloads might leave gaps in indexes over time, as InnoDB retains multiple versions of the same data due through its MVCC mechanism. See [Section 14.2.3, “InnoDB Multi-Versioning”](#).

## MyISAM Details

For MyISAM tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

## Other Considerations

`OPTIMIZE TABLE` returns a result set with the following columns.

Column	Value
Table	The table name
Op	Always <code>optimize</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
Msg_text	An informational message

For InnoDB tables prior to 5.7.4 and other table types, MySQL [locks the table](#) during the time `OPTIMIZE TABLE` is running. As of MySQL 5.7.4, `OPTIMIZE TABLE` is performed online for regular and partitioned InnoDB tables.

By default, the server writes `OPTIMIZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

`OPTIMIZE TABLE` does not sort R-tree indexes, such as spatial indexes on `POINT` columns. (Bug #23578)

`OPTIMIZE TABLE` catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `OPTIMIZE TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

### 13.7.2.5 REPAIR TABLE Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
      tbl_name [, tbl_name] ...
      [QUICK] [EXTENDED] [USE_FRM]
```

`REPAIR TABLE` repairs a possibly corrupted table, for certain storage engines only. By default, it has the same effect as `myisamchk --recover tbl_name`. `REPAIR TABLE` works for MyISAM,

`ARCHIVE`, and `CSV` tables. See [Section 15.2, “The MyISAM Storage Engine”](#) [Section 15.5, “The ARCHIVE Storage Engine”](#), and [Section 15.4, “The CSV Storage Engine”](#). This statement does not work with views.

This statement requires `SELECT` and `INSERT` privileges for the table.

`REPAIR TABLE` is supported for partitioned tables. However, the `USE_FRM` option cannot be used with this statement on a partitioned table.

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see [Section 13.1.6, “ALTER TABLE Syntax”](#), and [Section 18.3.4, “Maintenance of Partitions”](#).

Although normally you should never have to run `REPAIR TABLE`, if disaster strikes, this statement is very likely to get back all your data from a `MyISAM` table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use `REPAIR TABLE`. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 15.2.4, “MyISAM Table Problems”](#).

**Caution**

Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See [Chapter 7, Backup and Recovery](#).

**Warning**

If the server crashes during a `REPAIR TABLE` operation, it is essential after restarting it that you immediately execute another `REPAIR TABLE` statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

`REPAIR TABLE` returns a result set with the following columns.

Column	Value
Table	The table name
Op	Always <code>repair</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
Msg_text	An informational message

The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_text` normally should be `OK`. If you do not get `OK` for a `MyISAM` table, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`.) With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.

If you use the `QUICK` option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the `.frm` file. This kind of repair cannot be done with `myisamchk`.

**Note**

Use the `USE_FRM` option *only* if you cannot use regular `REPAIR` modes! Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:

- The current `AUTO_INCREMENT` value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records will remain unoccupied thereafter.
- The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that `USE_FRM` should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

**Caution**

If you use `USE_FRM` for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` will not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

If `USE_FRM` is *not* used, `REPAIR TABLE` checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as `CHECK TABLE ... FOR UPGRADE`. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), for more information. `REPAIR TABLE` without `USE_FRM` upgrades the `.frm` file to the current version.

By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

**Important**

In the event that a table on the master becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are *not* propagated to slaves.

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See [Section 8.6.3, “Speed of REPAIR TABLE Statements”](#).

`REPAIR TABLE` catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

## 13.7.3 Plugin and User-Defined Function Statements

### 13.7.3.1 CREATE FUNCTION Syntax for User-Defined Functions

```
CREATE [AGGREGATE] FUNCTION function_name RETURNS {STRING|INTEGER|REAL|DECIMAL}
SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

*function\_name* is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

*shared\_library\_name* is the base name of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see [Section 24.4.2.5, “UDF Compiling and Installing”](#).

To create a function, you must have the `INSERT` privilege for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name. If you do not have this table, you should run the `mysql_upgrade` command to create it. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see [Section 24.4.2, “Adding a New User-Defined Function”](#). For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_upgrade` program to create it (see [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#)).

#### Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

### 13.7.3.2 DROP FUNCTION Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named *function\_name*.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

#### Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

`DROP FUNCTION` is also used to drop stored functions (see [Section 13.1.22, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)).

### 13.7.3.3 INSTALL PLUGIN Syntax

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` table.

*plugin\_name* is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see [Section 24.2.4.2, “Plugin Data Structures”](#)). Plugin names are not case sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

*shared\_library\_name* is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the `plugin` directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` table. At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#). If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See [Section 5.1.3, “Server Command Options”](#).

To remove a plugin, use the `UNINSTALL PLUGIN` statement.

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.
- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

### 13.7.3.4 UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed server plugin. It requires the `DELETE` privilege for the `mysql.plugin` table.

*plugin\_name* must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

## 13.7.4 SET Syntax

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
  user_var_name = expr
  | [GLOBAL | SESSION] system_var_name = expr
  | [@@global. | @@session. | @@] system_var_name = expr
```

The `SET` statement assigns values to different types of variables that affect the operation of the server or your client.

This section describes use of `SET` for assigning values to variables. The `SET` statement can be used to assign values to these types of variables:

- System variables. See [Section 5.1.4, “Server System Variables”](#). System variables also can be set at server startup, as described in [Section 5.1.5, “Using System Variables”](#).

User-defined variables. See [Section 9.4, “User-Defined Variables”](#).

- Stored procedure and function parameters, and stored program local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).

Some variants of `SET` syntax are used in other contexts:

- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the connection to the server. These variants are described later in this section.
- `SET PASSWORD` assigns account passwords. See [Section 13.7.1.7, “SET PASSWORD Syntax”](#).
- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

The following discussion shows the different `SET` syntaxes that you can use to set variables. The examples use the `=` assignment operator, but you can also use the `:=` assignment operator for this purpose.

A user variable is written as `@var_name` and can be set as follows:

```
SET @var_name = expr;
```

Many system variables are dynamic and can be changed while the server runs by using the `SET` statement. For a list, see [Section 5.1.5.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it as `var_name`, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by `GLOBAL` or `@@global..`. The `SUPER` privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by `SESSION`, `@@session.`, or `@@`. Setting a session variable normally requires no special privilege, although there are exceptions (such as `sql_log_bin.`). A client can change its own session variables, but not those of any other client.
- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session..`
- If no modifier is present, `SET` changes the session variable.

A `SET` statement can contain multiple variable assignments, separated by commas. For example, the statement can assign values to a user-defined variable and a system variable. If you set several system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

The `@@var_name` syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable

change does not affect the session variable for any client that is currently connected (not even that of the client that issues the `SET GLOBAL` statement).

To prevent incorrect usage, MySQL produces an error if you use `SET GLOBAL` with a variable that can only be used with `SET SESSION` or if you do not specify `GLOBAL` (or `@@global.`) when setting a global variable.

To set a `SESSION` variable to the `GLOBAL` value or a `GLOBAL` value to the compiled-in MySQL default value, use the `DEFAULT` keyword. For example, the following two statements are identical in setting the session value of `max_join_size` to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, use of `DEFAULT` results in an error.

It is not permitted to assign the value `DEFAULT` to user-defined variables, stored procedure or function parameters, or stored program local variables. This results in a syntax error for user-defined variables, parameters, and local variables.

You can refer to the values of specific global or session system variables in expressions by using one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

#### Note

Some variables displayed by `SHOW VARIABLES` may not be available using `SELECT @@var_name` syntax; an `Unknown system variable` occurs. As a workaround in such cases, you can use `SHOW VARIABLES LIKE 'var_name'`.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

To display system variables names and values, use the `SHOW VARIABLES` statement. (See [Section 13.7.5.39, "SHOW VARIABLES Syntax"](#).)

The following list describes `SET` options that have nonstandard syntax (that is, options that are not set with `name = value` syntax).

- `CHARACTER SET {charset_name | DEFAULT}`

This maps all strings from and to the client with the given mapping. You can add new mappings by editing `sql/convert.cc` in the MySQL source distribution. `SET CHARACTER SET` sets

three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See [Section 10.1.4, “Connection Character Sets and Collations”](#).

The default mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET CHARACTER SET`.

- `NAMES {'charset_name' [COLLATE 'collation_name'] | DEFAULT}`

`SET NAMES` sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. The optional `COLLATE` clause may be used to specify a collation explicitly. See [Section 10.1.4, “Connection Character Sets and Collations”](#).

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET NAMES`.

## 13.7.5 SHOW Syntax

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW {BINARY | MASTER} LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW CHARACTER SET [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW SLAVE HOSTS
SHOW SLAVE STATUS [NONBLOCKING]
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
```

```
SHOW WARNINGS [LIMIT [offset,] row_count]
```

```
like_or_where:
  LIKE 'pattern'
  | WHERE expr
```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, '*pattern*' is a string that can contain the SQL “%” and “\_” wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See [Section 20.31, “Extensions to SHOW Statements”](#).

Many MySQL APIs (such as PHP) enable you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see [Chapter 23, Connectors and APIs](#), or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See [Chapter 20, INFORMATION\\_SCHEMA Tables](#).

### 13.7.5.1 SHOW BINARY LOGS Syntax

```
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#), that shows how to determine which logs can be purged.

```
mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name      | File_size |
+-----+-----+
| binlog.000015 | 724935   |
| binlog.000016 | 733481   |
+-----+-----+
```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

A user with the `SUPER` or `REPLICATION CLIENT` privilege may execute this statement.

### 13.7.5.2 SHOW BINLOG EVENTS Syntax

```
SHOW BINLOG EVENTS
  [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify '*log\_name*', the first binary log is displayed.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.9, “SELECT Syntax”](#).

#### Note

Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

**Note**

Some events relating to the setting of user and system variables are not included in the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

**Note**

`SHOW BINLOG EVENTS` does *not* work with relay log files. You can use `SHOW RELAYLOG EVENTS` for this purpose.

### 13.7.5.3 SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET
  [LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+-----+-----+-----+-----+
| Charset | Description                | Default collation | Maxlen |
+-----+-----+-----+-----+
| latin1  | cp1252 West European      | latin1_swedish_ci | 1      |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1      |
| latin5  | ISO 8859-9 Turkish        | latin5_turkish_ci  | 1      |
| latin7  | ISO 8859-13 Baltic        | latin7_general_ci  | 1      |
+-----+-----+-----+-----+
```

The `Maxlen` column shows the maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

### 13.7.5.4 SHOW COLLATION Syntax

```
SHOW COLLATION
  [LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+-----+-----+-----+-----+-----+-----+
| Collation      | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_german1_ci | latin1  | 5  |         |         | 0       |
| latin1_swedish_ci | latin1  | 8  | Yes     | Yes     | 0       |
| latin1_danish_ci  | latin1  | 15 |         |         | 0       |
| latin1_german2_ci | latin1  | 31 |         | Yes     | 2       |
| latin1_bin        | latin1  | 47 |         | Yes     | 0       |
| latin1_general_ci | latin1  | 48 |         |         | 0       |
| latin1_general_cs | latin1  | 49 |         |         | 0       |
| latin1_spanish_ci | latin1  | 94 |         |         | 0       |
+-----+-----+-----+-----+-----+-----+
```

The `Collation` and `Charset` columns indicate the names of the collation and the character set with which it is associated. `Id` is the collation ID. `Default` indicates whether the collation is the default for

its character set. `Compiled` indicates whether the character set is compiled into the server. `Sortlen` is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. `Default` is a reserved word, so to use it as an identifier, it must be quoted as such:

```
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
```

Collation	Charset	Id	Default	Compiled	Sortlen
big5_chinese_ci	big5	1	Yes	Yes	1
dec8_swedish_ci	dec8	3	Yes	Yes	1
cp850_general_ci	cp850	4	Yes	Yes	1
hp8_english_ci	hp8	6	Yes	Yes	1
koi8r_general_ci	koi8r	7	Yes	Yes	1
latin1_swedish_ci	latin1	8	Yes	Yes	1
...					

### 13.7.5.5 SHOW COLUMNS Syntax

```
SHOW [FULL] COLUMNS {FROM | IN} tbl_name [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```

`SHOW COLUMNS` displays information about the columns in a given table. It also works for views. The `LIKE` clause, if present, indicates which column names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

`SHOW COLUMNS` displays information only for those columns for which you have some privilege.

```
mysql> SHOW COLUMNS FROM City;
```

Field	Type	Null	Key	Default	Extra
Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	NO		0	

5 rows in set (0.00 sec)

If the data types differ from what you expect them to be based on a `CREATE TABLE` statement, note that MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in [Section 13.1.14.4, “Silent Column Specification Changes”](#).

The `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. In other words, these two statements are equivalent:

```
mysql> SHOW COLUMNS FROM mytable FROM mydb;
mysql> SHOW COLUMNS FROM mydb.mytable;
```

`SHOW COLUMNS` displays the following values for each table column:

`Field` indicates the column name.

`Type` indicates the column data type.

`Collation` indicates the collation for nonbinary string columns, or `NULL` for other columns. This value is displayed only if you use the `FULL` keyword.

The `Null` field contains `YES` if `NULL` values can be stored in the column, `NO` if not.

The `Key` field indicates whether the column is indexed:

- If `Key` is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
- If `Key` is `PRI`, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
- If `Key` is `UNI`, the column is the first column of a `UNIQUE` index. (A `UNIQUE` index permits multiple `NULL` values, but you can tell whether the column permits `NULL` by checking the `Null` field.)
- If `Key` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the `Key` values applies to a given column of a table, `Key` displays the one with the highest priority, in the order `PRI`, `UNI`, `MUL`.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

The `Default` field indicates the default value that is assigned to the column. This is `NULL` if the column has an explicit default of `NULL`, or if the column definition has no `DEFAULT` clause.

The `Extra` field contains any additional information that is available about a given column. The value is nonempty in these cases:

- `auto_increment` for columns that have the `AUTO_INCREMENT` attribute
- `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute
- `VIRTUAL GENERATED` or `VIRTUAL STORED` for generated columns

`Privileges` indicates the privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

`Comment` indicates any comment the column has. This value is displayed only if you use the `FULL` keyword.

`SHOW FIELDS` is a synonym for `SHOW COLUMNS`. You can also list a table's columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See [Section 13.8.1, “DESCRIBE Syntax”](#).

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 13.7.5, “SHOW Syntax”](#).

### 13.7.5.6 SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
```

Shows the `CREATE DATABASE` statement that creates the named database. If the `SHOW` statement includes an `IF NOT EXISTS` clause, the output too includes such a clause. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 5.1.4, “Server System Variables”](#).

### 13.7.5.7 SHOW CREATE EVENT Syntax

```
SHOW CREATE EVENT event_name
```

This statement displays the `CREATE EVENT` statement needed to re-create a given event. It requires the `EVENT` privilege for the database from which the event is to be shown. For example (using the same event `e_daily` defined and then altered in [Section 13.7.5.18, “SHOW EVENTS Syntax”](#)):

```
mysql> SHOW CREATE EVENT test.e_daily\G
***** 1. row *****
      Event: e_daily
      sql_mode:
      time_zone: SYSTEM
Create Event: CREATE EVENT `e_daily`
              ON SCHEDULE EVERY 1 DAY
              STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
              ON COMPLETION NOT PRESERVE
              ENABLE
              COMMENT 'Saves total number of sessions then
                      clears the table each day'
              DO BEGIN
                INSERT INTO site_activity.totals (time, total)
                  SELECT CURRENT_TIMESTAMP, COUNT(*)
                  FROM site_activity.sessions;
                DELETE FROM site_activity.sessions;
              END
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the event was created. `collation_connection` is the session value of the `collation_connection` system variable when the event was created. `Database Collation` is the collation of the database with which the event is associated.

The output reflects the current status of the event (`ENABLE`) rather than the status with which it was created.

### 13.7.5.8 SHOW CREATE FUNCTION Syntax

```
SHOW CREATE FUNCTION func_name
```

This statement is similar to `SHOW CREATE PROCEDURE` but for stored functions. See [Section 13.7.5.9, “SHOW CREATE PROCEDURE Syntax”](#).

### 13.7.5.9 SHOW CREATE PROCEDURE Syntax

```
SHOW CREATE PROCEDURE proc_name
```

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, `SHOW CREATE FUNCTION`, displays information about stored functions (see [Section 13.7.5.8, “SHOW CREATE FUNCTION Syntax”](#)).

To use either statement, you must be the user named in the routine `DEFINER` clause or have `SELECT` access to the `mysql.proc` table. If you do not have privileges for the routine itself, the value displayed for the `Create Procedure` or `Create Function` field will be `NULL`.

```
mysql> SHOW CREATE PROCEDURE test.simpleproc\G
***** 1. row *****
      Procedure: simpleproc
      sql_mode:
      Create Procedure: CREATE PROCEDURE `simpleproc` (OUT param1 INT)
                        BEGIN
                        SELECT COUNT(*) INTO param1 FROM t;
                        END
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
      Create Function: CREATE FUNCTION `hello` (s CHAR(20))
                       RETURNS CHAR(50)
                       RETURN CONCAT('Hello, ',s, '!')
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

### 13.7.5.10 SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
      Create Table: CREATE TABLE `t` (
        `id` int(11) NOT NULL AUTO_INCREMENT,
        `s` char(60) DEFAULT NULL,
        PRIMARY KEY (`id`)
      ) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

`SHOW CREATE TABLE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 5.1.4, “Server System Variables”](#).

### 13.7.5.11 SHOW CREATE TRIGGER Syntax

```
SHOW CREATE TRIGGER trigger_name
```

This statement shows the `CREATE TRIGGER` statement that creates the named trigger.

```
mysql> SHOW CREATE TRIGGER ins_sum\G
```

```

***** 1. row *****
      Trigger: ins_sum
      sql_mode: STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER='me'@'localhost' TRIGGER ins_sum
                        BEFORE INSERT ON account
                        FOR EACH ROW SET @sum = @sum + NEW.amount
character_set_client: utf8
collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci
                        Created: 2013-07-09 10:39:34.96

```

`SHOW CREATE TRIGGER` output has the following columns:

- `Trigger`: The trigger name.
- `sql_mode`: The SQL mode in effect when the trigger executes.
- `SQL Original Statement`: The `CREATE TRIGGER` statement that defines the trigger.
- `character_set_client`: The session value of the `character_set_client` system variable when the trigger was created.
- `collation_connection`: The session value of the `collation_connection` system variable when the trigger was created.
- `Database Collation`: The collation of the database with which the trigger is associated.
- `Created`: The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, `NULL` for triggers created prior to 5.7.2. This column was added in MySQL 5.7.2.

You can also obtain information about trigger objects from `INFORMATION_SCHEMA`, which contains a `TRIGGERS` table. See [Section 20.27, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

### 13.7.5.12 SHOW CREATE USER Syntax

```
SHOW CREATE USER user
```

This statement shows the `CREATE USER` statement that creates the named user. An error occurs if the user does not exist. The statement requires the `SELECT` privilege for the `mysql` database, except to see the privileges for the current user.

The account name uses the format described in [Section 6.2.3, “Specifying Account Names”](#). If you specify only the user name part of the account name, a host name part of `'%'` is used. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

```

mysql> SHOW CREATE USER 'root'@'localhost'\G
***** 1. row *****
CREATE USER for root@localhost: CREATE USER 'root'@'localhost'
IDENTIFIED WITH 'mysql_native_password'
AS '*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19'
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK

```

The output format is affected by the setting of the `log_built_in_as_identified_by_password` system variable (`log_backward_compatible_user_definitions` before MySQL 5.7.9).

This statement was added in MySQL 5.7.6.

### 13.7.5.13 SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows the `CREATE VIEW` statement that creates the named view.

```
mysql> SHOW CREATE VIEW v\G
***** 1. row *****
      View: v
      Create View: CREATE ALGORITHM=UNDEFINED
                   DEFINER=`bob`@`localhost`
                   SQL SECURITY DEFINER VIEW
                   `v` AS select 1 AS `a`,2 AS `b`
character_set_client: latin1
collation_connection: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the view was created. `collation_connection` is the session value of the `collation_connection` system variable when the view was created.

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege and the `SELECT` privilege for the view in question.

You can also obtain information about view objects from `INFORMATION_SCHEMA`, which contains a `VIEWS` table. See [Section 20.29, “The INFORMATION\\_SCHEMA VIEWS Table”](#).

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
***** 1. row *****
      View: v
      Create View: CREATE VIEW "v" AS select concat('a','b') AS "coll"
...
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

### 13.7.5.14 SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS}
     [LIKE 'pattern' | WHERE expr]
```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

### 13.7.5.15 SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

`SHOW ENGINE` displays operational information about a storage engine. It requires the `PROCESS` privilege. The statement has these variants:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE PERFORMANCE_SCHEMA STATUS
```

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard `InnoDB` Monitor about the state of the `InnoDB` storage engine. For information about the standard monitor and other `InnoDB` Monitors that provide information about `InnoDB` processing, see [Section 14.14, “InnoDB Monitors”](#).

`SHOW ENGINE INNODB MUTEX` displays `InnoDB mutex` and `rw-lock` statistics.

#### Note

`InnoDB` mutexes and rwlocks can also be monitored using [Performance Schema](#) tables. See [Section 14.13.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#).

`SHOW ENGINE INNODB MUTEX` output was removed in MySQL 5.7.2. It was revised and reintroduced in MySQL 5.7.8.

In MySQL 5.7.8, mutex statistics collection is configured dynamically using the following options:

- To enable the collection of mutex statistics, run:

```
SET GLOBAL innodb_monitor_enable='latch';
```

- To reset mutex statistics, run:

```
SET GLOBAL innodb_monitor_reset='latch';
```

- To disable the collection of mutex statistics, run:

```
SET GLOBAL innodb_monitor_disable='latch';
```

Collection of mutex statistics for `SHOW ENGINE INNODB MUTEX` can also be enabled by setting `innodb_monitor_enable='all'`, or disabled by setting `innodb_monitor_disable='all'`.

`SHOW ENGINE INNODB MUTEX` output has the following columns:

- `Type`

Always `InnoDB`.

- `Name`

Prior to MySQL 5.7.8, the `Name` field reports the source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is specific to your version of

MySQL. As of MySQL 5.7.8, only the mutex name is reported. File name and line number are still reported for rwlocks.

- `Status`

The mutex status.

Prior to MySQL 5.7.8, the `Status` field displays several values if `WITH_DEBUG` was defined at MySQL compilation time. If `WITH_DEBUG` was not defined, the statement displays only the `os_waits` value. In the latter case (without `WITH_DEBUG`), the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rwlocks (which permit multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex. Pre-MySQL 5.7.8 `Status` field values include:

- `count` indicates how many times the mutex was requested.
- `spin_waits` indicates how many times the spinlock had to run.
- `spin_rounds` indicates the number of spinlock rounds. (`spin_rounds` divided by `spin_waits` provides the average round count.)
- `os_waits` indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
- `os_yields` indicates the number of times a thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that permitting other threads to run will free the mutex so that it can be locked).
- `os_wait_times` indicates the amount of time (in ms) spent in operating system waits. In MySQL 5.7 timing is disabled and this value is always 0.

As of MySQL 5.7.8, the `Status` field reports the number of spins, waits, and calls. Statistics for low-level operating system mutexes, which are implemented outside of `InnoDB`, are not reported.

- `spins` indicates the number of spins.
- `waits` indicates the number of mutex waits.
- `calls` indicates how many times the mutex was requested.

`SHOW ENGINE INNODB MUTEX` skips the `mutexes` and `rw-locks` of `buffer pool` blocks, as the amount of output can be overwhelming on systems with a large buffer pool. (There is one mutex and one rw-lock in each 16K buffer pool block, and there are 65,536 blocks per gigabyte.) `SHOW ENGINE INNODB MUTEX` also does not list any mutexes or rw-locks that have never been waited on (`os_waits=0`). Thus, `SHOW ENGINE INNODB MUTEX` only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level `wait`.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.size
  Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.count
  Status: 10000
***** 5. row *****
```

```

Type: performance_schema
Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
Type: performance_schema
Name: performance_schema.memory
Status: 26459600
...

```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

`Name` values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: `(pfs_cond_class).size`, `(pfs_mutex_class).memory`.
- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples: `events_waits_history.size`, `mutex_instances.count`.
- A value that applies to the Performance Schema as a whole begins with `performance_schema`. Example: `performance_schema.memory`.

Buffer attributes have these meanings:

- `size` is the size of the internal record used by the implementation, such as the size of a row in a table. `size` values cannot be changed.
- `count` is the number of internal records, such as the number of rows in a table. `count` values can be changed using Performance Schema configuration options.
- For a table, `tbl_name.memory` is the product of `size` and `count`. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other `memory` values).

Some `size` and `count` attributes were named `row_size` and `row_count` before MySQL 5.7.1.

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a `SHOW ENGINE` value. For example, `events_waits_history_long.count` corresponds to `performance_schema_events_waits_history_long_size`. In other cases, the relationship is more complex. For example, `events_waits_history.count` corresponds to `performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` (the number of threads).

### 13.7.5.16 SHOW ENGINES Syntax

```
SHOW [STORAGE] ENGINES
```

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. This information can also be obtained from the `INFORMATION_SCHEMA ENGINES` table. See [Section 20.6, "The INFORMATION\\_SCHEMA ENGINES Table"](#).

```

mysql> SHOW ENGINES\G
***** 1. row *****
Engine: InnoDB
Support: DEFAULT
Comment: Supports transactions, row-level locking, and foreign keys

```

## SHOW Syntax

```
Transactions: YES
             XA: YES
             Savepoints: YES
***** 2. row *****
             Engine: MRG_MYISAM
             Support: YES
             Comment: Collection of identical MyISAM tables
Transactions: NO
             XA: NO

             Comment: Federated MySQL storage engine
Transactions: NO
             XA: NO
             Savepoints: NO
```

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors. The values shown in the `Support` column indicate the server's level of support for the storage engine, as shown in the following table.

Value	Meaning
YES	The engine is supported and is active
DEFAULT	Like YES, plus this is the default engine
NO	The engine is not supported

Value	Meaning
<code>DISABLED</code>	The engine is supported but has been disabled

A value of `NO` means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See [Section 5.2.2, “The Error Log”](#).

You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option.

All MySQL servers support `MyISAM` tables. It is not possible to disable `MyISAM`.

The `Transactions`, `XA`, and `Savepoints` columns indicate whether the storage engine supports transactions, XA transactions, and savepoints, respectively.

### 13.7.5.17 SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

`SHOW ERRORS` is a diagnostic statement that is similar to `SHOW WARNINGS`, except that it displays information only for errors, rather than for errors, warnings, and notes.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.9, “SELECT Syntax”](#).

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

`SHOW ERRORS` and `error_count` apply only to errors, not warnings or notes. In other respects, they are similar to `SHOW WARNINGS` and `warning_count`. In particular, `SHOW ERRORS` cannot display information for more than `max_error_count` messages, and `error_count` can exceed the value of `max_error_count` if the number of errors exceeds `max_error_count`.

For more information, see [Section 13.7.5.40, “SHOW WARNINGS Syntax”](#).

### 13.7.5.18 SHOW EVENTS Syntax

```
SHOW EVENTS [{FROM | IN} schema_name]
           [LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events. It requires the `EVENT` privilege for the database from which the events are to be shown.

In its simplest form, `SHOW EVENTS` lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora   | myschema |
+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> SHOW EVENTS\G
***** 1. row *****
      Db: myschema
      Name: e_daily
      Definer: jon@ghidora
      Time zone: SYSTEM
      Type: RECURRING
      Execute at: NULL
      Interval value: 10
      Interval field: SECOND
      Starts: 2006-02-09 10:41:23
      Ends: NULL
      Status: ENABLED
      Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

`SHOW EVENTS` output has the following columns:

- **Db:** The schema (database) on which the event is defined.
- **Name:** The name of the event.
- **Time zone:** The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.
- **Definer:** The account of the user who created the event, in '`user_name`'@'`host_name`' format.
- **Type:** The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).
- **Execute At:** The date and time when a transient event is set to execute. Shown as a `DATETIME` value.

For a recurring event, the value of this column is always `NULL`.

- **Interval Value:** For a recurring event, the number of intervals to wait between event executions.

For a transient event, the value of this column is always `NULL`.

- **Interval Field:** The time units used for the interval which a recurring event waits before repeating.

For a transient event, the value of this column is always `NULL`.

- **Starts:** The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event.

For a transient event, this column is always `NULL`.

- **Ends:** The end date and time for a recurring event. This is displayed as a `DATETIME` value, and defaults to `NULL` if no end date and time is defined for the event.

For a transient event, this column is always `NULL`.

- **Status:** The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.  
`SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave.
- **Originator:** The server ID of the MySQL server on which the event was created. Defaults to 0.
- `character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

For more information about `SLAVE_DISABLED` and the `Originator` column, see [Section 17.4.1.12, “Replication of Invoked Features”](#).

The event action statement is not shown in the output of `SHOW EVENTS`. Use `SHOW CREATE EVENT` or the `INFORMATION_SCHEMA.EVENTS` table.

Times displayed by `SHOW EVENTS` are given in the event time zone, as discussed in [Section 19.4.4, “Event Metadata”](#).

The columns in the output of `SHOW EVENTS` are similar to, but not identical to the columns in the `INFORMATION_SCHEMA.EVENTS` table. See [Section 20.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#).

### 13.7.5.19 SHOW FUNCTION CODE Syntax

```
SHOW FUNCTION CODE func_name
```

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See [Section 13.7.5.27, “SHOW PROCEDURE CODE Syntax”](#).

### 13.7.5.20 SHOW FUNCTION STATUS Syntax

```
SHOW FUNCTION STATUS
  [LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See [Section 13.7.5.28, “SHOW PROCEDURE STATUS Syntax”](#).

### 13.7.5.21 SHOW GRANTS Syntax

```
SHOW GRANTS [FOR user]
```

This statement lists the `GRANT` statement or statements that must be issued to duplicate the privileges that are granted to a MySQL user account. `SHOW GRANTS` requires the `SELECT` privilege for the `mysql` database, except to see the privileges for the current user.

The account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see [Section 13.7.1.4, “GRANT Syntax”](#).

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+-----+-----+
| Grants for root@localhost |
+-----+-----+
```

```
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context, such as within a stored procedure that is defined with `SQL SECURITY DEFINER`, the grants displayed are those of the definer and not the invoker.

`SHOW GRANTS` does not display the authentication plugin associated with the account. To see that information, use `SHOW CREATE USER`.

`SHOW GRANTS` displays only the privileges granted explicitly to the named account. Other privileges might be available to the account, but they are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` will not display them.

### 13.7.5.22 SHOW INDEX Syntax

```
SHOW {INDEX | INDEXES | KEYS}
     {FROM | IN} tbl_name
     [{FROM | IN} db_name]
     [WHERE expr]
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC. This statement requires some privilege for any column in the table.

`SHOW INDEX` returns the following fields:

- `Table`  
The name of the table.
- `Non_unique`  
0 if the index cannot contain duplicates, 1 if it can.
- `Key_name`  
The name of the index. If the index is the primary key, the name is always `PRIMARY`.
- `Seq_in_index`  
The column sequence number in the index, starting with 1.
- `Column_name`  
The column name.
- `Collation`  
How the column is sorted in the index. In MySQL, this can have values `"A"` (Ascending) or `NULL` (Not sorted).
- `Cardinality`  
An estimate of the number of unique values in the index. This is updated by running `ANALYZE TABLE` or `myisamchk -a`. `Cardinality` is counted based on statistics stored as integers, so

the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- [Sub\\_part](#)

The number of indexed characters if the column is only partly indexed, [NULL](#) if the entire column is indexed.

- [Packed](#)

Indicates how the key is packed. [NULL](#) if it is not.

- [Null](#)

Contains [YES](#) if the column may contain [NULL](#) values and `' '` if not.

- [Index\\_type](#)

The index method used ([BTREE](#), [FULLTEXT](#), [HASH](#), [RTREE](#)).

- [Comment](#)

Information about the index not described in its own column, such as [disabled](#) if the index is disabled.

- [Index\\_comment](#)

Any comment provided for the index with a [COMMENT](#) attribute when the index was created.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The [WHERE](#) clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

You can also list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

### 13.7.5.23 SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

This statement provides status information about the binary log files of the master. It requires either the [SUPER](#) or [REPLICATION CLIENT](#) privilege.

Example:

```
mysql> SHOW MASTER STATUS\G
***** 1. row *****
      File: master-bin.000002
      Position: 1307
      Binlog_Do_DB: test
      Binlog_Ignore_DB: manual, mysql
      Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

When global transaction IDs are in use, [Executed\\_Gtid\\_Set](#) shows the set of GTIDs for transactions that have been executed on the master. This is the same as the value for the [gtid\\_executed](#) system variable (named [gtid\\_done](#) prior to MySQL 5.6.9) on this server, as well as the value for [Executed\\_Gtid\\_Set](#) in the output of `SHOW SLAVE STATUS` on this server.

### 13.7.5.24 SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

`SHOW OPEN TABLES` lists the non-TEMPORARY tables that are currently open in the table cache. See [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#). The `FROM` clause, if present, restricts the tables shown to those present in the `db_name` database. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

`SHOW OPEN TABLES` output has the following columns:

- `Database`

The database containing the table.

- `Table`

The table name.

- `In_use`

The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` will be 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client will block waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- `Name_locked`

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

### 13.7.5.25 SHOW PLUGINS Syntax

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about server plugins. Plugin information is also available in the `INFORMATION_SCHEMA.PLUGINS` table. See [Section 20.15, “The INFORMATION\\_SCHEMA PLUGINS Table”](#).

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS\G
***** 1. row *****
  Name: binlog
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 2. row *****
  Name: CSV
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 3. row *****
```

```

Name: MEMORY
Status: ACTIVE
Type: STORAGE ENGINE
Library: NULL
License: GPL
***** 4. row *****
Name: MyISAM
Status: ACTIVE
Type: STORAGE ENGINE
Library: NULL
License: GPL
...

```

`SHOW PLUGINS` output has the following columns:

- **Name:** The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.
- **Status:** The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.
- **Type:** The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
- **Library:** The name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.
- **License:** How the plugin is licensed; for example, `GPL`.

For plugins installed with `INSTALL PLUGIN`, the `Name` and `Library` values are also registered in the `mysql.plugin` table.

For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see [Section 24.2, “The MySQL Plugin API”](#).

### 13.7.5.26 SHOW PRIVILEGES Syntax

```
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```

mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
Context: Tables
Comment: To alter the table
***** 2. row *****
Privilege: Alter routine
Context: Functions,Procedures
Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
Context: Databases
Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
...

```

Privileges belonging to a specific user are displayed by the [SHOW GRANTS](#) statement. See [Section 13.7.5.21, “SHOW GRANTS Syntax”](#), for more information.

### 13.7.5.27 SHOW PROCEDURE CODE Syntax

```
SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, [SHOW FUNCTION CODE](#), displays information about stored functions (see [Section 13.7.5.19, “SHOW FUNCTION CODE Syntax”](#)).

To use either statement, you must be the owner of the routine or have [SELECT](#) access to the `mysql.proc` table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is `Pos`, which is an ordinal number beginning with 0. The second column is `Instruction`, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
-> BEGIN
->   DECLARE fanta INT DEFAULT 55;
->   DROP TABLE t2;
->   LOOP
->     INSERT INTO t3 VALUES (fanta);
->   END LOOP;
-> END//
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SHOW PROCEDURE CODE p1//
+-----+-----+
| Pos | Instruction |
+-----+-----+
| 0 | set fanta@0 55 |
| 1 | stmt 9 "DROP TABLE t2" |
| 2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
| 3 | jump 2 |
+-----+-----+
4 rows in set (0.00 sec)
```

In this example, the nonexecutable `BEGIN` and `END` statements have disappeared, and for the `DECLARE variable_name` statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word `stmt` followed by a type (9 means `DROP`, 5 means `INSERT`, and so on). The final row contains an instruction `jump 2`, meaning `GOTO instruction #2`.

### 13.7.5.28 SHOW PROCEDURE STATUS Syntax

```
SHOW PROCEDURE STATUS
[LIKE 'pattern' | WHERE expr]
```

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, [SHOW FUNCTION STATUS](#), displays information about stored functions (see [Section 13.7.5.20, “SHOW FUNCTION STATUS Syntax”](#)).

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

```
mysql> SHOW PROCEDURE STATUS LIKE 'spl'\G
***** 1. row *****
      Db: test
      Name: spl
      Type: PROCEDURE
      Definer: testuser@localhost
      Modified: 2004-08-03 15:29:37
      Created: 2004-08-03 15:29:37
      Security_type: DEFINER
      Comment:
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

You can also get information about stored routines from the `ROUTINES` table in `INFORMATION_SCHEMA`. See [Section 20.19, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).

### 13.7.5.29 SHOW PROCESSLIST Syntax

```
SHOW [FULL] PROCESSLIST
```

`SHOW PROCESSLIST` shows you which threads are running. You can also get this information from the `INFORMATION_SCHEMA.PROCESSLIST` table or the `mysqladmin processlist` command. If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the `Info` field.

Process information is also available from the `performance_schema.threads` table. However, access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

The `SHOW PROCESSLIST` statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `SUPER` privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the `KILL` statement. See [Section 13.7.6.4, “KILL Syntax”](#).

Here is an example of `SHOW PROCESSLIST` output:

```
mysql> SHOW FULL PROCESSLIST\G
***** 1. row *****
Id: 1
User: system user
Host:
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 2
User: system user
Host:
db: NULL
```

```

Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave
      I/O thread to update it
Info: NULL
***** 3. row *****
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 4. row *****
Id: 3113
User: replikator
Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 5. row *****
Id: 3123
User: stefan
Host: localhost
db: apollon
Command: Query
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)

```

The columns produced by `SHOW PROCESSLIST` have the following meanings:

- `Id`

The connection identifier. This is the same type of value displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function.

- `User`

The MySQL user who issued the statement. If this is `system user`, it refers to a nonclient thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. `event_scheduler` refers to the thread that monitors scheduled events. For `system user`, there is no host specified in the `Host` column.

- `Host`

The host name of the client issuing the statement (except for `system user` where there is no host). `SHOW PROCESSLIST` reports the host name for TCP/IP connections in `host_name:client_port` format to make it easier to determine which client is doing what.

- `db`

The default database, if one is selected, otherwise `NULL`.

- `Command`

The type of command the thread is executing. For descriptions for thread commands, see [Section 8.14, “Examining Thread Information”](#). The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See [Section 5.1.6, “Server Status Variables”](#)

- `Time`

The time in seconds that the thread has been in its current state. For a slave SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. See [Section 17.2.2, “Replication Implementation Details”](#).

- `State`

An action, event, or state that indicates what the thread is doing. Descriptions for `State` values can be found at [Section 8.14, “Examining Thread Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

For the `SHOW PROCESSLIST` statement, the value of `State` is `NULL`.

- `Info`

The statement the thread is executing, or `NULL` if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `Info` value shows the `SELECT` statement.

### 13.7.5.30 SHOW PROFILE Syntax

```
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]
```

```
type:
  ALL
  | BLOCK IO
  | CONTEXT SWITCHES
  | CPU
  | IPC
  | MEMORY
  | PAGE FAULTS
  | SOURCE
  | SWAPS
```

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

#### Note

These statements are deprecated and will be removed in a future MySQL release. Use the [Performance Schema](#) instead; see [Section 21.16.1, “Query Profiling Using Performance Schema”](#).

Profiling is controlled by the `profiling` session variable, which has a default value of 0 (`OFF`). Profiling is enabled by setting `profiling` to 1 or `ON`:

```
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement `n`. The values of `n` correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to `row_count` rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output `offset` rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see [Section 8.14, “Examining Thread Information”](#)).

Optional `type` values may be specified to display specific additional types of information:

- `ALL` displays all information
- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times
- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```
mysql> SELECT @@profiling;
+-----+
| @@profiling |
+-----+
|           0 |
+-----+
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE t1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
+-----+-----+-----+
| Query_ID | Duration | Query |
+-----+-----+-----+

```

**Note**

Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

You can also get profiling information from the `PROFILING` table in `INFORMATION_SCHEMA`. See [Section 20.17, “The INFORMATION\\_SCHEMA PROFILING Table”](#). For example, the following queries produce the same result:

```

SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;

```

**13.7.5.31 SHOW PROFILES Syntax**

```
SHOW PROFILES
```

The `SHOW PROFILES` statement, together with `SHOW PROFILE`, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see [Section 13.7.5.30, “SHOW PROFILE Syntax”](#).

**Note**

These statements are deprecated and will be removed in a future MySQL release. Use the Performance Schema instead; see [Chapter 21, MySQL Performance Schema](#).

### 13.7.5.32 SHOW RELAYLOG EVENTS Syntax

```
SHOW RELAYLOG EVENTS
  [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the relay log of a replication slave. If you do not specify 'log\_name', the first relay log is displayed. This statement has no effect on the master.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.9, “SELECT Syntax”](#).

#### Note

Issuing a `SHOW RELAYLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the slave).

#### Note

Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

### 13.7.5.33 SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of replication slaves currently registered with the master.

`SHOW SLAVE HOSTS` should be executed on a server that acts as a replication master. The statement displays information about servers that are or have been connected as replication slaves, with each row of the result corresponding to one slave server, as shown here:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host      | Port  | Master_id | Slave_UUID |
+-----+-----+-----+-----+-----+
| 192168010 | iconnect2 | 3306  | 192168011 | 14cb6624-7f93-11e0-b2c0-c80aa9429562 |
| 1921680101 | athena    | 3306  | 192168011 | 07af4990-f41f-11df-a566-7ac56fdaf645 |
+-----+-----+-----+-----+-----+
```

- **Server\_id**: The unique server ID of the slave server, as configured in the slave server's option file, or on the command line with `--server-id=value` [2426].
- **Host**: The host name of the slave server as specified on the slave with the `--report-host` option. This can differ from the machine name as configured in the operating system.
- **User**: The slave server user name as, specified on the slave with the `--report-user` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Password**: The slave server password as, specified on the slave with the `--report-password` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Port**: The port on the master to which the slave server is listening, as specified on the slave with the `--report-port` option.

A zero in this column means that the slave port (`--report-port`) was not set.

- `Master_id`: The unique server ID of the master server that the slave server is replicating from. This is the server ID of the server on which `SHOW SLAVE HOSTS` is executed, so this same value is listed for each row in the result.
- `Slave_UUID`: The globally unique ID of this slave, as generated on the slave and found in the slave's `auto.cnf` file.

### 13.7.5.34 SHOW SLAVE STATUS Syntax

```
SHOW SLAVE STATUS [NONBLOCKING # Removed in MySQL 5.7.6]
                 [FOR CHANNEL channel]
```

This statement provides status information on essential parameters of the slave threads. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

Between MySQL 5.7.1 and MySQL 5.7.5, an optional `NONBLOCKING` clause could be used. The `NONBLOCKING` clause caused `SHOW SLAVE STATUS`, when run concurrently with `STOP SLAVE`, to return without waiting for `STOP SLAVE` to finish shutting down the slave SQL thread or slave I/O thread (or both). This option was intended for use in monitoring and other applications where getting an immediate response from `SHOW SLAVE STATUS` was more important than ensuring that it returned the latest data. This option was removed in MySQL 5.7.6 due to locking changes in replication administrative statements. As of MySQL 5.7.9 the non-blocking behavior of `SHOW SLAVE STATUS` is fixed and the option became unnecessary.

If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
        Master_Host: localhost
        Master_User: root
        Master_Port: 13000
        Connect_Retry: 60

        Replicate_Rewrite_DB:
            Channel_name:
1 row in set (0.00 sec)

```

As of MySQL 5.7.2, the Performance Schema provides tables that expose replication information. This is similar to the information available from the [SHOW SLAVE STATUS](#) statement, but represented in table form. For details, see [Section 21.9.10, “Performance Schema Replication Tables”](#).

The following list describes the fields returned by [SHOW SLAVE STATUS](#). For additional information about interpreting their meanings, see [Section 17.1.7.1, “Checking Replication Status”](#).

- [Slave\\_IO\\_State](#)

A copy of the [State](#) field of the [SHOW PROCESSLIST](#) output for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. For a listing of possible states, see [Section 8.14.5, “Replication Slave I/O Thread States”](#).

- [Master\\_Host](#)

The master host that the slave is connected to.

- [Master\\_User](#)

The user name of the account used to connect to the master.

- [Master\\_Port](#)

The port used to connect to the master.

- [Connect\\_Retry](#)

The number of seconds between connect retries (default 60). This can be set with the [CHANGE MASTER TO](#) statement.

- [Master\\_Log\\_File](#)

The name of the master binary log file from which the I/O thread is currently reading.

- [Read\\_Master\\_Log\\_Pos](#)

The position in the current master binary log file up to which the I/O thread has read.

- [Relay\\_Log\\_File](#)

The name of the relay log file from which the SQL thread is currently reading and executing.

- [Relay\\_Log\\_Pos](#)

The position in the current relay log file up to which the SQL thread has read and executed.

- `Relay_Master_Log_File`

The name of the master binary log file containing the most recent event executed by the SQL thread.

- `Slave_IO_Running`

Whether the I/O thread is started and has connected successfully to the master. Internally, the state of this thread is represented by one of the following three values:

- **MYSQL\_SLAVE\_NOT\_RUN.** The slave I/O thread is not running. For this state, `Slave_IO_Running` is `No`.
- **MYSQL\_SLAVE\_RUN\_NOT\_CONNECT.** The slave I/O thread is running, but is not connected to a replication master. For this state, `Slave_IO_Running` depends on the server version as shown in the following table.

MySQL Version	Slave_IO_Running
4.1 (4.1.13 and earlier); 5.0 (5.0.11 and earlier)	Yes
4.1 (4.1.14 and later); 5.0 (5.0.12 and later)	No
5.1 (5.1.45 and earlier)	No
5.1 (5.1.46 and later); 5.5; 5.6	Connecting

- **MYSQL\_SLAVE\_RUN\_CONNECT.** The slave I/O thread is running, and is connected to a replication master. For this state, `Slave_IO_Running` is `Yes`.

The value of the `Slave_running` system status variable corresponds with this value.

- `Slave_SQL_Running`

Whether the SQL thread is started.

- `Replicate_Do_DB`, `Replicate_Ignore_DB`

The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- `Replicate_Do_Table`, `Replicate_Ignore_Table`, `Replicate_Wild_Do_Table`, `Replicate_Wild_Ignore_Table`

The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- `Last_Errno`, `Last_Error`

These columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

#### Note

When the slave SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW SLAVE STATUS` shows a nonzero value for `Last_SQL_Errno` even though `Slave_SQL_Running` still displays `Yes`.

- `Skip_Counter`

The current value of the `sql_slave_skip_counter` system variable. See [Section 13.4.2.5, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

- `Exec_Master_Log_Pos`

The position in the current master binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the `CHANGE MASTER TO` statement's `MASTER_LOG_POS` option when starting a new slave from an existing slave, so that the new slave reads from this point. The coordinates given by (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log correspond to the coordinates given by (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause this value to be a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not. If these gaps need to be corrected, use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `Relay_Log_Space`

The total combined size of all existing relay log files.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no `UNTIL` clause was specified
- `Master` if the slave is reading until a given position in the master's binary log
- `Relay` if the slave is reading until a given position in its relay log
- `SQL_BEFORE_GTIDS` if the slave SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the `gtid_set`.
- `SQL_AFTER_GTIDS` if the slave threads are processing all transactions until the last transaction in the `gtid_set` has been processed by both threads.
- `SQL_AFTER_MTS_GAPS` if a multi-threaded slave's SQL threads are running until no more gaps are found in the relay log.

`Until_Log_File` and `Until_Log_Pos` indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

For more information on `UNTIL` clauses, see [Section 13.4.2.6, “START SLAVE Syntax”](#).

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_CRL_File`, `Master_SSL_CRL_Path`, `Master_SSL_Key`, `Master_SSL_Verify_Server_Cert`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`,

`MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, and `MASTER_SSL_VERIFY_SERVER_CERT` options to the `CHANGE MASTER TO` statement. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

- `Seconds_Behind_Master`

This field is an indication of how “late” the slave is:

- When the slave is actively processing updates, this field shows the difference between the current timestamp on the slave and the original timestamp logged on the master for the event currently being processed on the slave.
- When no event is currently being processed on the slave, this value is 0.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread. If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is *not* a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, *this column is useful only for fast networks*.

This time difference computation works even if the master and slave do not have identical clock times, provided that the difference, computed when the slave I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of `Seconds_Behind_Master` less reliable.

In MySQL 5.7, this field is `NULL` (undefined or unknown) if the slave SQL thread is not running, or if the SQL thread has consumed all of the relay log and the slave I/O thread is not running. (In older versions of MySQL, this field was `NULL` if the slave SQL thread or the slave I/O thread was not running or was not connected to the master.) If the I/O thread is running but the relay log is exhausted, `Seconds_Behind_Master` is set to 0.

The value of `Seconds_Behind_Master` is based on the timestamps stored in events, which are preserved through replication. This means that if a master M1 is itself a slave of M0, any event from M1's binary log that originates from M0's binary log has M0's timestamp for that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the problem for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, the `Seconds_Behind_Master` value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

When using a multi-threaded slave, you should keep in mind that this value is based on `Exec_Master_Log_Pos`, and so may not reflect the position of the most recently committed transaction.

- `Last_IO_Errno`, `Last_IO_Error`

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, the error values also appear in the slave's error log.

I/O error information includes a timestamp showing when the most recent I/O thread error occurred. This timestamp uses the format `YYMMDD HH:MM:SS`, and appears in the `Last_SQL_Error_Timestamp` column.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `Last_SQL_Errno`, `Last_SQL_Error`

The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_SQL_Error` value is not empty, the error values also appear in the slave's error log.

If the slave is multi-threaded, the SQL thread is the coordinator for worker threads. In this case, as of MySQL 5.7.2, the `Last_SQL_Error` field shows exactly what the `Last_Error_Message` column in the Performance Schema `replication_applier_status_by_coordinator` table shows. The field value is modified to suggest that there may be more failures in the other worker threads which can be seen in the `replication_applier_status_by_worker` table that shows each worker thread's status. If that table is not available, the slave error log can be used. The log or the `replication_applier_status_by_worker` table should also be used to learn more about the failure shown by `SHOW SLAVE STATUS` or the coordinator table.

SQL error information includes a timestamp showing when the most recent SQL thread error occurred. This timestamp uses the format `YYMMDD HH:MM:SS`, and appears in the `Last_SQL_Error_Timestamp` column.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

In MySQL 5.7, all error codes and messages displayed in the `Last_SQL_Errno` and `Last_SQL_Error` columns correspond to error values listed in [Section B.3, "Server Error Codes and Messages"](#). This was not always true in previous versions. (Bug #11760365, Bug #52768)

- `Replicate_Ignore_Server_Ids`

In MySQL 5.7, you set a slave to ignore events from 0 or more masters using the `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement. By default this is blank, and is usually modified only when using a circular or other multi-master replication setup. The message shown for `Replicate_Ignore_Server_Ids` when not blank consists of a comma-delimited list of one or more numbers, indicating the server IDs to be ignored. For example:

```
Replicate_Ignore_Server_Ids: 2, 6, 9
```

#### Note

`Ignored_server_ids` also shows the server IDs to be ignored, but is a space-delimited list, which is preceded by the total number of server IDs to be ignored. For example, if a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS = (2,6,9)` option has been issued to tell a slave to ignore masters having the server ID 2, 6, or 9, that information appears as shown here:

```
Ignored_server_ids: 3, 2, 6, 9
```

The first number (in this case 3) shows the number of server IDs being ignored.

`Replicate_Ignore_Server_Ids` filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such `--replicate-do-table`, which apply to the SQL thread.

- `Master_Server_Id`

The `server_id` value from the master.

- `Master_UUID`

The `server_uuid` [2426] value from the master.

- `Master_Info_File`

The location of the `master.info` file.

- `SQL_Delay`

The number of seconds that the slave must lag the master.

- `SQL_Remaining_Delay`

When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains the number of delay seconds remaining. At other times, this field is `NULL`.

- `Slave_SQL_Running_State`

The state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`. [Section 8.14.6, “Replication Slave SQL Thread States”](#), provides a listing of possible states

- `Master_Retry_Count`

The number of times the slave can attempt to reconnect to the master in the event of a lost connection. This value can be set using the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement (preferred) or the older `--master-retry-count` server option (still supported for backward compatibility).

- `Master_Bind`

The network interface that the slave is bound to, if any. This is set using the `MASTER_BIND` option for the `CHANGE MASTER TO` statement.

- `Last_IO_Error_Timestamp`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent I/O error took place.

- `Last_SQL_Error_Timestamp`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the last SQL error occurred.

- `Retrieved_Gtid_Set`

The set of global transaction IDs corresponding to all transactions received by this slave. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the `Gtid_log_event` is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

When all relay logs are lost due to executing `RESET SLAVE` or `CHANGE MASTER TO`, or due to the effects of the `--relay-log-recovery` option, the set is cleared. When `relay_log_purge = 1`, the newest relay log is always kept, and the set is not cleared.

Prior to MySQL 5.7.1, this value was printed using uppercase. In MySQL 5.7.1 and later, it is always printed using lowercase. (Bug #15869441)

- `Executed_Gtid_Set`

The set of global transaction IDs written in the binary log. This is the same as the value for the global `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW MASTER STATUS` on this server. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

Prior to MySQL 5.7.1, this value was printed using uppercase. In MySQL 5.7.1 and later, it is always printed using lowercase. (Bug #15869441)

- `Auto_Position`

1 if autopositioning is in use; otherwise 0.

This column was added in MySQL 5.7.1. (Bug #15992220)

- [Replicate\\_Rewrite\\_DB](#)

Beginning with MySQL 5.7.3, the [Replicate\\_Rewrite\\_DB](#) value displays any replication filtering rules that were specified. For example, if the following replication filter rule was set:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=((db1,db2), (db3,db4));
```

the [Replicate\\_Rewrite\\_DB](#) value displays:

```
Replicate_Rewrite_DB: (db1,db2),(db3,db4)
```

For more information, see [Section 13.4.2.2, “CHANGE REPLICATION FILTER Syntax”](#).

- [Channel\\_name](#)

The replication channel which is being displayed. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.3, “Replication Channels”](#) for more information.

### 13.7.5.35 SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS
     [LIKE 'pattern' | WHERE expr]
```

#### Note

As of MySQL 5.7.6, the value of the [show\\_compatibility\\_56](#) system variable affects the information available from and privileges required for the statement described here. For details, see the description of that variable in [Section 5.1.4, “Server System Variables”](#).

`SHOW STATUS` provides server status information (see [Section 5.1.6, “Server Status Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- Performance Schema tables. See [Section 21.9.13, “Performance Schema Status Variable Tables”](#).
- The `GLOBAL_STATUS` and `SESSION_STATUS` tables. See [Section 20.9, “The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables”](#).
- The `mysqladmin extended-status` command. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

`SHOW STATUS` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.
- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.

- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at [Section 5.1.6, “Server Status Variables”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in [Section 5.1.6, “Server Status Variables”](#).

```
mysql> SHOW STATUS;
+-----+-----+
| Variable_name      | Value      |
+-----+-----+
| Aborted_clients    | 0          |
| Aborted_connects   | 0          |
| Bytes_received     | 155372598  |
| Bytes_sent         | 1176560426 |
| Connections        | 30023      |
| Created_tmp_disk_tables | 0          |
| Created_tmp_tables  | 8340       |
| Created_tmp_files  | 60         |
| ...               |           |
| Open_tables        | 1          |
| Open_files         | 2          |
| Open_streams       | 0          |
| Opened_tables      | 44600      |
| Questions          | 2026873    |
| ...               |           |
| Table_locks_immediate | 1920382    |
| Table_locks_waited  | 0          |
| Threads_cached     | 0          |
| Threads_created    | 30022      |
| Threads_connected  | 1          |
| Threads_running    | 1          |
| Uptime             | 80380      |
+-----+-----+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+-----+-----+
| Variable_name      | Value      |
+-----+-----+
| Key_blocks_used    | 14955      |
| Key_read_requests  | 96854827   |
| Key_reads          | 162040     |
| Key_write_requests | 7589728    |
| Key_writes         | 3813196    |
+-----+-----+
```

### 13.7.5.36 SHOW TABLE STATUS Syntax

```
SHOW TABLE STATUS [{FROM | IN} db_name]
                    [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-TEMPORARY table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

This statement also displays information about views.

`SHOW TABLE STATUS` output has the following columns:

- **Name**  
The name of the table.
- **Engine**  
The storage engine for the table. See [Chapter 15, Alternative Storage Engines](#).
- **Version**  
The version number of the table's `.frm` file.
- **Row\_format**  
The row-storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). For `MyISAM` tables, (`Dynamic` corresponds to what `myisamchk -dvv` reports as `Packed`. The format of `InnoDB` tables is reported as `Redundant` or `Compact`. For the `Barracuda` file format of the `InnoDB Plugin`, the format may be `Compressed` or `Dynamic`.
- **Rows**  
The number of rows. Some storage engines, such as `MyISAM`, store the exact count. For other storage engines, such as `InnoDB`, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.  
  
The `Rows` value is `NULL` for tables in the `INFORMATION_SCHEMA` database.
- **Avg\_row\_length**  
The average row length.
- **Data\_length**  
The length of the data file.
- **Max\_data\_length**  
The maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.
- **Index\_length**  
The length of the index file.
- **Data\_free**  
The number of allocated but unused bytes.  
  
This information is also shown for `InnoDB` tables (previously, it was in the `Comment` value). `InnoDB` tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.  
  
For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the `INFORMATION_SCHEMA.PARTITIONS` table, as shown in this example:

```
SELECT      SUM(DATA_FREE)
FROM        INFORMATION_SCHEMA.PARTITIONS
WHERE      TABLE_SCHEMA = 'mydb'
AND        TABLE_NAME   = 'mytable';
```

For more information, see [Section 20.14](#), “The `INFORMATION_SCHEMA PARTITIONS` Table”.

- `Auto_increment`

The next `AUTO_INCREMENT` value.

- `Create_time`

When the table was created.

- `Update_time`

When the data file was last updated. For some storage engines, this value is `NULL`. For example, `InnoDB` stores multiple tables in its `system tablespace` and the data file timestamp does not apply. Even with `file-per-table` mode with each `InnoDB` table in a separate `.ibd` file, `change buffering` can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For `MyISAM`, the data file timestamp is used; however, on Windows the timestamp is not updated by updates so the value is inaccurate.

- `Check_time`

When the table was last checked. Not all storage engines update this time, in which case the value is always `NULL`.

- `Collation`

The table's character set and collation.

- `Checksum`

The live checksum value (if any).

- `Create_options`

Extra options used with `CREATE TABLE`. The original options supplied when `CREATE TABLE` is called are retained and the options reported here may differ from the active table settings and options.

- `Comment`

The comment used when creating the table (or information as to why MySQL could not access the table information).

For `MEMORY` tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

For views, all the fields displayed by `SHOW TABLE STATUS` are `NULL` except that `Name` indicates the view name and `Comment` says `view`.

### 13.7.5.37 SHOW TABLES Syntax

```
SHOW [FULL] TABLES [{FROM | IN} db_name]
                    [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLES` lists the non-`TEMPORARY` tables in a given database. You can also get this list using the `mysqlshow db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31](#), “Extensions to `SHOW` Statements”.

Matching performed by the `LIKE` clause is dependent on the setting of the `lower_case_table_names` system variable.

This statement also lists any views in the database. The `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column are `BASE TABLE` for a table and `VIEW` for a view.

If you have no privileges for a base table or view, it does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

### 13.7.5.38 SHOW TRIGGERS Syntax

```
SHOW TRIGGERS [{FROM | IN} db_name]
              [LIKE 'pattern' | WHERE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement returns results only for databases and tables for which you have the `TRIGGER` privilege. The `LIKE` clause, if present, indicates which table names to match (not trigger names) and causes the statement to display triggers for those tables. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

For the trigger `ins_sum` as defined in [Section 19.3, “Using Triggers”](#), the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%'\G
***** 1. row *****
      Trigger: ins_sum
      Event: INSERT
      Table: account
      Statement: SET @sum = @sum + NEW.amount
      Timing: BEFORE
      Created: 2013-07-09 10:39:34.96
      sql_mode: NO_ENGINE_SUBSTITUTION
      Definer: me@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci
```

`SHOW TRIGGERS` output has the following columns:

- **Trigger:** The trigger name.
- **Event:** The type of operation that causes trigger activation. The value is `'INSERT'`, `'UPDATE'`, or `'DELETE'`.
- **Table:** The table for which the trigger is defined.
- **Statement:** The trigger body; that is, the statement executed when the trigger activates.
- **Timing:** Whether the trigger activates before or after the triggering event. The value is `'BEFORE'` or `'AFTER'`.
- **Created:** The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, `NULL` for triggers created prior to 5.7.2.
- **sql\_mode:** The SQL mode in effect when the trigger executes.
- **Definer:** The account of the user who created the trigger, in `'user_name'@'host_name'` format.
- **character\_set\_client:** The session value of the `character_set_client` system variable when the trigger was created.
- **collation\_connection:** The session value of the `collation_connection` system variable when the trigger was created.

- **Database Collation:** The collation of the database with which the trigger is associated.

You can also obtain information about trigger objects from `INFORMATION_SCHEMA`, which contains a `TRIGGERS` table. See [Section 20.27, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

### 13.7.5.39 SHOW VARIABLES Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES
     [LIKE 'pattern' | WHERE expr]
```

#### Note

As of MySQL 5.7.6, the value of the `show_compatibility_56` system variable affects the information available from and privileges required for the statement described here. For details, see the description of that variable in [Section 5.1.4, “Server System Variables”](#).

`SHOW VARIABLES` shows the values of MySQL system variables (see [Section 5.1.4, “Server System Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- Performance Schema tables. See [Section 21.9.12, “Performance Schema System Variable Tables”](#).
- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables. See [Section 20.10, “The INFORMATION\\_SCHEMA GLOBAL\\_VARIABLES and SESSION\\_VARIABLES Tables”](#).
- The `mysqladmin variables` command. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW VARIABLES`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 20.31, “Extensions to SHOW Statements”](#).

`SHOW VARIABLES` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.
- With a `SESSION` modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each system variable is listed at [Section 5.1.4, “Server System Variables”](#).

`SHOW VARIABLES` is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the `SET` statement. See [Section 5.1.5, “Using System Variables”](#), and [Section 13.7.4, “SET Syntax”](#).

Partial output is shown here. The list of names and values may differ for your server. [Section 5.1.4, “Server System Variables”](#), describes the meaning of each variable, and [Section 8.12.2, “Tuning Server Parameters”](#), provides information about tuning them.

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
auto_increment_increment	1
auto_increment_offset	1
autocommit	ON
automatic_sp_privileges	ON
back_log	50

wait_timeout	28800
warning_count	0

With a [LIKE](#) clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the “%” wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because “\_” is a wildcard that matches any single character, you should escape it as “\\_” to match it literally. In practice, this is rarely necessary.

### 13.7.5.40 SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

`SHOW WARNINGS` is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as `INSERT`, `UPDATE`, and `LOAD DATA INFILE` as well as DDL statements such as `CREATE TABLE` and `ALTER TABLE`.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.9, “SELECT Syntax”](#).

`SHOW WARNINGS` is also used following `EXPLAIN EXTENDED`, to display the extra information generated by `EXPLAIN` when the `EXTENDED` keyword is used. See [Section 8.8.3, “EXPLAIN EXTENDED Output Format”](#).

As of MySQL 5.7.2, `SHOW WARNINGS` displays information about the conditions resulting from execution of the most recent nondiagnostic statement in the current session. If the most recent statement resulted in an error during parsing, `SHOW WARNINGS` shows the resulting conditions, regardless of statement type (diagnostic or nondiagnostic).

Before MySQL 5.7.2, `SHOW WARNINGS` displays information about the conditions resulting from the most recent statement in the current session that generated messages. It shows nothing if the most recent statement used a table and generated no messages. (That is, statements that use a table but generate no messages clear the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

The `SHOW COUNT(*) WARNINGS` diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` system variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

A difference in these statements is that the first is a diagnostic statement that does not clear the message list. The second, because it is a `SELECT` statement is considered nondiagnostic and, as of MySQL 5.7.2, does clear the message list.

A related diagnostic statement, `SHOW ERRORS`, shows only error conditions (it excludes warnings and notes), and `SHOW COUNT(*) ERRORS` statement displays the total number of errors. See [Section 13.7.5.17, “SHOW ERRORS Syntax”](#). `GET DIAGNOSTICS` can be used to examine information for individual conditions. See [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#).

Here is a simple example that shows data-conversion warnings for `INSERT`:

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
Level: Warning
Code: 1048
Message: Column 'a' cannot be null
***** 3. row *****
Level: Warning
Code: 1264
Message: Out of range value for column 'a' at row 3
3 rows in set (0.00 sec)
```

The `max_error_count` system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that `SHOW WARNINGS` displays. To change the number of messages the server can store, change the value of `max_error_count`. The default is 64.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @@warning_count;
+-----+
| @@warning_count |
+-----+
| 3 |
+-----+
1 row in set (0.01 sec)
```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note | 1051 | Unknown table 'test.no_such_table' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See [Section 23.8.7.78](#), “`mysql_warning_count()`”.

In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see [Section 4.5.1.2](#), “`mysql Commands`”). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+-----+
| 1/0 |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.03 sec)

Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

## 13.7.6 Other Administrative Statements

### 13.7.6.1 BINLOG Syntax

```
BINLOG 'str'
```

`BINLOG` is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See [Section 4.6.7](#), “`mysqlbinlog — Utility for Processing Binary Log Files`”.) The '*str*' value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the `SUPER` privilege.

This statement can execute only format description events and row events.

### 13.7.6.2 CACHE INDEX Syntax

```
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  [PARTITION (partition_list | ALL)]
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name [, index_name] ...)]

partition_list:
  partition_name [, partition_name] [, ...]
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for `MyISAM` tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+-----+-----+-----+-----+
| Table | Op           | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+-----+-----+-----+-----+
```

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See [Section 5.1.5.1, “Structured System Variables”](#).

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

In MySQL 5.7, this statement is also supported for partitioned `MyISAM` tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
  ENGINE=MyISAM
  PARTITION BY HASH(c1)
  PARTITIONS 4;

SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;

CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;
```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`.
- Creates 2 key caches named `kc_fast` and `kc_slow`
- Assigns the index for partition `p0` to the `kc_fast` key cache and the index for partitions `p1` and `p3` to the `kc_slow` key cache; the index for the remaining partition (`p2`) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table `pt` to a single key cache named `kc_all`, you can use either one of the following 2 statements:

```
CACHE INDEX pt PARTITION (ALL) IN kc_all;

CACHE INDEX pt IN kc_all;
```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, then the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions do not have to be contiguous, and you are not required to list their names in any particular order. Indexes for any

partitions that are not explicitly assigned to a key cache automatically use the server's default key cache.

In MySQL 5.7, index preloading is also supported for partitioned `MyISAM` tables. For more information, see [Section 13.7.6.5, “LOAD INDEX INTO CACHE Syntax”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

### 13.7.6.3 FLUSH Syntax

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
      flush_option [, flush_option] ...
```

The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute `FLUSH`, you must have the `RELOAD` privilege. Specific flush options might require additional privileges, as described later.

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

#### Note

`FLUSH LOGS`, `FLUSH TABLES WITH READ LOCK` (with or without a table list), and `FLUSH TABLES tbl_name ... FOR EXPORT` are not written to the binary log in any case because they would cause problems if replicated to a slave.

Sending a `SIGHUP` signal to the server causes several flush operations to occur that are similar to various forms of the `FLUSH` statement. See [Section 5.1.11, “Server Response to Signals”](#).

The `FLUSH` statement causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

The `RESET` statement is similar to `FLUSH`. See [Section 13.7.6.6, “RESET Syntax”](#), for information about using the `RESET` statement with replication.

`flush_option` can be any of the following items.

- `DES_KEY_FILE`

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- `HOSTS`

Empties the host cache. You should flush the host cache if some of your hosts change IP address or if the error message `Host 'host_name' is blocked` occurs. (See [Section B.5.2.6, “Host 'host\\_name' is blocked”](#).) When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host cache enables further connection attempts from the host. The default value of `max_connect_errors` is 100. To avoid this error message, start the server with `max_connect_errors` set to a large value.

- `[log_type] LOGS | RELAY LOGS [ channel_option]`

With no `log_type` option, `FLUSH LOGS` closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

`FLUSH LOGS` has no effect on tables used for the general query log or for the slow query log (see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

With a `log_type` option, only the specified log type is flushed. These `log_type` options are permitted:

- `BINARY` closes and reopens the binary log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.
- `ENGINE` closes and reopens any flushable logs for installed storage engines. This causes `InnoDB` to flush its logs to disk.
- `ERROR` closes and reopens the error log file.
- `GENERAL` closes and reopens the general query log file.
- `RELAY` closes and reopens the relay log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

The `FOR CHANNEL channel` clause added in MySQL 5.7.6 enables you to choose which replication channel to apply a `FLUSH RELAY LOGS` statement to. If no clause is set and no extra replication channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. If multiple replication channels exist and no clause is set, *all* replication channels are flushed. Execute a `FLUSH RELAY LOGS FOR CHANNEL channel` statement to flush a specific replication channel's relay log. See [Section 17.2.3, “Replication Channels”](#) for more information.

#### Note

The `FOR CHANNEL channel` clause can only be used with the `RELAY LOGS log_type`.

- `SLOW` closes and reopens the slow query log file.
- `OPTIMIZER_COSTS`

Rereads the cost model tables so that the optimizer starts using the current cost estimates stored in them. The server writes a warning to the error log for any unrecognized entries. (For information about these tables, see [Section 8.9.5, “The Optimizer Cost Model”](#).) This operation affects only sessions that begin subsequent to the flush. Existing sessions continue to use the cost estimates that were current when they began.

This option was added in MySQL 5.7.5.

- `PRIVILEGES`

Reloads the privileges from the grant tables in the `mysql` database.

The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

- `QUERY CACHE`

Defragment the query cache to better utilize its memory. `FLUSH QUERY CACHE` does not remove any queries from the cache, unlike `FLUSH TABLES` or `RESET QUERY CACHE`.

- `STATUS`

**Note**

As of MySQL 5.7.6, the value of the `show_compatibility_56` system variable affects the operation of this option. For details, see the description of that variable in [Section 5.1.4, “Server System Variables”](#).

This option adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets `Max_used_connections` to the current number of open connections. This is something you should use only when debugging a query. See [Section 1.7, “How to Report Bugs or Problems”](#).

- [TABLES](#)

`FLUSH TABLES` flushes tables, and, depending on the variant used, acquires locks. The permitted syntax is discussed later in this section.

- [USER\\_RESOURCES](#)

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections. See [Section 6.3.4, “Setting Account Resource Limits”](#).

The `mysqladmin` utility provides a command-line interface to some flush operations, using commands such as `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, and `flush-tables`. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

**Note**

It is not possible to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See [Section C.1, “Restrictions on Stored Programs”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

**FLUSH TABLES Syntax**

`FLUSH TABLES` has several forms, described following. If any variant of the `TABLES` option is used in a `FLUSH` statement, it must be the only option used. `FLUSH TABLE` is a synonym for `FLUSH TABLES`.

- [FLUSH TABLES](#)

Closes all open tables, forces all tables in use to be closed, and flushes the query cache. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement.

In MySQL 5.7, `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

- `FLUSH TABLES tbl_name [, tbl_name] ...`

With a list of one or more comma-separated table names, this statement is like `FLUSH TABLES` with no names except that the server flushes only the named tables. No error occurs if a named table does not exist.

- [FLUSH TABLES WITH READ LOCK](#)

Closes all open tables and locks all tables for all databases with a global read lock. This is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.
- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see [Section 5.2.1](#), “[Selecting General Query and Slow Query Log Output Destinations](#)”).

- `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK`

This statement flushes and acquires read locks for the named tables. The statement first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the statement flushes the tables from the table cache, reopens the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the metadata locks from exclusive to shared. After the statement acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

Because this statement acquires table locks, you must have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

Use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

This variant of `FLUSH` enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction in MySQL 5.7 that `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`.

This statement does not perform an implicit `UNLOCK TABLES`, so an error results if you use the statement while there is any active `LOCK TABLES` or use it a second time without first releasing the locks acquired.

If a flushed table was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

- `FLUSH TABLES tbl_name [, tbl_name] ... FOR EXPORT`

This `FLUSH TABLES` variant applies to `InnoDB` tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

The statement works like this:

1. It acquires shared metadata locks for the named tables. The statement blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them. When the locks have been acquired, the statement blocks transactions that attempt to update the tables while permitting read-only operations to continue.

2. It checks whether all storage engines for the tables support `FOR EXPORT`. If any do not, an `ER_ILLEGAL HA` error occurs and the statement fails.
3. The statement notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.
4. The statement puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the `FOR EXPORT` statement completes.

The `FLUSH TABLES ... FOR EXPORT` statement requires that you have the `SELECT` privilege for each table. Because this statement acquires table locks, you must also have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

InnoDB supports `FOR EXPORT` for tables that have their own `.ibd` file (that is, tables that were created with the `innodb_file_per_table` setting enabled). InnoDB ensures when notified by the `FOR EXPORT` statement that any changes have been flushed to disk. This permits a binary copy of table contents to be made while the `FOR EXPORT` statement is in effect because the `.ibd` file is transaction consistent and can be copied while the server is running. `FOR EXPORT` does not apply to InnoDB system tablespace files, or to InnoDB tables that have any `FULLTEXT` indexes.

`FLUSH TABLES ... FOR EXPORT` does not work with partitioned InnoDB tables prior to MySQL 5.7.4, but is supported for such tables in MySQL 5.7.4 and later. (Bug #16943907)

When notified by `FOR EXPORT`, InnoDB writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, InnoDB also produces a file named `table_name.cfg` in the same database directory as the table. The `.cfg` file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the `FOR EXPORT` statement completes, InnoDB will have flushed all `dirty pages` to the table data files. Any `change buffer` entries are merged prior to flushing. At this point, the tables are locked and quiescent: The tables are in a transactionally consistent state on disk and you can copy the `.ibd` tablespace files along with the corresponding `.cfg` files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see [Section 14.4.6, “Copying File-Per-Table Tablespaces to Another Server”](#).

After you are done with the tables, use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use `FLUSH TABLES ... FOR EXPORT` produce an error:

```
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
LOCK TABLES ... READ
LOCK TABLES ... WRITE
```

While `FLUSH TABLES ... FOR EXPORT` is in effect within the session, attempts to use any of these statements produce an error:

```
FLUSH TABLES WITH READ LOCK
FLUSH TABLES ... WITH READ LOCK
```

```
FLUSH TABLES ... FOR EXPORT
```

### 13.7.6.4 KILL Syntax

```
KILL [CONNECTION | QUERY] processlist_id
```

Each connection to `mysql` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread processlist identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given *processlist\_id*, after terminating any statement the connection is executing.
- `KILL QUERY` terminates the statement the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

#### Note

You cannot use `KILL` with the Embedded MySQL Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- During `ALTER TABLE` operations, the kill flag is checked before each block of rows are read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.
- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

#### Warning

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

### 13.7.6.5 LOAD INDEX INTO CACHE Syntax

```

LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [PARTITION (partition_list | ALL)]
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]

partition_list:
  partition_name[, partition_name][, ...]

```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

`LOAD INDEX INTO CACHE` is used only for `MyISAM` tables. In MySQL 5.7, it is also supported for partitioned `MyISAM` tables; in addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

`IGNORE LEAVES` is also supported for partitioned `MyISAM` tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```

mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op           | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+

```

This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

In MySQL 5.7, it is possible to preload indexes on specific partitions of partitioned `MyISAM` tables. For example, of the following 2 statements, the first preloads indexes for partition `p0` of a partitioned table `pt`, while the second preloads the indexes for partitions `p1` and `p3` of the same table:

```

LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);

```

To preload the indexes for all partitions in table `pt`, you can use either one of the following 2 statements:

```

LOAD INDEX INTO CACHE pt PARTITION (ALL);
LOAD INDEX INTO CACHE pt;

```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, then the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions do not have to be contiguous, and you are not required to list their names in any particular order.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. You can determine index block sizes for a table by using `myisamchk -dv` and checking the `Blocksize` column.

### 13.7.6.6 RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See [Section 13.7.6.3, “FLUSH Syntax”](#).

The `RESET` statement causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

`reset_option` can be any of the following:

- `MASTER`

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- `QUERY CACHE`

Removes all query results from the query cache.

- `SLAVE`

Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

### 13.7.6.7 SHUTDOWN Syntax

```
SHUTDOWN
```

This statement stops the MySQL server. It requires the `SHUTDOWN` privilege.

`SHUTDOWN` was added in MySQL 5.7.9. It provides a SQL-level interface to the same functionality available using the `mysqladmin shutdown` command or the `mysql_shutdown()` C API function.

## 13.8 MySQL Utility Statements

### 13.8.1 DESCRIBE Syntax

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see [Section 13.7.5.5, “SHOW COLUMNS Syntax”](#), and [Section 13.8.2, “EXPLAIN Syntax”](#).

### 13.8.2 EXPLAIN Syntax

```
{EXPLAIN | DESCRIBE | DESC}
  tbl_name [col_name | wild]

{EXPLAIN | DESCRIBE | DESC}
  [explain_type]
  {explainable_stmt | FOR CONNECTION connection_id}
```

```

explain_type: {
  EXTENDED
  | PARTITIONS
  | FORMAT = format_name
}

format_name: {
  TRADITIONAL
  | JSON
}

explainable_stmt: {
  SELECT statement
  | DELETE statement
  | INSERT statement
  | REPLACE statement
  | UPDATE statement
}

```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query). The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

## Obtaining Table Structure Information

`DESCRIBE` provides information about the columns in a table:

```

mysql> DESCRIBE City;
+-----+-----+-----+-----+-----+-----+
| Field      | Type      | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| Id         | int(11)   | NO   | PRI | NULL    | auto_increment |
| Name      | char(35)  | NO   |     |         |                |
| Country   | char(3)   | NO   | UNI |         |                |
| District  | char(20)  | YES  | MUL |         |                |
| Population | int(11)   | NO   |     | 0       |                |
+-----+-----+-----+-----+-----+-----+

```

`DESCRIBE` is a shortcut for `SHOW COLUMNS`. These statements also display information for views. The description for `SHOW COLUMNS` provides more information about the output columns. See [Section 13.7.5.5, “SHOW COLUMNS Syntax”](#).

By default, `DESCRIBE` displays information about all columns in the table. *col\_name*, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. *wild*, if given, is a pattern string. It can contain the SQL “%” and “\_” wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 13.7.5, “SHOW Syntax”](#).

## Obtaining Execution Plan Information

The `EXPLAIN` statement provides information about how MySQL executes statements:

- In MySQL 5.7, permitted explainable statements for `EXPLAIN` are `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE`.
- When `EXPLAIN` is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the

statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see [Section 8.8.2, “EXPLAIN Output Format”](#).

- When `EXPLAIN` is used with `FOR CONNECTION connection_id` rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See [Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).
- `EXPLAIN EXTENDED` can be used to obtain additional execution plan information. See [Section 8.8.3, “EXPLAIN EXTENDED Output Format”](#).

As of MySQL 5.7.3, the `EXPLAIN` statement is changed so that the effect of the `EXTENDED` keyword is always enabled. `EXTENDED` is still recognized for backward compatibility, but is superfluous and is deprecated; its use results in a warning. It will be removed from `EXPLAIN` syntax in a future MySQL release.

- `EXPLAIN PARTITIONS` is useful for examining queries involving partitioned tables. See [Section 18.3.5, “Obtaining Information About Partitions”](#).

As of MySQL 5.7.3, the `EXPLAIN` statement is changed so that the effect of the `PARTITIONS` keyword is always enabled. `PARTITIONS` is still recognized for backward compatibility, but is superfluous and is deprecated; its use results in a warning. It will be removed from `EXPLAIN` syntax in a future MySQL release.

- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format. With `FORMAT = JSON`, the output includes extended and partition information.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 13.2.9, “SELECT Syntax”](#).)

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see [MySQL Internals: Tracing the Optimizer](#).

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 13.7.2.1, “ANALYZE TABLE Syntax”](#).

## 13.8.3 HELP Syntax

```
HELP 'search_string'
```

The `HELP` statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.10, “Server-Side Help”](#)).

The `HELP` statement searches the help tables for the given search string and displays the result of the search. The search string is not case sensitive.

The search string can contain the wildcard characters “%” and “\_”. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP 'rep%'` returns a list of topics that begin with `rep`.

The `HELP` statement understands several types of search strings:

- At the most general level, use `contents` to retrieve a list of the top-level help categories:

```
HELP 'contents'
```

- For a list of topics in a given help category, such as [Data Types](#), use the category name:

```
HELP 'data types'
```

- For help on a specific help topic, such as the [ASCII\(\)](#) function or the [CREATE TABLE](#) statement, use the associated keyword or keywords:

```
HELP 'ascii'
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response [HELP](#) returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the [mysql](#) client, but note that [mysql](#) itself reformats [HELP](#) result sets in a different way.

- Empty result set

No match could be found for the search string.

- Result set containing a single row with three columns

This means that the search string yielded a hit for the help topic. The result has three columns:

- **name**: The topic name.
- **description**: Descriptive help text for the topic.
- **example**: Usage example or examples. This column might be blank.

Example: `HELP 'replace'`

Yields:

```
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)

Returns the string str with all occurrences of the string from_str
replaced by the string to_str. REPLACE() performs a case-sensitive
match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- **name**: The help topic name.
- **is\_it\_category**: **Y** if the name represents a help category, **N** if it does not. If it does not, the **name** value when specified as the argument to the [HELP](#) statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'status'`

Yields:

```

+-----+-----+
| name                | is_it_category |
+-----+-----+
| SHOW                | N              |
| SHOW ENGINE         | N              |
| SHOW MASTER STATUS | N              |
| SHOW PROCEDURE STATUS | N             |
| SHOW SLAVE STATUS   | N              |
| SHOW STATUS         | N              |
| SHOW TABLE STATUS  | N              |
+-----+-----+

```

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- `source_category_name`: The help category name.
- `name`: The category or topic name
- `is_it_category`: `Y` if the name represents a help category, `N` if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'functions'`

Yields:

```

+-----+-----+-----+
| source_category_name | name                | is_it_category |
+-----+-----+-----+
| Functions           | CREATE FUNCTION     | N              |
| Functions           | DROP FUNCTION       | N              |
| Functions           | Bit Functions       | Y              |
| Functions           | Comparison operators | Y              |
| Functions           | Control flow functions | Y              |
| Functions           | Date and Time Functions | Y              |
| Functions           | Encryption Functions | Y              |
| Functions           | Information Functions | Y              |
| Functions           | Logical operators   | Y              |
| Functions           | Miscellaneous Functions | Y              |
| Functions           | Numeric Functions   | Y              |
| Functions           | String Functions    | Y              |
+-----+-----+-----+

```

## 13.8.4 USE Syntax

`USE db_name`

The `USE db_name` statement tells MySQL to use the `db_name` database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

```

USE db1;
SELECT COUNT(*) FROM mytable; # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable; # selects from db2.mytable

```

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;  
SELECT author_name,editor_name FROM author,db2.editor  
WHERE author.editor_id = db2.editor.editor_id;
```

## 14.1 Introduction to InnoDB

**InnoDB** is a general-purpose storage engine that balances high reliability and high performance. In MySQL 5.7, **InnoDB** is the default MySQL storage engine. Issuing the `CREATE TABLE` statement without an `ENGINE=` clause creates an **InnoDB** table.

### Key Advantages of InnoDB

Key advantages of **InnoDB** tables include:

- Its **DML** operations follow the **ACID** model, with **transactions** featuring **commit**, **rollback**, and **crash-recovery** capabilities to protect user data.
- Row-level **locking** and Oracle-style **consistent reads** increase multi-user concurrency and performance.
- **InnoDB** tables arrange your data on disk to optimize queries based on **primary keys**.
- To maintain data **integrity**, **InnoDB** also supports **FOREIGN KEY** constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across different tables.
- You can freely mix **InnoDB** tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a **join** operation to combine data from **InnoDB** and **MEMORY** tables in a single query.
- **InnoDB** has been designed for CPU efficiency and maximum performance when processing large data volumes.

**Table 14.1 InnoDB Storage Engine Features**

<b>Storage limits</b>	64TB	<b>Transactions</b>	Yes	<b>Locking granularity</b>	Row
<b>MVCC</b>	Yes	<b>Geospatial data type support</b>	Yes	<b>Geospatial indexing support</b>	Yes <sup>a</sup>
<b>B-tree indexes</b>	Yes	<b>T-tree indexes</b>	No	<b>Hash indexes</b>	No <sup>b</sup>
<b>Full-text search indexes</b>	Yes <sup>c</sup>	<b>Clustered indexes</b>	Yes	<b>Data caches</b>	Yes
<b>Index caches</b>	Yes	<b>Compressed data</b>	Yes <sup>d</sup>	<b>Encrypted data<sup>e</sup></b>	Yes
<b>Cluster database support</b>	No	<b>Replication support<sup>f</sup></b>	Yes	<b>Foreign key support</b>	Yes
<b>Backup / point-in-time recovery<sup>g</sup></b>	Yes	<b>Query cache support</b>	Yes	<b>Update statistics for data dictionary</b>	Yes

<sup>a</sup>InnoDB support for geospatial indexing is available in MySQL 5.7.5 and higher.

<sup>b</sup>InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

<sup>c</sup>InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and higher.

<sup>d</sup>Compressed InnoDB tables require the InnoDB Barracuda file format.

<sup>e</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>f</sup>Implemented in the server, rather than in the storage engine.

<sup>g</sup>Implemented in the server, rather than in the storage engine.

The **InnoDB** storage engine maintains its own **buffer pool** for caching data and indexes in main memory. By default, with the `innodb_file_per_table` setting enabled, each new **InnoDB** table and its associated indexes are stored in a separate file. When the `innodb_file_per_table` option is disabled, **InnoDB** stores tables and indexes in the single **system tablespace**, which may consist of several files (or raw disk partitions). As of MySQL 5.7.6, **InnoDB** tables can also be stored in **general**

[tablespaces](#), which are shared tablespaces that can store data for multiple tables. [InnoDB](#) tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

To compare the features of [InnoDB](#) with other storage engines provided with MySQL, see the *Storage Engine Features* table in [Chapter 15, Alternative Storage Engines](#).

## InnoDB Enhancements and New Features

For information about [InnoDB](#) enhancements and new features in MySQL 5.7, refer to:

- The [InnoDB](#) enhancements list in [Section 1.4, “What Is New in MySQL 5.7”](#), which provides an overview of the features added in MySQL 5.7.
- The [Release Notes](#), which provide information about changes in each version.

## Additional Resources

- For [InnoDB](#)-related terms and definitions, see [MySQL Glossary](#).
- A forum dedicated to the [InnoDB](#) storage engine is available here: [MySQL Forums::InnoDB](#).
- [InnoDB](#) is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

### 14.1.1 InnoDB as the Default MySQL Storage Engine

[InnoDB](#) is the default storage engine in MySQL 5.7. [InnoDB](#) is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. [InnoDB](#) row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. [InnoDB](#) stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, [InnoDB](#) also supports [FOREIGN KEY](#) referential-integrity constraints.

Unless you have configured a different default storage engine, issuing the [CREATE TABLE](#) statement without an [ENGINE=](#) clause creates an [InnoDB](#) table.

## Benefits of InnoDB Tables

If you use [MyISAM](#) tables but are not committed to them for technical reasons, you may find [InnoDB](#) tables beneficial for the following reasons:

- If your server crashes because of a hardware or software issue, regardless of what was happening in the database at the time, you don't need to do anything special after restarting the database. [InnoDB crash recovery](#) automatically finalizes any changes that were committed before the time of the crash, and undoes any changes that were in process but not committed. Just restart and continue where you left off.
- The [InnoDB buffer pool](#) caches table and index data as the data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information, and speeds up processing.
- If you split up related data into different tables, you can set up [foreign keys](#) that enforce [referential integrity](#). Update or delete data, and the related data in other tables is updated or deleted automatically. Try to insert data into a secondary table without corresponding data in the primary table, and the bad data gets kicked out automatically.
- If data becomes corrupted on disk or in memory, a [checksum](#) mechanism alerts you to the bogus data before you use it.
- When you design your database with appropriate [primary key](#) columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in [WHERE](#) clauses, [ORDER BY](#) clauses, [GROUP BY](#) clauses, and [join](#) operations.

- Inserts, updates, and deletes are optimized by an automatic mechanism called [change buffering](#). [InnoDB](#) not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O.
- Performance benefits are not limited to giant tables with long-running queries. When the same rows are accessed over and over from a table, a feature called the [Adaptive Hash Index](#) takes over to make these lookups even faster, as if they came out of a hash table.
- You can compress tables and associated indexes.
- You can create and drop indexes with much less impact on performance and availability.
- Truncating a [file\\_per\\_table](#) tablespace is very fast, and can free up disk space for the operating system to reuse, rather than freeing up space within the [system tablespace](#) that only [InnoDB](#) could reuse.
- The storage layout for table data is more efficient for [BLOB](#) and long text fields, with the [DYNAMIC](#) row format.
- You can monitor the internal workings of the storage engine by querying [INFORMATION\\_SCHEMA](#) tables.
- You can monitor the performance details of the storage engine by querying [Performance Schema](#) tables.

For [InnoDB](#)-specific tuning techniques you can apply in your application code, see [Section 8.5](#), “[Optimizing for InnoDB Tables](#)”.

## Recent Improvements for InnoDB Tables

MySQL continues to work on addressing use cases that formerly required [MyISAM](#) tables. In MySQL 5.6 and higher:

- [InnoDB](#) can perform full-text search using the [FULLTEXT](#) index type. See [Section 14.2.7.3](#), “[InnoDB FULLTEXT Indexes](#)” for details.
- [InnoDB](#) now performs better with read-only or read-mostly workloads. Automatic optimizations apply to [InnoDB](#) queries in [autocommit](#) mode, and you can explicitly mark transactions as read-only with the syntax `START TRANSACTION READ ONLY`. See [Section 8.5.3](#), “[Optimizing InnoDB Read-Only Transactions](#)” for details.
- Applications distributed on read-only media can now use [InnoDB](#) tables. See [Section 14.3.2](#), “[Configuring InnoDB for Read-Only Operation](#)” for details.

## Best Practices for InnoDB Tables

Some general best practices for [InnoDB](#) tables include:

- Specifying a [primary key](#) for every table using the most frequently queried column or columns, or an [auto-increment](#) value if there is no obvious primary key.
- Using [joins](#) wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define [foreign keys](#) on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which can improve performance. Foreign keys also propagate deletes or updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.
- Turning off [autocommit](#). Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).
- Grouping sets of related [DML](#) operations into [transactions](#), by bracketing them with `START TRANSACTION` and `COMMIT` statements. While you don't want to commit too often, you also don't

want to issue huge batches of `INSERT`, `UPDATE`, or `DELETE` statements that run for hours without committing.

- Not using `LOCK TABLES` statements. InnoDB can handle multiple sessions all reading and writing to the same table at once, without sacrificing reliability or high performance. To get exclusive write access to a set of rows, use the `SELECT ... FOR UPDATE` syntax to lock just the rows you intend to update.
- Enabling the `innodb_file_per_table` option to put the data and indexes for individual tables into separate files, instead of in a single giant `system tablespace`. This setting is required to use some of the other features, such as table `compression` and fast `truncation`.

The `innodb_file_per_table` option is enabled by default as of MySQL 5.6.6.

- Evaluating whether your data and access patterns benefit from the InnoDB table `compression` feature (`ROW_FORMAT=COMPRESSED`) on the `CREATE TABLE` statement. You can compress InnoDB tables without sacrificing read/write capability.
- Running your server with the option `--sql_mode=NO_ENGINE_SUBSTITUTION` to prevent tables being created with a different storage engine if there is an issue with the engine specified in the `ENGINE=` clause of `CREATE TABLE`.

### Testing and Benchmarking with InnoDB as Default Storage Engine

If InnoDB is not your default storage engine, you can determine if your database server or applications work correctly with InnoDB by restarting the server with `--default-storage-engine=InnoDB` defined on the command line or with `default-storage-engine=innodb` defined in the `[mysqld]` section of the `my.cnf` configuration file.

Since changing the default storage engine only affects new tables as they are created, run all your application installation and setup steps to confirm that everything installs properly. Then exercise all the application features to make sure all the data loading, editing, and querying features work. If a table relies on some MyISAM-specific feature, you'll receive an error; add the `ENGINE=MyISAM` clause to the `CREATE TABLE` statement to avoid the error.

If you did not make a deliberate decision about the storage engine, and you just want to preview how certain tables work when they're created under InnoDB, issue the command `ALTER TABLE table_name ENGINE=InnoDB;` for each table. Or, to run test queries and other statements without disturbing the original table, make a copy like so:

```
CREATE TABLE InnoDB_Table (...) ENGINE=InnoDB AS SELECT * FROM MyISAM_Table;
```

To get a true idea of the performance with a full application under a realistic workload, install the latest MySQL server and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the master and the slaves.

### Verifying that InnoDB is the Default Storage Engine

To verify that InnoDB is the default storage engine:

- Issue the `SHOW ENGINES` command to view the different MySQL storage engines. Look for `DEFAULT` in the InnoDB line. Alternatively, query the `INFORMATION_SCHEMA ENGINES` table.
- If InnoDB is not present, you have a `mysqld` binary that was compiled without InnoDB support and you need to get a different one.

- If [InnoDB](#) is present but disabled, go back through your startup options and configuration file and get rid of any `skip-innodb` option.

## 14.1.2 Checking InnoDB Availability

To determine whether your server supports [InnoDB](#), use the `SHOW ENGINES` statement. (Now that [InnoDB](#) is the default MySQL storage engine, only very specialized environments might not support it.)

## 14.1.3 Turning Off InnoDB

Oracle recommends [InnoDB](#) as the preferred storage engine for typical database applications, from single-user wikis and blogs running on a local system, to high-end applications pushing the limits of performance. In MySQL 5.7, [InnoDB](#) is the default storage engine for new tables.

As of MySQL 5.7.5, [InnoDB](#) cannot be disabled. The `--skip-innodb` option is deprecated and has no effect, and its use results in a warning. It will be removed in a future MySQL release. This also applies to its synonyms (`--innodb=OFF`, `--disable-innodb`, and so forth). Before 5.7.5, if you do not want to use [InnoDB](#) tables:

- Start the server with the `--innodb=OFF` or `--skip-innodb` option to disable the [InnoDB](#) storage engine.
- Because the default storage engine is [InnoDB](#), the server will not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and [TEMPORARY](#) tables.
- To prevent the server from crashing when the [InnoDB-related information\\_schema tables](#) are queried, also disable the plugins associated with those tables. Specify in the `[mysqld]` section of the MySQL configuration file:

```
loose-innodb-trx=0
loose-innodb-locks=0
loose-innodb-lock-waits=0
loose-innodb-cmp=0
loose-innodb-cmp-per-index=0

```

## 14.2 InnoDB Concepts and Architecture

The information in this section provides background to help you get the most performance and functionality from using [InnoDB](#) tables. It is intended for:

- Anyone switching to MySQL from another database system, to explain what things might seem familiar and which might be all-new.

- Anyone moving from [MyISAM](#) tables to [InnoDB](#), now that [InnoDB](#) is the default MySQL storage engine.
- Anyone considering their application architecture or software stack, to understand the design considerations, performance characteristics, and scalability of [InnoDB](#) tables at a detailed level.

In this section, you will learn:

- How [InnoDB](#) closely adheres to [ACID](#) principles.
- How [InnoDB](#) implements [transactions](#), and how the inner workings of transactions compare with other database systems you might be familiar with.
- How [InnoDB](#) implements [row-level locking](#) to allow queries and DML statements to read and write the same table simultaneously.
- How multi-version concurrency control ([MVCC](#)) keeps transactions from viewing or modifying each others' data before the appropriate time.
- The physical layout of [InnoDB](#)-related objects on disk, such as [tables](#), [indexes](#), [tablespaces](#), [undo logs](#), and the [redo log](#).

### 14.2.1 MySQL and the ACID Model

The [ACID](#) model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the [InnoDB](#) storage engine that adhere closely to the ACID model, so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the [InnoDB](#) storage engine, interact with the categories of the ACID model:

- **A:** atomicity.
- **C:** consistency.
- **I:** isolation.
- **D:** durability.

#### Atomicity

The **atomicity** aspect of the ACID model mainly involves [InnoDB transactions](#). Related MySQL features include:

- Autocommit setting.
- [COMMIT](#) statement.
- [ROLLBACK](#) statement.
- Operational data from the [INFORMATION\\_SCHEMA](#) tables.

#### Consistency

The **consistency** aspect of the ACID model mainly involves internal [InnoDB](#) processing to protect data from crashes. Related MySQL features include:

- [InnoDB doublewrite buffer](#).
- [InnoDB crash recovery](#).

## Isolation

The **isolation** aspect of the ACID model mainly involves [InnoDB transactions](#), in particular the [isolation level](#) that applies to each transaction. Related MySQL features include:

- [Autocommit](#) setting.
- `SET ISOLATION LEVEL` statement.
- The low-level details of [InnoDB locking](#). During performance tuning, you see these details through `INFORMATION_SCHEMA` tables.

## Durability

The **durability** aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of buy “new hardware”.) Related MySQL features include:

- [InnoDB doublewrite buffer](#), turned on and off by the `innodb_doublewrite` configuration option.
- Configuration option `innodb_flush_log_at_trx_commit`.
- Configuration option `sync_binlog`.
- Configuration option `innodb_file_per_table`.
- Write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- Battery-backed cache in a storage device.
- The operating system used to run MySQL, in particular its support for the `fsync()` system call.
- Uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.
- Your backup strategy, such as frequency and types of backups, and backup retention periods.
- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

## 14.2.2 The InnoDB Transaction Model and Locking

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, you must understand the notions of [transactions](#) and [locking](#) as they relate to the InnoDB storage engine.

In the [InnoDB](#) transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. [InnoDB](#) does locking on the row level and runs queries as nonlocking consistent reads by default, in the style of Oracle. The lock information in [InnoDB](#) is stored so space-efficiently that lock escalation is not needed: Typically, several users are permitted to lock every row in [InnoDB](#) tables, or any random subset of the rows, without causing [InnoDB](#) memory exhaustion.

In [InnoDB](#), all user activity occurs inside a transaction. If autocommit mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new

connection with autocommit enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See [Section 14.18.4, “InnoDB Error Handling”](#).

A session that has autocommit enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

If autocommit mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all InnoDB locks that were set during the current transaction.

In terms of the SQL:1992 transaction [isolation levels](#), the default InnoDB level is `REPEATABLE READ`. InnoDB offers all four transaction isolation levels described by the SQL standard: `READ UNCOMMITTED`, `READ COMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.

A user can change the isolation level for a single session or for all subsequent connections with the `SET TRANSACTION` statement. To set the server's default isolation level for all connections, use the `--transaction-isolation` option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see [Section 13.3.6, “SET TRANSACTION Syntax”](#).

In [row-level locking](#), InnoDB normally uses next-key locking. That means that besides index records, InnoDB can also lock the [gap](#) preceding an index record to block insertions by other sessions where the indexed values would be inserted in that gap within the tree data structure. A next-key lock refers to a lock that locks an index record and the gap before it. A gap lock refers to a lock that locks only the gap before some index record.

For more information about row-level locking, and the circumstances under which gap locking is disabled, see [Section 14.2.2.4, “InnoDB Record, Gap, and Next-Key Locks”](#).

To handle locking for operations involving `SPATIAL` indexes, next-key locking does not work well to support `REPEATABLE READ` or `SERIALIZABLE` transaction isolation levels. In this case, InnoDB uses predicate locking. See [Section 14.2.2.6, “Predicate Locking for Spatial Indexes”](#).

### 14.2.2.1 InnoDB Lock Modes

InnoDB implements standard row-level locking where there are two types of locks, [shared \(S\) locks](#) and [exclusive \(X\) locks](#). For information about record, gap, and next-key lock types, see [Section 14.2.2.4, “InnoDB Record, Gap, and Next-Key Locks”](#).

- A [shared \(S\) lock](#) permits the transaction that holds the lock to read a row.
- An [exclusive \(X\) lock](#) permits the transaction that holds the lock to update or delete a row.

If transaction `T1` holds a shared (S) lock on row `r`, then requests from some distinct transaction `T2` for a lock on row `r` are handled as follows:

- A request by `T2` for an `S` lock can be granted immediately. As a result, both `T1` and `T2` hold an `S` lock on `r`.
- A request by `T2` for an `X` lock cannot be granted immediately.

If a transaction `T1` holds an `X` lock on row `r`, a request from some distinct transaction `T2` for a lock of either type on `r` cannot be granted immediately. Instead, transaction `T2` has to wait for transaction `T1` to release its lock on row `r`.

## Intention Locks

Additionally, InnoDB supports *multiple granularity locking* which permits coexistence of record locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called **intention locks** are used. Intention locks are table locks in InnoDB that indicate which type of lock (shared or exclusive) a transaction will require later for a row in that table. There are two types of intention locks used in InnoDB (assume that transaction **T** has requested a lock of the indicated type on table **t**):

- **Intention shared (IS)**: Transaction **T** intends to set **S** locks on individual rows in table **t**.
- **Intention exclusive (IX)**: Transaction **T** intends to set **X** locks on those rows.

For example, `SELECT ... LOCK IN SHARE MODE` sets an **IS** lock and `SELECT ... FOR UPDATE` sets an **IX** lock.

The intention locking protocol is as follows:

- Before a transaction can acquire an **S** lock on a row in table **t**, it must first acquire an **IS** or stronger lock on **t**.
- Before a transaction can acquire an **X** lock on a row, it must first acquire an **IX** lock on **t**.

These rules can be conveniently summarized by means of the following *lock type compatibility matrix*.

	<b>X</b>	<b>IX</b>	<b>S</b>	<b>IS</b>
<b>X</b>	Conflict	Conflict	Conflict	Conflict
<b>IX</b>	Conflict	Compatible	Conflict	Compatible
<b>S</b>	Conflict	Conflict	Compatible	Compatible
<b>IS</b>	Conflict	Compatible	Compatible	Compatible

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause **deadlock**, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of **IX** and **IS** locks is to show that someone is locking a row, or going to lock a row in the table.

## Deadlock Example

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an **S** lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+-----+
| i     |
+-----+
| 1     |
```

+-----+

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an *X* lock. The lock cannot be granted because it is incompatible with the *S* lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an *X* lock to delete the row. However, that lock request cannot be granted because client B already has a request for an *X* lock and is waiting for client A to release its *S* lock. Nor can the *S* lock held by A be upgraded to an *X* lock because of the prior request by B for an *X* lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

```
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

At that point, the lock request for the other client can be granted and it deletes the row from the table.

#### Note

If the `LATEST DETECTED DEADLOCK` section of InnoDB Monitor output includes a message stating, “`TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION,`” this indicates that the number of transactions on the wait-for list has reached a limit of 200, which is defined by `LOCK_MAX_DEPTH_IN_DEADLOCK_CHECK`. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back.

The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by the transactions on the wait-for list. The limit of 1,000,000 locks is defined by `LOCK_MAX_N_STEPS_IN_DEADLOCK_CHECK`.

### 14.2.2.2 Consistent Nonlocking Reads

A **consistent read** means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction **isolation level** is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

**Note**

The snapshot of the database state applies to `SELECT` statements within a transaction, not necessarily to `DML` statements. If you insert or modify some rows and then commit that transaction, a `DELETE` or `UPDATE` statement issued from another concurrent `REPEATABLE READ` transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz'; -- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz'; -- Deletes several rows recently committed by other t
SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc'; -- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc'; -- Affects 10 rows: another txn just commi
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba'; -- Returns 10: this txn can now see the ro
```

You can advance your timepoint by committing your transaction and then doing another `SELECT` or `START TRANSACTION WITH CONSISTENT SNAPSHOT`.

This is called *multi-versioned concurrency control*.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

```

      Session A          Session B
time
|
|   SET autocommit=0;   SET autocommit=0;
|
|   SELECT * FROM t;
|   empty set
|
|
|
v   SELECT * FROM t;
    empty set
    COMMIT;
    SELECT * FROM t;
    empty set
    COMMIT;
    SELECT * FROM t;
    -----
    |  1  |  2  |
    -----

```

If you want to see the “freshest” state of the database, use either the `READ COMMITTED` isolation level or a [locking read](#):

```
SELECT * FROM t LOCK IN SHARE MODE;
```

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With `LOCK IN SHARE MODE`, a locking read occurs instead: A `SELECT` blocks until the transaction containing the freshest rows ends (see [Section 14.2.2.3, “Locking Reads \(SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE\)”](#)).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over `DROP TABLE`, because MySQL cannot use a table that has been dropped and InnoDB destroys the table.
- Consistent read does not work over `ALTER TABLE`, because that statement makes a temporary copy of the original table and deletes the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken. In this case, the transaction returns an error: `ER_TABLE_DEF_CHANGED`, “Table definition has changed, please retry transaction”.

The type of read varies for selects in clauses like `INSERT INTO ... SELECT`, `UPDATE ... (SELECT)`, and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `LOCK IN SHARE MODE`:

- By default, InnoDB uses stronger locks and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.
- To use a consistent read in such cases, enable the `innodb_locks_unsafe_for_binlog` option and set the isolation level of the transaction to `READ UNCOMMITTED`, `READ COMMITTED`, or `REPEATABLE READ` (that is, anything other than `SERIALIZABLE`). In this case, no locks are set on rows read from the selected table.

### 14.2.2.3 Locking Reads (SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE)

If you query data and then insert or update related data within the same transaction, the regular `SELECT` statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of [locking reads](#) that offer extra safety:

- `SELECT ... LOCK IN SHARE MODE` sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.
- For index records the search encounters, `SELECT ... FOR UPDATE` locks the rows and any associated index entries, the same as if you issued an `UPDATE` statement for those rows. Other transactions are blocked from updating those rows, from doing `SELECT ... LOCK IN SHARE MODE`, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying [undo logs](#) on an in-memory copy of the record.)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these “pointer” values.

All locks set by `LOCK IN SHARE MODE` and `FOR UPDATE` queries are released when the transaction is committed or rolled back.

#### Note

Locking of rows for update using `SELECT FOR UPDATE` only applies when autocommit is disabled (either by beginning transaction with `START`

`TRANSACTION` or by setting `autocommit` to 0. If autocommit is enabled, the rows matching the specification are not locked.

## Usage Examples

Suppose that you want to insert a new row into a table `child`, and make sure that the child row has a parent row in table `parent`. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table `PARENT` and verify that the parent row exists. Can you safely insert the child row to table `CHILD`? No, because some other session could delete the parent row in the moment between your `SELECT` and your `INSERT`, without you being aware of it.

To avoid this potential issue, perform the `SELECT` using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

After the `LOCK IN SHARE MODE` query returns the parent `'Jones'`, you can safely add the child record to the `CHILD` table and commit the transaction. Any transaction that tries to read or write to the applicable row in the `PARENT` table waits until you are finished, that is, the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table `CHILD_CODES`, used to assign a unique identifier to each child added to table `CHILD`. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the `CHILD` table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using `FOR UPDATE`, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

### 14.2.2.4 InnoDB Record, Gap, and Next-Key Locks

InnoDB has several types of record-level locks including record locks, gap locks, and next-key locks. For information about shared locks, exclusive locks, and intention locks, see [Section 14.2.2.1, “InnoDB Lock Modes”](#).

- Record lock: This is a lock on an index record.
- Gap lock: This is a lock on a gap between index records, or a lock on the gap before the first or after the last index record.

- Next-key lock: This is a combination of a record lock on the index record and a gap lock on the gap before the index record.

## Record Locks

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See [Section 14.2.7.2, “Clustered and Secondary Indexes”](#).

## Next-key Locks

By default, InnoDB operates in `REPEATABLE READ` transaction isolation level. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see [Section 14.2.2.5, “Avoiding the Phantom Problem Using Next-Key Locking”](#)).

Next-key locking combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where `(` or `)` denote exclusion of the interval endpoint and `[` or `]` denote inclusion of the endpoint:

```
(negative infinity, 10]
(10, 11]
(11, 13]
(13, 20]
(20, positive infinity)
```

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

## Gap Locks

The next-key locking example in the previous section shows that a gap might span a single index value, multiple index values, or even be empty.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

A type of gap lock called an insert intention gap lock is set by `INSERT` operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in InnoDB are “purely inhibitive”, which means they only stop other transactions from inserting to the gap. Thus, a gap X-lock has the same effect as a gap S-lock.

## Disabling Gap Locking

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED` or enable the `innodb_locks_unsafe_for_binlog` system variable (which is now deprecated). Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level or enabling `innodb_locks_unsafe_for_binlog`: Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, InnoDB does a “semi-consistent” read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

### 14.2.2.5 Avoiding the Phantom Problem Using Next-Key Locking

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where `id` would be bigger than 100, the locks set by InnoDB include a lock on the gap following `id` value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read

prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in [Section 14.2.2.4, “InnoDB Record, Gap, and Next-Key Locks”](#). This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

### 14.2.2.6 Predicate Locking for Spatial Indexes

As of MySQL 5.7.5, InnoDB supports `SPATIAL` indexing of columns containing spatial columns (see [Section 11.5.3.5, “Optimizing Spatial Analysis”](#)).

To handle locking for operations involving `SPATIAL` indexes, next-key locking does not work well to support `REPEATABLE READ` or `SERIALIZABLE` transaction isolation levels. There is no absolute ordering concept in multidimensional data, so it is not clear which is the “next” key.

To enable support of isolation levels for tables with `SPATIAL` indexes, InnoDB uses predicate locks. A `SPATIAL` index contains minimum bounding rectangle (MBR) values, so InnoDB enforces consistent read on the index by setting a predicate lock on the MBR value used for a query. Other transactions cannot insert or modify a row that would match the query condition.

### 14.2.2.7 Locks Set by Different SQL Statements in InnoDB

A `locking read`, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are `WHERE` conditions in the statement that would exclude the row. InnoDB does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The locks are normally `next-key locks` that also block inserts into the “gap” immediately before the record. However, `gap locking` can be disabled explicitly, which causes next-key locking not to be used. For more information, see [Section 14.2.2.4, “InnoDB Record, Gap, and Next-Key Locks”](#). The transaction isolation level also can affect which locks are set; see [Section 13.3.6, “SET TRANSACTION Syntax”](#).

If a secondary index is used in a search and index record locks to be set are exclusive, InnoDB also retrieves the corresponding clustered index records and sets locks on them.

Differences between shared and exclusive locks are described in [Section 14.2.2.1, “InnoDB Lock Modes”](#).

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

For `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`, locks are acquired for scanned rows, and expected to be released for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the `WHERE` clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a `UNION`, scanned (and locked) rows from a table might be inserted into a temporary table before evaluation whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.

InnoDB sets specific types of locks as follows.

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, the search sets shared next-key locks on the index records it encounters.
- `SELECT ... FROM ... LOCK IN SHARE MODE` sets shared next-key locks on all index records the search encounters.

- For index records the search encounters, `SELECT ... FROM ... FOR UPDATE` blocks other sessions from doing `SELECT ... FROM ... LOCK IN SHARE MODE` or from reading in certain transaction isolation levels. Consistent reads will ignore any locks set on the records that exist in the read view.
- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- `INSERT` sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insertion intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an InnoDB table `t1` has the following structure:

```
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;  
DELETE FROM t1 WHERE i = 1;
```

Session 2:

```
START TRANSACTION;  
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;  
INSERT INTO t1 VALUES(1);
```

Session 1:

```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- `INSERT ... ON DUPLICATE KEY UPDATE` differs from a simple `INSERT` in that an exclusive next-key lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs.
- `REPLACE` is done like an `INSERT` if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.
- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive index record lock (without a gap lock) on each row inserted into `T`. If the transaction isolation level is `READ COMMITTED`, or `innodb_locks_unsafe_for_binlog` is enabled and the transaction isolation level is not `SERIALIZABLE`, InnoDB does the search on `S` as a consistent read (no locks). Otherwise, InnoDB sets shared next-key locks on rows from `S`. InnoDB has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement must be executed in exactly the same way it was done originally.

`CREATE TABLE ... SELECT ...` performs the `SELECT` with shared next-key locks or as a consistent read, as for `INSERT ... SELECT`.

When a `SELECT` is used in the constructs `REPLACE INTO t SELECT ... FROM s WHERE ...` or `UPDATE t ... WHERE col IN (SELECT ... FROM s ...)`, InnoDB sets shared next-key locks on rows from table `s`.

- While initializing a previously specified `AUTO_INCREMENT` column on a table, InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, InnoDB uses a specific `AUTO-INC` table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other sessions cannot insert into the table while the `AUTO-INC` table lock is held; see [Section 14.2.2, “The InnoDB Transaction Model and Locking”](#).

InnoDB fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.

- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above InnoDB knows about row-level locks.

Otherwise, InnoDB's automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in [Section 14.2.2.9, "Deadlock Detection and Rollback"](#). See also [Section 14.5.7, "Limits on InnoDB Tables"](#).

### 14.2.2.8 Implicit Transaction Commit and Rollback

By default, MySQL starts the session for each new connection with autocommit mode enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See [Section 14.18.4, "InnoDB Error Handling"](#).

If a session that has autocommit disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see [Section 13.3.3, "Statements That Cause an Implicit Commit"](#).

### 14.2.2.9 Deadlock Detection and Rollback

InnoDB automatically detects transaction [deadlocks](#) and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement rolls back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction rolls back.

For techniques to organize database operations to avoid deadlocks, see [Section 14.2.2.10, "How to Cope with Deadlocks"](#).

### 14.2.2.10 How to Cope with Deadlocks

This section builds on the conceptual information about deadlocks in [Section 14.2.2.9, "Deadlock Detection and Rollback"](#). It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

[Deadlocks](#) are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really "atomic"; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- At any time, issue the `SHOW ENGINE INNODB STATUS` command to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.
- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the `innodb_print_all_deadlocks` configuration option. Information about each deadlock, not just the latest one, is recorded in the MySQL [error log](#). Disable this option when you are finished debugging.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Keep transactions small and short in duration to make them less prone to collision.
- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive `mysql` session open for a long time with an uncommitted transaction.
- If you use [locking reads](#) (`SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.
- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of `INSERT`, `UPDATE`, and `DELETE` statements in different places.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to permit a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as `InnoDB` tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the `InnoDB` instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

### 14.2.3 InnoDB Multi-Versioning

InnoDB is a [multi-versioned storage engine](#): it keeps information about old versions of changed rows, to support transactional features such as concurrency and [rollback](#). This information is stored in the tablespace in a data structure called a [rollback segment](#) (after an analogous data structure in Oracle). InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a [consistent read](#).

Internally, InnoDB adds three fields to each row stored in the database. A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated. A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If InnoDB generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

Commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. InnoDB only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a [purge](#), and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such a case, throttle new row operations, and allocate more resources to the purge thread by tuning the `innodb_max_purge_lag` system variable. See [Section 14.11, “InnoDB Startup Options and System Variables”](#) for more information.

## Multi-Versioning and Secondary Indexes

InnoDB multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, InnoDB looks up the database record in the clustered index. In the clustered index, the record's `DB_TRX_ID` is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the [covering index](#) technique is not used. Instead of returning values from the index structure, InnoDB looks up the record in the clustered index.

However, if the [index condition pushdown \(ICP\)](#) optimization is enabled, and parts of the `WHERE` condition can be evaluated using only fields from the index, the MySQL server still pushes this part of the `WHERE` condition down to the storage engine where it is evaluated using the index. If no matching records are found, the clustered index lookup is avoided. If matching records are found, even among delete-marked records, InnoDB looks up the record in the clustered index.

## 14.2.4 InnoDB Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change InnoDB table data, which result from SQL statements or low-level API calls. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically during initialization, and before the connections are accepted. For information about the role of the redo log in crash recovery, see [Section 14.15.1, “The InnoDB Recovery Process”](#).

By default, the redo log is physically represented on disk as a set of files, named `ib_logfile0` and `ib_logfile1`. MySQL writes to the redo log files in a circular fashion. Data in the redo log is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo log is represented by an ever-increasing LSN value.

Disk layout for the redo log is configured using the following options:

- `innodb_log_file_size`: Defines the size of each redo log file in bytes. By default, redo log files are 50331648 bytes (48MB) in size. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB.
- `innodb_log_files_in_group`: The number of log files in the log group. The default is to create two files named `ib_logfile0` and `ib_logfile1`.
- `innodb_log_group_home_dir`: The directory path to the InnoDB log files. If you do not specify a value, the log files are created in the MySQL data directory (`datadir`).

To change your initial redo log configuration, refer to [Section 14.4.2, “Changing the Number or Size of InnoDB Redo Log Files”](#). For information about optimizing redo logging, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

### 14.2.4.1 Group Commit for Redo Log Flushing

InnoDB, like any other ACID-compliant database engine, flushes the redo log of a transaction before it is committed. InnoDB uses group commit functionality to group multiple such flush requests together to avoid one flush for each commit. With group commit, InnoDB issues a single write to the log file to perform the commit action for multiple user transactions that commit at about the same time, significantly improving throughput.

For more information about performance of `COMMIT` and other transactional operations, see [Section 8.5.2, “Optimizing InnoDB Transaction Management”](#).

## 14.2.5 InnoDB Undo Logs

An undo log (or rollback segment) is a storage area that holds copies of data modified by active transactions. If another transaction needs to see the original data (as part of a consistent read operation), the unmodified data is retrieved from this storage area. By default, this area is physically part of the system tablespace. However, as of MySQL 5.6.3, undo logs can reside in separate tablespaces. For more information, see [Section 14.4.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#). For more information about undo logs and multi-versioning, see [Section 14.2.3, “InnoDB Multi-Versioning”](#).

InnoDB supports 128 undo logs. As of MySQL 5.7.2, 32 of 128 undo logs were reserved as non-redo undo logs for temporary table transactions. Each transaction that updates a temporary table (excluding read-only transactions) is assigned two undo logs, one redo-enabled undo log and one non-redo undo

log. Read-only transactions are only assigned non-redo undo logs, as read-only transactions are only permitted to modify temporary tables.

This leaves 96 available undo logs, each of which supports up to 1023 concurrent data-modifying transactions, for a total limit of approximately 96K concurrent data-modifying transactions. The 96K limit assumes that transactions do not modify temporary tables. If all data-modifying transactions also modify temporary tables, the total limit would be approximately 32K concurrent data modifying transactions. For more information about undo logs that are reserved for temporary table transactions, see [Section 14.2.6, “InnoDB Temporary Table Undo Logs”](#).

The `innodb_undo_logs` option defines the number of undo logs used by InnoDB.

## 14.2.6 InnoDB Temporary Table Undo Logs

MySQL 5.7.2 introduces a new type of undo log for both normal and compressed temporary tables and related objects. This type of [undo log](#) is not a redo log, as temporary tables are not recovered during crash recovery and do not require redo logs. Temporary table undo logs are, however, used for rollback while the server is running. This special type of non-redo undo log benefits performance by avoiding redo logging I/O for temporary tables and related objects. Temporary table undo logs reside in the temporary tablespace. The default temporary tablespace file, `ibtmp1`, is located in the data directory by default and is always recreated on server startup. A user defined location for the temporary tablespace file can be specified by setting `innodb_temp_data_file_path`.

With this change, 32 [rollback segments](#) are now reserved for temporary table [undo logs](#) for transactions that modify temporary tables and related objects. This reduces the maximum number of rollback segments available for data-modifying transactions that generate undo records from 128 to 96, which reduces the limit on concurrent data-modifying transactions from 128K to 96K. For more information see [Section 14.2.3, “InnoDB Multi-Versioning”](#) and [Section 14.5.7, “Limits on InnoDB Tables”](#).

## 14.2.7 InnoDB Table and Index Structures

This section describes how InnoDB tables, indexes, and their associated metadata is represented at the physical level. This information is primarily useful for performance tuning and troubleshooting.

### 14.2.7.1 Role of the .frm File for InnoDB Tables

MySQL stores its data dictionary information for tables in [.frm files](#) in database directories. Unlike other MySQL storage engines, InnoDB also encodes information about the table in its own internal data dictionary inside the tablespace. When MySQL drops a table or a database, it deletes one or more [.frm](#) files as well as the corresponding entries inside the InnoDB data dictionary. You cannot move InnoDB tables between databases simply by moving the [.frm](#) files.

### 14.2.7.2 Clustered and Secondary Indexes

Every InnoDB table has a special index called the [clustered index](#) where the data for the rows is stored. Typically, the clustered index is synonymous with the [primary key](#). To get the best performance from queries, inserts, and other database operations, you must understand how InnoDB uses the clustered index to optimize the most common lookup and DML operations for each table.

- When you define a `PRIMARY KEY` on your table, InnoDB uses it as the clustered index. Define a primary key for each table that you create. If there is no logical unique and non-null column or set of columns, add a new [auto-increment](#) column, whose values are filled in automatically.
- If you do not define a `PRIMARY KEY` for your table, MySQL locates the first `UNIQUE` index where all the key columns are `NOT NULL` and InnoDB uses it as the clustered index.
- If the table has no `PRIMARY KEY` or suitable `UNIQUE` index, InnoDB internally generates a hidden clustered index on a synthetic column containing row ID values. The rows are ordered by the ID that

InnoDB assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

## How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the index search leads directly to the page with all the row data. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record. (For example, MyISAM uses one file for data rows and another for index records.)

## How Secondary Indexes Relate to the Clustered Index

All indexes other than the clustered index are known as [secondary indexes](#). In InnoDB, each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. InnoDB uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

For coding guidelines to take advantage of InnoDB clustered and secondary indexes, see [Section 8.3.2, “Using Primary Keys”](#) [Section 8.3, “Optimization and Indexes”](#) [Section 8.5, “Optimizing for InnoDB Tables”](#) [Section 8.3.2, “Using Primary Keys”](#).

### 14.2.7.3 InnoDB FULLTEXT Indexes

FULLTEXT indexes are created on text-based columns (CHAR, VARCHAR, or TEXT columns) to help speed up queries and DML operations on data contained within those columns, omitting any words that are defined as stopwords.

A FULLTEXT index can be defined as part of a CREATE TABLE statement, or added later using ALTER TABLE or CREATE INDEX.

Full-text searching is performed using MATCH() ... AGAINST [1446] syntax. For usage information, see [Section 12.9, “Full-Text Search Functions”](#).

## Full-Text Index Design

InnoDB FULLTEXT indexes have an inverted index design. Inverted indexes store a list of words, and for each word, a list of documents that the word appears in. To support proximity search, position information for each word is also stored, as a byte offset.

## Full-text Index Tables

For each InnoDB FULLTEXT index, a set of index tables is created, as shown in the following example:

```
CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200),
  FULLTEXT idx (opening_line)
) ENGINE=InnoDB;
```

```
mysql> SELECT table_id, name, space from INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE name LIKE 'test/%';
```

table_id	name	space
333	test/FTS_0000000000000147_0000000000001c9_INDEX_1	289
334	test/FTS_0000000000000147_0000000000001c9_INDEX_2	290
335	test/FTS_0000000000000147_0000000000001c9_INDEX_3	291
336	test/FTS_0000000000000147_0000000000001c9_INDEX_4	292
337	test/FTS_0000000000000147_0000000000001c9_INDEX_5	293
338	test/FTS_0000000000000147_0000000000001c9_INDEX_6	294
330	test/FTS_0000000000000147_BEING_DELETED	286
331	test/FTS_0000000000000147_BEING_DELETED_CACHE	287

332	test/FTS_0000000000000147_CONFIG	288
328	test/FTS_0000000000000147_DELETED	284
329	test/FTS_0000000000000147_DELETED_CACHE	285
327	test/opening_lines	283

The first six tables represent the inverted index and are referred to as auxiliary index tables. When incoming documents are tokenized, the individual words (also referred to as “tokens”) are inserted into the index tables along with position information and the associated Document ID (`DOC_ID`). The words are fully sorted and partitioned among the six index tables based on the character set sort weight of the word's first character.

The inverted index is partitioned into six auxiliary index tables to support parallel index creation. By default, two threads tokenize, sort, and insert words and associated data into the index tables. The number of threads is configurable using the `innodb_ft_sort_pll_degree` option. When creating `FULLTEXT` indexes on large tables, consider increasing the number of threads.

Auxiliary index table names are prefixed with `FTS_` and postfixed with `INDEX_*`. Each index table is associated with the indexed table by a hex value in the index table name that matches the `table_id` of the indexed table. For example, the `table_id` of the `test/opening_lines` table is 327, for which the hex value is 0x147. As shown in the preceding example, the “147” hex value appears in the names of index tables that are associated with the `test/opening_lines` table.

A hex value representing the `index_id` of the `FULLTEXT` index also appears in auxiliary index table names. For example, in the auxiliary table name `test/FTS_0000000000000147_0000000000001c9_INDEX_1`, the hex value `1c9` has a decimal value of 457. The index defined on the `opening_lines` table (`idx`) can be identified by querying the `INFORMATION_SCHEMA.INNODB_SYS_INDEXES` table for this value (457).

```
mysql> SELECT index_id, name, table_id, space from INFORMATION_SCHEMA.INNODB_SYS_INDEXES
WHERE index_id=457;
+-----+-----+-----+-----+
| index_id | name | table_id | space |
+-----+-----+-----+-----+
|      457 | idx  |      327 |    283 |
+-----+-----+-----+-----+
```

Index tables are stored in their own tablespace if the primary table is created in a file-per-table tablespace.

#### Note

Due to a bug introduced in MySQL 5.6.5, index tables were created in the `InnoDB` system tablespace (space 0) even though the primary table was created in a file-per-table tablespace. The bug is fixed in MySQL 5.6.20 and MySQL 5.7.5 (Bug#18635485). As of MySQL 5.7.8, auxiliary index tables are always stored in the same tablespace as the primary table and have the same row format as the primary table (MySQL Bug #75869).

The other index tables shown in the preceding example are used for deletion handling and for storing the internal state of the `FULLTEXT` index.

- `FTS_*_DELETED` and `FTS_*_DELETED_CACHE`: Contain the document IDs (`DOC_ID`) for documents that are deleted but whose data is not yet removed from the full-text index. The `FTS_*_DELETED_CACHE` is the in-memory version of the `FTS_*_DELETED` table.
- `FTS_*_BEING_DELETED` and `FTS_*_BEING_DELETED_CACHE`: Contain the document IDs (`DOC_ID`) for documents that are deleted and whose data is currently in the process of being removed from the full-text index. The `FTS_*_BEING_DELETED_CACHE` table is the in-memory version of the `FTS_*_BEING_DELETED` table.
- `FTS_*_CONFIG`: Stores information about the internal state of the `FULLTEXT` index. Most importantly, it stores the `FTS_SYNCED_DOC_ID`, which identifies documents that have been

parsed and flushed to disk. In case of crash recovery, `FTS_SYNCED_DOC_ID` values are used to identify documents that have not been flushed to disk so that the documents can be re-parsed and added back to the `FULLTEXT` index cache. To view the data in this table, query the `INFORMATION_SCHEMA.INNODB_FT_CONFIG` table.

## Full-Text Index Cache

When a document is inserted, it is tokenized, and the individual words and associated data are inserted into the `FULLTEXT` index. This process, even for small documents, could result in numerous small insertions into the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, `InnoDB` uses a `FULLTEXT` index cache to temporarily cache index table insertions for recently inserted rows. This in-memory cache structure holds insertions until the cache is full and then batch flushes them to disk (to the auxiliary index tables). You can query the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table to view tokenized data for recently inserted rows.

The caching and batch flushing behavior avoids frequent updates to auxiliary index tables, which could result in concurrent access issues during busy insert and update times. The batching technique also avoids multiple insertions for the same word, and minimizes duplicate entries. Instead of flushing each word individually, insertions for the same word are merged and flushed to disk as a single entry, improving insertion efficiency while keeping auxiliary index tables as small as possible.

The `innodb_ft_cache_size` variable is used to configure the full-text index cache size (on a per-table basis), which affects how often the full-text index cache is flushed. You can also define a global full-text index cache size limit for all tables in a given instance using the `innodb_ft_total_cache_size` option.

The full-text index cache stores the same information as auxiliary index tables. However, the full-text index cache only caches tokenized data for recently inserted rows. The data that is already flushed to disk (to the full-text auxiliary tables) is not brought back into the full-text index cache when queried. The data in auxiliary index tables is queried directly, and results from the auxiliary index tables are merged with results from the full-text index cache before being returned.

## InnoDB Full-Text Document ID and `FTS_DOC_ID` Column

`InnoDB` uses a unique document identifier referred to as a Document ID (`DOC_ID`) to map words in the full-text index to document records where the word appears. The mapping requires an `FTS_DOC_ID` column on the indexed table. If an `FTS_DOC_ID` column is not defined, `InnoDB` automatically adds a hidden `FTS_DOC_ID` column when the full-text index is created. The following example demonstrates this behavior.

The following table definition does not include an `FTS_DOC_ID` column:

```
CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200)
) ENGINE=InnoDB;
```

When you create a full-text index on the table using `CREATE FULLTEXT INDEX` syntax, a warning is returned which reports that `InnoDB` is rebuilding the table to add the `FTS_DOC_ID` column.

```
mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (0.19 sec)
Records: 0 Duplicates: 0 Warnings: 1
```

```
mysql> SHOW WARNINGS;
```

```
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 124 | InnoDB rebuilding table to add column FTS_DOC_ID |
+-----+-----+-----+
```

The same warning is returned when using `ALTER TABLE` to add a full-text index to a table that does not have an `FTS_DOC_ID` column. If you create a full-text index at `CREATE TABLE` time and do not specify an `FTS_DOC_ID` column, InnoDB adds a hidden `FTS_DOC_ID` column, without warning.

Defining an `FTS_DOC_ID` column at `CREATE TABLE` time reduces the time required to create a full-text index on a table that is already loaded with data. If an `FTS_DOC_ID` column is defined on a table prior to loading data, the table and its indexes do not have to be rebuilt to add the new column. If you are not concerned with `CREATE FULLTEXT INDEX` performance, leave out the `FTS_DOC_ID` column to have InnoDB create it for you. InnoDB creates a hidden `FTS_DOC_ID` column along with a unique index (`FTS_DOC_ID_INDEX`) on the `FTS_DOC_ID` column. If you want to create your own `FTS_DOC_ID` column, the column must be defined as `BIGINT UNSIGNED NOT NULL` and named `FTS_DOC_ID` (all upper case), as in the following example:

#### Note

The `FTS_DOC_ID` column does not need to be defined as an `AUTO_INCREMENT` column but `AUTO_INCREMENT` could make loading data easier.

```
CREATE TABLE opening_lines (
  FTS_DOC_ID BIGINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200)
) ENGINE=InnoDB;
```

If you choose to define the `FTS_DOC_ID` column yourself, you are responsible for managing the column to avoid empty or duplicate values. `FTS_DOC_ID` values cannot be reused, which means `FTS_DOC_ID` values must be ever increasing.

Optionally, you can create the required unique `FTS_DOC_ID_INDEX` (all upper case) on the `FTS_DOC_ID` column.

```
CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on opening_lines(FTS_DOC_ID);
```

If you do not create the `FTS_DOC_ID_INDEX`, InnoDB creates it automatically.

## InnoDB Full-Text Index Deletion Handling

Deleting a record that has a full-text index column could result in numerous small deletions in the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, the Document ID (`DOC_ID`) of a deleted document is logged in a special `FTS_*_DELETED` table whenever a record is deleted from an indexed table, and the indexed record remains in the full-text index. Before returning query results, information in the `FTS_*_DELETED` table is used to filter out deleted Document IDs. The benefit of this design is that deletions are fast and inexpensive. The drawback is that the size of the index is not immediately reduced after deleting records. To remove full-text index entries for deleted records, you must run `OPTIMIZE TABLE` on the indexed table with `innodb_optimize_fulltext_only=ON` to rebuild the full-text index. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

## InnoDB Full-Text Index Transaction Handling

InnoDB `FULLTEXT` indexes have special transaction handling characteristics due its caching and batch processing behavior. Specifically, updates and insertions on a `FULLTEXT` index are processed at transaction commit time, which means that a `FULLTEXT` search can only see committed data. The following example demonstrates this behavior. The `FULLTEXT` search only returns a result after the inserted lines are committed.

```
mysql> CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200),
```

```

FULLTEXT idx (opening_line)
) ENGINE=InnoDB;

mysql> BEGIN;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
('Call me Ishmael.','Herman Melville','Moby-Dick'),
('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
('I am an invisible man.','Ralph Ellison','Invisible Man'),
('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),
('It was love at first sight.','Joseph Heller','Catch-22'),
('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'),
('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'),
('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');
Query OK, 8 rows affected (0.00 sec)
Records: 8  Duplicates: 0  Warnings: 0

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+-----+
| COUNT(*) |
+-----+
|          0 |
+-----+

mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+-----+
| COUNT(*) |
+-----+
|          1 |
+-----+

```

## Monitoring InnoDB Full-Text Indexes

You can monitor and examine the special text-processing aspects of [InnoDB FULLTEXT](#) indexes by querying the following [INFORMATION\\_SCHEMA](#) tables:

- [INNODB\\_FT\\_CONFIG](#)
- [INNODB\\_FT\\_INDEX\\_TABLE](#)
- [INNODB\\_FT\\_INDEX\\_CACHE](#)
- [INNODB\\_FT\\_DEFAULT\\_STOPWORD](#)
- [INNODB\\_FT\\_DELETED](#)
- [INNODB\\_FT\\_BEING\\_DELETED](#)

You can also view basic information for [FULLTEXT](#) indexes and tables by querying [INNODB\\_SYS\\_INDEXES](#) and [INNODB\\_SYS\\_TABLES](#).

See [Section 14.12.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#) for more information.

### 14.2.7.4 Physical Structure of an InnoDB Index

With the exception of spatial indexes, [InnoDB](#) indexes are [B-tree](#) data structures. Spatial indexes use [R-trees](#), which are specialized data structures for indexing multi-dimensional data. Index records are stored in the leaf pages of their B-tree or R-tree data structure. The default size of an index page is 16KB.

When new records are inserted into an [InnoDB clustered index](#), [InnoDB](#) tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential

order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full.

As of MySQL 5.7.5, InnoDB performs a bulk load when creating or rebuilding B-tree indexes. This method of index creation is known as a sorted index build. `innodb_fill_factor` defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. Sorted index builds are not supported for spatial indexes. For more information, see [Section 14.2.7.8, “Sorted Index Builds”](#). As of MySQL 5.7.8, an `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

If the fill factor of an InnoDB index page drops below the `MERGE_THRESHOLD`, which is 50% by default if not specified, InnoDB tries to contract the index tree to free the page. The `MERGE_THRESHOLD` setting applies to both B-tree and R-tree indexes. For more information, see [Section 14.3.12, “Configuring the Merge Threshold for Index Pages”](#).

You can configure the `page size` for all InnoDB tablespaces in a MySQL instance by setting the `innodb_page_size` configuration option before creating the instance. Once the page size for an instance is set, you cannot change it. Supported sizes are 64KB, 32KB, 16KB (default), 8KB, and 4KB, corresponding to the option values `64k`, `32k`, `16k`, `8k`, and `4k`.

Support for 32KB and 64KB pages sizes was added in MySQL 5.7.6. For more information, refer to the `innodb_page_size` documentation.

A MySQL instance using a particular InnoDB page size cannot use data files or log files from an instance that uses a different page size.

### 14.2.7.5 Change Buffer

The change buffer is a special data structure that caches changes to [secondary index](#) pages when affected pages are not in the [buffer pool](#). The buffered changes, which may result from `INSERT`, `UPDATE`, or `DELETE` operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

Unlike [clustered indexes](#), secondary indexes are usually non-unique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read-in secondary index pages from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are numerous secondary indexes to update and many affected rows. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed. In fact, change buffer merging may continue to occur after a server shutdown and restart (see [Section 14.18.2, “Forcing InnoDB Recovery”](#) for more information).

In memory, the change buffer occupies part of the InnoDB buffer pool. On disk, the change buffer is part of the system tablespace, so that index changes remain buffered across database restarts.

The type of data cached in the change buffer is governed by the `innodb_change_buffering` configuration option. For more information see, [Section 14.3.5, “Configuring InnoDB Change Buffering”](#). You can also configure the maximum change buffer size. For more information, see [Section 14.3.5.1, “Configuring the Change Buffer Maximum Size”](#).

### Monitoring the Change Buffer

The following options are available for change buffer monitoring:

- [InnoDB Standard Monitor](#) output includes status information for the change buffer. To view monitor data, issue the `SHOW ENGINE INNODB STATUS` command.

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Change buffer status information is located under the `INSERT BUFFER AND ADAPTIVE HASH INDEX` heading and appears similar to the following:

```
-----
INSERT BUFFER AND ADAPTIVE HASH INDEX
-----
Ibuf: size 1, free list len 0, seg size 2, 0 merges
merged operations:
  insert 0, delete mark 0, delete 0
discarded operations:
  insert 0, delete mark 0, delete 0
Hash table size 4425293, used cells 32, node heap has 1 buffer(s)
13577.57 hash searches/s, 202.47 non-hash searches/s
```

For a description of each data point, see [Section 14.14.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

- The `INFORMATION_SCHEMA.INNODB_METRICS` table provides most of the data points found in [InnoDB Standard Monitor](#) output, plus other data points. To view change buffer metrics and a description of each, issue the following query:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%ibuf%'\G
```

For `INNODB_METRICS` table usage information, see [Section 14.12.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

- The `INFORMATION_SCHEMA.INNODB_BUFFER_PAGE` table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by `PAGE_TYPE`. `IBUF_INDEX` is the page type for change buffer index pages, and `IBUF_BITMAP` is the page type for change buffer bitmap pages.

### Warning

Querying the `INNODB_BUFFER_PAGE` table can introduce significant performance overhead. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

For example, you can query the `INNODB_BUFFER_PAGE` table to determine the approximate number of `IBUF_INDEX` and `IBUF_BITMAP` pages as a percentage of total buffer pool pages.

```
SELECT
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
   WHERE PAGE_TYPE LIKE 'IBUF%')
  AS change_buffer_pages,
  (
    SELECT COUNT(*)
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  ) AS total_pages,
  (
    SELECT ((change_buffer_pages/total_pages)*100)
  ) AS change_buffer_page_percentage;
+-----+-----+-----+
| change_buffer_pages | total_pages | change_buffer_page_percentage |
+-----+-----+-----+
|                25 |          8192 |                   0.3052 |
+-----+-----+-----+
```

For information about other data provided by the `INNODB_BUFFER_PAGE` table, see [Section 20.30.17, “The INFORMATION\\_SCHEMA INNODB\\_BUFFER\\_PAGE Table”](#). For related usage information, see [Section 14.12.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

- [Performance Schema](#) provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query:

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/ibuf_bitmap_mutex	YES	YES
wait/synch/mutex/innodb/ibuf_mutex	YES	YES
wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex	YES	YES

For information about monitoring [InnoDB](#) mutex waits, see [Section 14.13.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#).

### 14.2.7.6 Adaptive Hash Indexes

The feature known as the [adaptive hash index](#) (AHI) lets [InnoDB](#) perform more like an in-memory database on systems with appropriate combinations of workload and ample memory for the [buffer pool](#), without sacrificing any transactional features or reliability. This feature is enabled by the [innodb\\_adaptive\\_hash\\_index](#) option, or turned off by the `--skip-innodb_adaptive_hash_index` at server startup.

Based on the observed pattern of searches, MySQL builds a hash index using a prefix of the index key. The prefix of the key can be any length, and it may be that only some of the values in the B-tree appear in the hash index. Hash indexes are built on demand for those pages of the index that are often accessed.

If a table fits almost entirely in main memory, a hash index can speed up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. [InnoDB](#) has a mechanism that monitors index searches. If [InnoDB](#) notices that queries could benefit from building a hash index, it does so automatically.

With some [workloads](#), the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Sometimes, the read/write lock that guards access to the adaptive hash index can become a source of contention under heavy workloads, such as multiple concurrent joins. Queries with `LIKE` operators and `%` wildcards also tend not to benefit from the AHI. For workloads where the adaptive hash index is not needed, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether this feature is appropriate for a particular system, consider running benchmarks with it both enabled and disabled, using a realistic workload. The architectural changes in MySQL 5.6 and higher make more workloads suitable for disabling the adaptive hash index than in earlier releases, although it is still enabled by default.

As of MySQL 5.7.8, the adaptive hash index search system is partitioned. Each index is bound to a specific partition, and each partition is protected by a separate latch. Partitioning is controlled by the [innodb\\_adaptive\\_hash\\_index\\_parts](#) configuration option. Prior to MySQL 5.7.8, the adaptive hash index search system was protected by a single latch which could become a point of contention under heavy workloads. The [innodb\\_adaptive\\_hash\\_index\\_parts](#) option is set to 8 by default. The maximum setting is 512.

The hash index is always built based on an existing [B-tree](#) index on the table. [InnoDB](#) can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that [InnoDB](#) observes for the B-tree index. A hash index can be partial, covering only those pages of the index that are often accessed.

You can monitor the use of the adaptive hash index and the contention for its use in the [SEMAPHORES](#) section of the output of the `SHOW ENGINE INNODB STATUS` command. If you see many threads waiting on an RW-latch created in `btr0sea.c`, then it might be useful to disable adaptive hash indexing.

For more information about the performance characteristics of hash indexes, see [Section 8.3.8, “Comparison of B-Tree and Hash Indexes”](#).

### 14.2.7.7 Physical Row Structure

The physical row structure of an [InnoDB](#) table depends on the row format specified when the table is created. If a row format is not specified, the default row format is used. In MySQL 5.7.6 and earlier, [InnoDB](#) uses the [Antelope](#) file format and its [COMPACT](#) row format by default. In MySQL 5.7.7, the [innodb\\_file\\_format](#) default was changed to [Barracuda](#), and in MySQL 5.7.9, the default row format is defined by the [innodb\\_default\\_row\\_format](#) configuration option, which has a default value of [DYNAMIC](#).

The [REDUNDANT](#) format is available to retain compatibility with older versions of MySQL.

To check the row format of an [InnoDB](#) table, you can use [SHOW TABLE STATUS](#). For example:

```
mysql> SHOW TABLE STATUS IN test1\G
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 16384
      Data_free: 0
      Auto_increment: 1
      Create_time: 2014-10-31 16:02:01
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
```

You can also check the row format of an [InnoDB](#) table by querying [INFORMATION\\_SCHEMA.INNODB\\_SYS\\_TABLES](#).

```
mysql> SELECT NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test1/t1';
+-----+-----+
| NAME      | ROW_FORMAT |
+-----+-----+
| test1/t1  | Compact    |
+-----+-----+
```

The [COMPACT](#) row format decreases row storage space by about 20% at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, [COMPACT](#) format is likely to be faster. If the workload is a rare case that is limited by CPU speed, [COMPACT](#) format might be slower.

Rows in [InnoDB](#) tables that use [REDUNDANT](#) row format have the following characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index.

- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. InnoDB does not truncate trailing spaces from `VARCHAR` columns.
- An SQL `NULL` value reserves one or two bytes in the record directory. Besides that, an SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. Reserving the fixed space for `NULL` values enables an update of the column from `NULL` to a non-`NULL` value to be done in place without causing fragmentation of the index page.

Rows in InnoDB tables that use `COMPACT` row format have the following characteristics:

- Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.
- The variable-length part of the record header contains a bit vector for indicating `NULL` columns. If the number of columns in the index that can be `NULL` is  $N$ , the bit vector occupies  $\text{CEILING}(N/8)$  bytes. (For example, if there are anywhere from 9 to 15 columns that can be `NULL`, the bit vector uses two bytes.) Columns that are `NULL` do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are `NOT NULL` and have a fixed length, the record header has no variable-length part.
- For each non-`NULL` variable-length field, the record header contains the length of the column in one or two bytes. Two bytes will only be needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.
- The record header is followed by the data contents of the non-`NULL` columns.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index. If any of these primary key fields are variable length, the record header for each secondary index will have a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.
- Internally, InnoDB stores fixed-length, fixed-width character columns such as `CHAR(10)` in a fixed-length format. InnoDB does not truncate trailing spaces from `VARCHAR` columns.
- Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. InnoDB does not truncate trailing spaces from `VARCHAR` columns.
- An SQL `NULL` value reserves one or two bytes in the record directory. Besides that, an SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. Reserving the fixed space for `NULL` values enables an update of the column from `NULL` to a non-`NULL` value to be done in place without causing fragmentation of the index page.
- Internally, InnoDB attempts to store `utf8 CHAR(N)` and `utf8mb4 CHAR(N)` columns in  $N$  bytes by trimming trailing spaces. If the byte length of a `CHAR(N)` column value exceeds  $N$  bytes, InnoDB trims trailing spaces to a minimum of the column value byte length. The maximum

length of a `CHAR(N)` column is the maximum character byte length  $\times N$ , as reported by the `CHARACTER_OCTET_LENGTH` column of the `INFORMATION_SCHEMA.COLUMNS` table.

InnoDB reserves a minimum of  $N$  bytes for `CHAR(N)`. Reserving the minimum space  $N$  in many cases enables column updates to be done in place without causing fragmentation of the index page.

By comparison, for `ROW_FORMAT=REDUNDANT`, `utf8` and `utf8mb4` columns occupy the maximum character byte length  $\times N$ . `ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPRESSED` handle `CHAR` storage in the same way as `ROW_FORMAT=COMPACT`.

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format. For information about these row formats, see [Section 14.8.3, “DYNAMIC and COMPRESSED Row Formats”](#).

### 14.2.7.8 Sorted Index Builds

As of MySQL 5.7.5, InnoDB performs a bulk load instead of inserting one index record at a time when creating or rebuilding indexes. This method of index creation is also known as a sorted index build. Sorted index builds are not supported for spatial indexes.

There are three phases to an index build. In the first phase, the [clustered index](#) is scanned, and index entries are generated and added to the sort buffer. When the [sort buffer](#) becomes full, entries are sorted and written out to a temporary intermediate file. This process is also known as a “run”. In the second phase, with one or more runs written to the temporary intermediate file, a merge sort is performed on all entries in the file. In the third and final phase, the sorted entries are inserted into the [B-tree](#).

Prior to the introduction of sorted index builds, index entries were inserted into the B-tree one record at a time using insert APIs. This method involved opening a B-tree [cursor](#) to find the insert position and then inserting entries into a B-tree page using an [optimistic](#) insert. If an insert failed due to a page being full, a [pessimistic](#) insert would be performed, which involves opening a B-tree cursor and splitting and merging B-tree nodes as necessary to find space for the entry. The drawbacks of this “top-down” method of building an index are the cost of searching for an insert position and the constant splitting and merging of B-tree nodes.

Sorted index builds use a bottom up approach to building an index. With this approach, a reference to the right-most leaf page is held at all levels of the B-tree. The right-most leaf page at the necessary B-tree depth is allocated and entries are inserted according to their sorted order. Once a leaf page is full, a node pointer is appended to the parent page and a sibling leaf page is allocated for the next insert. This process continues until all entries are inserted, which may result in inserts up to the root level. When a sibling page is allocated, the reference to the previously pinned leaf page is released, and the newly allocated leaf page becomes the right-most leaf page and new default insert location.

### Reserving B-tree Page Space for Future Index Growth

To set aside space for future index growth, you can use the `innodb_fill_factor` configuration option to reserve a percentage of B-tree page space. For example, setting `innodb_fill_factor` to 80 will reserve 20 percent of the space in B-tree pages during a sorted index build. This setting applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for `TEXT` or `BLOB` entries. The amount of space that is reserved may not be exactly as configured, as the `innodb_fill_factor` value is interpreted as a hint rather than a hard limit.

### Sorted Index Builds and Fulltext Index Support

Sorted index builds are supported for [fulltext indexes](#). Previously, SQL was used to insert entries into a fulltext index.

### Sorted Index Builds and Compressed Tables

For [compressed tables](#), the previous index creation method appended entries to both compressed and uncompressed pages. When the modification log (representing free space on the compressed page)

became full, the compressed page would be recompressed. If compression failed due to a lack of space, the page would be split. With sorted index builds, entries are only appended to uncompressed pages. When an uncompressed page becomes full, it is compressed. Adaptive padding is used to ensure that compression succeeds in most cases, but if compression fails, the page is split and compression is attempted again. This process continues until compression is successful. For additional information about compression of B-Tree pages, see [Section 14.6.1.5, “How Compression Works for InnoDB Tables”](#).

## Sorted Index Builds and Redo Logging

[Redo logging](#) is turned off during a sorted index build. Instead, there is a [checkpoint](#) to ensure that the index build can withstand a crash or failure. The checkpoint forces a write of all dirty pages to disk. During a sorted index build, the [page cleaner](#) thread is signaled periodically to flush [dirty pages](#) to ensure that the checkpoint operation can be processed quickly. Normally, the page cleaner thread flushes dirty pages when the number of clean pages falls below a set threshold. For sorted index builds, dirty pages are flushed promptly to reduce checkpoint overhead and to parallelize IO and CPU activity.

## Sorted Index Builds and Optimizer Statistics

Sorted index builds may result in [optimizer](#) statistics that differ from those generated by the previous method of index creation. The difference in statistics, which is not expected to affect workload performance, is due to the different algorithm that is used to populate the index.

## 14.2.8 InnoDB Mutex and Read/Write Lock Implementation

In MySQL and [InnoDB](#), multiple threads of execution access shared data structures. [InnoDB](#) synchronizes these accesses with its own implementation of [mutexes](#) and [read/write locks](#). Historically, [InnoDB](#) protected the internal state of a read/write lock with an [InnoDB](#) mutex, and the internal state of an [InnoDB](#) mutex was protected by a [Pthreads](#) mutex, as in IEEE Std 1003.1c (POSIX.1c).

On many platforms, [Atomic](#) operations can often be used to synchronize the actions of multiple threads more efficiently than Pthreads. Each operation to acquire or release a lock can be done in fewer CPU instructions, wasting less time when threads contend for access to shared data structures. This in turn means greater scalability on multi-core platforms.

On platforms that support [Atomic](#) operations, [InnoDB](#) now implements mutexes and read/write locks with the [built-in functions provided by the GNU Compiler Collection \(GCC\) for atomic memory access](#) instead of using the Pthreads approach. More specifically, [InnoDB](#) compiled with GCC version 4.1.2 or later uses the atomic builtins instead of a `pthread_mutex_t` to implement [InnoDB](#) mutexes and read/write locks.

On 32-bit Microsoft Windows, [InnoDB](#) implements mutexes (but not read/write locks) with hand-written assembler instructions. Beginning with Microsoft Windows 2000, functions for [Interlocked Variable Access](#) are available that are similar to the built-in functions provided by GCC. On Windows 2000 and higher, [InnoDB](#) makes use of the Interlocked functions, which support read/write locks and 64-bit platforms.

Solaris 10 introduced library functions for atomic operations, and [InnoDB](#) uses these functions by default. When MySQL is compiled on Solaris 10 or later with a compiler that does not support the [built-in functions provided by the GNU Compiler Collection \(GCC\) for atomic memory access](#), [InnoDB](#) uses the library functions.

On platforms where the GCC, Windows, or Solaris functions for atomic memory access are not available, [InnoDB](#) uses the traditional Pthreads method of implementing mutexes and read/write locks.

When MySQL starts, [InnoDB](#) writes a message to the log file indicating whether atomic memory access is used for mutexes, for mutexes and read/write locks, or neither. If suitable tools are used to build [InnoDB](#) and the target CPU supports the atomic operations required, [InnoDB](#) uses the built-

in functions for mutexing. If, in addition, the compare-and-swap operation can be used on thread identifiers (`pthread_t`), then InnoDB uses the instructions for read-write locks as well.

If you are building from source, ensure that the build process properly takes advantage of your platform capabilities.

For more information about the performance implications of locking, see [Section 8.11, “Optimizing Locking Operations”](#).

## 14.3 InnoDB Configuration

This section provides configuration information and procedures for InnoDB initialization, startup, and various components and features of the InnoDB storage engine. For information about optimizing database operations for InnoDB tables, see [Section 8.5, “Optimizing for InnoDB Tables”](#).

### 14.3.1 InnoDB Initialization and Startup Configuration

The first decisions to make about InnoDB configuration involve how to lay out InnoDB data files, and how much memory to allocate for the InnoDB storage engine. You record these choices either by recording them in a configuration file that MySQL reads at startup, or by specifying them as command-line options in a startup script. The full list of options, descriptions, and allowed parameter values is at [Section 14.11, “InnoDB Startup Options and System Variables”](#).

#### Overview of InnoDB Tablespace and Log Files

Two important disk-based resources managed by the InnoDB storage engine are its tablespace data files and its log files. If you specify no InnoDB configuration options, MySQL creates an auto-extending data file, slightly larger than 12MB, named `ibdata1` and two log files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Their size is given by the size of the `innodb_log_file_size` system variable. To get good performance, explicitly provide InnoDB parameters as discussed in the following examples. Naturally, edit the settings to suit your hardware and requirements.

The examples shown here are representative. See [Section 14.11, “InnoDB Startup Options and System Variables”](#) for additional information about InnoDB-related configuration parameters.

#### Considerations for Storage Devices

In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. The example illustrates how to do this. It places the two data files on different disks and places the log files on the third disk. InnoDB fills the tablespace beginning with the first data file. You can also use raw disk partitions (raw devices) as InnoDB data files, which may speed up I/O. See [Section 14.4.3, “Using Raw Disk Partitions for the System Tablespace”](#).

#### Caution

InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very `fsync()` system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, perform some “pull-the-plug” tests before using anything in production. On OS X 10.3 and up, InnoDB uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATA/SATA disk drives, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

With regard to InnoDB recovery capabilities that protect user data, InnoDB uses a file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default (`innodb_doublewrite=ON`). The doublewrite buffer adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations. It is recommended that the `innodb_doublewrite` option remains enabled if you are concerned with data integrity or possible failures. For additional information about the doublewrite buffer, see [Section 14.9, “InnoDB Disk I/O and File Space Management”](#).

### Caution

If reliability is a consideration for your data, do not configure InnoDB to use data files or log files on NFS volumes. Potential problems vary according to OS and version of NFS, and include such issues as lack of protection from conflicting writes, and limitations on maximum file sizes.

## Specifying the Location and Size for InnoDB Tablespace Files

To set up the InnoDB tablespace files, use the `innodb_data_file_path` option in the `[mysqld]` section of the `my.cnf` option file. On Windows, you can use `my.ini` instead. The value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (“;”) characters:

```
innodb_data_file_path=datafile_spec1[:datafile_spec2]...
```

For example, the following setting explicitly creates a minimally sized system tablespace:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend
```

This setting configures a single 12MB data file named `ibdata1` that is auto-extending. No location for the file is given, so by default, InnoDB creates it in the MySQL data directory.

Sizes are specified using `K`, `M`, or `G` suffix letters to indicate units of KB, MB, or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the file name, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` and `max` attributes can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, InnoDB extends the data file if it runs out of free space in the tablespace. The increment is 8MB at a time by default. To modify the increment, change the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. For tablespace reconfiguration instructions, see [Section 14.4.1, “Resizing the InnoDB System Tablespace”](#).

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. Use the `max` attribute only in cases where constraining disk usage is of critical importance, because exceeding the maximum size causes a fatal error, possibly including a crash. The following configuration permits `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```

InnoDB creates tablespace files in the MySQL data directory by default. To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to use two files named `ibdata1` and `ibdata2` but create them in the `/ibdata` directory, configure InnoDB like this:

```
[mysqld]
innodb_data_home_dir = /ibdata
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

### Note

InnoDB does not create directories, so make sure that the `/ibdata` directory exists before you start the server. This is also true of any log file directories that you configure. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files or log files.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name, adding a path name separator (slash or backslash) between values if necessary. If the `innodb_data_home_dir` option is not specified in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/ibdata/ibdata1:50M;/ibdata/ibdata2:50M:autoextend
```

## Specifying InnoDB Configuration Options

**Sample `my.cnf` file for small systems.** Suppose that you have a computer with 512MB RAM and one hard disk. The following example shows possible configuration parameters in `my.cnf` or `my.ini` for InnoDB, including the `autoextend` attribute. The example suits most users, both on Unix and Windows, who do not want to distribute InnoDB data files and log files onto several disks. It creates an auto-extending data file `ibdata1` and two InnoDB log files `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

```
[mysqld]
# You can write your other MySQL server options here
# ...
# Data files must be able to hold your data and indexes.
# Make sure that you have enough free disk space.
innodb_data_file_path = ibdata1:12M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory
innodb_buffer_pool_size=256M
```

```
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=64M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
```

Note that data files must be less than 2GB in some file systems. The combined size of the log files can be up to 512GB. The combined size of data files must be slightly larger than 10MB.

## Setting Up the InnoDB System Tablespace

When you create an [InnoDB](#) system tablespace for the first time, it is best that you start the MySQL server from the command prompt. [InnoDB](#) then prints the information about the database creation to the screen, so you can see what is happening. For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 5.7\bin`, you can start it like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld" --console
```

If you do not send server output to the screen, check the server's error log to see what [InnoDB](#) prints during the startup process.

## Editing the MySQL Configuration File

You can place [InnoDB](#) options in the `[mysqld]` group of any option file that your server reads when it starts. The locations for option files are described in [Section 4.2.6, "Using Option Files"](#).

If you installed MySQL on Windows using the installation and configuration wizards, the option file will be the `my.ini` file located in your MySQL installation directory. See [Section 2.3.3, "Installing MySQL on Microsoft Windows Using MySQL Installer"](#).

If your PC uses a boot loader where the `C:` drive is not the boot drive, your only option is to use the `my.ini` file in your Windows directory (typically `C:\WINDOWS`). You can use the `SET` command at the command prompt in a console window to print the value of `WINDIR`:

```
C:\> SET WINDIR
windir=C:\WINDOWS
```

To make sure that `mysqld` reads options only from a specific file, use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=your_path_to_my_cnf
```

**Sample `my.cnf` file for large systems.** Suppose that you have a Linux computer with 2GB RAM and three 60GB hard disks at directory paths `/`, `/dr2` and `/dr3`. The following example shows possible configuration parameters in `my.cnf` for [InnoDB](#).

```
[mysqld]
# You can write your other MySQL server options here
# ...
innodb_data_home_dir =
#
# Data files must be able to hold your data and indexes
innodb_data_file_path = /db/ibdata1:2000M;/dr2/db/ibdata2:2000M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory,
# but make sure on Linux x86 total memory usage is < 2GB
innodb_buffer_pool_size=1G
innodb_log_group_home_dir = /dr3/iblogs
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=250M
innodb_log_buffer_size=8M
```

```
#
innodb_flush_log_at_trx_commit=1
innodb_lock_wait_timeout=50
#
# Uncomment the next line if you want to use it
#innodb_thread_concurrency=5
```

## Determining the Maximum Memory Allocation for InnoDB

### Warning

On 32-bit GNU/Linux x86, be careful not to set memory usage too high. `glibc` may permit the process heap to grow over thread stacks, which crashes your server. It is a risk if the value of the following expression is close to or exceeds 2GB:

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

**Tuning other `mysqld` server parameters.** The following values are typical and suit most users:

```
[mysqld]
skip-external-locking
max_connections=200
read_buffer_size=1M
sort_buffer_size=1M
#
# Set key_buffer to 5 - 50% of your RAM depending on how much
# you use MyISAM tables, but keep key_buffer_size + InnoDB
# buffer pool size < 80% of your RAM
key_buffer_size=value
```

On Linux, if the kernel is enabled for large page support, `InnoDB` can use large pages to allocate memory for its buffer pool and additional memory pool. See [Section 8.12.5.2, “Enabling Large Page Support”](#).

## 14.3.2 Configuring InnoDB for Read-Only Operation

You can now query `InnoDB` tables where the MySQL data directory is on read-only media, by enabling the `--innodb-read-only` configuration option at server startup.

### How to Enable

To prepare an instance for read-only operation, make sure all the necessary information is **flushed** to the data files before storing it on the read-only medium. Run the server with change buffering disabled (`innodb_change_buffering=0`) and do a **slow shutdown**.

To enable read-only mode for an entire MySQL instance, specify the following configuration options at server startup:

- `--innodb-read-only=1`
- If the instance is on read-only media such as a DVD or CD, or the `/var` directory is not writeable by all: `--pid-file=path_on_writeable_media` and `--event-scheduler=disabled`

### Usage Scenarios

This mode of operation is appropriate in situations such as:

- Distributing a MySQL application, or a set of MySQL data, on a read-only storage medium such as a DVD or CD.
- Multiple MySQL instances querying the same data directory simultaneously, typically in a data warehousing configuration. You might use this technique to avoid [bottlenecks](#) that can occur with a heavily loaded MySQL instance, or you might use different configuration options for the various instances to tune each one for particular kinds of queries.
- Querying data that has been put into a read-only state for security or data integrity reasons, such as archived backup data.

#### Note

This feature is mainly intended for flexibility in distribution and deployment, rather than raw performance based on the read-only aspect. See [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for ways to tune the performance of read-only queries, which do not require making the entire server read-only.

## How It Works

When the server is run in read-only mode through the `--innodb-read-only` option, certain InnoDB features and components are reduced or turned off entirely:

- No [change buffering](#) is done, in particular no merges from the change buffer. To make sure the change buffer is empty when you prepare the instance for read-only operation, disable change buffering (`innodb_change_buffering=0`) and do a [slow shutdown](#) first.
- There is no [crash recovery](#) phase at startup. The instance must have performed a [slow shutdown](#) before being put into the read-only state.
- Because the [redo log](#) is not used in read-only operation, you can set `innodb_log_file_size` to the smallest size possible (1 MB) before making the instance read-only.
- All background threads other than I/O read threads are turned off. As a consequence, a read-only instance cannot encounter any [deadlocks](#).
- Information about deadlocks, monitor output, and so on is not written to temporary files. As a consequence, `SHOW ENGINE INNODB STATUS` does not produce any output.
- If the MySQL server is started with `--innodb-read-only` but the data directory is still on writeable media, the root user can still perform [DCL](#) operations such as `GRANT` and `REVOKE`.
- Changes to configuration option settings that would normally change the behavior of write operations, have no effect when the server is in read-only mode.
- The [MVCC](#) processing to enforce [isolation levels](#) is turned off. All queries read the latest version of a record, because update and deletes are not possible.
- The [undo log](#) is not used. Disable any settings for the `innodb_undo_tablespaces` and `innodb_undo_directory` configuration options.

## 14.3.3 InnoDB Buffer Pool Configuration

This section provides configuration information and procedures for the InnoDB buffer pool. For additional information, see [Section 8.10.1, “The InnoDB Buffer Pool”](#).

### 14.3.3.1 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A [read-ahead](#) request is an I/O request to prefetch multiple pages in the [buffer pool](#) asynchronously, in anticipation that these pages will be needed soon. The requests bring in all the pages in one [extent](#). InnoDB uses two read-ahead algorithms to improve I/O performance:

**Linear** read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when InnoDB performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, InnoDB would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read in the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive InnoDB is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, InnoDB initiates an asynchronous read-ahead operation of the entire following extent. It can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, InnoDB triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, InnoDB would trigger an asynchronous read-ahead even if as few as 8 pages in the extent were accessed sequentially. You can set the value of this parameter in the MySQL [configuration file](#), or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

**Random** read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, InnoDB asynchronously issues a request to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable `innodb_random_read_ahead` to `ON`.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the `InnoDB_buffer_pool_read_ahead`, `InnoDB_buffer_pool_read_ahead_evicted`, and `InnoDB_buffer_pool_read_ahead_rnd` global status variables. This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.

For more information about I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#) and [Section 8.12.3, “Optimizing Disk I/O”](#).

### 14.3.3.2 Configuring the Rate of InnoDB Buffer Pool Flushing

InnoDB performs certain tasks in the background, including [flushing of dirty pages](#) (those pages that have been changed but are not yet written to the database files) from the [buffer pool](#). InnoDB flushes buffer pool pages if the percentage of dirty pages in the buffer pool exceeds `innodb_max_dirty_pages_pct`. As of MySQL 5.7.5, InnoDB flushes buffer pool pages if the percentage of dirty pages in the buffer pool is greater than or equal to `innodb_max_dirty_pages_pct` (Bug#13029450).

InnoDB uses an algorithm to estimate the required rate of flushing, based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that buffer flush activity keeps up with the need to keep the buffer pool “clean”. Automatically adjusting the rate of flushing can help to avoid sudden dips in throughput, when excessive buffer pool flushing limits the I/O capacity available for ordinary read and write activity.

InnoDB uses its log files in a circular fashion. Before reusing a portion of a log file, InnoDB flushes to disk all dirty buffer pool pages whose redo entries are contained in that portion of the log file, a process known as a [sharp checkpoint](#). If a workload is write-intensive, it generates a lot of redo information, all written to the log file. If all available space in the log files is used up, a sharp checkpoint occurs, causing a temporary reduction in throughput. This situation can happen even though `innodb_max_dirty_pages_pct` is not reached.

InnoDB uses a heuristic-based algorithm to avoid such a scenario, by measuring the number of dirty pages in the buffer pool and the rate at which redo is being generated. Based on these numbers, InnoDB decides how many dirty pages to flush from the buffer pool each second. This self-adapting algorithm is able to deal with sudden changes in the workload.

Internal benchmarking has also shown that this algorithm not only maintains throughput over time, but can also improve overall throughput significantly.

Because adaptive flushing can significantly affect the I/O pattern of a workload, the `innodb_adaptive_flushing` configuration parameter lets you turn off this feature. The default value for `innodb_adaptive_flushing` is `TRUE`, enabling the adaptive flushing algorithm. You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

### 14.3.3.3 Making the Buffer Pool Scan Resistant

Rather than using a strictly `LRU` algorithm, InnoDB uses a technique to minimize the amount of data that is brought into the `buffer pool` and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as `read-ahead` and `full table scans` bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the `LRU` list. All newly read pages are inserted at a location that by default is `3/8` from the tail of the `LRU` list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus pages that are never accessed never make it to the front portion of the `LRU` list, and “age out” sooner than with a strict `LRU` approach. This arrangement divides the `LRU` list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for `LRU` eviction.

For an explanation of the inner workings of the InnoDB buffer pool and the specifics of its `LRU` replacement algorithm, see [Section 8.10.1, “The InnoDB Buffer Pool”](#).

You can control the insertion point in the `LRU` list, and choose whether InnoDB applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of “old” blocks in the `LRU` list. The default value of `innodb_old_blocks_pct` is `37`, corresponding to the original fixed ratio of `3/8`. The value range is `5` (new pages in the buffer pool age out very quickly) to `95` (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar `LRU` strategy).

The optimization that keeps the buffer pool from being churned by `read-ahead` can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the `LRU` list. The default value of `innodb_old_blocks_time` is `1000`. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` are dynamic, global and can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` command. Changing the setting requires the `SUPER` privilege.

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports additional statistics. The `BUFFER POOL AND MEMORY` section looks like:

```
Total memory allocated 1107296256; in additional pool allocated 0
Dictionary memory allocated 80360
Buffer pool size      65535
Free buffers          0
Database pages       63920
Old database pages   23600
Modified db pages    34969
Pending reads        32
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 414946, not young 2930673
1274.75 young/s, 16521.90 non-young/s
Pages read 486005, created 3178, written 160585
2132.37 reads/s, 3.40 creates/s, 323.74 writes/s
```

```
Buffer pool hit rate 950 / 1000, young-making rate 30 / 1000 not 392 / 1000
Pages read ahead 1510.10/s, evicted without access 0.00/s
LRU len: 63920, unzip_LRU len: 0
I/O sum[43690]:cur[221], unzip sum[0]:cur[0]
```

- `Old database pages` is the number of pages in the “old” segment of the LRU list.
- `Pages made young` and `not young` is the total number of “old” pages that have been made young or not respectively.
- `young/s` and `non-young/s` is the rate at which page accesses to the “old” pages have resulted in making such pages young or otherwise respectively since the last invocation of the command.
- `young-making rate` and `not` provides the same rate but in terms of overall buffer pool accesses instead of accesses just to the “old” pages.

### Note

Per second averages provided in `InnoDB Monitor` output are based on the elapsed time between the current time and the last time `InnoDB Monitor` output was printed.

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

For more information about the InnoDB buffer pool, see [Section 8.10.1, “The InnoDB Buffer Pool”](#).

### 14.3.3.4 Using Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a `buffer pool` size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the InnoDB buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only

when you set the `innodb_buffer_pool_size` to a size of 1 gigabyte or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1 gigabyte.

For more information about the InnoDB buffer pool, see [Section 8.10.1, “The InnoDB Buffer Pool”](#).

### 14.3.3.5 Preloading the InnoDB Buffer Pool for Faster Restart

To avoid a lengthy `warmup` period after restarting the server, particularly for instances with large [InnoDB buffer pools](#), you can save the [InnoDB](#) buffer pool state at server shutdown and restore the buffer pool to the same state at server startup.

#### Note

The `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` configuration options are enabled by default as of MySQL 5.7.7, and the default value for `innodb_buffer_pool_dump_pct` is reduced from 100 to 25.

After you restart a busy server, there is typically a warmup period with steadily increasing throughput, as disk pages that were in the [InnoDB](#) buffer pool are brought back into memory (as the same data is queried, updated, and so on). The ability to restore the buffer pool to the pre-shutdown state shortens the warmup period as it allows you to immediately reload disk pages that were in the buffer pool before the restart, rather than waiting for DML operations to access the corresponding rows. The I/O requests can be performed in large batches, making the overall I/O faster. The page loading happens in the background, and does not delay the database startup.

In addition to saving the buffer pool state at shutdown and restoring it at startup, you can also save and restore the buffer pool state at any time, while the server is running. For example, you might save the state of the buffer pool after reaching a stable throughput under a steady workload. You might restore the previous buffer pool state after running reports or maintenance jobs that bring data pages into the buffer pool that are only needed during the time period for those operations, or after some other period with a non-typical workload.

Although the buffer pool itself could be many gigabytes in size, the data that [InnoDB](#) saves on disk is tiny by comparison. Only tablespace IDs and page IDs necessary to locate the appropriate pages are saved to disk. This information is derived from the `INNODB_BUFFER_PAGE_LRU_INFORMATION_SCHEMA` table. By default, tablespace ID and page ID data is saved in a file named `ib_buffer_pool`, which is saved to the [InnoDB](#) data directory. The file name can be modified using the `innodb_buffer_pool_filename` configuration parameter.

Because the data is cached in and aged out of the buffer pool as it is with regular database operations, there is no problem if the disk pages are recently updated, or if a DML operation involves data that has not yet been loaded. The loading mechanism skips requested pages that no longer exist.

The underlying mechanism involves a background thread that is dispatched to perform the dump and load operations.

Disk pages from compressed tables are loaded into the buffer pool in their compressed form. Uncompression happens as usual when the page contents are accessed during the course of DML operations. Because decompression is a CPU-intensive process, it is more efficient for concurrency to perform the operation in one of the connection threads rather than in the single thread that performs the buffer pool restore operation.

### Configuring the Dump Percentage for Buffer Pool Pages

Before you dump pages from the buffer pool, configure the percentage of most-recently-used buffer pool pages that you want to dump by setting the `innodb_buffer_pool_dump_pct` option. If you plan to dump buffer pool pages while the server is running, you can configure the option dynamically:

```
SET GLOBAL innodb_buffer_dump_pct=40;
```

If you plan to dump buffer pool pages at server shutdown, set `innodb_buffer_pool_dump_pct` in your configuration file.

```
[mysqld]
innodb_buffer_dump_pct=40
```

The `innodb_buffer_pool_dump_pct` default value was changed from 100 (dump all pages) to 25 (dump 25% of most-recently-used pages) in MySQL 5.7.7 when `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` were enabled by default.

### Saving the Buffer Pool State

To save the state of the InnoDB buffer pool at server shutdown, issue the statement:

```
SET GLOBAL innodb_buffer_pool_dump_at_shutdown=ON;
```

`innodb_buffer_pool_dump_at_shutdown` is enabled by default in MySQL 5.7.7.

To save the state of the InnoDB buffer pool while MySQL server is running, issue the statement:

```
SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

### Restoring the Buffer Pool State

To restore the InnoDB buffer pool state at server startup, specify the `--innodb_buffer_pool_load_at_startup` option when starting the server:

```
mysqld --innodb_buffer_pool_load_at_startup=ON;
```

`innodb_buffer_pool_load_at_startup` is enabled by default in MySQL 5.7.7.

To restore the InnoDB buffer pool state while MySQL is running, issue the statement:

```
SET GLOBAL innodb_buffer_pool_load_now=ON;
```

### Displaying Buffer Pool Dump Progress

To display progress when saving the InnoDB buffer pool state to disk, use one of the following options:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';
```

or:

```
SELECT variable_value FROM information_schema.global_status WHERE
variable_name = 'INNODB_BUFFER_POOL_DUMP_STATUS';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:18:02). If the operation is in progress, status information is provided (e.g. Dumping buffer pool 5/7, page 237/2873).

### Displaying Buffer Pool Load Progress

To display progress when loading the InnoDB buffer pool, use one of the following options:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_load_status';
```

or:

```
SELECT variable_value FROM information_schema.global_status WHERE
variable_name = 'INNODB_BUFFER_POOL_LOAD_STATUS';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:23:24). If the operation is in progress, status information is provided (e.g. Loaded 123/22301 pages).

## Aborting a Buffer Pool Load

To abort a buffer pool load operation, issue the statement:

```
SET GLOBAL innodb_buffer_pool_load_abort=ON;
```

## Monitoring Buffer Pool Load Progress Using Performance Schema

As of MySQL 5.7.6, you can monitor buffer pool load progress using [Performance Schema](#).

The following example demonstrates how to enable the `stage/innodb/buffer pool load` stage event instrument and related consumer tables to monitor buffer pool load progress.

For information about buffer pool dump and load procedures used in this example, see [Section 14.3.3.5, “Preloading the InnoDB Buffer Pool for Faster Restart”](#). For information about Performance Schema stage event instruments and related consumers, see [Section 21.9.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/buffer pool load` instrument:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES' WHERE NAME LIKE 'stage/innodb/buffer%';
Query OK, 1 row affected (0.00 sec)
Rows matched: 1 Changed: 1 Warnings: 0
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES' WHERE NAME LIKE '%stages%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0
```

3. Dump the current buffer pool state by enabling `innodb_buffer_pool_dump_now`.

```
mysql> SET GLOBAL innodb_buffer_pool_dump_now=ON;
Query OK, 0 rows affected (0.00 sec)
```

4. Check the buffer pool dump status to ensure that the operation has completed.

```
mysql> SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status'\G
***** 1. row *****
Variable_name: Innodb_buffer_pool_dump_status
Value: Buffer pool(s) dump completed at 150202 16:38:58
```

5. Load the buffer pool by enabling `innodb_buffer_pool_load_now`:

```
mysql> SET GLOBAL innodb_buffer_pool_load_now=ON;
Query OK, 0 rows affected (0.01 sec)
```

6. Check the current status of the buffer pool load operation by querying the Performance Schema `events_stages_current` table. The `WORK_COMPLETED` column shows the number of buffer pool pages loaded. The `WORK_ESTIMATED` column provides an estimate of the remaining work, in pages.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_current;
+-----+-----+-----+
| EVENT_NAME                | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/buffer pool load |          5353 |          7167 |
+-----+-----+-----+
```

The `events_stages_current` table returns an empty set if the buffer pool load operation has completed. In this case, you can check the `events_stages_history` table to view data for the completed event. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history;
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/buffer pool load	7167	7167

**Note**

You can also monitor buffer pool load progress using Performance Schema when loading the buffer pool at startup using `innodb_buffer_pool_load_at_startup`. In this case, the `stage/innodb/buffer pool load` instrument and related consumers must also be enabled at startup. For more information, see [Section 21.2.2, “Performance Schema Startup Configuration”](#).

### 14.3.3.6 Tuning InnoDB Buffer Pool Flushing

The configuration options `innodb_flush_neighbors` and `innodb_lru_scan_depth` let you fine-tune certain aspects of the **flushing** process for the **InnoDB buffer pool**. These options primarily help write-intensive **workloads**. With heavy **DML** activity, flushing can fall behind if it is not aggressive enough, resulting in excessive memory use in the buffer pool; or, disk writes due to flushing can saturate your I/O capacity if that mechanism is too aggressive. The ideal settings depend on your workload, data access patterns, and storage configuration (for example, whether data is stored on **HDD** or **SSD** devices).

For systems with constant heavy **workloads**, or workloads that fluctuate widely, several configuration options let you fine-tune the **flushing** behavior for **InnoDB** tables: `innodb_adaptive_flushing_lwm`, `innodb_max_dirty_pages_pct_lwm`, `innodb_io_capacity_max`, and `innodb_flushing_avg_loops`. These options feed into the formula used by the `innodb_adaptive_flushing` option.

The `innodb_adaptive_flushing`, `innodb_io_capacity` and `innodb_max_dirty_pages_pct` options are limited or extended by the following options: `innodb_adaptive_flushing_lwm`, `innodb_io_capacity_max` and `innodb_max_dirty_pages_pct_lwm`:

- The **InnoDB adaptive flushing** mechanism is not appropriate in all cases. It gives the most benefit when the **redo log** is in danger of filling up. The `innodb_adaptive_flushing_lwm` option specifies a “low water mark” percentage of redo log capacity; when that threshold is crossed, **InnoDB** turns on adaptive flushing even if not specified by the `innodb_adaptive_flushing` option.
- If flushing activity falls far behind, **InnoDB** can flush more aggressively than specified by `innodb_io_capacity`. `innodb_io_capacity_max` represents an upper limit on the I/O capacity used in such emergency situations, so that the spike in I/O does not consume all the capacity of the server.
- **InnoDB** tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed the value of `innodb_max_dirty_pages_pct`. The default value for `innodb_max_dirty_pages_pct` is 75.

**Note**

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 14.3.3.2, “Configuring the Rate of InnoDB Buffer Pool Flushing”](#).

The `innodb_max_dirty_pages_pct_lwm` option specifies a “low water mark” value that represents the percentage of dirty pages where pre-flushing is enabled to control the dirty page ratio and ideally prevent the percentage of dirty pages from reaching `innodb_max_dirty_pages_pct`. A value of `innodb_max_dirty_pages_pct_lwm=0` disables the “pre-flushing” behavior.

Most of the options referenced above are most applicable to servers that run write-heavy workloads for long periods of time and have little reduced load time to catch up with changes waiting to be written to disk.

`innodb_flushing_avg_loops` defines the number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, which controls how quickly adaptive flushing responds to foreground load changes. Setting a high value for `innodb_flushing_avg_loops` means that InnoDB keeps the previously calculated snapshot longer, so adaptive flushing responds more slowly. A high value also reduces positive feedback between foreground and background work, but when setting a high value it is important to ensure that InnoDB redo log utilization does not reach 75% (the hardcoded limit at which async flushing starts) and that the `innodb_max_dirty_pages_pct` setting keeps the number of dirty pages to a level that is appropriate for the workload.

Systems with consistent workloads, a large `innodb_log_file_size`, and small spikes that do not reach 75% redo log space utilization should use a high `innodb_flushing_avg_loops` value to keep flushing as smooth as possible. For systems with extreme load spikes or log files that do not provide a lot of space, consider a smaller `innodb_flushing_avg_loops` value. The smaller value will allow flushing to closely track the load and help avoid reaching 75% redo log space utilization.

### 14.3.3.7 Resizing the InnoDB Buffer Pool Online

As of MySQL 5.7.5, the `innodb_buffer_pool_size` configuration option can be set dynamically using a `SET` statement, allowing you to resize the buffer pool without restarting the server. For example:

```
mysql> SET GLOBAL innodb_buffer_pool_size=402653184;
```

Active transactions, and operations performed through InnoDB APIs, should be completed before resizing the buffer pool. When initiating a resizing operation, the operation does not start until all active transactions are completed. Once the resizing operation is in progress, new transactions and operations that require access to the buffer pool must wait until the resizing operation finishes. The exception to this rule is that concurrent access to the buffer pool is permitted while the buffer pool is defragmented and pages are withdrawn during an operation to decrease buffer pool size. A drawback of allowing concurrent access is that it could result in a temporary shortage of available pages while pages are being withdrawn.

#### Note

Nested transactions could fail if initiated after the buffer pool resizing operation begins.

When you increase or decrease `innodb_buffer_pool_size` online, the operation is performed in chunks. Chunk size is defined by the `innodb_buffer_pool_chunk_size` configuration option. For example, if `innodb_buffer_pool_chunk_size` is 128 MB, which is the default value, you can resize the buffer pool by one or more 128 MB chunks. In the following example, buffer pool size is increased by two chunks, from 128 MB (134217728 bytes) to 384 MB (402653184 bytes).

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|           134217728 |
+-----+

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|           134217728 |
+-----+

mysql> SET GLOBAL innodb_buffer_pool_size=402653184;
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|                402653184 |
+-----+
```

Increasing or decreasing `innodb_buffer_pool_size` by a value that is not divisible by `innodb_buffer_pool_chunk_size` returns a warning and adjusts the `innodb_buffer_pool_size` value to a valid value.

### Configuring InnoDB Buffer Pool Chunk Size

`innodb_buffer_pool_chunk_size` can be increased or decreased in 1MB (1048576 byte) units but can only be modified at startup, in a command line string or in a configuration file.

Command line:

```
./mysqld --innodb_buffer_pool_chunk_size=134217728
```

Configuration file:

```
[mysqld]
innodb_buffer_pool_chunk_size=134217728
```

The following conditions apply when altering the `innodb_buffer_pool_chunk_size` value:

- If `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.

For example, if the buffer pool is initialized with a size of 2GB (2147483648 bytes), 4 buffer pool instances, and a chunk size of 1GB (1073741824 bytes), chunk size will be truncated to a value equal to `innodb_buffer_pool_size / innodb_buffer_pool_instances`, as shown below:

```
./mysqld --innodb_buffer_pool_size=2147483648 --innodb_buffer_pool_instances=4
--innodb_buffer_pool_chunk_size=1073741824;
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|                2147483648 |
+-----+
```

```
mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
|                                4 |
+-----+
```

```
# Chunk size was set to 1GB (1073741824 bytes) on startup but was
# truncated to innodb_buffer_pool_size / innodb_buffer_pool_instances
```

```
mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|                   536870912 |
+-----+
```

- Buffer pool size must always be a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than current buffer pool size. The adjustment occurs when the buffer pool is initialized. This behavior is demonstrated in the following example:

```

# The buffer pool has a default size of 128MB (134217728 bytes)

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|           134217728 |
+-----+

# The chunk size is also 128MB (134217728 bytes)

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|           134217728 |
+-----+

# There is a single buffer pool instance

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
|                1 |
+-----+

# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (134217728 - 1048576 = 133169152):

shell$ ./mysqld --innodb_buffer_pool_chunk_size=133169152

mysql> select @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|           133169152 |
+-----+

# Buffer pool size increases from 134217728 to 266338304
# Buffer pool size is automatically adjusted to a multiple of
# the innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances that
# is not less than current buffer pool size

mysql> select @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|           266338304 |
+-----+

```

This example demonstrates the same behaviour but with multiple buffer pool instances:

```

# The buffer pool has a default size of 2GB (2147483648 bytes)

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|           2147483648 |
+-----+

# The chunk size is .5 GB (536870912 bytes)

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|           536870912 |
+-----+

```

```

# There are 4 buffer pool instances

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+

```

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can increase the size of the buffer pool, as shown in the examples above. Before you change `innodb_buffer_pool_chunk_size`, calculate the effect it will have on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

### Note

To avoid potential performance issues, the number of chunks ( $\text{innodb\_buffer\_pool\_size} / \text{innodb\_buffer\_pool\_chunk\_size}$ ) should not exceed 1000.

## Monitoring Online Buffer Pool Resize Progress

The `Innodb_buffer_pool_resize_status` variable reports the progress of the buffer pool resizing operation. For example:

```

mysql> SHOW STATUS WHERE Variable_name='InnoDB_buffer_pool_resize_status';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_resize_status | Resizing also other hash tables. |
+-----+-----+

```

The progress of the resizing operation is also logged in the server error log file. This example shows notes that are logged when increasing the size of the buffer pool:

```

[Note] InnoDB: Resizing buffer pool from 134217728 to 4294967296. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was added.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 134217728 to 4294967296.
[Note] InnoDB: re-enabled adaptive hash index.

```

This example shows notes that are logged when decreasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 4294967296 to 134217728. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : start to withdraw the last 253952 blocks.
[Note] InnoDB: buffer pool 0 : withdrew 253952 blocks from free list. tried to relocate 0 pages. (253952)
[Note] InnoDB: buffer pool 0 : withdrawn target 253952 blocks.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was freed.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 4294967296 to 134217728.
[Note] InnoDB: re-enabled adaptive hash index.
```

### Buffer Pool Resizing Internals

The resizing operation is performed by a background thread. When increasing the size of the buffer pool, the resizing operation:

- Adds pages in `chunks` (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Coverts hash tables, lists, and pointers to use new addresses in memory
- Adds new pages to the free list

While these operations are in progress, other threads are blocked from accessing the buffer pool.

When decreasing the size of the buffer pool, the resizing operation:

- Defragments the buffer pool and withdraws (frees) pages
- Removes pages in `chunks` (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Coverts hash tables, lists, and pointers to use new addresses in memory

Of these operations, only defragmenting the buffer pool and withdrawing pages allow other threads to access to the buffer pool concurrently.

### 14.3.4 Configuring the Memory Allocator for InnoDB

When `InnoDB` was developed, the memory allocators supplied with operating systems and run-time libraries were often lacking in performance and scalability. At that time, there were no memory allocator libraries tuned for multi-core CPUs. Therefore, `InnoDB` implemented its own memory allocator in the `mem` subsystem. This allocator is guarded by a single mutex, which may become a `bottleneck`. `InnoDB` also implements a wrapper interface around the system allocator (`malloc` and `free`) that is likewise guarded by a single mutex.

Today, as multi-core systems have become more widely available, and as operating systems have matured, significant improvements have been made in the memory allocators provided with operating systems. New memory allocators perform better and are more scalable than they were in the past. The leading high-performance memory allocators include `Hoard`, `libumem`, `mtmalloc`, `ptmalloc`, `tbbmalloc`, and `TCMalloc`. Most workloads, especially those where memory is frequently allocated and released (such as multi-table joins), benefit from using a more highly tuned memory allocator as opposed to the internal, `InnoDB`-specific memory allocator.

You can control whether `InnoDB` uses its own memory allocator or an allocator of the operating system, by setting the value of the system configuration parameter `innodb_use_sys_malloc` in the MySQL option file (`my.cnf` or `my.ini`). If set to `ON` or `1` (the default), `InnoDB` uses the `malloc` and `free` functions of the underlying system rather than manage memory pools itself. This parameter is not dynamic, and takes effect only when the system is started. To continue to use the `InnoDB` memory allocator, set `innodb_use_sys_malloc` to `0`.

When the `InnoDB` memory allocator is disabled, `InnoDB` ignores the value of the parameter `innodb_additional_mem_pool_size`. The `InnoDB` memory allocator uses an additional memory

pool for satisfying allocation requests without having to fall back to the system memory allocator. When the `InnoDB` memory allocator is disabled, all such allocation requests are fulfilled by the system memory allocator.

On Unix-like systems that use dynamic linking, replacing the memory allocator may be as easy as making the environment variable `LD_PRELOAD` or `LD_LIBRARY_PATH` point to the dynamic library that implements the allocator. On other systems, some relinking may be necessary. Please refer to the documentation of the memory allocator library of your choice.

Since `InnoDB` cannot track all memory use when the system memory allocator is used (`innodb_use_sys_malloc` is `ON`), the section “BUFFER POOL AND MEMORY” in the output of the `SHOW ENGINE INNODB STATUS` command only includes the buffer pool statistics in the “Total memory allocated”. Any memory allocated using the `mem` subsystem or using `ut_malloc` is excluded.

#### Note

`innodb_use_sys_malloc` and `innodb_additional_mem_pool_size` were deprecated in MySQL 5.6.3 and are removed in MySQL 5.7.4.

For more information about the performance implications of `InnoDB` memory usage, see [Section 8.10, “Buffering and Caching”](#).

## 14.3.5 Configuring InnoDB Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. `InnoDB` has a `change buffer` that caches changes to secondary index entries when the relevant `page` is not in the `buffer pool`, thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded to the buffer pool, and the updated page is later flushed to disk. The `InnoDB` main thread merges buffered changes when the server is nearly idle, and during a `slow shutdown`.

Because it can result in fewer disk reads and writes, the change buffer feature is most valuable for workloads that are I/O-bound, for example applications with a high volume of DML operations such as bulk inserts.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working set fits entirely within the buffer, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

You can control the extent to which `InnoDB` performs change buffering using the `innodb_change_buffering` configuration parameter. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. The default `innodb_change_buffering` value is `all`.

Permitted `innodb_change_buffering` values include:

- `all`

The default value: buffer inserts, delete-marking operations, and purges.

- `none`

Do not buffer any operations.

- `inserts`

Buffer insert operations.

- **deletes**

Buffer delete-marking operations.

- **changes**

Buffer both inserts and delete-marking operations.

- **purges**

Buffer the physical deletion operations that happen in the background.

You can set the `innodb_change_buffering` parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege. Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.

For related information, see [Section 14.2.7.5, “Change Buffer”](#). For information about configuring change buffer size, see [Section 14.3.5.1, “Configuring the Change Buffer Maximum Size”](#).

### 14.3.5.1 Configuring the Change Buffer Maximum Size

As of MySQL 5.6.2, the `innodb_change_buffer_max_size` configuration option allows you to configure the maximum size of the change buffer as a percentage of the total size of the buffer pool. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

You might consider increasing `innodb_change_buffer_max_size` on a MySQL server with heavy insert, update, and delete activity, where change buffer merging does not keep pace with new change buffer entries, causing the change buffer to reach its maximum size limit.

You might consider decreasing `innodb_change_buffer_max_size` on a MySQL server with static data used for reporting, or if the change buffer consumes too much of the memory space that is shared with the buffer pool, causing pages to age out of the buffer pool sooner than desired.

Test different settings with a representative workload to determine an optimal configuration. The `innodb_change_buffer_max_size` setting is dynamic, which allows you modify the setting without restarting the server.

### 14.3.6 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system [threads](#) to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads. Scalability improvements in MySQL 5.5 and up reduce the need to limit the number of concurrently executing threads inside InnoDB.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter `innodb_thread_concurrency`. Once the number of executing threads reaches this limit,

additional threads sleep for a number of microseconds, set by the configuration parameter `innodb_thread_sleep_delay`, before being placed into the queue.

Previously, it required experimentation to find the optimal value for `innodb_thread_sleep_delay`, and the optimal value could change depending on the workload. In MySQL 5.6.3 and higher, you can set the configuration option `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

The default value for `innodb_thread_concurrency` and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of `innodb_thread_concurrency` is 0, so that by default there is no limit on the number of concurrently executing threads.

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if `innodb_thread_concurrency` is 0, the value of `innodb_thread_sleep_delay` is ignored.

When there is a limit on the number of threads (when `innodb_thread_concurrency` is > 0), InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a *single SQL statement* to enter InnoDB without observing the limit set by `innodb_thread_concurrency`. Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns a specified number of “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe `innodb_thread_concurrency`. Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB to perform row operations. If the tickets run out, the thread is evicted, and `innodb_thread_concurrency` is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to enter InnoDB, tickets are assigned again. The number of tickets assigned is specified by the global option `innodb_concurrency_tickets`, which is 5000 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as `innodb_adaptive_hash_index`.

For general performance information about MySQL thread handling, see [Section 8.12.6.1, “How MySQL Uses Threads for Client Connections”](#).

### 14.3.7 Configuring the Number of Background InnoDB I/O Threads

InnoDB uses background [threads](#) to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages, using the configuration parameters `innodb_read_io_threads` and `innodb_write_io_threads`. These parameters signify the number of background threads used for read and write requests respectively. They are effective on all supported platforms. You can set the value of these parameters in the MySQL option file (`my.cnf` or `my.ini`); you cannot change them dynamically. The default value for these parameters is 4 and the permissible values range from 1–64.

The purpose of this change is to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is the [read-ahead](#) requests. InnoDB tries to balance the load of incoming requests in such way that most of the background threads share work equally. InnoDB also attempts to allocate read requests from the same extent to the same thread to increase the chances of coalescing the requests together.

If you have a high end I/O subsystem and you see more than  $64 \times \text{innodb\_read\_io\_threads}$  pending read requests in `SHOW ENGINE INNODB STATUS`, you might gain by increasing the value of `innodb_read_io_threads`.

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

### 14.3.8 Configuring the InnoDB Master Thread I/O Rate

The [master thread](#) in InnoDB is a thread that performs various tasks in the background. Most of these tasks are I/O related, such as flushing dirty pages from the buffer pool or writing changes from the insert buffer to the appropriate secondary indexes. The master thread attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the free I/O bandwidth available and tune its activities to take advantage of this free capacity. Historically, InnoDB has used a hard coded value of 100 IOPs (input/output operations per second) as the total I/O capacity of the server.

The parameter `innodb_io_capacity` indicates the overall I/O capacity available to InnoDB. This parameter should be set to approximately the number of I/O operations that the system can perform per second. The value depends on your system configuration. When `innodb_io_capacity` is set, the master threads estimates the I/O bandwidth available for background tasks based on the set value. Setting the value to `100` reverts to the old behavior.

You can set the value of `innodb_io_capacity` to any number 100 or greater. The default value is `200`, reflecting that the performance of typical modern I/O devices is higher than in the early days of MySQL. Typically, values around the previous default of 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and SSDs benefit from higher values.

The `innodb_io_capacity` setting is a total limit for all buffer pool instances. When dirty pages are flushed, the `innodb_io_capacity` limit is divided equally among buffer pool instances. For more information, see the `innodb_io_capacity` system variable description.

You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

The `innodb_flush_sync` configuration option, introduced in MySQL 5.7.8, causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. `innodb_flush_sync` is enabled by default.

Formerly, the InnoDB master thread also performed any needed [purge](#) operations. In MySQL 5.6.5 and higher, those I/O operations are moved to other background threads, whose number is controlled by the `innodb_purge_threads` configuration option.

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

### 14.3.9 Configuring Spin Lock Polling

Many InnoDB [mutexes](#) and [rw-locks](#) are reserved for a short time. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a while before sleeping. If the mutex or rw-lock becomes available during this polling period, the thread can continue immediately, in the same time slice. However, too-frequent polling by multiple threads of a shared object can cause “cache ping pong”, different processors invalidating portions of each others' cache. InnoDB minimizes this issue by waiting a random time between subsequent polls. The delay is implemented as a busy loop.

You can control the maximum delay between testing a mutex or rw-lock using the parameter `innodb_spin_wait_delay`. The duration of the delay loop depends on the C compiler and the target processor. (In the 100MHz Pentium era, the unit of delay was one microsecond.) On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting `innodb_spin_wait_delay=0`. On a system with multiple processor

chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The default value of `innodb_spin_wait_delay` is 6. The spin wait delay is a dynamic global parameter that you can specify in the MySQL option file (`my.cnf` or `my.ini`) or change at runtime with the command `SET GLOBAL innodb_spin_wait_delay=delay`, where `delay` is the desired maximum delay. Changing the setting requires the `SUPER` privilege.

For performance considerations for InnoDB locking operations, see [Section 8.11, “Optimizing Locking Operations”](#).

### 14.3.10 Configuring InnoDB Purge Scheduling

The `purge` operations (a type of garbage collection) that InnoDB performs automatically is now done in one or more separate threads, rather than as part of the `master thread`. This change improves scalability, because the main database operations run independently from maintenance work happening in the background.

To control this feature, increase the value of the configuration option `innodb_purge_threads`. If DML action is concentrated on a single table or a few tables, keep the setting low so that the threads do not contend with each other for access to the busy tables. If DML operations are spread across many tables, increase the setting. Its maximum is 32.

There is another related configuration option, `innodb_purge_batch_size` with a default value of 300 and maximum value of 5000. This option is mainly intended for experimentation and tuning of purge operations, and should not be interesting to typical users.

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

### 14.3.11 Configuring Optimizer Statistics for InnoDB

This section describes how to configure persistent and non-persistent optimizer statistics for InnoDB tables.

Persistent optimizer statistics are persisted across server restarts, allowing for greater [plan stability](#) and more consistent query performance. Persistent optimizer statistics also provide control and flexibility with these additional benefits:

- You can use the `innodb_stats_auto_recalc` configuration option to control whether statistics are updated automatically after substantial changes to a table.
- You can use the `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses with `CREATE TABLE` and `ALTER TABLE` statements to configure optimizer statistics for individual tables.
- You can query optimizer statistics data in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables.
- You can view the `last_update` column of the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to see when statistics were last updated.
- You can manually modify the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to force a specific query optimization plan or to test alternative plans without modifying the database.

The persistent optimizer statistics feature is enabled by default (`innodb_stats_persistent=ON`).

Non-persistent optimizer statistics are cleared on each server restart and after some other operations, and recomputed on the next table access. As a result, different estimates could be produced when recomputing statistics, leading to different choices in execution plans and variations in query performance.

This section also provides information about estimating `ANALYZE TABLE` complexity, which may be useful when attempting to achieve a balance between accurate statistics and `ANALYZE TABLE` execution time.

### 14.3.11.1 Configuring Persistent Optimizer Statistics Parameters

The persistent optimizer statistics feature improves [plan stability](#) by storing statistics to disk and making them persistent across server restarts so that the [optimizer](#) is more likely to make consistent choices each time for a given query.

Optimizer statistics are persisted to disk when `innodb_stats_persistent=ON` or when individual tables are created or altered with `STATS_PERSISTENT=1`. `innodb_stats_persistent` is enabled by default.

Formerly, optimizer statistics were cleared on each server restart and after some other operations, and recomputed on the next table access. Consequently, different estimates could be produced when recalculating statistics, leading to different choices in query execution plans and thus variations in query performance.

Persistent statistics are stored in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables, as described in [InnoDB Persistent Statistics Tables](#).

To revert to using non-persistent optimizer statistics, you can modify tables using an `ALTER TABLE tbl_name STATS_PERSISTENT=0` statement. For related information, see [Section 14.3.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#)

### Configuring Automatic Statistics Calculation for Persistent Optimizer Statistics

The `innodb_stats_auto_recalc` configuration option, which is enabled by default, determines whether statistics are calculated automatically whenever a table undergoes substantial changes (to more than 10% of the rows). You can also configure automatic statistics recalculation for individual tables using a `STATS_AUTO_RECALC` clause in a `CREATE TABLE` or `ALTER TABLE` statement. `innodb_stats_auto_recalc` is enabled by default.

Because of the asynchronous nature of automatic statistics recalculation (which occurs in the background), statistics may not be recalculated instantly after running a DML operation that affects more than 10% of a table, even when `innodb_stats_auto_recalc` is enabled. In some cases, statistics recalculation may be delayed by a few seconds. If up-to-date statistics are required immediately after changing significant portions of a table, run `ANALYZE TABLE` to initiate a synchronous (foreground) recalculation of statistics.

If `innodb_stats_auto_recalc` is disabled, ensure the accuracy of optimizer statistics by issuing the `ANALYZE TABLE` statement for each applicable table after making substantial changes to indexed columns. You might run this statement in your setup scripts after representative data has been loaded into the table, and run it periodically after DML operations significantly change the contents of indexed columns, or on a schedule at times of low activity. When a new index is added to an existing table, index statistics are calculated and added to the `innodb_index_stats` table regardless of the value of `innodb_stats_auto_recalc`.

#### Caution

To ensure statistics are gathered when a new index is created, either enable the `innodb_stats_auto_recalc` option, or run `ANALYZE TABLE` after creating each new index when the persistent statistics mode is enabled.

### Configuring Optimizer Statistics Parameters for Individual Tables

`innodb_stats_persistent`, `innodb_stats_auto_recalc`, and `innodb_stats_persistent_sample_pages` are global configuration options. To override these

system-wide settings and configure optimizer statistics parameters for individual tables, you can define `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses in `CREATE TABLE` or `ALTER TABLE` statements.

- `STATS_PERSISTENT` specifies whether to enable [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table.
- `STATS_AUTO_RECALC` specifies whether to automatically recalculate [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table.
- `STATS_SAMPLE_PAGES` specifies the number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`.

All three clauses are specified in the following `CREATE TABLE` example:

```
CREATE TABLE `t1` (
  `id` int(8) NOT NULL auto_increment,
  `data` varchar(255),
  `date` datetime,
  PRIMARY KEY (`id`),
  INDEX `DATE_IX` (`date`)
) ENGINE=InnoDB,
  STATS_PERSISTENT=1,
  STATS_AUTO_RECALC=1,
  STATS_SAMPLE_PAGES=25;
```

## Configuring the Number of Sampled Pages for InnoDB Optimizer Statistics

The MySQL query optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. Operations such as `ANALYZE TABLE` cause InnoDB to sample random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_persistent_sample_pages`, which can be set at runtime.

`innodb_stats_persistent_sample_pages` has a default value of 20. As a general guideline, consider modifying this parameter when encountering the following issues:

1. *Statistics are not accurate enough and the optimizer chooses suboptimal plans*, as shown by `EXPLAIN` output. The accuracy of statistics can be checked by comparing the actual cardinality of an index (as returned by running `SELECT DISTINCT` on the index columns) with the estimates provided in the `mysql.innodb_index_stats` persistent statistics table.

If it is determined that statistics are not accurate enough, the value of `innodb_stats_persistent_sample_pages` should be increased until the statistics estimates are sufficiently accurate. Increasing `innodb_stats_persistent_sample_pages` too much, however, could cause `ANALYZE TABLE` to run slowly.

2. *`ANALYZE TABLE` is too slow*. In this case `innodb_stats_persistent_sample_pages` should be decreased until `ANALYZE TABLE` execution time is acceptable. Decreasing the value too much, however, could lead to the first problem of inaccurate statistics and suboptimal query execution plans.

If a balance cannot be achieved between accurate statistics and `ANALYZE TABLE` execution time, consider decreasing the number of indexed columns in the table or limiting the number of partitions to reduce `ANALYZE TABLE` complexity. The number of columns in the table's primary key is also important to consider, as primary key columns are appended to each non-unique index.

For related information, see [Section 14.3.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

## InnoDB Persistent Statistics Tables

The persistent statistics feature relies on the internally managed tables in the `mysql` database, named `innodb_table_stats` and `innodb_index_stats`. These tables are set up automatically in all install, upgrade, and build-from-source procedures.

**Table 14.2 Columns of `innodb_table_stats`**

Column name	Description
<code>database_name</code>	Database name
<code>table_name</code>	Table name, partition name, or subpartition name
<code>last_update</code>	A timestamp indicating the last time that InnoDB updated this row
<code>n_rows</code>	The number of rows in the table
<code>clustered_index_size</code>	The size of the primary index, in pages
<code>sum_of_other_index_sizes</code>	The total size of other (non-primary) indexes, in pages

**Table 14.3 Columns of `innodb_index_stats`**

Column name	Description
<code>database_name</code>	Database name
<code>table_name</code>	Table name, partition name, or subpartition name
<code>index_name</code>	Index name
<code>last_update</code>	A timestamp indicating the last time that InnoDB updated this row
<code>stat_name</code>	The name of the statistic, whose value is reported in the <code>stat_value</code> column
<code>stat_value</code>	The value of the statistic that is named in <code>stat_name</code> column
<code>sample_size</code>	The number of pages sampled for the estimate provided in the <code>stat_value</code> column
<code>stat_description</code>	Description of the statistic that is named in the <code>stat_name</code> column

Both the `innodb_table_stats` and `innodb_index_stats` tables include a `last_update` column showing when InnoDB last updated index statistics, as shown in the following example:

```
mysql> select * from innodb_table_stats \G
***** 1. row *****
      database_name: sakila
      table_name: actor
      last_update: 2014-05-28 16:16:44
      n_rows: 200
      clustered_index_size: 1
      sum_of_other_index_sizes: 1
      ...
```

```
mysql> select * from innodb_index_stats \G
***** 1. row *****
      database_name: sakila
      table_name: actor
      index_name: PRIMARY
```

```
last_update: 2014-05-28 16:16:44
  stat_name: n_diff_pfx01
  stat_value: 200
  sample_size: 1
  ...
```

The `innodb_table_stats` and `innodb_index_stats` tables are ordinary tables and can be updated manually. The ability to update statistics manually makes it possible to force a specific query optimization plan or test alternative plans without modifying the database. If you manually update statistics, issue the `FLUSH TABLE tbl_name` command to make MySQL reload the updated statistics.

### InnoDB Persistent Statistics Tables Example

The `innodb_table_stats` table contains one row per table. The data collected is demonstrated in the following example.

Table `t1` contains a primary index (columns `a`, `b`) secondary index (columns `c`, `d`), and unique index (columns `e`, `f`):

```
CREATE TABLE t1 (
a INT, b INT, c INT, d INT, e INT, f INT,
PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, the table appears as follows:

```
mysql> SELECT * FROM t1;
+----+-----+-----+-----+-----+-----+
| a | b | c | d | e | f |
+----+-----+-----+-----+-----+-----+
| 1 | 1 | 10 | 11 | 100 | 101 |
| 1 | 2 | 10 | 11 | 200 | 102 |
| 1 | 3 | 10 | 11 | 100 | 103 |
| 1 | 4 | 10 | 12 | 200 | 104 |
| 1 | 5 | 10 | 12 | 100 | 105 |
+----+-----+-----+-----+-----+-----+
```

To immediately update statistics, run `ANALYZE TABLE` (if `innodb_stats_auto_recalc` is enabled, statistics are updated automatically within a few seconds assuming that the 10% threshold for changed table rows is reached):

```
mysql> ANALYZE TABLE t1;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | analyze | status | OK |
+-----+-----+-----+-----+
```

Table statistics for table `t1` show the last time InnoDB updated the table statistics (2014-03-14 14:36:34), the number of rows in the table (5), the clustered index size (1 page), and the combined size of the other indexes (2 pages).

```
mysql> SELECT * FROM mysql.innodb_table_stats WHERE table_name like 't1'\G
***** 1. row *****
      database_name: test
      table_name: t1
      last_update: 2014-03-14 14:36:34
      n_rows: 5
      clustered_index_size: 1
      sum_of_other_index_sizes: 2
```

The `innodb_index_stats` table contains multiple rows for each index. Each row in the `innodb_index_stats` table provides data related to a particular index statistic which is named in the `stat_name` column and described in the `stat_description` column. For example:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
```

```
-> FROM mysql.innodb_index_stats WHERE table_name like 't1';
```

index_name	stat_name	stat_value	stat_description
PRIMARY	n_diff_pfx01	1	a
PRIMARY	n_diff_pfx02	5	a,b
PRIMARY	n_leaf_pages	1	Number of leaf pages in the index
PRIMARY	size	1	Number of pages in the index
il	n_diff_pfx01	1	c
il	n_diff_pfx02	2	c,d
il	n_diff_pfx03	2	c,d,a
il	n_diff_pfx04	5	c,d,a,b
il	n_leaf_pages	1	Number of leaf pages in the index
il	size	1	Number of pages in the index
i2uniq	n_diff_pfx01	2	e
i2uniq	n_diff_pfx02	5	e,f
i2uniq	n_leaf_pages	1	Number of leaf pages in the index
i2uniq	size	1	Number of pages in the index

The `stat_name` column shows the following types of statistics:

- `size`: Where `stat_name=size`, the `stat_value` column displays the total number of pages in the index.
- `n_leaf_pages`: Where `stat_name=n_leaf_pages`, the `stat_value` column displays the number of leaf pages in the index.
- `n_diff_pfxNN`: Where `stat_name=n_diff_pfx01`, the `stat_value` column displays the number of distinct values in the first column of the index. Where `stat_name=n_diff_pfx02`, the `stat_value` column displays the number of distinct values in the first two columns of the index, and so on. Additionally, where `stat_name=n_diff_pfxNN`, the `stat_description` column shows a comma separated list of the index columns that are counted.

To further illustrate the `n_diff_pfxNN` statistic, which provides cardinality data, consider the `t1` table example. As shown below, the `t1` table is created with a primary index (columns `a, b`), a secondary index (columns `c, d`), and a unique index (columns `e, f`):

```
CREATE TABLE t1 (
  a INT, b INT, c INT, d INT, e INT, f INT,
  PRIMARY KEY (a, b), KEY il (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, the table appears as follows:

```
mysql> SELECT * FROM t1;
```

a	b	c	d	e	f
1	1	10	11	100	101
1	2	10	11	200	102
1	3	10	11	100	103
1	4	10	12	200	104
1	5	10	12	100	105

When you query the `index_name`, `stat_name`, `stat_value`, and `stat_description` where `stat_name LIKE 'n_diff%'`, the following result set is returned:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
-> FROM mysql.innodb_index_stats
-> WHERE table_name like 't1' AND stat_name LIKE 'n_diff%';
```

index_name	stat_name	stat_value	stat_description
PRIMARY	n_diff_pfx01	1	a
PRIMARY	n_diff_pfx02	5	a,b
il	n_diff_pfx01	1	c

i1	n_diff_pfx02	2	c,d
i1	n_diff_pfx03	2	c,d,a
i1	n_diff_pfx04	5	c,d,a,b
i2uniq	n_diff_pfx01	2	e
i2uniq	n_diff_pfx02	5	e,f

For the `PRIMARY` index, there are two `n_diff%` rows. The number of rows is equal to the number of columns in the index.

**Note**

For non-unique indexes, InnoDB appends the columns of the primary key.

- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `a`). The number of distinct values in column `a` is confirmed by viewing the data in column `a` in table `t1`, in which there is a single distinct value (1). The counted column (`a`) is shown in the `stat_description` column of the result set.
- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`a,b`). The number of distinct values in columns `a` and `b` is confirmed by viewing the data in columns `a` and `b` in table `t1`, in which there are five distinct values: (1,1), (1,2), (1,3), (1,4) and (1,5). The counted columns (`a,b`) are shown in the `stat_description` column of the result set.

For the secondary index (`i1`), there are four `n_diff%` rows. Only two columns are defined for the secondary index (`c,d`) but there are four `n_diff%` rows for the secondary index because InnoDB suffixes all non-unique indexes with the primary key. As a result, there are four `n_diff%` rows instead of two to account for the both the secondary index columns (`c,d`) and the primary key columns (`a,b`).

- Where `index_name=i1` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `c`). The number of distinct values in column `c` is confirmed by viewing the data in column `c` in table `t1`, in which there is a single distinct value: (10). The counted column (`c`) is shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx02`, the `stat_value` is 2, which indicates that there are two distinct values in the first two columns of the index (`c,d`). The number of distinct values in columns `c` and `d` is confirmed by viewing the data in columns `c` and `d` in table `t1`, in which there are two distinct values: (10,11) and (10,12). The counted columns (`c,d`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx03`, the `stat_value` is 2, which indicates that there are two distinct values in the first three columns of the index (`c,d,a`). The number of distinct values in columns `c`, `d`, and `a` is confirmed by viewing the data in column `c`, `d`, and `a` in table `t1`, in which there are two distinct values: (10,11,1) and (10,12,1). The counted columns (`c,d,a`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx04`, the `stat_value` is 5, which indicates that there are five distinct values in the four columns of the index (`c,d,a,b`). The number of distinct values in columns `c`, `d`, `a` and `b` is confirmed by viewing the data in columns `c`, `d`, `a`, and `b` in table `t1`, in which there are five distinct values: (10,11,1,1), (10,11,1,2), (10,11,1,3), (10,12,1,4) and (10,12,1,5). The counted columns (`c,d,a,b`) are shown in the `stat_description` column of the result set.

For the unique index (`i2uniq`), there are two `n_diff%` rows.

- Where `index_name=i2uniq` and `stat_name=n_diff_pfx01`, the `stat_value` is 2, which indicates that there are two distinct values in the first column of the index (column `e`). The number of distinct values in column `e` is confirmed by viewing the data in column `e` in table `t1`,

in which there are two distinct values: (100) and (200). The counted column (*e*) is shown in the `stat_description` column of the result set.

- Where `index_name=i2uniq` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (*e*, *f*). The number of distinct values in columns *e* and *f* is confirmed by viewing the data in columns *e* and *f* in table `t1`, in which there are five distinct values: (100,101), (200,102), (100,103), (200,104) and (100,105). The counted columns (*e*, *f*) are shown in the `stat_description` column of the result set.

## Retrieving Index Size Using the `innodb_index_stats` Table

The size of indexes for tables, partitions, or subpartitions can be retrieved using the `innodb_index_stats` table. In the following example, index sizes are retrieved for table `t1`. For a definition of table `t1` and corresponding index statistics, see [InnoDB Persistent Statistics Tables Example](#).

```
mysql> SELECT SUM(stat_value) pages, index_name,
-> SUM(stat_value)*@@innodb_page_size size
-> FROM mysql.innodb_index_stats WHERE table_name='t1'
-> AND stat_name = 'size' GROUP BY index_name;
```

pages	index_name	size
1	PRIMARY	16384
1	i1	16384
1	i2uniq	16384

For partitions or subpartitions, the same query with a modified `WHERE` clause can be used to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table `t1`:

```
mysql> SELECT SUM(stat_value) pages, index_name,
-> SUM(stat_value)*@@innodb_page_size size
-> FROM mysql.innodb_index_stats WHERE table_name like 't1#P%'
-> AND stat_name = 'size' GROUP BY index_name;
```

### 14.3.11.2 Configuring Non-Persistent Optimizer Statistics Parameters

This section describes how to configure non-persistent optimizer statistics. Optimizer statistics are not persisted to disk when `innodb_stats_persistent=OFF` or when individual tables are created or altered with `STATS_PERSISTENT=0`. Instead, statistics are stored in memory, and are lost when the server is shut down. Statistics are also updated periodically by certain operations and under certain conditions.

As of MySQL 5.6.6, optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

## Optimizer Statistics Updates

Optimizer statistics are updated when:

- Running `ANALYZE TABLE`.
- Running `SHOW TABLE STATUS`, `SHOW INDEX`, or querying the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables with the `innodb_stats_on_metadata` option enabled.

The default setting for `innodb_stats_on_metadata` was changed to `OFF` when persistent optimizer statistics were enabled by default in MySQL 5.6.6. Enabling `innodb_stats_on_metadata` may reduce access speed for schemas that have a large number of tables or indexes, and reduce stability of execution plans for queries that involve InnoDB tables. `innodb_stats_on_metadata` is configured globally using a `SET` statement.

```
SET GLOBAL innodb_stats_on_metadata=ON
```

- Starting a `mysql` client with the `--auto-rehash` option enabled, which is the default. The `auto-rehash` option causes all InnoDB tables to be opened, and the open table operations cause statistics to be recalculated.

To improve the start up time of the `mysql` client and to updating statistics, you can turn off `auto-rehash` using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

- A table is first opened.
- InnoDB detects that 1 / 16 of table has been modified since the last time statistics were updated.

## Configuring the Number of Sampled Pages

The MySQL query optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. When InnoDB updates optimizer statistics, it samples random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_transient_sample_pages`. The default number of sampled pages is 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in [joins](#). Unnecessary [full table scans](#) for such tables can be a substantial performance issue. See [Section 8.2.1.20, “How to Avoid Full Table Scans”](#) for tips on tuning such queries. `innodb_stats_transient_sample_pages` is a global parameter that can be set at runtime.

The value of `innodb_stats_transient_sample_pages` affects the index sampling for all InnoDB tables and indexes when `innodb_stats_persistent=0`. Be aware of the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in inaccurate estimates of cardinality.
- Increasing the `innodb_stats_transient_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a significant slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`.
- The optimizer might choose very different query plans based on different estimates of index selectivity.

Whatever value of `innodb_stats_transient_sample_pages` works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of `ANALYZE TABLE`, it does not make sense to increase the index sample size, run `ANALYZE TABLE`, then decrease sample size again.

Smaller tables generally require fewer index samples than larger tables. If your database has many large tables, consider using a higher value for `innodb_stats_transient_sample_pages` than if you have mostly smaller tables.

### 14.3.11.3 Estimating ANALYZE TABLE Complexity for InnoDB Tables

`ANALYZE TABLE` complexity for InnoDB tables is dependent on:

- The number of pages sampled, as defined by `innodb_stats_persistent_sample_pages`.
- The number of indexed columns in a table

- The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating `ANALYZE TABLE` complexity would be:

The value of `innodb_stats_persistent_sample_pages` \* number of indexed columns in a table \* the number of partitions

Typically, the greater the resulting value, the greater the execution time for `ANALYZE TABLE`.

#### Note

`innodb_stats_persistent_sample_pages` defines the number of pages sampled at a global level. To set the number of pages sampled for an individual table, use the `STATS_SAMPLE_PAGES` option with `CREATE TABLE` or `ALTER TABLE`. For more information, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

If `innodb_stats_persistent=OFF`, the number of pages sampled is defined by `innodb_stats_transient_sample_pages`. See [Section 14.3.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#) for additional information.

For a more in-depth approach to estimating `ANALYZE TABLE` complexity, consider the following example.

In **Big O notation**, `ANALYZE TABLE` complexity is described as:

```
O(n_sample
  * (n_cols_in_uniq_i
    + n_cols_in_non_uniq_i
    + n_cols_in_pk * (1 + n_non_uniq_i))
  * n_part)
```

where:

- `n_sample` is the number of pages sampled (defined by `innodb_stats_persistent_sample_pages`)
- `n_cols_in_uniq_i` is total number of all columns in all unique indexes (not counting the primary key columns)
- `n_cols_in_non_uniq_i` is the total number of all columns in all non-unique indexes
- `n_cols_in_pk` is the number of columns in the primary key (if a primary key is not defined, InnoDB creates a single column primary key internally)
- `n_non_uniq_i` is the number of non-unique indexes in the table
- `n_part` is the number of partitions. If no partitions are defined, the table is considered to be a single partition.

Now, consider the following table (table `t`), which has a primary key (2 columns), a unique index (2 columns), and two non-unique indexes (two columns each):

```
CREATE TABLE t (
  a INT,
  b INT,
  c INT,
  d INT,
  e INT,
  f INT,
  g INT,
  h INT,
  PRIMARY KEY (a, b),
```

```
UNIQUE KEY iluniq (c, d),
KEY i2nonuniq (e, f),
KEY i3nonuniq (g, h)
);
```

For the column and index data required by the algorithm described above, query the `mysql.innodb_index_stats` persistent index statistics table for table `t`. The `n_diff_pfx%` statistics show the columns that are counted for each index. For example, columns `a` and `b` are counted for the primary key index. For the non-unique indexes, the primary key columns (`a`,`b`) are counted in addition to the user defined columns.

**Note**

For additional information about the `InnoDB` persistent statistics tables, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#)

```
SELECT index_name, stat_name, stat_description
FROM mysql.innodb_index_stats
WHERE
database_name='test' AND
table_name='t' AND
stat_name like 'n_diff_pfx%';
```

index_name	stat_name	stat_description
PRIMARY	n_diff_pfx01	a
PRIMARY	n_diff_pfx02	a,b
iluniq	n_diff_pfx01	c
iluniq	n_diff_pfx02	c,d
i2nonuniq	n_diff_pfx01	e
i2nonuniq	n_diff_pfx02	e,f
i2nonuniq	n_diff_pfx03	e,f,a
i2nonuniq	n_diff_pfx04	e,f,a,b
i3nonuniq	n_diff_pfx01	g
i3nonuniq	n_diff_pfx02	g,h
i3nonuniq	n_diff_pfx03	g,h,a
i3nonuniq	n_diff_pfx04	g,h,a,b

Based on the index statistics data shown above and the table definition, the following values can be determined:

- `n_cols_in_uniq_i`, the total number of all columns in all unique indexes not counting the primary key columns, is 2 (`c` and `d`)
- `n_cols_in_non_uniq_i`, the total number of all columns in all non-unique indexes, is 4 (`e`, `f`, `g` and `h`)
- `n_cols_in_pk`, the number of columns in the primary key, is 2 (`a` and `b`)
- `n_non_uniq_i`, the number of non-unique indexes in the table, is 2 (`i2nonuniq` and `i3nonuniq`)
- `n_part`, the number of partitions, is 1.

You can now calculate `innodb_stats_persistent_sample_pages * (2 + 4 + 2 * (1 + 2)) * 1` to determine the number of leaf pages that are scanned. With `innodb_stats_persistent_sample_pages` set to the default value of 20, and with a default page size of 16 KiB (`innodb_page_size=16384`), you can then estimate that `20 * 12 * 16384 bytes` are read for table `t`, or about 4 MiB.

**Note**

All 4 MiB may not be read from disk, as some leaf pages may already be cached in the buffer pool.

### 14.3.12 Configuring the Merge Threshold for Index Pages

Starting in MySQL 5.7.6, you can configure the `MERGE_THRESHOLD` value for index pages. If the “page-full” percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an `UPDATE` operation, `InnoDB` attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value. The minimum `MERGE_THRESHOLD` value is 1 and the maximum value is 50.

When the “page-full” percentage for an index page falls below 50%, which is the default `MERGE_THRESHOLD` setting, `InnoDB` attempts to merge the index page with a neighboring page. If both pages are close to 50% full, a page split can occur soon after the pages are merged. If this merge-split behavior occurs frequently, it can have an adverse affect on performance. To avoid frequent merge-splits, you can lower the `MERGE_THRESHOLD` value so that `InnoDB` attempts page merges at a lower “page-full” percentage. Merging pages at a lower page-full percentage leaves more room in index pages and helps reduce merge-split behaviour.

The `MERGE_THRESHOLD` for index pages can be defined for a table or for individual indexes. A `MERGE_THRESHOLD` value defined for an individual index takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, the `MERGE_THRESHOLD` value defaults to 50.

#### Setting `MERGE_THRESHOLD` for a Table

You can set the `MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause of the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
) COMMENT='MERGE_THRESHOLD=45';
```

You can also set the `MERGE_THRESHOLD` value for an existing table using the `table_option COMMENT` clause with `ALTER TABLE`:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
);

ALTER TABLE t1 COMMENT='MERGE_THRESHOLD=40';
```

#### Setting `MERGE_THRESHOLD` for Individual Indexes

To set the `MERGE_THRESHOLD` value for an individual index, you can use the `index_option COMMENT` clause with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, as shown in the following examples:

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE TABLE`:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40'
);
```

- Setting `MERGE_THRESHOLD` for an individual index using `ALTER TABLE`:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
);

ALTER TABLE t1 DROP KEY id_index;
ALTER TABLE t1 ADD KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40';
```

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE INDEX`:

```
CREATE TABLE t1 (id INT);
```

```
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

**Note**

You cannot modify the `MERGE_THRESHOLD` value at the index level for `GEN_CLUST_INDEX`, which is the clustered index created by `InnoDB` when an `InnoDB` table is created without a primary key or unique key index. You can only modify the `MERGE_THRESHOLD` value for `GEN_CLUST_INDEX` by setting `MERGE_THRESHOLD` for the table.

**Querying the `MERGE_THRESHOLD` Value for an Index**

The current `MERGE_THRESHOLD` value for an index can be obtained by querying the `INNODB_SYS_INDEXES` table. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE NAME='id_index' \G
***** 1. row *****
INDEX_ID: 91
NAME: id_index
TABLE_ID: 68
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
MERGE_THRESHOLD: 40
```

You can use `SHOW CREATE TABLE` to view the `MERGE_THRESHOLD` value for a table, if explicitly defined using the `table_option COMMENT` clause:

```
mysql> SHOW CREATE TABLE t2 \G
***** 1. row *****
Table: t2
Create Table: CREATE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  KEY `id_index` (`id`) COMMENT 'MERGE_THRESHOLD=40'
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

**Note**

A `MERGE_THRESHOLD` value defined at the index level takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, `MERGE_THRESHOLD` defaults to 50% (`MERGE_THRESHOLD=50`, which is the previously hardcoded value).

Likewise, you can use `SHOW INDEX` to view the `MERGE_THRESHOLD` value for an index, if explicitly defined using the `index_option COMMENT` clause:

```
mysql> SHOW INDEX FROM t2 \G
***** 1. row *****
Table: t2
Non_unique: 1
Key_name: id_index

Index_comment: MERGE_THRESHOLD=40
```

**Measuring the Effect of `MERGE_THRESHOLD` Settings**

The `INNODB_METRICS` table provides two counters that can be used to measure the effect of a `MERGE_THRESHOLD` setting on index page merges.

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE NAME like '%index_page_merge%';
```

NAME	COMMENT
index_page_merge_attempts	Number of index page merge attempts
index_page_merge_successful	Number of successful index page merges

When lowering the `MERGE_THRESHOLD` value, the objectives are:

- A smaller number of page merge attempts and successful page merges
- A similar number of page merge attempts and successful page merges

A `MERGE_THRESHOLD` setting that is too small could result in large data files due to an excessive amount of empty page space.

For information about using `INNODB_METRICS` counters, see [Section 14.12.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

## 14.4 InnoDB Tablespace Management

### 14.4.1 Resizing the InnoDB System Tablespace

This section describes how to increase or decrease the size of the `InnoDB` system tablespace.

#### Increasing the Size of the InnoDB System Tablespace

The easiest way to increase the size of the `InnoDB` system tablespace is to configure it from the beginning to be auto-extending. Specify the `autoextend` attribute for the last data file in the tablespace definition. Then `InnoDB` increases the size of that file automatically in 8MB increments when it runs out of space. The increment size can be changed by setting the value of the `innodb_autoextend_increment` system variable, which is measured in megabytes.

You can expand the system tablespace by a defined amount by adding another data file:

1. Shut down the MySQL server.
2. If the previous last data file is defined with the keyword `autoextend`, change its definition to use a fixed size, based on how large it has actually grown. Check the size of the data file, round it down to the closest multiple of 1024 × 1024 bytes (= 1MB), and specify this rounded size explicitly in `innodb_data_file_path`.
3. Add a new data file to the end of `innodb_data_file_path`, optionally making that file auto-extending. Only the last data file in the `innodb_data_file_path` can be specified as auto-extending.
4. Start the MySQL server again.

For example, this tablespace has just one auto-extending data file `ibdata1`:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to use a fixed size and adding a new auto-extending data file:

```
innodb_data_home_dir =
```

```
innodb_data_file_path = /ibdata/ibdata1:988M:/disk2/ibdata2:50M:autoextend
```

When you add a new data file to the system tablespace configuration, make sure that the filename does not refer to an existing file. InnoDB creates and initializes the file when you restart the server.

### Decreasing the Size of the InnoDB System Tablespace

You cannot remove a data file from the system tablespace. To decrease the system tablespace size, use this procedure:

1. Use `mysqldump` to dump all your InnoDB tables, including InnoDB tables located in the MySQL database. As of 5.6, there are five InnoDB tables included in the MySQL database:

```
mysql> select table_name from information_schema.tables where table_schema='mysql' and engine='InnoDB';
+-----+
| table_name |
+-----+
| innodb_index_stats |
| innodb_table_stats |
| slave_master_info |
| slave_relay_log_info |
| slave_worker_info |
+-----+
5 rows in set (0.00 sec)
```

2. Stop the server.
3. Remove all the existing tablespace files (`*.ibd`), including the `ibdata` and `ib_log` files. Do not forget to remove `*.ibd` files for tables located in the MySQL database.
4. Remove any `.frm` files for InnoDB tables.
5. Configure a new tablespace.
6. Restart the server.
7. Import the dump files.

#### Note

If your databases only use the InnoDB engine, it may be simpler to dump all databases, stop the server, remove all databases and InnoDB log files, restart the server, and import the dump files.

### 14.4.2 Changing the Number or Size of InnoDB Redo Log Files

To change the number or the size of your InnoDB redo log files, perform the following steps:

1. Stop the MySQL server and make sure that it shuts down without errors.
2. Edit `my.cnf` to change the log file configuration. To change the log file size, configure `innodb_log_file_size`. To increase the number of log files, configure `innodb_log_files_in_group`.
3. Start the MySQL server again.

If InnoDB detects that the `innodb_log_file_size` differs from the redo log file size, it will write a log checkpoint, close and remove the old log files, create new log files at the requested size, and open the new log files.

### 14.4.3 Using Raw Disk Partitions for the System Tablespace

You can use raw disk partitions as data files in the [InnoDB system tablespace](#). This technique enables nonbuffered I/O on Windows and on some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether this change actually improves performance on your system.

When you use a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if you run the server as the `mysql` user, the partition must be readable and writable by `mysql`. If you run the server with the `--memlock` option, the server must be run as `root`, so the partition must be readable and writable by `root`.

The procedures described below involve option file modification. For additional information, see [Section 4.2.6, “Using Option Files”](#).

## Allocating a Raw Disk Partition on Linux and Unix Systems

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
```

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server, InnoDB reinitializes the partition and your changes are lost. (As a safety measure InnoDB prevents users from modifying data when any partition with `newraw` is specified.)
3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Graw;/dev/hdd2:2Graw
```

4. Restart the server. InnoDB now permits changes to be made.

## Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the `innodb_data_file_path` setting differs slightly on Windows.

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D:10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition.
3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
```

```
innodb_data_file_path=//./D::10Graw
```

- Restart the server. `InnoDB` now permits changes to be made.

## 14.4.4 InnoDB File-Per-Table Tablespaces

Historically, all `InnoDB` tables and indexes were stored in the `system tablespace`. This monolithic approach was targeted at machines dedicated entirely to database processing, with carefully planned data growth, where any disk storage allocated to MySQL would never be needed for other purposes. `InnoDB`'s `file-per-table tablespace` feature provides a more flexible alternative, where each `InnoDB` table and its indexes are stored in a separate `.ibd` data file. Each such `.ibd` data file represents an individual `tablespace`. This feature is controlled by the `innodb_file_per_table` configuration option, which is enabled by default in MySQL 5.6.6 and higher.

### Advantages of File-Per-Table Tablespaces

- You can reclaim disk space when truncating or dropping a table stored in a file-per-table tablespace. Truncating or dropping tables stored in the system tablespace creates free space internally in the system tablespace data files (`ibdata files`) which can only be used for new `InnoDB` data.
- The `TRUNCATE TABLE` operation is faster when run on tables stored in file-per-table tablespaces.
- You can store specific tables on separate storage devices, for I/O optimization, space management, or backup purposes. In previous releases, you had to move entire database directories to other drives and create symbolic links in the MySQL data directory, as described in [Section 8.12.4, “Using Symbolic Links”](#). In MySQL 5.6.6 and higher, you can specify the location of each table using the syntax `CREATE TABLE ... DATA DIRECTORY = absolute_path_to_directory`, as explained in [Section 14.4.5, “Creating a File-Per-Table Tablespace Outside the Data Directory”](#).
- You can run `OPTIMIZE TABLE` to compact or recreate a file-per-table tablespace. When you run an `OPTIMIZE TABLE`, `InnoDB` creates a new `.ibd` file with a temporary name, using only the space required to store actual data. When the optimization is complete, `InnoDB` removes the old `.ibd` file and replaces it with the new one. If the previous `.ibd` file grew significantly but the actual data only accounted for a portion of its size, running `OPTIMIZE TABLE` can reclaim the unused space.
- You can move individual `InnoDB` tables rather than entire databases.
- You can copy individual `InnoDB` tables from one MySQL instance to another (known as the `transportable tablespace` feature).
- Tables created in file-per-table tablespaces use the `Barracuda` file format. The `Barracuda` file format enables features such as `compressed` and `dynamic` row formats.
- You can enable more efficient storage for tables with large `BLOB` or `TEXT` columns using the `dynamic row format`.
- File-per-table tablespaces may improve chances for a successful recovery and save time when a corruption occurs, when a server cannot be restarted, or when backup and binary logs are unavailable.
- File-per-table tablespaces are convenient for per-table status reporting when copying or backing up tables.
- You can monitor table size at a file system level, without accessing MySQL.
- Common Linux file systems do not permit concurrent writes to a single file when `innodb_flush_method` is set to `O_DIRECT`. As a result, there are possible performance improvements when using file-per-table tablespaces in conjunction with `innodb_flush_method`.
- The system tablespace stores the data dictionary and undo logs, and has a 64TB size limit. By comparison, each file-per-table tablespace has a 64TB size limit, which provides you with room for growth. See [Section C.10.3, “Limits on Table Size”](#) for related information.

## Potential Disadvantages of File-Per-Table Tablespaces

- With file-per-table tablespaces, each table may have unused space, which can only be utilized by rows of the same table. This could lead to wasted space if not properly managed.
- `fsync` operations must run on each open table rather than on a single file. Because there is a separate `fsync` operation for each file, write operations on multiple tables cannot be combined into a single I/O operation. This may require InnoDB to perform a higher total number of `fsync` operations.
- `mysqld` must keep one open file handle per table, which may impact performance if you have numerous tables in file-per-table tablespaces.
- More file descriptors are used.
- `innodb_file_per_table` is enabled by default in MySQL 5.6.6 and higher. You may consider disabling it if backward compatibility with MySQL 5.5 or 5.1 is a concern. Disabling `innodb_file_per_table` prevents `ALTER TABLE` from moving an InnoDB table from the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` recreates the table (`ALGORITHM=COPY`).

For example, when restructuring the clustered index for an InnoDB table, the table is re-created using the current setting for `innodb_file_per_table`. This behavior does not apply when adding or dropping InnoDB secondary indexes. When a secondary index is created without rebuilding the table, the index is stored in the same file as the table data, regardless of the current `innodb_file_per_table` setting. This behaviour also does not apply to tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax. These tables are not affected by the `innodb_file_per_table` setting.

- If many tables are growing there is potential for more fragmentation which can impede `DROP TABLE` and table scan performance. However, when fragmentation is managed, having files in their own tablespace can improve performance.
- The buffer pool is scanned when dropping a file-per-table tablespace, which can take several seconds for buffer pools that are tens of gigabytes in size. The scan is performed with a broad internal lock, which may delay other operations. Tables in the system tablespace are not affected.
- The `innodb_autoextend_increment` variable, which defines increment size (in MB) for extending the size of an auto-extending shared tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

### 14.4.4.1 Enabling and Disabling File-Per-Table Tablespaces

The `innodb_file_per_table` option is enabled by default as of MySQL 5.6.6.

To set the `innodb_file_per_table` option at startup, start the server with the `--innodb_file_per_table` command-line option, or add this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table=1
```

You can also set `innodb_file_per_table` dynamically, while the server is running:

```
SET GLOBAL innodb_file_per_table=1;
```

With `innodb_file_per_table` enabled, you can store InnoDB tables in a `tbl_name.ibd` file. Unlike the MyISAM storage engine, with its separate `tbl_name.MYD` and `tbl_name.MYI` files

for indexes and data, **InnoDB** stores the data and the indexes together in a single `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you disable `innodb_file_per_table` in your startup options and restart the server, or disable it with the `SET GLOBAL` command, **InnoDB** creates new tables inside the system tablespace unless you have explicitly placed the table in file-per-table tablespace or general tablespace using the `CREATE TABLE ... TABLESPACE` option, introduced in MySQL 5.7.6.

You can always read and write any **InnoDB** tables, regardless of the file-per-table setting.

To move a table from the system tablespace to its own tablespace, change the `innodb_file_per_table` setting and rebuild the table:

```
SET GLOBAL innodb_file_per_table=1;
ALTER TABLE table_name ENGINE=InnoDB;
```

Tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax are not affected by the `innodb_file_per_table` setting. To move these tables from the system tablespace to a file-per-table tablespace, they must be moved explicitly using `ALTER TABLE ... TABLESPACE` syntax.

### Note

**InnoDB** always needs the system tablespace because it puts its internal **data dictionary** and **undo logs** there. The `.ibd` files are not sufficient for **InnoDB** to operate.

When a table is moved out of the system tablespace into its own `.ibd` file, the data files that make up the system tablespace remain the same size. The space formerly occupied by the table can be reused for new **InnoDB** data, but is not reclaimed for use by the operating system. When moving large **InnoDB** tables out of the system tablespace, where disk space is limited, you may prefer to enable `innodb_file_per_table` and recreate the entire instance using the `mysqldump` command. As mentioned above, tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax are not affected by the `innodb_file_per_table` setting. These tables must be moved individually.

## 14.4.5 Creating a File-Per-Table Tablespace Outside the Data Directory

To create a new **InnoDB file-per-table** tablespace in a specific location outside the MySQL data directory, use the `DATA DIRECTORY = absolute_path_to_directory` clause of the `CREATE TABLE` statement.

Plan the location in advance, because you cannot use the `DATA DIRECTORY` clause with the `ALTER TABLE` statement. The directory you specify could be on another storage device with particular performance or capacity characteristics, such as a fast **SSD** or a high-capacity **HDD**.

Within the destination directory, MySQL creates a subdirectory corresponding to the database name, and within that a `.ibd` file for the new table. In the database directory beneath the MySQL `DATADIR` directory, MySQL creates a `table_name.isl` file containing the path name for the table. The `.isl` file is treated by MySQL like a symbolic link. (**Using actual symbolic links** has never been supported for **InnoDB** tables.)

The following example demonstrates creating a file-per-table tablespace outside the MySQL data directory. It shows the `.ibd` created in the specified directory, and the `.isl` created in the database directory beneath the MySQL data directory.

```
mysql> USE test;
Database changed
```

```
mysql> SHOW VARIABLES LIKE 'innodb_file_per_table';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_file_per_table | ON |
+-----+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/alternative/directory';
Query OK, 0 rows affected (0.03 sec)

# MySQL creates a .ibd file for the new table in a subdirectory that corresponding
# to the database name

db_user@ubuntu:~/alternative/directory/test$ ls
t1.ibd

# MySQL creates a .isl file containing the path name for the table in a directory
# beneath the MySQL data directory

db_user@ubuntu:~/mysql/data/test$ ls
db.opt t1.frm t1.isl
```

As of MySQL 5.7.6, you can also use `CREATE TABLE ... TABLESPACE` in combination with the `DATA DIRECTORY` clause to create a file-per-table tablespace outside the MySQL data directory. To do so, you must specify `innodb_file_per_table` as the tablespace name.

```
CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE = innodb_file_per_table
DATA DIRECTORY = '/alternative/directory';
```

You do not have to enable `innodb_file_per_table` when using this method.

## Usage Notes:

- MySQL initially holds the `.ibd` file open, preventing you from dismounting the device, but might eventually close the table if the server is busy. Be careful not to accidentally dismount an external device while MySQL is running, or to start MySQL while the device is disconnected. Attempting to access a table when the associated `.ibd` file is missing causes a serious error that requires a server restart.

A server restart might fail if the `.ibd` file is still not at the expected path. In this case, manually remove the `table_name.isl` file in the database directory, and after restarting perform a `DROP TABLE` to delete the `.frm` file and remove the information about the table from the [data dictionary](#).

- Do not put MySQL tables on an NFS-mounted volume. NFS uses a message-passing protocol to write to files, which could cause data inconsistency if network messages are lost or received out of order.
- If you use an LVM snapshot, file copy, or other file-based mechanism to back up the `.ibd` file, always use the `FLUSH TABLES ... FOR EXPORT` statement first to make sure all changes that were buffered in memory are **flushed** to disk before the backup occurs.
- The `DATA DIRECTORY` clause is a supported alternative to [using symbolic links](#), which has always been problematic and was never supported for individual `InnoDB` tables.

## 14.4.6 Copying File-Per-Table Tablespaces to Another Server

This section describes how to copy [file-per-table](#) tablespaces from one database server to another, otherwise known as the [Transportable Tablespaces](#) feature. Prior to MySQL 5.7.4, only non-partitioned `InnoDB` tables are supported. As of MySQL 5.7.4, partitioned `InnoDB` tables and individual `InnoDB` table partitions and subpartitions are also supported.

For information about other `InnoDB` table copying methods, see [Section 14.5.2, “Moving or Copying InnoDB Tables to Another Machine”](#).

There are many reasons why you might copy an [InnoDB file-per-table](#) tablespace to a different database server:

- To run reports without putting extra load on a production server.
- To set up identical data for a table on a new [slave server](#).
- To restore a backed-up version of a table or partition after a problem or mistake.
- As a faster way of moving data around than importing the results of a [mysqldump](#) command. The data is available immediately, rather than having to be re-inserted and the indexes rebuilt.
- To move a [file-per-table](#) tablespace to a server with storage medium that better suits system requirements. For example, you may want to have busy tables on an [SSD](#) device, or large tables on a high-capacity [HDD](#) device.

## Limitations and Usage Notes

- The tablespace copy procedure is only possible when `innodb_file_per_table` is set to `ON`, which is the default setting as of MySQL 5.6.6. Tables residing in the shared system tablespace cannot be quiesced.
- When a table is quiesced, only read-only transactions are allowed on the affected table.
- When importing a tablespace, the page size must match the page size of the importing instance.
- Prior to MySQL 5.7.4, `DISCARD TABLESPACE` is not supported for partitioned tables meaning that transportable tablespaces is also unsupported. If you run `ALTER TABLE ... DISCARD TABLESPACE` on a partitioned table, the following error is returned: `ERROR 1031 (HY000): Table storage engine for 'part' doesn't have this option`. As of MySQL 5.7.4, `ALTER TABLE ... DISCARD TABLESPACE` is supported for partitioned [InnoDB](#) tables, and `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is supported for [InnoDB](#) table partitions.
- `DISCARD TABLESPACE` is not supported for tablespaces with a parent-child (primary key-foreign key) relationship when `foreign_key_checks` is set to `1`. Before discarding a tablespace for parent-child tables, set `foreign_key_checks=0`. Partitioned [InnoDB](#) tables do not support foreign keys.
- `ALTER TABLE ... IMPORT TABLESPACE` does not enforce foreign key constraints on imported data. If there are foreign key constraints between tables, all tables should be exported at the same (logical) point in time. Partitioned [InnoDB](#) tables do not support foreign keys.
- `ALTER TABLE ... IMPORT TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` do not require a `.cfg` metadata file to import a tablespace. However, metadata checks are not performed when importing without a `.cfg` file, and a warning similar to the following will be issued:

```
Message: InnoDB: IO Read error: (2, No such file or directory) Error opening '.\test\t.cfg', will attempt to import without schema verification
1 row in set (0.00 sec)
```

The ability to import without a `.cfg` file may be more convenient when no schema mismatches are expected. Additionally, the ability to import without a `.cfg` file could be useful in crash recovery scenarios in which metadata cannot be collected from an `.ibd` file.

- Due to a `.cfg` metadata file limitation, schema mismatches are not reported for partition type or partition definition differences when importing tablespace files for partitioned tables. Column differences are reported.
- When running `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition

and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.

- In MySQL 5.6 or later, importing a tablespace file from another server works if both servers have GA (General Availability) status and their versions are within the same series. Otherwise, the file must have been created on the server into which it is imported.
- In replication scenarios, `innodb_file_per_table` must be set to `ON` on both the master and slave.
- On Windows, `InnoDB` stores database, tablespace, and table names internally in lowercase. To avoid import problems on case-sensitive operating systems such as Linux and UNIX, create all databases, tablespaces, and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating databases, tablespaces, or tables:

```
[mysqld]
lower_case_table_names=1
```

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported with tables that belong to an `InnoDB` general tablespace. For more information, see `CREATE TABLESPACE`.
- As of MySQL 5.7.9, the default row format for `InnoDB` tables is configurable using the `innodb_default_row_format` configuration option. Attempting to import a table that does not explicitly define a row format (`ROW_FORMAT`), or that uses `ROW_FORMAT=DEFAULT`, could result in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For related information, see [Section 14.8.2, “Specifying the Row Format for a Table”](#).

#### 14.4.6.1 Transportable Tablespace Examples

##### Example 1: Copying an InnoDB Table From One Server To Another

This procedure demonstrates how to copy a regular `InnoDB` table from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a full table restore on the same instance.

1. On the source server, create a table if one does not exist:

```
mysql> use test;
mysql> CREATE TABLE t(c1 INT) engine=InnoDB;
```

2. On the destination server, create a table if one does not exist:

```
mysql> use test;
mysql> CREATE TABLE t(c1 INT) engine=InnoDB;
```

3. On the destination server, discard the existing tablespace. (Before a tablespace can be imported, `InnoDB` must discard the tablespace that is attached to the receiving table.)

```
mysql> ALTER TABLE t DISCARD TABLESPACE;
```

4. On the source server, run `FLUSH TABLES ... FOR EXPORT` to quiesce the table and create the `.cfg` metadata file:

```
mysql> use test;
mysql> FLUSH TABLES t FOR EXPORT;
```

The metadata (`.cfg`) is created in the `InnoDB` data directory.

**Note**

`FLUSH TABLES ... FOR EXPORT` is available as of MySQL 5.6.6. The statement ensures that changes to the named table have been flushed to disk so that a binary table copy can be made while the server is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` file in the same database directory as the table. The `.cfg` file contains metadata used for schema verification when importing the tablespace file.

- Copy the `.ibd` file and `.cfg` metadata file from the source server to the destination server. For example:

```
shell> scp /path/to/datadir/test/t.{ibd,cfg} destination-server:/path/to/datadir/test
```

**Note**

The `.ibd` file and `.cfg` file must be copied before releasing the shared locks, as described in the next step.

- On the source server, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> use test;
mysql> UNLOCK TABLES;
```

- On the destination server, import the tablespace:

```
mysql> use test;
mysql> ALTER TABLE t IMPORT TABLESPACE;
```

**Note**

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data. If there are foreign key constraints between tables, all tables should be exported at the same (logical) point in time. In this case you would stop updating the tables, commit all transactions, acquire shared locks on the tables, and then perform the export operation.

**Example 2: Copying an InnoDB Partitioned Table From One Server To Another**

This procedure demonstrates how to copy a partitioned InnoDB table from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a full restore of a partitioned InnoDB table on the same instance.

- On the source server, create a partitioned table if one does not exist. In the following example, a table with three partitions (p0, p1, p2) is created:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the `/datadir/test` directory, you will see a separate tablespace (`.ibd`) file for each of the three partitions.

```
mysql> \! ls /path/to/datadir/test/
db.opt t1.frm t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd
```

- On the destination server, create the same partitioned table:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the `/datadir/test` directory, you will see a separate tablespace (`.ibd`) file for each of the three partitions.

```
mysql> \! ls /path/to/datadir/test/
db.opt t1.frm t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd
```

3. On the destination server, discard the tablespace for the partitioned table. (Before the tablespace can be imported on the destination server, the tablespace that is attached to the receiving table must be discarded.)

```
mysql> ALTER TABLE t1 DISCARD TABLESPACE;
```

The three `.ibd` files that make up the tablespace for the partitioned table are discarded from the `/datadir/test` directory, leaving the following files:

```
mysql> \! ls /path/to/datadir/test/
db.opt t1.frm
```

4. On the source server, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table and create the `.cfg` metadata files:

```
mysql> use test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

Metadata (`.cfg`) files, one for each tablespace (`.ibd`) file, are created in the `/datadir/test` directory on the source server:

```
mysql> \! ls /path/to/datadir/test/
db.opt t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd
t1.frm t1#P#p0.cfg t1#P#p1.cfg t1#P#p2.cfg
```

#### Note

`FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that binary table copy can be made while the server is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` metadata file for the table's tablespace files in the same database directory as the table. The `.cfg` files contain metadata used for schema verification when importing tablespace files. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

5. Copy the `.ibd` and `.cfg` files from the source server database directory to the destination server database directory. For example:

```
shell> scp /path/to/datadir/test/t1*.{ibd,cfg} destination-server:/path/to/datadir/test
```

#### Note

The `.ibd` and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

6. On the source server, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> use test;
mysql> UNLOCK TABLES;
```

7. On the destination server, import the tablespace for the partitioned table:

```
mysql> use test;
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

### Example 3: Copying InnoDB Table Partitions From One Server To Another

This procedure demonstrates how to copy [InnoDB](#) table partitions from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a restore of [InnoDB](#) table partitions on the same instance. In the following example, a partitioned table with four partitions (p0, p1, p2, p3) is created on the source server. Two of the partitions (p2 and p3) are copied to the destination server.

1. On the source server, create a partitioned table if one does not exist. In the following example, a table with four partitions (p0, p1, p2, p3) is created:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, you will see a separate tablespace (`.ibd`) file for each of the four partitions.

```
mysql> \! ls /path/to/datadir/test/
db.opt t1.frm t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd t1#P#p3.ibd
```

2. On the destination server, create the same partitioned table:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, you will see a separate tablespace (`.ibd`) file for each of the four partitions.

```
mysql> \! ls /path/to/datadir/test/
db.opt t1.frm t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd t1#P#p3.ibd
```

3. On the destination server, discard the tablespace partitions that you plan to import from the source server. (Before tablespace partitions can be imported on the destination server, the corresponding partitions that are attached to the receiving table must be discarded.)

```
mysql> ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

The `.ibd` files for the two discarded partitions are removed from the `/datadir/test` directory on the destination server, leaving the following files:

```
mysql> \! ls /path/to/datadir/test/
db.opt t1.frm t1#P#p0.ibd t1#P#p1.ibd
```

#### Note

When `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.

- On the source server, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table and create the `.cfg` metadata files.

```
mysql> use test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

The metadata files (`.cfg` files) are created in the `/datadir/test` directory on the source server. There is a `.cfg` file for each tablespace (`.ibd`) file.

```
mysql> \! ls /path/to/datadir/test/
db.opt  t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd  t1#P#p3.ibd
t1.frm  t1#P#p0.cfg  t1#P#p1.cfg  t1#P#p2.cfg  t1#P#p3.cfg
```

#### Note

`FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that binary table copy can be made while the server is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` metadata file for the table's tablespace files in the same database directory as the table. The `.cfg` files contain metadata used for schema verification when importing tablespace files. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

- Copy the `.ibd` and `.cfg` files from the source server database directory to the destination server database directory. In this example, only the `.ibd` and `.cfg` files for partition 2 (p2) and partition 3 (p3) are copied to the `data` directory on the destination server. Partition 0 (p0) and partition 1 (p1) remain on the source server.

```
shell> scp t1#P#p2.ibd t1#P#p2.cfg t1#P#p3.ibd t1#P#p3.cfg destination-server:/path/to/datadir/test
```

#### Note

The `.ibd` files and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

- On the source server, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> use test;
mysql> UNLOCK TABLES;
```

- On the destination server, import the tablespace partitions (p2 and p3):

```
mysql> use test;
mysql> ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

#### Note

When `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.

### 14.4.6.2 Transportable Tablespace Internals

The following information describes internals and error log messaging for the transportable tablespaces copy procedure for a regular InnoDB table.

When `ALTER TABLE ... DISCARD TABLESPACE` is run on the destination instance:

- The table is locked in X mode.
- The tablespace is detached from the table.

When `FLUSH TABLES ... FOR EXPORT` is run on the source instance:

- The table being flushed for export is locked in shared mode.
- The purge coordinator thread is stopped.
- Dirty pages are synchronized to disk.
- Table metadata is written to the binary `.cfg` file.

Expected error log messages for this operation:

```
2013-09-24T13:10:19.903526Z 2 [Note] InnoDB: Sync to disk of '"test"."t"' started.
2013-09-24T13:10:19.903586Z 2 [Note] InnoDB: Stopping purge
2013-09-24T13:10:19.903725Z 2 [Note] InnoDB: Writing table metadata to './test/t.cfg'
2013-09-24T13:10:19.904014Z 2 [Note] InnoDB: Table '"test"."t"' flushed to disk
```

When `UNLOCK TABLES` is run on the source instance:

- The binary `.cfg` file is deleted.
- The shared lock on the table or tables being imported is released and the purge coordinator thread is restarted.

Expected error log messages for this operation:

```
2013-09-24T13:10:21.181104Z 2 [Note] InnoDB: Deleting the meta-data file './test/t.cfg'
2013-09-24T13:10:21.181180Z 2 [Note] InnoDB: Resuming purge
```

When `ALTER TABLE ... IMPORT TABLESPACE` is run on the destination instance, the import algorithm performs the following operations for each tablespace being imported:

- Each tablespace page is checked for corruption.
- The space ID and log sequence numbers (LSNs) on each page are updated
- Flags are validated and LSN updated for the header page.
- Btree pages are updated.
- The page state is set to dirty so that it will be written to disk.

Expected error log messages for this operation:

```
2013-07-18 15:15:01 34960 [Note] InnoDB: Importing tablespace for table 'test/t' that was exported from hos
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase I - Update all pages
2013-07-18 15:15:01 34960 [Note] InnoDB: Sync to disk
2013-07-18 15:15:01 34960 [Note] InnoDB: Sync to disk - done!
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase III - Flush changes to disk
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase IV - Flush complete
```

### Note

You may also receive a warning that a tablespace is discarded (if you discarded the tablespace for the destination table) and a message stating that statistics could not be calculated due to a missing `.ibd` file:

```
2013-07-18 15:14:38 34960 [Warning] InnoDB: Table "test"."t" tablespace is set as dis
2013-07-18 15:14:38 7f34d9a37700 InnoDB: cannot calculate statistics for table "test"
http://dev.mysql.com/doc/refman/5.7/en/innodb-troubleshooting.html
```

## 14.4.7 Storing InnoDB Undo Logs in Separate Tablespaces

You can store [InnoDB undo logs](#) in one or more separate [undo tablespaces](#) outside of the [system tablespace](#). This layout is different from the default configuration where the undo log is part of the [system tablespace](#). The I/O patterns for the undo log make these tablespaces good candidates to move to [SSD](#) storage, while keeping the system tablespace on hard disk storage. Users cannot drop the separate tablespaces created to hold [InnoDB](#) undo logs, or the individual [segments](#) inside those tablespaces. However, as of MySQL 5.7.5, undo logs stored in undo tablespaces can be truncated. For more information, see [Section 14.4.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

Because these files handle I/O operations formerly done inside the system tablespace, we broaden the definition of system tablespace to include these new files.

Undo logs are also referred to as [rollback segments](#).

This feature involves the following new or renamed configuration options:

- `innodb_undo_tablespaces`
- `innodb_undo_directory`
- `innodb_rollback_segments` becomes `innodb_undo_logs`. The old name is still available for compatibility.

Because the [InnoDB undo log](#) feature involves setting two non-dynamic startup variables (`innodb_undo_tablespaces` and `innodb_undo_directory`), this feature can only be enabled when initializing a MySQL instance.

### Usage Notes

To use this feature, follow these steps:

1. Decide on a path to hold the undo logs. You will specify that path as the argument to the `innodb_undo_directory` option in your MySQL configuration file or startup script. If no path is specified, undo tablespaces are created in the MySQL data directory, as defined by `datadir`.
2. Decide on a starting value for the `innodb_undo_logs` option. You can start with a relatively low value and increase it over time to examine the effect on performance.

As of MySQL 5.7.2, 32 of 128 undo logs were reserved as non-redo undo logs (rollback segments) for temporary table transactions. To allocate undo logs to undo tablespaces, `innodb_undo_logs` must be set to a value greater than 33. For example, if you have two undo tablespaces (`innodb_undo_tablespaces=2`), `innodb_undo_logs` must be set to 35 to assign one undo log to each of the two undo tablespaces.

- The first undo log (rollback segment) always resides in the system tablespace (when undo tablespaces are present, this undo log is inactive).
  - Undo logs 2 to 33 reside in the shared temporary tablespace (`ibtmp1`).
  - The 34th undo log resides in the first undo tablespace.
  - The 35th undo log resides in the second undo tablespace.
3. Decide on a non-zero value for the `innodb_undo_tablespaces` option. The multiple undo logs specified by the `innodb_undo_logs` value are divided between this number of separate

tablespaces (represented by `.ibd` files). This value is fixed for the life of the MySQL instance, so if you are uncertain about the optimal value, estimate on the high side.

4. Create a new MySQL instance, using the values you chose in the configuration file or in your MySQL startup script. Use a realistic workload with data volume similar to your production servers. Alternatively, use the transportable tablespaces feature to copy existing database tables to your newly configured MySQL instance. See [Section 14.4.6, “Copying File-Per-Table Tablespaces to Another Server”](#) for more information.
5. Benchmark the performance of I/O intensive workloads.
6. Periodically increase the value of `innodb_undo_logs` and rerun performance tests. Find the value where you stop experiencing gains in I/O performance.
7. Deploy a new production instance using the ideal settings for these options. Set it up as a [slave server](#) in a [replication](#) configuration, or transfer data from an earlier production instance.

## Performance and Scalability Considerations

Keeping the undo logs in separate files allows the MySQL team to implement I/O and memory optimizations related to this transactional data. For example, because the undo data is written to disk and then rarely used (only in case of crash recovery), it does not need to be kept in the file system memory cache, in turn allowing a higher percentage of system memory to be devoted to the [InnoDB buffer pool](#).

The typical SSD best practice of keeping the [InnoDB](#) system tablespace on a hard drive and moving the per-table tablespaces to SSD, is assisted by moving the undo information into separate tablespace files.

## Internals

The physical tablespace files are named `undoN`, where `N` is the space ID, including leading zeros.

MySQL instances containing separate undo tablespaces cannot be downgraded to earlier releases such as MySQL 5.5 or 5.1.

### Note

As of MySQL 5.7.5, you can truncate undo logs that reside in undo tablespaces. For more information, see [Section 14.4.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

## 14.4.8 Truncating Undo Logs That Reside in Undo Tablespaces

As of MySQL 5.7.5, you can truncate [undo logs](#) that reside in [undo tablespaces](#), provided that the following conditions are true:

- Your MySQL instance is configured with a minimum of two undo tablespaces (`innodb_undo_tablespaces=2`). When an undo tablespace is truncated, it is temporarily taken offline. For the server to function, there must be at least one other active undo tablespace. The number of undo tablespaces is defined by the `innodb_undo_tablespaces` option, which can only be set when the MySQL instance is initialized. The default value is 0. To check the value of `innodb_undo_tablespaces`, submit the following query:

```
mysql> SELECT @@innodb_undo_tablespaces;
+-----+
| @@innodb_undo_tablespaces |
+-----+
| 2 |
+-----+
1 row in set (0.00 sec)
```

- `innodb_undo_logs`, which defines the number of [rollback segments](#) used by `InnoDB`, must be set to 35 or greater. A setting of 35 or greater ensures that a redo-enabled undo log is assigned to each of the two undo tablespaces. With an `innodb_undo_logs` setting of 35:
  - The first rollback segment always resides in the [system tablespace](#) (when undo tablespaces are present, this rollback segment is inactive)
  - Rollback segments 2 to 33 reside in the shared temporary tablespace (`ibtmp1`)
  - The 34th rollback segment resides in the first undo tablespace (if present)
  - The 35th rollback segment resides in the second undo tablespace (if present)

There is a many-to-one relationship between rollback segments and undo tablespaces. If the number of allocated rollback segments is greater than 35, the “additional” rollback segments are assigned to undo tablespaces in a round-robin fashion. For example, if you have 2 undo tablespaces (undo tablespace 1 and undo-tablespace 2) and `innodb_undo_logs=37`, undo-tablespace 1 and undo-tablespace 2 would each be assigned a second rollback segment.

By default, `innodb_undo_logs` is set to 128, which is also the maximum value. To check the value of `innodb_undo_logs`, submit the following query:

```
mysql> SELECT @@innodb_undo_logs;
+-----+
| @@innodb_undo_logs |
+-----+
|                128 |
+-----+
1 row in set (0.00 sec)
```

`innodb_undo_logs` is a dynamic global variable and can be configured using a `SET GLOBAL` statement:

```
mysql> SET GLOBAL innodb_undo_logs=128;
```

## Enabling Truncation of Undo Tablespaces

To truncate undo logs that reside in undo tablespaces, you must first enable `innodb_undo_log_truncate`.

```
mysql> SET GLOBAL innodb_undo_log_truncate=ON;
```

When you enable `innodb_undo_log_truncate`, undo tablespace files that exceed the size limit defined by `innodb_max_undo_log_size` are marked for truncation. `innodb_max_undo_log_size` is a dynamic global variable with a default value of 1024 MiB (1073741824 bytes).

```
mysql> SELECT @@innodb_max_undo_log_size;
+-----+
| @@innodb_max_undo_log_size |
+-----+
|                1073741824 |
+-----+
1 row in set (0.00 sec)
```

You can configure `innodb_max_undo_log_size` using a `SET GLOBAL` statement:

```
mysql> SET GLOBAL innodb_max_undo_log_size=2147483648;
Query OK, 0 rows affected (0.00 sec)
```

When `innodb_undo_log_truncate` is enabled:

1. Undo tablespaces that exceed the `innodb_max_undo_log_size` setting are marked for truncation. Selection of an undo tablespace for truncation is performed in a round-robin fashion to avoid truncating the same undo tablespace each time.

2. Rollback segments residing in the selected undo tablespace are made inactive so that they are not allocated to new transactions. Existing transactions that are currently using rollback segments are allowed to complete.
3. The `purge` system frees rollback segments that are no longer needed.
4. After all rollback segments in the undo tablespace are freed, the truncate operation runs and the undo tablespace is truncated to its initial size. The initial size of an undo tablespace file is 10MB.

#### Note

If you check the size of an undo tablespace after a truncation operation, the file size may be larger than 10MB due to immediate use following the completion of the truncation operation. The `innodb_undo_directory` option defines the location of undo tablespace files. The default value of “.” represents directory where `InnoDB` creates its other log files by default.

```
mysql> select @@innodb_undo_directory;
+-----+
| @@innodb_undo_directory |
+-----+
| .                         |
+-----+
1 row in set (0.00 sec)
```

5. The rollback segments are reactivated so that they can be allocated to new transactions.

## Expediting Truncation of Undo Tablespace Files

An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. To expedite the truncation of undo tablespaces, you can use the `innodb_purge_rseg_truncate_frequency` option to temporarily increase the frequency with which the purge system frees rollback segments. By default, `innodb_purge_rseg_truncate_frequency` is 128, which is also the maximum value.

```
mysql> select @@innodb_purge_rseg_truncate_frequency;
+-----+
| @@innodb_purge_rseg_truncate_frequency |
+-----+
|                                     128 |
+-----+
1 row in set (0.00 sec)
```

To increase the frequency with which the purge thread frees rollback segments, decrease the value of `innodb_purge_rseg_truncate_frequency`. For example:

```
mysql> SET GLOBAL innodb_purge_rseg_truncate_frequency=32;
Query OK, 0 rows affected (0.00 sec)
```

## Performance Impact of Truncating Undo Tablespace Files Online

While an undo tablespace truncation operation is in progress, rollback segments in one undo tablespace are temporarily deactivated. For example, if you have 2 undo tablespaces (`innodb_undo_tablespaces=2`) and 128 allocated undo logs (`innodb_undo_logs=128`), 95 of the undo logs reside in the two undo tablespaces (48 rollback segments in one undo tablespace and 47 in the other). If the first undo tablespace is taken offline, 48 undo logs are made inactive, reducing the undo log resource by slightly more than half. While the truncation operation is in progress, the remaining undo logs assume responsibility for the entire system load, which may result in a slight performance degradation. The degree of performance degradation depends on a number of factors including:

- Number of undo tablespaces
- Number of undo logs

- Undo tablespace size
- Speed of the I/O subsystem
- Existing long running transactions
- System load

## 14.4.9 InnoDB General Tablespaces

A *general tablespace* is a new type of [InnoDB](#) tablespace, introduced in MySQL 5.7.6. The general tablespace feature provides the following capabilities:

- Similar to the system tablespace, general tablespaces are shared tablespaces that can store data for multiple tables.
- General tablespaces have a potential memory advantage over [file-per-table tablespaces](#). The server keeps tablespace metadata in memory for the lifetime of a tablespace. Multiple tables in fewer general tablespaces consume less memory for tablespace metadata than the same number of tables in separate file-per-table tablespaces.
- General tablespace data files may be placed in a directory relative to or independent of the MySQL data directory, which provides you with many of the data file and storage management capabilities of [file-per-table tablespaces](#). As with file-per-table tablespaces, the ability to place data files outside of the MySQL data directory allows you to manage performance of critical tables separately, setup RAID or DRBD for specific tables, or bind tables to particular disks, for example.
- General tablespaces support both Antelope and Barracuda file formats, and therefore support all table row formats and associated features. With support for both file formats, general tablespaces have no dependence on [innodb\\_file\\_format](#) or [innodb\\_file\\_per\\_table](#) settings, nor do these variables have any effect on general tablespaces.
- The [TABLESPACE](#) option can be used with [CREATE TABLE](#) to create tables in a general tablespaces, file-per-table tablespace, or in the system tablespace.
- The [TABLESPACE](#) option can be used with [ALTER TABLE](#) to move tables between general tablespaces, file-per-table tablespaces, and the system tablespace. Previously, it was not possible to move a table from a file-per-table tablespace to the system tablespace. With the general tablespace feature, you can now do so.

### Creating a General Tablespace

General tablespaces are created using [CREATE TABLESPACE](#) syntax.

```
CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
  [FILE_BLOCK_SIZE = value]
  [ENGINE [=] engine_name]
```

A general tablespace may be created in the MySQL data directory or in a directory outside of the MySQL data directory. To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the MySQL data directory is not supported. Also, when creating a general tablespace outside of the MySQL data directory, the directory must exist prior to creating the tablespace.

As of MySQL 5.7.8, an [isl](#) file is created in the MySQL data directory when a general tablespace is created outside of the MySQL data directory.

Examples:

Creating a general tablespace in the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
```

Creating a general tablespace in a directory outside of the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '/my/tablespace/directory/ts1.ibd' Engine=InnoDB;
```

You can specify a path that is relative to the MySQL data directory as long as the tablespace directory is not under the MySQL data directory. In this example, the `my_tablespace` directory is at the same level as the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '../my_tablespace/ts1.ibd' Engine=InnoDB;
```

**Note**

The `ENGINE = InnoDB` clause must be defined as part of the `CREATE TABLESPACE` statement or `InnoDB` must be defined as the default storage engine (`default_storage_engine=InnoDB`).

### Adding Tables to a General Tablespace

After creating an InnoDB general tablespace, you can use `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` to add tables to the tablespace, as shown in the following examples:

CREATE TABLE:

```
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;
```

ALTER TABLE:

```
mysql> ALTER TABLE t2 TABLESPACE ts1;
```

For detailed syntax information, see `CREATE TABLE` and `ALTER TABLE`.

### General Tablespace Row Format Support

General tablespaces support all table row formats (`REDUNDANT`, `COMPACT`, `DYNAMIC`, `COMPRESSED`) with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes.

For a general tablespace to contain compressed tables (`ROW_FORMAT=COMPRESSED`), `FILE_BLOCK_SIZE` must be specified, and the `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value. Also, the physical page size of the compressed table (`KEY_BLOCK_SIZE`) must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16K` and `FILE_BLOCK_SIZE=8K`, the `KEY_BLOCK_SIZE` of the table must be 8.

The following table shows permitted `FILE_BLOCK_SIZE` and `KEY_BLOCK_SIZE` values for each `innodb_page_size` value. `FILE_BLOCK_SIZE` values may also be specified in bytes. To determine a valid `KEY_BLOCK_SIZE` value for a given `FILE_BLOCK_SIZE`, divide the `FILE_BLOCK_SIZE` value by 1024. Table compression is not support for 32K and 64K InnoDB page sizes. For more information about `KEY_BLOCK_SIZE`, see `CREATE TABLE`, and [Section 14.6.1.2, “Creating Compressed Tables”](#).

**Table 14.4 FILE\_BLOCK\_SIZE and KEY\_BLOCK\_SIZE Values for CREATE TABLESPACE**

InnoDB Page Size ( <code>innodb_page_size</code> )	Permitted FILE_BLOCK_SIZE Values	Permitted KEY_BLOCK_SIZE Values
64K	64K (65536)	Compression is not supported
32K	32K (32768)	Compression is not supported

InnoDB Page Size ( <code>innodb_page_size</code> )	Permitted <code>FILE_BLOCK_SIZE</code> Values	Permitted <code>KEY_BLOCK_SIZE</code> Values
16K	16K (16384)	N/A: If <code>innodb_page_size</code> is equal to <code>FILE_BLOCK_SIZE</code> , the tablespace cannot contain a compressed table.
	8K (8192)	8
	4K (4096)	4
	2K (2048)	2
	1K (1024)	1
8K	8K (8192)	N/A: If <code>innodb_page_size</code> is equal to <code>FILE_BLOCK_SIZE</code> , the tablespace cannot contain a compressed table.
	4K (4096)	4
	2K (2048)	2
	1K (1024)	1
4K	4K (4096)	N/A: If <code>innodb_page_size</code> is equal to <code>FILE_BLOCK_SIZE</code> , the tablespace cannot contain a compressed table.
	2K (2048)	2
	1K (1024)	1

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

If you do not specify `FILE_BLOCK_SIZE` when creating a general tablespace, `FILE_BLOCK_SIZE` defaults to `innodb_page_size`. When `FILE_BLOCK_SIZE` is equal to `innodb_page_size`, the tablespace may only contain tables with an uncompressed row format (`COMPACT`, `REDUNDANT`, and `DYNAMIC` row formats).

## Moving Non-Partitioned Tables Between Tablespaces Using ALTER TABLE

You can use `ALTER TABLE` with the `TABLESPACE` option to move a non-partitioned InnoDB table to an existing general tablespace, to a new file-per-table tablespace, or to the system tablespace.

### Note

Running an `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` operation on a *partitioned* table only modifies the table's default tablespace. It does not move the table's partitions.

To move a non-partitioned table from a file-per-table tablespace or from the system tablespace to a general tablespace, specify the name of the general tablespace. The general tablespace must exist. See `CREATE TABLESPACE` for more information.

```
ALTER TABLE tbl_name TABLESPACE [=] tablespace_name
```

To move a non-partitioned table from a general tablespace or file-per-table tablespace to the system tablespace, specify `innodb_system` as the tablespace name.

```
ALTER TABLE tbl_name ... TABLESPACE [=] innodb_system
```

To move a non-partitioned table from the system tablespace or a general tablespace to a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

```
ALTER TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
```

`ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

`ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

The `DATA DIRECTORY` clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the `TABLESPACE` option.

## General Tablespace Table Partition Support

The `TABLESPACE` option may be used to assign individual table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the system tablespace. General tablespace support for table partitions and subpartitions was added in MySQL 5.7.8. All partitions must belong to the same storage engine. Usage is demonstrated in the following examples.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' Engine=InnoDB;

mysql> CREATE TABLE t1 (a INT, b INT) ENGINE = InnoDB
-> PARTITION BY RANGE(a) SUBPARTITION BY KEY(b) (
-> PARTITION p1 VALUES LESS THAN (100) TABLESPACE=`ts1`,
-> PARTITION p2 VALUES LESS THAN (1000) TABLESPACE=`ts2`,
-> PARTITION p3 VALUES LESS THAN (10000) TABLESPACE `innodb_file_per_table`,
-> PARTITION p4 VALUES LESS THAN (100000) TABLESPACE `innodb_system`);

mysql> CREATE TABLE t2 (a INT, b INT) ENGINE = InnoDB
-> PARTITION BY RANGE(a) SUBPARTITION BY KEY(b) (
-> PARTITION p1 VALUES LESS THAN (100) TABLESPACE=`ts1`
-> (SUBPARTITION sp1,
-> SUBPARTITION sp2),
-> PARTITION p2 VALUES LESS THAN (1000)
-> (SUBPARTITION sp3,
-> SUBPARTITION sp4 TABLESPACE=`ts2`),
-> PARTITION p3 VALUES LESS THAN (10000)
-> (SUBPARTITION sp5 TABLESPACE `innodb_system`,
-> SUBPARTITION sp6 TABLESPACE `innodb_file_per_table`));
```

The `TABLESPACE` option is also supported with `ALTER TABLE`.

```
mysql> ALTER TABLE t1 ADD PARTITION (PARTITION p5 VALUES LESS THAN (1000000) TABLESPACE = `ts1`);
```

### Note

If the `TABLESPACE = tablespace_name` option is not defined, the `ALTER TABLE ... ADD PARTITION` operation adds the partition to the table's default tablespace, which can be specified at the table level during `CREATE TABLE` or `ALTER TABLE`.

To verify that partitions were placed in the specified tablespaces, you can query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`:

```
mysql> SELECT NAME, SPACE, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
-> WHERE NAME LIKE '%t1%';
+-----+-----+-----+
```

```

+-----+-----+-----+
| NAME                | SPACE | SPACE_TYPE |
+-----+-----+-----+
| test/t1#P#p1#SP#p1sp0 |    57 | General    |
| test/t1#P#p2#SP#p2sp0 |    58 | General    |
| test/t1#P#p3#SP#p3sp0 |    59 | Single     |
| test/t1#P#p4#SP#p4sp0 |     0 | System     |
| test/t1#P#p5#SP#p5sp0 |    57 | General    |
+-----+-----+-----+

mysql> SELECT NAME, SPACE, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
-> WHERE NAME LIKE '%t2%';

+-----+-----+-----+
| NAME                | SPACE | SPACE_TYPE |
+-----+-----+-----+
| test/t2#P#p1#SP#sp1 |    57 | General    |
| test/t2#P#p1#SP#sp2 |    57 | General    |
| test/t2#P#p2#SP#sp3 |    60 | Single     |
| test/t2#P#p2#SP#sp4 |    58 | General    |
| test/t2#P#p3#SP#sp5 |     0 | System     |
| test/t2#P#p3#SP#sp6 |    61 | Single     |
+-----+-----+-----+

```

## Moving Table Partitions Between Tablespaces Using ALTER TABLE

To move table partitions to a different tablespace, you must move each partition using an `ALTER TABLE tbl_name REORGANIZE PARTITION` statement.

The following example demonstrates how to move table partitions to a different tablespace. `INFORMATION_SCHEMA.INNODB_SYS_TABLES` and `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` are queried to verify that partitions are placed in the expected tablespace.

### Note

If the `TABLESPACE = tablespace_name` option is not defined in the `REORGANIZE PARTITION` statement, InnoDB moves the partition to the table's default tablespace. In this example, tablespace `ts1`, which is defined at the table level, is the default tablespace for table `t1`. Partition `P3` is moved from the system tablespace to tablespace `ts1` since no `TABLESPACE` option is specified in the `ALTER TABLE t1 REORGANIZE PARTITION` statement for partition `P3`.

To change a partitioned table's default tablespace, you can run `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` on the *partitioned* table.

```

mysql> CREATE TABLESPACE ts1 ADD DATAFILE 'ts1.ibd';
mysql> CREATE TABLESPACE ts2 ADD DATAFILE 'ts2.ibd';

mysql> CREATE TABLE t1 ( a INT NOT NULL, PRIMARY KEY (a))
-> ENGINE=InnoDB TABLESPACE ts1
-> PARTITION BY RANGE (a) PARTITIONS 3 (
-> PARTITION P1 VALUES LESS THAN (2),
-> PARTITION P2 VALUES LESS THAN (4) TABLESPACE `innodb_file_per_table`,
-> PARTITION P3 VALUES LESS THAN (6) TABLESPACE `innodb_system`);

mysql> SELECT A.NAME as partition_name, A.SPACE_TYPE as space_type, B.NAME as space_name
-> FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES A
-> LEFT JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES B
-> ON A.SPACE = B.SPACE WHERE A.NAME LIKE '%t1%' ORDER BY A.NAME;

+-----+-----+-----+
| partition_name | space_type | space_name |
+-----+-----+-----+
| test/t1#P#P1  | General   | ts1        |
| test/t1#P#P2  | Single    | test/t1#P#P2 |
| test/t1#P#P3  | System    | NULL       |
+-----+-----+-----+

mysql> ALTER TABLE t1 REORGANIZE PARTITION P1

```

```

-> INTO (PARTITION P1 VALUES LESS THAN (2) TABLESPACE = `ts2`);

mysql> ALTER TABLE t1 REORGANIZE PARTITION P2
-> INTO (PARTITION P2 VALUES LESS THAN (4) TABLESPACE = `ts2`);

mysql> ALTER TABLE t1 REORGANIZE PARTITION P3
-> INTO (PARTITION P3 VALUES LESS THAN (6));

mysql> SELECT A.NAME AS partition_name, A.SPACE_TYPE AS space_type, B.NAME AS space_name
-> FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES A
-> LEFT JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES B
-> ON A.SPACE = B.SPACE WHERE A.NAME LIKE '%t1%' ORDER BY A.NAME;
+-----+-----+-----+
| partition_name | space_type | space_name |
+-----+-----+-----+
| test/t1#P#P1   | General    | ts2        |
| test/t1#P#P2   | General    | ts2        |
| test/t1#P#P3   | General    | ts1        |
+-----+-----+-----+

```

### Dropping a General Tablespace

The `DROP TABLESPACE` statement is used to drop an InnoDB general tablespace.

All tables must be dropped from the tablespace prior to a `DROP TABLESPACE` operation. If the tablespace is not empty, `DROP TABLESPACE` returns an error.

A general InnoDB tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

A general tablespace does not belong to any particular database. A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the `DROP DATABASE` operation drops all tables that belong to the tablespace. A general tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd` data file which can only be used for new InnoDB data. Space is not released back to the operating system as it is when a file-per-table tablespace is deleted during a `DROP TABLE` operation.

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace `ts1` is created with a single table. The table must be dropped before dropping the tablespace.

```

mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts10 Engine=InnoDB;
Query OK, 0 rows affected (0.02 sec)

mysql> DROP TABLE t1;
Query OK, 0 rows affected (0.01 sec)

mysql> DROP TABLESPACE ts1;
Query OK, 0 rows affected (0.01 sec)

```

#### Note

`tablespace_name` is a case-sensitive identifier in MySQL.

### General Tablespace Limitations

- A generated or existing tablespace cannot be changed to a general tablespace.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.

- Partitioned [InnoDB](#) tables, and using the `TABLESPACE=tablespace_name` to assign individual table partitions or subpartitions to a general tablespace, are only supported in MySQL 5.7.8 or higher.
- Tables stored in a general tablespace may only be opened in MySQL 5.7.6 or later.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new [InnoDB](#) data. Space is not released back to the operating system as it is for file-per-table tablespaces.
- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- General tablespaces created on Windows using a relative data file path cannot be opened on Unix-like systems. This limitation is removed in MySQL 5.7.8 (Bug #20555168).
- In MySQL 5.7.6 and MySQL 5.7.7, tables stored in general tablespaces may not open (due to a missing general tablespace file) after moving the MySQL data directory to a new location. This limitation is addressed in MySQL 5.7.8 with the introduction of `isl` files for general tablespaces created outside of the MySQL data directory (Bug #20563954).

For more information see [Section 13.1.15, “CREATE TABLESPACE Syntax”](#).

## 14.5 InnoDB Table Management

### 14.5.1 Creating InnoDB Tables

To create an [InnoDB](#) table, use the `CREATE TABLE` statement. You do not need to specify the `ENGINE=InnoDB` clause if [InnoDB](#) is defined as the default storage engine, which is the default as of MySQL 5.5. You might still use `ENGINE=InnoDB` clause if you plan to use `mysqldump` or replication to replay the `CREATE TABLE` statement on a server where the default storage engine is not [InnoDB](#).

```
-- Default storage engine = InnoDB.  
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a));  
-- Backward-compatible with older MySQL.  
CREATE TABLE t2 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

An [InnoDB](#) table and its indexes can be created in the [system tablespace](#), in a [file-per-table](#) tablespace, or in a [general tablespace](#) (introduced in MySQL 5.7.6). When `innodb_file_per_table` is enabled, which is the default setting as of MySQL 5.6.6, an [InnoDB](#) table is implicitly created in an individual file-per-table tablespace. Conversely, when `innodb_file_per_table` is disabled, an [InnoDB](#) table is implicitly created in the system tablespace. With the introduction of general tablespaces in MySQL 5.7.6, you can use `CREATE TABLE ... TABLESPACE` syntax to explicitly create an [InnoDB](#) table in any of the three tablespace types.

When you create an [InnoDB](#) table, MySQL creates a `.frm file` in a database directory under the MySQL data directory. For a table created in a file-per-table tablespace, an `.ibd file` is also created. A table created in the system tablespace is created in the existing system tablespace `ibdata files`. A table created in a general tablespace is created in an existing general tablespace `.ibd file`.

Internally, [InnoDB](#) adds an entry for each table to the [InnoDB](#) data dictionary. The entry includes the database name. For example, if table `t1` is created in the `test` database, the data dictionary entry is `'test/t1'`. This means you can create a table of the same name (`t1`) in a different database, and the table names do not collide inside [InnoDB](#).

### Viewing the Properties of InnoDB Tables

To view the properties of [InnoDB](#) tables, issue a `SHOW TABLE STATUS` statement:

```
mysql > SHOW TABLE STATUS FROM test LIKE 't%' \G;
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 0
      Data_free: 0
      Auto_increment: NULL
      Create_time: 2015-03-16 15:13:31
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
1 row in set (0.00 sec)
```

In the status output, you see the [Row format](#) property of table `t1` is `Compact`. The [Dynamic](#) or [Compressed](#) row format is required take advantage of [InnoDB](#) features such as table compression and off-page storage for long column values. To use these row formats, you can enable [innodb\\_file\\_per\\_table](#) (the default as of MySQL 5.6.6) and set [innodb\\_file\\_format](#) to [Barracuda](#), which implicitly creates [InnoDB](#) tables in file-per-table tablespaces:

```
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=barracuda;
CREATE TABLE t3 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=DYNAMIC;
CREATE TABLE t4 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=COMPRESSED;
```

Or, you can use `CREATE TABLE ... TABLESPACE` syntax to create an [InnoDB](#) table in a general tablespace. General tablespaces support all row formats. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
```

`CREATE TABLE ... TABLESPACE` syntax can also be used to create [InnoDB](#) tables with a [Dynamic](#) row format in the system tablespace, along side tables with a [Compact](#) or [Redundant](#) row format.

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE = innodb_system ROW_FORMAT=DYNAMIC;
```

[InnoDB](#) table properties may also be queried using the [InnoDB](#) Information Schema system tables:

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G
***** 1. row *****
      TABLE_ID: 45
      NAME: test/t1
      FLAG: 1
      N_COLS: 5
      SPACE: 35
      FILE_FORMAT: Antelope
      ROW_FORMAT: Compact
      ZIP_PAGE_SIZE: 0
      SPACE_TYPE: Single
1 row in set (0.00 sec)
```

## Defining a Primary Key for InnoDB Tables

Always set up a [primary key](#) for each [InnoDB](#) table, specifying the column or columns that:

- Are referenced by the most important queries.
- Are never left blank.
- Never have duplicate values.

- Rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on (`firstname`, `lastname`) because more than one person can have the same name, some people have blank last names, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an [auto-increment](#) column so that ascending values are filled in automatically as rows are inserted:

```
-- The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));
-- The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

Although the table works correctly without defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. It is recommended that you always specify a primary key in the `CREATE TABLE` statement. If you create the table, load data, and then run `ALTER TABLE` to add a primary key later, that operation is much slower than defining the primary key when creating the table.

## 14.5.2 Moving or Copying InnoDB Tables to Another Machine

This section describes techniques for moving or copying some or all [InnoDB](#) tables to a different server. For example, you might move an entire MySQL instance to a larger, faster server; you might clone an entire MySQL instance to a new replication slave server; you might copy individual tables to another server to develop and test an application, or to a data warehouse server to produce reports.

Techniques for moving or copying [InnoDB](#) tables include:

- [Transportable Tablespaces](#)
- [MySQL Enterprise Backup](#)
- [Copying Data Files \(Cold Backup Method\)](#)
- [Export and Import \(mysqldump\)](#)

### Using Lowercase Names for Cross-Platform Moving or Copying

On Windows, [InnoDB](#) always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

### Transportable Tablespaces

Introduced in MySQL 5.6.6, the transportable tablespaces feature uses `FLUSH TABLES ... FOR EXPORT` to ready [InnoDB](#) tables for copying from one server instance to another. To use this feature, [InnoDB](#) tables must be created with `innodb_file_per_table` set to `ON` so that each [InnoDB](#) table has its own tablespace. For usage information, see [Section 14.4.6, “Copying File-Per-Table Tablespaces to Another Server”](#).

### MySQL Enterprise Backup

The MySQL Enterprise Backup product lets you back up a running MySQL database, including [InnoDB](#) and [MyISAM](#) tables, with minimal disruption to operations while producing a consistent snapshot of the database. When MySQL Enterprise Backup is copying [InnoDB](#) tables, reads and

writes to both [InnoDB](#) and [MyISAM](#) tables can continue. During the copying of [MyISAM](#) and other non-InnoDB tables, reads (but not writes) to those tables are permitted. In addition, MySQL Enterprise Backup can create compressed backup files, and back up subsets of [InnoDB](#) tables. In conjunction with the MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as part of the MySQL Enterprise subscription.

For more details about MySQL Enterprise Backup, see [Section 25.2, “MySQL Enterprise Backup Overview”](#).

## Copying Data Files (Cold Backup Method)

You can move an [InnoDB](#) database simply by copying all the relevant files listed under "Cold Backups" in [Section 14.15, “InnoDB Backup and Recovery”](#).

Like [MyISAM](#) data files, [InnoDB](#) data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used [FLOAT](#) or [DOUBLE](#) data types in your tables, then the procedure is the same: simply copy the relevant files.

## Portability Considerations for File-Per-Table .ibd Files

When you move or copy file-per-table [.ibd](#) files, the database directory name must be the same on the source and destination systems. The table definition stored in the [InnoDB](#) shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.

To move an [.ibd](#) file and the associated table from one database to another, use a [RENAME TABLE](#) statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an [.ibd](#) file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the [.ibd](#) file, because doing so changes the table ID stored inside the tablespace.
2. Issue this [ALTER TABLE](#) statement to delete the current [.ibd](#) file:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

3. Copy the backup [.ibd](#) file to the proper database directory.
4. Issue this [ALTER TABLE](#) statement to tell [InnoDB](#) to use the new [.ibd](#) file for the table:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

### Note

The [ALTER TABLE ... IMPORT TABLESPACE](#) feature does not enforce foreign key constraints on imported data.

In this context, a “clean” [.ibd](#) file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the [.ibd](#) file.
- There are no unmerged insert buffer entries in the [.ibd](#) file.
- Purge has removed all delete-marked index records from the [.ibd](#) file.
- `mysqld` has flushed all modified pages of the [.ibd](#) file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of InnoDB is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the InnoDB installation.
2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

## Export and Import (mysqldump)

You can use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

One way to increase the performance of this method is to switch off `autocommit` mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

### 14.5.3 Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with `autocommit` mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of `DML` statements and commit them or roll them back all together.

To use multiple-statement `transactions`, switch `autocommit` off with the SQL statement `SET autocommit = 0` and end each transaction with `COMMIT` or `ROLLBACK` as appropriate. To leave `autocommit` on, begin each transaction with `START TRANSACTION` and end it with `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+-----+-----+
| a     | b     |
+-----+-----+
```

```
+-----+-----+
| 10 | Heikki |
+-----+-----+
1 row in set (0.00 sec)
mysql>
```

## Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

### 14.5.4 Converting Tables from MyISAM to InnoDB

If you have existing tables, and applications that use them, that you want to convert to `InnoDB` for better reliability and scalability, use the following guidelines and tips. This section assumes most such tables were originally `MyISAM`, which was formerly the default.

#### Reduce Memory Usage for MyISAM, Increase Memory Usage for InnoDB

As you transition away from `MyISAM` tables, lower the value of the `key_buffer_size` configuration option to free memory no longer needed for caching results. Increase the value of the `innodb_buffer_pool_size` configuration option, which performs a similar role of allocating cache memory for `InnoDB` tables. The `InnoDB` buffer pool caches both table data and index data, so it does double duty in speeding up lookups for queries and keeping query results in memory for reuse.

- Allocate as much memory to this option as you can afford, often up to 80% of physical memory on the server.
- If the operating system runs short of memory for other processes and begins to swap, reduce the `innodb_buffer_pool_size` value. Swapping is such an expensive operation that it drastically reduces the benefit of the cache memory.
- If the `innodb_buffer_pool_size` value is several gigabytes or higher, consider increasing the values of `innodb_buffer_pool_instances`. Doing so helps on busy servers where many connections are reading data into the cache at the same time.
- On a busy server, run benchmarks with the Query Cache turned off. The `InnoDB` buffer pool provides similar benefits, so the Query Cache might be tying up memory unnecessarily.

#### Watch Out for Too-Long Or Too-Short Transactions

Because `MyISAM` tables do not support `transactions`, you might not have paid much attention to the `autocommit` configuration option and the `COMMIT` and `ROLLBACK` statements. These keywords are important to allow multiple sessions to read and write `InnoDB` tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a `mysql` session for interactive experiments, always `COMMIT` (to finalize the changes) or `ROLLBACK` (to undo the changes) when finished. Close down interactive sessions rather than leaving them open for long periods, to avoid keeping transactions open for long periods by accident.
- Make sure that any error handlers in your application also `ROLLBACK` incomplete changes or `COMMIT` completed changes.

- `ROLLBACK` is a relatively expensive operation, because `INSERT`, `UPDATE`, and `DELETE` operations are written to `InnoDB` tables prior to the `COMMIT`, with the expectation that most changes will be committed successfully and rollbacks will be rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.
- When loading large volumes of data with a sequence of `INSERT` statements, periodically `COMMIT` the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you `TRUNCATE TABLE` and start over from the beginning rather than doing a `ROLLBACK`.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each `COMMIT`, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on `InnoDB` tables, you should use the setting `autocommit=0`. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive `INSERT`, `UPDATE`, or `DELETE` statements. From a safety perspective, this allows you to issue a `ROLLBACK` statement to recover lost or garbled data if you make a mistake on the `mysql` command line, or in an exception handler in your application.
- The time when `autocommit=1` is suitable for `InnoDB` tables is when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to `COMMIT` or `ROLLBACK`, and `InnoDB` can [automatically optimize the read-only workload](#).
- If you make a series of related changes, finalize all those changes at once with a single `COMMIT` at the end. For example, if you insert related pieces of information into several tables, do a single `COMMIT` after making all the changes. Or if you run many consecutive `INSERT` statements, do a single `COMMIT` after all the data is loaded; if you are doing millions of `INSERT` statements, perhaps split up the huge transaction by issuing a `COMMIT` every ten thousand or hundred thousand records, so the transaction does not grow too large.
- Remember that even a `SELECT` statement opens a transaction, so after running some report or debugging queries in an interactive `mysql` session, either issue a `COMMIT` or close the `mysql` session.

## Don't Worry Too Much About Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of `SHOW ENGINE INNODB STATUS`. Despite the scary-sounding name, a [deadlock](#) is not a serious issue for `InnoDB` tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. MySQL immediately detects this condition and cancels ([rolls back](#)) the “smaller” transaction, allowing the other to proceed.

Your applications do need error-handling logic to restart a transaction that is forcibly cancelled like this. When you re-issue the same SQL statements as before, the original timing issue no longer applies: either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the `innodb_print_all_deadlocks` option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the `SHOW ENGINE INNODB STATUS` output.

## Plan the Storage Layout

To get the best performance from `InnoDB` tables, you can adjust a number of parameters related to storage layout.

When you convert `MyISAM` tables that are large, frequently accessed, and hold vital data, investigate and consider the `innodb_file_per_table`, `innodb_file_format`, and `innodb_page_size`

configuration options, and the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses of the `CREATE TABLE` statement.

During your initial experiments, the most important setting is `innodb_file_per_table`. When this setting is enabled, which is the default as of MySQL 5.6.6, new InnoDB tables are implicitly created in `file-per-table` tablespaces. In contrast with the InnoDB system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support the Barracuda file format and associated features such as table compression and off-page storage for long variable-length columns. For more information, see [Section 14.4.4, “InnoDB File-Per-Table Tablespaces”](#).

As of MySQL 5.7.6, you can also store InnoDB tables in a shared general tablespace. General tablespaces support the Barracuda file format and can contain multiple tables. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

## Converting an Existing Table

To convert a non-InnoDB table to use InnoDB use `ALTER TABLE`:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

### Important

Do not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the InnoDB type. This is an unsupported operation. The system tables must always be of the MyISAM type.

## Cloning the Structure of a Table

You might make an InnoDB table that is a clone of a MyISAM table, rather than doing the `ALTER TABLE` conversion, to test the old and new table side-by-side before switching.

Create an empty InnoDB table with identical column and index definitions. Use `show create table table_name\G` to see the full `CREATE TABLE` statement to use. Change the `ENGINE` clause to `ENGINE=INNODB`.

## Transferring Existing Data

To transfer a large volume of data into an empty InnoDB table created as shown in the previous section, insert the rows with `INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns`.

You can also create the indexes for the InnoDB table after inserting the data. Historically, creating new secondary indexes was a slow operation for InnoDB, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;
... import operation ...
SET unique_checks=1;
```

For big tables, this saves disk I/O because InnoDB can use its `change buffer` to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `unique_checks` permits but does not require storage engines to ignore duplicate keys.

To get better control over the insertion process, you might insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, increase the size of the [InnoDB](#) buffer pool to reduce disk I/O, to a maximum of 80% of physical memory. You can also increase the sizes of the [InnoDB](#) log files.

## Storage Requirements

If you intend to make several temporary copies of your data in [InnoDB](#) tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. As mentioned previously, when the [innodb\\_file\\_per\\_table](#) option is enabled, newly created [InnoDB](#) tables are implicitly created in file-per-table tablespaces.

Whether you convert the [MyISAM](#) table directly or create a cloned [InnoDB](#) table, make sure that you have sufficient disk space to hold both the old and new tables during the process. [InnoDB](#) tables require more disk space than [MyISAM](#) tables. If an `ALTER TABLE` operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, [InnoDB](#) uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see [Section 14.18.2, “Forcing InnoDB Recovery”](#).

## Carefully Choose a PRIMARY KEY for Each Table

The [PRIMARY KEY](#) clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. Perhaps you have phoned a financial institution where you are asked for an account number. If you do not have the number, you are asked for a dozen different pieces of information to “uniquely identify” yourself. The primary key is like that unique account number that lets you get straight down to business when querying or modifying the information in a table. Every row in the table must have a primary key value, and no two rows can have the same primary key value.

Here are some guidelines for the primary key, followed by more detailed explanations.

- Declare a [PRIMARY KEY](#) for each table. Typically, it is the most important column that you refer to in [WHERE](#) clauses when looking up a single row.
- Declare the [PRIMARY KEY](#) clause in the original `CREATE TABLE` statement, rather than adding it later through an `ALTER TABLE` statement.
- Choose the column and its data type carefully. Prefer numeric columns over character or string ones.
- Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.
- An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a [primary key](#) to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any [secondary indexes](#), because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the [buffer pool](#), speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a `VARCHAR`, consider adding a new unsigned `AUTO_INCREMENT` column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as `UNIQUE NOT NULL` to enforce the same constraints as the `PRIMARY KEY` clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the `PRIMARY KEY` clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

## Application Performance Considerations

The extra reliability and scalability features of `InnoDB` do require more disk storage than equivalent `MyISAM` tables. You might change the column and index definitions slightly, for better space utilization, reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you do set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for `join` queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned `INT` column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see [Section 11.2.1, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#).

## Understand Files Associated with InnoDB Tables

`InnoDB` files require more care and planning than `MyISAM` files do:

- You must not delete the `ibdata` files that represent the `InnoDB` system tablespace.
- Copying `InnoDB` tables from one server to another requires issuing the `FLUSH TABLES ... FOR EXPORT` statement first, and copying the `table_name.cfg` file along with the `table_name.ibd` file.

## 14.5.5 AUTO\_INCREMENT Handling in InnoDB

`InnoDB` provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with `AUTO_INCREMENT` columns. To use the `AUTO_INCREMENT` mechanism with an `InnoDB` table, an `AUTO_INCREMENT` column must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

This section describes the behavior of `AUTO_INCREMENT` lock modes, usage implications for different `AUTO_INCREMENT` lock mode settings, and how `InnoDB` initializes the `AUTO_INCREMENT` counter.

- [InnoDB AUTO\\_INCREMENT Lock Modes](#)
- [InnoDB AUTO\\_INCREMENT Lock Mode Usage Implications](#)

- [InnoDB AUTO\\_INCREMENT Counter Initialization](#)

## InnoDB AUTO\_INCREMENT Lock Modes

This section describes the behavior of `AUTO_INCREMENT` lock modes used to generate auto-increment values, and how each lock mode affects replication. Auto-increment lock modes are configured at startup using the `innodb_autoinc_lock_mode` configuration parameter.

The following terms are used in describing `innodb_autoinc_lock_mode` settings:

- “INSERT-like” statements

All statements that generate new rows in a table, including `INSERT`, `INSERT ... SELECT`, `REPLACE`, `REPLACE ... SELECT`, and `LOAD DATA`. Includes “simple-inserts”, “bulk-inserts”, and “mixed-mode” inserts.

- “Simple inserts”

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row `INSERT` and `REPLACE` statements that do not have a nested subquery, but not `INSERT ... ON DUPLICATE KEY UPDATE`.

- “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements, but not plain `INSERT`. InnoDB will assign new values for the `AUTO_INCREMENT` column one at a time as each row is processed.

- “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an `AUTO_INCREMENT` column of table `t1`:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

Another type of “mixed-mode insert” is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the `AUTO_INCREMENT` column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` configuration parameter. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively.

- `innodb_autoinc_lock_mode = 0` (“traditional” lock mode)

The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` configuration parameter was introduced in MySQL 5.1. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with “mixed-mode inserts”, due to possible differences in semantics.

In this lock mode, all “INSERT-like” statements obtain a special table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

In the case of statement-based replication, this means that when an SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple `INSERT` statements is deterministic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple `INSERT` statements

were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```
CREATE TABLE t1 (
  c1 INT(11) NOT NULL AUTO_INCREMENT,
  c2 VARCHAR(10) DEFAULT NULL,
  PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

```
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

InnoDB cannot tell in advance how many rows will be retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the Tx1 `INSERT ... SELECT` statement will be consecutive, and the (single) auto-increment value used by the `INSERT` statement in Tx2 will either be smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results will be the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements using auto-increment safe for use with statement-based replication. However, those table-level locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in Tx2 depends on precisely when the statement executes. If the `INSERT` of Tx2 executes while the `INSERT` of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are nondeterministic, and may vary from run to run.

Under the `consecutive` lock mode, InnoDB can avoid using table-level `AUTO-INC` locks for “simple insert” statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the `interleaved` lock mode can be used to eliminate all use of table-level `AUTO-INC` locks for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

- `innodb_autoinc_lock_mode = 1` (“consecutive” lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special `AUTO-INC` table-level lock and hold it until the end of the statement. This applies to all `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. Only one statement holding the `AUTO-INC` lock can execute at a time.

“Simple inserts” (for which the number of rows to be inserted is known in advance) avoid table-level `AUTO-INC` locks by obtaining the required number of auto-increment values under the control of a mutex (a light-weight lock) that is only held for the duration of the allocation process, *not* until the

statement completes. No table-level `AUTO-INC` lock is used unless an `AUTO-INC` lock is held by another transaction. If another transaction holds an `AUTO-INC` lock, a “simple insert” waits for the `AUTO-INC` lock, as if it were a “bulk insert”.

This lock mode ensures that, in the presence of `INSERT` statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “`INSERT`-like” statement are consecutive, and operations are safe for statement-based replication.

Simply put, this lock mode significantly improves scalability while being safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are *consecutive*. There is *no change* in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an `AUTO_INCREMENT` column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, InnoDB allocates more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

- `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “`INSERT`-like” statements use the table-level `AUTO-INC` lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is *not safe* when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “`INSERT`-like” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is *interleaved* across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there will be no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

## InnoDB AUTO\_INCREMENT Lock Mode Usage Implications

- Using auto-increment with replication

If you are using statement-based replication, set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use `innodb_autoinc_lock_mode = 2` (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

- “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost”. Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “`INSERT`-like” statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an `AUTO_INCREMENT` column of a table.

- Specifying NULL or 0 for the `AUTO_INCREMENT` column

In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the `AUTO_INCREMENT` column in an `INSERT`, InnoDB treats the row as if the value was not specified and generates a new value for it.

- Assigning a negative value to the `AUTO_INCREMENT` column

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if you assign a negative value to the `AUTO_INCREMENT` column.

- If the `AUTO_INCREMENT` value becomes larger than the maximum integer for the specified integer type

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

- Gaps in auto-increment values for “bulk inserts”

With `innodb_autoinc_lock_mode` set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement will be consecutive, without gaps, because the table-level `AUTO-INC` lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` set to 2 (“interleaved”), there may be gaps in the auto-increment values generated by “bulk inserts,” but only if there are concurrently executing “`INSERT`-like” statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- Auto-increment values assigned by “mixed-mode inserts”

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement will behave differently in lock modes 0, 1, and 2. For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100. Consider the following “mixed-mode insert” statement:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` set to 0 (“traditional”), the four new rows will be:

```
+-----+-----+
| c1   | c2   |
+-----+-----+
| 1    | a    |
| 101  | b    |
| 5    | c    |
| 102  | d    |
+-----+-----+
```

The next available auto-increment value will be 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing “`INSERT`-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 (“consecutive”), the four new rows will also be:

```
+-----+-----+
| c1   | c2   |
+-----+-----+
```

1	a
101	b
5	c
102	d

However, in this case, the next available auto-increment value will be 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing “INSERT-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 (“interleaved”), the four new rows will be:

c1	c2
1	a
x	b
5	c
y	d

The values of `x` and `y` will be unique and larger than any previously generated rows. However, the specific values of `x` and `y` will depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number was the value 4:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` setting, this statement will generate a duplicate-key error 23000 (Can't write; duplicate key in table) because 5 will be allocated for the row (NULL, 'b') and insertion of the row (5, 'c') will fail.

## InnoDB AUTO\_INCREMENT Counter Initialization

This section describes how InnoDB initializes `AUTO_INCREMENT` counters.

If you specify an `AUTO_INCREMENT` column for an InnoDB table, the table handle in the InnoDB data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

To initialize an auto-increment counter after a server restart, InnoDB executes the equivalent of the following statement on the first insert into a table containing an `AUTO_INCREMENT` column.

```
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```

InnoDB increments the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. By default, the value is incremented by 1. This default can be overridden by the `auto_increment_increment` configuration setting.

If the table is empty, InnoDB uses the value 1. This default can be overridden by the `auto_increment_offset` configuration setting.

If a `SHOW TABLE STATUS` statement examines the table before the auto-increment counter is initialized, InnoDB initializes but does not increment the value. The value is stored for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction. InnoDB follows the same procedure for initializing the auto-increment counter for a newly created table.

After the auto-increment counter has been initialized, if you do not explicitly specify a value for an `AUTO_INCREMENT` column, `InnoDB` increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies the column value, and the value is greater than the current counter value, the counter is set to the specified column value.

`InnoDB` uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, `InnoDB` reinitializes the counter for each table for the first `INSERT` to the table, as described earlier.

A server restart also cancels the effect of the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, which you can use with `InnoDB` tables to set the initial counter value or alter the current counter value.

## 14.5.6 InnoDB and FOREIGN KEY Constraints

This section describes differences in the `InnoDB` storage engine's handling of foreign keys as compared with that of the MySQL Server.

### Foreign Key Definitions

Foreign key definitions for `InnoDB` tables are subject to the following conditions:

- `InnoDB` permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- `InnoDB` does not currently support foreign keys for tables with user-defined partitioning. This means that no user-partitioned `InnoDB` table may contain foreign key references or columns referenced by foreign keys.
- `InnoDB` allows a foreign key constraint to reference a non-unique key. *This is an `InnoDB` extension to standard SQL.*

### Referential Actions

Referential actions for foreign keys of `InnoDB` tables are subject to the following conditions:

- While `SET DEFAULT` is allowed by the MySQL Server, it is rejected as invalid by `InnoDB`. `CREATE TABLE` and `ALTER TABLE` statements using this clause are not allowed for `InnoDB` tables.
- If there are several rows in the parent table that have the same referenced key value, `InnoDB` acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, `InnoDB` does not permit the deletion of any of those parent rows.
- `InnoDB` performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.
- Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, `InnoDB` checks `UNIQUE` and `FOREIGN KEY` constraints row-by-row. When performing foreign key checks, `InnoDB` sets shared row-level locks on child or parent records it has to look at. `InnoDB` checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until `InnoDB` implements deferred

constraint checking, some things will be impossible, such as deleting a record that refers to itself using a foreign key.

## Foreign Key Usage and Error Information

You can obtain general information about foreign keys and their usage from querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table, and more information more specific to InnoDB tables can be found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, also in the `INFORMATION_SCHEMA` database. See also [Section 13.1.14.3, “Using FOREIGN KEY Constraints”](#).

In addition to `SHOW ERRORS`, in the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), you can obtain a detailed explanation of the most recent InnoDB foreign key error by checking the output of `SHOW ENGINE INNODB STATUS`.

### 14.5.7 Limits on InnoDB Tables

#### Warning

Do *not* convert MySQL system tables in the `mysql` database from MyISAM to InnoDB tables. This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or re-generate them with the `mysql_install_db` program.

#### Warning

It is not a good idea to configure InnoDB to use data files or log files on NFS volumes. Otherwise, the files might be locked by other processes and become unavailable for use by MySQL.

### Maximums and Minimums

- A table can contain a maximum of 1017 columns (raised in MySQL 5.6.9 from the earlier limit of 1000). Virtual generated columns are included in this limit.
- A table can contain a maximum of 64 [secondary indexes](#).
- By default, an index key for a single-column index can be up to 767 bytes. The same length limit applies to any index key prefix. See [Section 13.1.11, “CREATE INDEX Syntax”](#). For example, you might hit this limit with a [column prefix](#) index of more than 255 characters on a `TEXT` or `VARCHAR` column, assuming a UTF-8 character set and the maximum of 3 bytes for each character. When the `innodb_large_prefix` configuration option is enabled, this length limit is raised to 3072 bytes, for InnoDB tables that use the `DYNAMIC` and `COMPRESSED` row formats.

Attempting to use an index prefix length that is greater than the allowed maximum value produces an error. To avoid such errors for replication configurations, avoid setting the `innodb_large_prefix` option on the master if it cannot also be set on the slaves, and the slaves have unique indexes that could be affected by this limit.

- The InnoDB internal maximum key length is 3500 bytes, but MySQL itself restricts this to 3072 bytes. This limit applies to the length of the combined index key in a multi-column index.
- If you reduce the InnoDB [page size](#) to 8KB or 4KB by specifying the `innodb_page_size` option when creating the MySQL instance, the maximum length of the index key is lowered proportionally, based on the limit of 3072 bytes for a 16KB page size. That is, the maximum index key length is 1536 bytes when the page size is 8KB, and 768 bytes when the page size is 4KB.
- The maximum row length, except for variable-length columns (`VARBINARY`, `VARCHAR`, `BLOB` and `TEXT`), is slightly less than half of a database page for 4KB, 8KB, 16KB, and 32KB page sizes. For example, the maximum row length for the default `innodb_page_size` of 16KB is about 8000 bytes.

For an InnoDB page size of 64KB, the maximum row length is about 16000 bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in [Section 14.9.2, “File Space Management”](#).

- Although InnoDB supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- On some older operating systems, files must be less than 2GB. This is not a limitation of InnoDB itself, but if you require a large tablespace, you will need to configure it using several smaller data files rather than one large data file.
- The combined size of the InnoDB log files can be up to 512GB.
- The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.
- The default database page size in InnoDB is 16KB. You can lower the page size to 8KB or 4KB by specifying the `innodb_page_size` option when creating the MySQL instance.

#### Note

Prior to MySQL 5.7.6, increasing the page size is not a supported operation. There is no guarantee that InnoDB will function normally with a page size greater than 16KB. Problems compiling or running InnoDB may occur. In particular, `ROW_FORMAT=COMPRESSED` in the Barracuda file format assumes that the page size is at most 16KB and uses 14-bit pointers.

As of MySQL 5.7.6, 32KB and 64KB page sizes are supported but `ROW_FORMAT=COMPRESSED` is still unsupported for page sizes greater than 16KB. For both 32KB and 64KB page sizes, the maximum record size is 16KB. For `innodb_page_size=32k`, extent size is 2MB. For `innodb_page_size=64k`, extent size is 4MB.

A MySQL instance using a particular InnoDB page size cannot use data files or log files from an instance that uses a different page size. This limitation could affect restore or downgrade operations using data from MySQL 5.6, which does support page sizes other than 16KB.

## Restrictions on InnoDB Tables

- `ANALYZE TABLE` determines index cardinality (as displayed in the `Cardinality` column of `SHOW INDEX` output) by doing `random dives` to each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on InnoDB tables but not 100% accurate because it does not take all rows into account.

You can make the `statistics` collected by `ANALYZE TABLE` more precise and more stable by turning on the `innodb_stats_persistent` configuration option, as explained in [Section 14.3.11.1,](#)

“[Configuring Persistent Optimizer Statistics Parameters](#)”. When that setting is enabled, it is important to run `ANALYZE TABLE` after major changes to indexed column data, because the statistics are not recalculated periodically (such as after a server restart) as they traditionally have been.

You can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable (if the persistent statistics setting is turned on), or the `innodb_stats_transient_sample_pages` system variable (if the persistent statistics setting is turned off).

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See [Section 5.1.4, “Server System Variables”](#), and [Section B.5.5, “Optimizer-Related Issues”](#).

- If statements or transactions are running on a table and `ANALYZE TABLE` is run on the same table followed by a second `ANALYZE TABLE` operation, the second `ANALYZE TABLE` operation is blocked until the statements or transactions are completed. This behaviour occurs because `ANALYZE TABLE` marks the currently loaded table definition as obsolete when `ANALYZE TABLE` is finished running. New statements or transactions (including a second `ANALYZE TABLE` statement) must load the new table definition into the table cache, which cannot occur until currently running statements or transactions are completed and the old table definition is purged. Loading multiple concurrent table definitions is not supported.
- `SHOW TABLE STATUS` does not give accurate statistics on InnoDB tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. To process a `SELECT COUNT(*) FROM t` statement, InnoDB scans an index of the table, which takes some time if the index is not entirely in the buffer pool. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. If an approximate row count is sufficient, `SHOW TABLE STATUS` can be used. See [Section 8.5, “Optimizing for InnoDB Tables”](#).
- On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names.
- An `AUTO_INCREMENT` column `ai_col` must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.
- InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column while initializing a previously specified `AUTO_INCREMENT` column on a table.

With `innodb_autoinc_lock_mode=0`, InnoDB uses a special `AUTO-INC` table lock mode where the lock is obtained and held to the end of the current SQL statement while accessing the auto-increment counter. Other clients cannot insert into the table while the `AUTO-INC` table lock is held. The same behavior occurs for “bulk inserts” with `innodb_autoinc_lock_mode=1`. Table-level `AUTO-INC` locks are not used with `innodb_autoinc_lock_mode=2`. For more information, See [Section 14.5.5, “AUTO\\_INCREMENT Handling in InnoDB”](#).

- When you restart the MySQL server, InnoDB may reuse an old value that was generated for an `AUTO_INCREMENT` column but never stored (that is, a value that was generated during an old transaction that was rolled back).
- When an `AUTO_INCREMENT` integer column runs out of values, a subsequent `INSERT` operation returns a duplicate-key error. This is general MySQL behavior, similar to how MyISAM works.

- `DELETE FROM tbl_name` does not regenerate the table but instead deletes all rows, one by one.
- Cascaded foreign key actions do not activate triggers.
- You cannot create a table with a column name that matches the name of an internal InnoDB column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR`, and `DB_MIX_ID`). The server reports error 1005 and refers to error -1 in the error message. This restriction applies only to use of the names in uppercase.

## Locking and Transactions

- `LOCK TABLES` acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an InnoDB table lock. Versions of MySQL before 4.1.2 did not acquire InnoDB table locks; the old behavior can be selected by setting `innodb_table_locks=0`. If no InnoDB table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.

In MySQL 5.7, `innodb_table_locks=0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- All InnoDB locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on InnoDB tables in `autocommit=1` mode because the acquired InnoDB table locks would be released immediately.
- You cannot lock additional tables in the middle of a transaction because `LOCK TABLES` performs an implicit `COMMIT` and `UNLOCK TABLES`.
- The limit on data-modifying transactions is now  $96 * 1023$  concurrent transactions that generate undo records. As of MySQL 5.7.2, 32 of 128 rollback segments are assigned to non-redo logs for transactions that modify temporary tables and related objects. This reduces the maximum number of concurrent data-modifying transactions from 128K to 96K. The 96K limit assumes that transactions do not modify temporary tables. If all data-modifying transactions also modify temporary tables, the limit is 32K concurrent transactions.

## 14.6 InnoDB Table and Page Compression

This section provides information about the InnoDB table compression and InnoDB page compression features. The page compression feature, referred to as [transparent page compression](#), was introduced in MySQL 5.7.8.

Using the compression features of InnoDB, you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with [secondary indexes](#), because index data is compressed also. Compression can be especially important for [SSD](#) storage devices, because they tend to have lower capacity than [HDD](#) devices.

### 14.6.1 InnoDB Table Compression

This section describes InnoDB table compression, which is supported with InnoDB tables that reside in [file\\_per\\_table](#) tablespaces or [general tablespaces](#). Table compression is enabled using the `ROW_FORMAT=COMPRESSED` attribute with `CREATE TABLE` or `ALTER TABLE`.

#### 14.6.1.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are [disk-bound](#). Data [compression](#) enables smaller database size, reduced I/O, and

improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An InnoDB table created with `ROW_FORMAT=COMPRESSED` can use a smaller [page size](#) on disk than the configured `innodb_page_size` value. Smaller pages require less I/O to read from and write to disk, which is especially valuable for [SSD](#) devices.

The compressed page size is specified through the `CREATE TABLE` or `ALTER TABLE` `KEY_BLOCK_SIZE` parameter. The different page size requires that the table be placed in a [file-per-table](#) tablespace or [general tablespace](#) rather than in the [system tablespace](#), as the system tablespace cannot store compressed tables. For more information, see [Section 14.4.4, “InnoDB File-Per-Table Tablespaces”](#), and [Section 14.4.9, “InnoDB General Tablespaces”](#).

The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, MySQL also creates an uncompressed page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are [evicted](#) from the buffer pool when space is needed, and then uncompressed again on the next access.

### 14.6.1.2 Creating Compressed Tables

Compressed tables can be created in [file-per-table](#) tablespaces or in [general tablespaces](#). Table compression is not available for the InnoDB [system tablespace](#). The system tablespace (space 0, the [.ibdata files](#)) can contain user-created tables, but it also contains internal system data, which is never compressed. Thus, compression applies only to tables (and indexes) stored in file-per-table or general tablespaces.

#### Creating a Compressed Table in File-Per-Table Tablespace

To create a compressed table in a file-per-table tablespace, `innodb_file_per_table` must be enabled (the default in MySQL 5.6.6) and `innodb_file_format` must be set to `Barracuda`. You can set these parameters in the MySQL configuration file (`my.cnf` or `my.ini`) or dynamically, using a `SET` statement.

After the `innodb_file_per_table` and `innodb_file_format` options are configured, specify the `ROW_FORMAT=COMPRESSED` clause or `KEY_BLOCK_SIZE` clause, or both, in a `CREATE TABLE` or `ALTER TABLE` statement to create a compressed table in a file-per-table tablespace.

For example, you might use the following statements:

```
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
CREATE TABLE t1
  (c1 INT PRIMARY KEY)
  ROW_FORMAT=COMPRESSED
  KEY_BLOCK_SIZE=8;
```

#### Creating a Compressed Table in a General Tablespace

To create a compressed table in a general tablespace, `FILE_BLOCK_SIZE` must be defined for the general tablespace, which is specified when the tablespace is created. The `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value, and the page size of the compressed table, defined by the `CREATE TABLE` or `ALTER TABLE KEY_BLOCK_SIZE`

clause, must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16384` and `FILE_BLOCK_SIZE=8192`, the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

The following example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

## Notes

- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the `KEY_BLOCK_SIZE` setting defaults to half the `innodb_page_size` value.
- If you specify a valid `KEY_BLOCK_SIZE` value, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.
- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic [workload](#). For general tablespaces, keep in mind that dropping a table does not reduce the size of the general tablespace `.ibd` file, nor does it return disk space to the operating system. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).
- The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by InnoDB if necessary. For file-per-table tablespaces, the `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. If you specify a value greater than the `innodb_page_size` value, the specified value is ignored, a warning is issued, and `KEY_BLOCK_SIZE` is set to half of the `innodb_page_size` value. If `innodb_strict_mode=ON`, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. For general tablespaces, valid `KEY_BLOCK_SIZE` values depend on the `FILE_BLOCK_SIZE` setting of the tablespace. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).
- Support for 32k and 64k page sizes was added in MySQL 5.7.6 but these page sizes do not support compression. For more information, refer to the [innodb\\_page\\_size](#) documentation.
- The default uncompressed size of InnoDB data pages is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the tablespace data file (`.ibd` file). The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.
- When creating a compressed table in a file-per-table tablespace, setting `KEY_BLOCK_SIZE` equal to the InnoDB page size does not typically result in much compression. For example, setting `KEY_BLOCK_SIZE=16` typically would not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT` columns, because such values often do compress well, and might therefore require fewer [overflow pages](#) as described in [Section 14.6.1.5, “How Compression Works for InnoDB Tables”](#). For general tablespaces, a `KEY_BLOCK_SIZE` value equal to the InnoDB page size is not permitted. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).
- All indexes of a table (including the [clustered index](#)) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax for InnoDB tables, and are ignored if they are specified (although, if specified, they will appear in the output of the `SHOW CREATE TABLE` statement).

- For performance-related configuration options, see [Section 14.6.1.3, “Tuning Compression for InnoDB Tables”](#).

### Restrictions on Compressed Tables

- MySQL versions prior to 5.1 cannot process compressed tables.
- Compressed tables cannot be stored in the [InnoDB](#) system tablespace.
- General tablespaces can contain multiple tables, but compressed and uncompressed tables cannot coexist within the same general tablespace.
- Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.

#### 14.6.1.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in [InnoDB Data Storage and Compression](#) ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.
- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a [data warehouse](#) (primarily queries) or an [OLTP](#) system (mix of queries and [DML](#)).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive [compression failures](#) at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see [Section 14.6.1.4, “Monitoring Compression at Runtime”](#) for ways to verify the effectiveness of those choices under real-world conditions.

### When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific [workload](#) and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

### Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in [CHAR](#), [VARCHAR](#), [TEXT](#) or [BLOB](#) columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) [page size](#). It might be that the [primary key](#) (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being

stored “off-page”, as discussed in [Section 14.8.3, “DYNAMIC and COMPRESSED Row Formats”](#). Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as [gzip](#) or WinZip) on a copy of the [.ibd file](#) for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the [page size](#), 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) in a [file-per-table](#) tablespace and look at the size of the resulting [.ibd file](#). For example:

```
use test;
set global innodb_file_per_table=1;
set global innodb_file_format=Barracuda;
set global autocommit=0;

-- Create an uncompressed table with a million or two rows.
create table big_table as select * from information_schema.columns;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
commit;
alter table big_table add id int unsigned not null primary key auto_increment;

show create table big_table\G

select count(id) from big_table;

-- Check how much space is needed for the uncompressed table.
\! ls -l data/test/big_table.ibd

create table key_block_size_4 like big_table;
alter table key_block_size_4 key_block_size=4 row_format=compressed;

insert into key_block_size_4 select * from big_table;
commit;

-- Check how much space is needed for a compressed table
-- with particular compression settings.
\! ls -l data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```
-rw-rw---- 1 cirrus staff 310378496 Jan  9 13:44 data/test/big_table.ibd
-rw-rw---- 1 cirrus staff  83886080 Jan  9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular [workload](#):

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the [INFORMATION\\_SCHEMA.INNODB\\_CMP](#) table.

- For more elaborate tests involving workloads with multiple compressed tables, run queries against the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because the statistics in the `INNODB_CMP_PER_INDEX` table are expensive to collect, you must enable the configuration option `innodb_cmp_per_index_enabled` before querying that table, and you might restrict such testing to a development server or a non-critical [slave server](#).
- Run some typical SQL statements against the compressed table you are testing.
- Examine the ratio of successful compression operations to overall compression operations by querying the `INFORMATION_SCHEMA.INNODB_CMP` or `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table, and comparing `COMPRESS_OPS` to `COMPRESS_OPS_OK`.
- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.
- If you get a high proportion of [compression failures](#), you can adjust `innodb_compression_level`, `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` options as described in [Section 14.6.1.6, “Compression for OLTP Workloads”](#), and try further tests.

## Database Compression versus Application Compression

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

### Compressing in the Database

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

### Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, you might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

### Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

### Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing `BLOBs` or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are `INSERTs` that use a monotonically increasing primary key, and there are few secondary indexes, there is little

need to reorganize and recompress index pages. Since MySQL can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, `DELETE` operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

## Configuration Characteristics and Compression

Reading and writing database [pages](#) from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the [buffer pool](#) for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

## Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in [Compression of B-Tree Pages](#).

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the [B-tree](#) nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, `KEY_BLOCK_SIZE=8` is usually a safe choice.

### 14.6.1.4 Monitoring Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from [Section 14.6.1.3, “Tuning Compression for InnoDB Tables”](#), and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the [Information Schema](#) tables described in [Example 14.10, “Using the Compression Information Schema Tables”](#). These tables reflect the internal use of memory and the rates of compression used overall.

The `INNODB_CMP` table reports information about compression activity for each compressed page size (`KEY_BLOCK_SIZE`) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The `INNODB_CMP_PER_INDEX` table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each InnoDB table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The `INNODB_CMP_PER_INDEX` table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different workloads, data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the `innodb_cmp_per_index_enabled` configuration option before you can query the `INNODB_CMP_PER_INDEX` table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits B-tree nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` and `INNODB_CMP_PER_INDEX` tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of `INSERT`, `UPDATE` and `DELETE` operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations (`COMPRESS_OPS_OK`) is a high percentage of the total number of compression operations (`COMPRESS_OPS`), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase `KEY_BLOCK_SIZE` for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

### 14.6.1.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about `compression` for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

#### Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known `zlib library`, which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many

cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the [file-per-table](#) tablespace or [general tablespace](#) `.idb` files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the [workload](#), this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the [innodb\\_compression\\_level](#) configuration option.

### InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a [B-tree](#) index (the [clustered index](#)). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) [primary key](#) and all the other columns of the table.

[Secondary indexes](#) in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of [overflow pages](#) used to store long [VARCHAR](#), [BLOB](#), or [TEXT](#) columns, as explained in the following sections.

### Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a [compression failure](#)), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for [OLTP](#) applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it. The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the [innodb\\_compression\\_failure\\_threshold\\_pct](#), and [innodb\\_compression\\_pad\\_pct\\_max](#) configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If [innodb\\_strict\\_mode](#) is [ON](#), MySQL checks the maximum row size during [CREATE TABLE](#) or [CREATE INDEX](#). If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when [innodb\\_strict\\_mode](#) is [OFF](#), and a subsequent [INSERT](#) or [UPDATE](#) statement attempts to create an index entry that does not fit in the size of the compressed page, the

operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

`innodb_strict_mode` is not applicable to general tablespaces, which also support compressed tables. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 13.1.15, “CREATE TABLESPACE Syntax”](#).

## Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, `BLOB`, `VARCHAR`, and `TEXT` columns that are not part of the primary key may be stored on separately allocated [overflow pages](#). We refer to these columns as [off-page columns](#). Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of `BLOB`, `TEXT`, or `VARCHAR` columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

### Note

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

Tables created in older versions of MySQL use the [Antelope](#) file format, which supports only `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT`. In these formats, MySQL stores the first 768 bytes of `BLOB`, `VARCHAR`, and `TEXT` columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as `JPEG`, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

For [file-per-table](#) tablespaces, using a 16K compressed page size can reduce storage and I/O costs for `BLOB`, `VARCHAR`, or `TEXT` columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form. General tablespaces do not support a 16K compressed page size (`KEY_BLOCK_SIZE`). For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

## Compression and the InnoDB Buffer Pool

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if `innodb_page_size` is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the [buffer pool](#), then uncompresses the page to its original form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can [evict](#) from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that [hot](#) (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an [I/O-bound](#) or [CPU-bound](#) manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

## Compression and the InnoDB Redo Log Files

Before a compressed page is written to a [data file](#), MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for [crash recovery](#), even in the unlikely case that the `zlib` library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of [log files](#), or a need for more frequent [checkpoints](#), can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

Compressed tables require the [Barracuda](#) file format. To create a compressed table in a file-per-table tablespace, `innodb_file_per_table` must be enabled and `innodb_file_format` must be set to [Barracuda](#). There is no dependence on the `innodb_file_format` setting when creating a compressed table in a general tablespace. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#). The [MySQL Enterprise Backup](#) product supports the [Barracuda](#) file format.

### 14.6.1.6 Compression for OLTP Workloads

Traditionally, the [InnoDB compression](#) feature was recommended primarily for read-only or read-mostly [workloads](#), such as in a [data warehouse](#) configuration. The rise of [SSD](#) storage devices, which are fast but relatively small and expensive, makes compression attractive also for [OLTP](#) workloads: high-traffic, interactive web sites can reduce their storage requirements and their I/O operations per second ([IOPS](#)) by using compressed tables with applications that do frequent [INSERT](#), [UPDATE](#), and [DELETE](#) operations.

Configuration options introduced in MySQL 5.6 let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:

- `innodb_compression_level` lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during

compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

- `innodb_compression_failure_threshold_pct` specifies a cutoff point for [compression failures](#) during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by `innodb_compression_pad_pct_max`.
- `innodb_compression_pad_pct_max` lets you adjust the maximum amount of space reserved within each [page](#) to record changes to compressed rows, without needing to compress the entire page again. The higher the value, the more changes can be recorded without recompressing the page. MySQL uses a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations “fail” at runtime, requiring an expensive operation to split the compressed page.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the `innodb_buffer_pool_size` configuration option.

### 14.6.1.7 SQL Compression Syntax Warnings and Errors

This section describes syntax warnings and errors that you may encounter when using the table compression feature with [file-per-table](#) tablespaces and [general tablespaces](#).

#### SQL Compression Syntax Warnings and Errors for File-Per-Table Tablespaces

When `innodb_strict_mode` is enabled (the default as of MySQL 5.7.7), specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following error if `innodb_file_per_table` is disabled or if `innodb_file_format` is set to [Antelope](#) rather than [Barracuda](#).

```
ERROR 1031 (HY000): Table storage engine for 't1' doesn't have this option
```

#### Note

The table is not created if the current configuration does not permit using compressed tables.

When `innodb_strict_mode` is disabled, specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following warnings if `innodb_file_per_table` is disabled.

```
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1478 | InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table. |
| Warning | 1478 | InnoDB: ignoring KEY_BLOCK_SIZE=4. |
| Warning | 1478 | InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table. |
| Warning | 1478 | InnoDB: assuming ROW_FORMAT=DYNAMIC. |
+-----+-----+-----+
```

Similar warnings are issued if `innodb_file_format` is set to [Antelope](#) rather than [Barracuda](#).

#### Note

These messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

The “non-strict” behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=COMPACT` instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper settings for the configuration parameters `innodb_file_format` and `innodb_file_per_table`.

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored).

Level	Code	Message
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.

If you are running with `innodb_strict_mode` enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 14.5, “`ROW_FORMAT` and `KEY_BLOCK_SIZE` Options” provides an overview the `ROW_FORMAT` and `KEY_BLOCK_SIZE` options that are used with `CREATE TABLE` or `ALTER TABLE`.

**Table 14.5 `ROW_FORMAT` and `KEY_BLOCK_SIZE` Options**

Option	Usage Notes	Description
<code>ROW_FORMAT=REDUNDANT</code>	Storage format used prior to MySQL 5.0.3	Less efficient than <code>ROW_FORMAT=COMPACT</code> ; for backward compatibility
<code>ROW_FORMAT=COMPACT</code>	Default storage format since MySQL 5.0.3	Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page
<code>ROW_FORMAT=DYNAMIC</code>	File-per-table tablespaces require <code>innodb_file_format=Barracuda</code>	Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)
<code>ROW_FORMAT=COMPRESSED</code>	File-per-table tablespaces require <code>innodb_file_format=Barracuda</code>	Compresses the table and indexes using zlib
<code>KEY_BLOCK_SIZE=n</code>	File-per-table tablespaces require <code>innodb_file_format=Barracuda</code>	Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies <code>ROW_FORMAT=COMPRESSED</code> . For general tablespaces, a <code>KEY_BLOCK_SIZE</code> value equal to the InnoDB page size is not permitted.

Table 14.6, “`CREATE/ALTER TABLE` Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is `OFF`, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
-> ENGINE=INNODB KEY_BLOCK_SIZE=33333;
ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)

mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
```

```

+-----+-----+-----+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333. |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-----+-----+-----+

```

Table 14.6 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF

Syntax	Warning or Error Condition	Resulting <code>ROW_FORMAT</code> , as shown in <code>SHOW TABLE STATUS</code>
<code>ROW_FORMAT=REDUNDANT</code>	None	REDUNDANT
<code>ROW_FORMAT=COMPACT</code>	None	COMPACT
<code>ROW_FORMAT=COMPRESSED</code> or <code>ROW_FORMAT=DYNAMIC</code> or <code>KEY_BLOCK_SIZE</code> is specified	Ignored for file-per-table tablespaces unless both <code>innodb_file_format=Barracuda</code> and <code>innodb_file_per_table</code> are enabled. General tablespaces support all row formats (with some restrictions) regardless of <code>innodb_file_format</code> and <code>innodb_file_per_table</code> settings. See Section 14.4.9, “InnoDB General Tablespaces”.	the default row format for file-per-table tablespaces; the specified row format for general tablespaces
Invalid <code>KEY_BLOCK_SIZE</code> is specified (not 1, 2, 4, 8 or 16)	<code>KEY_BLOCK_SIZE</code> is ignored	the specified row format, or the default row format
<code>ROW_FORMAT=COMPRESSED</code> and valid <code>KEY_BLOCK_SIZE</code> are specified	None; <code>KEY_BLOCK_SIZE</code> specified is used	COMPRESSED
<code>KEY_BLOCK_SIZE</code> is specified with <code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code> row format	<code>KEY_BLOCK_SIZE</code> is ignored	REDUNDANT, COMPACT or DYNAMIC
<code>ROW_FORMAT</code> is not one of <code>REDUNDANT</code> , <code>COMPACT</code> , <code>DYNAMIC</code> or <code>COMPRESSED</code>	Ignored if recognized by the MySQL parser. Otherwise, an error is issued.	the default row format or N/A

When `innodb_strict_mode` is ON, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters and issues errors. When `innodb_strict_mode` is OFF, MySQL issues warnings instead of errors for ignored invalid parameters. `innodb_strict_mode` is ON by default as of MySQL 5.7.7.

When `innodb_strict_mode` is ON, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters. For compatibility with earlier versions of MySQL, strict mode is not enabled by default; instead, MySQL issues warnings (not errors) for ignored invalid parameters.

It is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

## SQL Compression Syntax Warnings and Errors for General Tablespaces

- If `FILE_BLOCK_SIZE` was not defined for the general tablespace when the tablespace was created, the tablespace cannot contain compressed tables. If you attempt to add a compressed table, an error is returned, as shown in the following example:

```

mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPRESSED

```

```
KEY_BLOCK_SIZE=8;  
ERROR 1478 (HY000): InnoDB: Tablespace `ts1` cannot contain a COMPRESSED table
```

- Attempting to add a table with an invalid `KEY_BLOCK_SIZE` to a general tablespace returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;  
Query OK, 0 rows affected (0.01 sec)  
  
mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED  
KEY_BLOCK_SIZE=4;  
ERROR 1478 (HY000): InnoDB: Tablespace `ts2` uses block size 8192 and cannot  
contain a table with physical page size 4096
```

For general tablespaces, the `KEY_BLOCK_SIZE` of the table must be equal to the `FILE_BLOCK_SIZE` of the tablespace divided by 1024. For example, if the `FILE_BLOCK_SIZE` of the tablespace is 8192, the `KEY_BLOCK_SIZE` of the table must be 8.

- Attempting to add a table with an uncompressed row format to a general tablespace configured to store compressed tables returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts3` ADD DATAFILE 'ts3.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;  
Query OK, 0 rows affected (0.01 sec)  
  
mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts3 ROW_FORMAT=COMPACT;  
ERROR 1478 (HY000): InnoDB: Tablespace `ts3` uses block size 8192 and cannot  
contain a table with physical page size 16384
```

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 13.1.15, “CREATE TABLESPACE Syntax”](#).

For more information about using compressed tables with general tablespaces, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

## 14.6.2 InnoDB Page Compression

As of MySQL 5.7.8, `InnoDB` supports page-level compression for tables that reside in `file_per_table` tablespaces. This feature is referred to as *Transparent Page Compression*. Page compression is enabled by specifying the `COMPRESSION` attribute with `CREATE TABLE` or `ALTER TABLE`. Supported compression algorithms include `Zlib` and `LZ4`.

### Supported Platforms

Page compression requires sparse file and hole punching support. Page compression is supported on Windows with NTFS, and on the following subset of MySQL-supported Linux platforms where the kernel level provides hole punching support:

- RHEL 7 and derived distributions that use kernel version 3.10.0-123 or higher
- OEL 5.10 (UEK2) kernel version 2.6.39 or higher
- OEL 6.5 (UEK3) kernel version 3.8.13 or higher
- OEL 7.0 kernel version 3.8.13 or higher
- SLE11 kernel version 3.0-x
- SLE12 kernel version 3.12-x
- OES11 kernel version 3.0-x
- Ubuntu 14.0.4 LTS kernel version 3.13 or higher
- Ubuntu 12.0.4 LTS kernel version 3.2 or higher

- Debian 7 kernel version 3.2 or higher

### Note

All of the available file systems for a given Linux distribution may not support hole punching.

## How Page Compression Works

When a page is written, it is compressed using the specified compression algorithm. The compressed data is written to disk, where the hole punching mechanism releases empty blocks from the end of the page. If compression fails, data is written out as-is.

## Hole Punch Size on Linux

On Linux systems, the file system block size is the unit size used for hole punching. Therefore, page compression only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the file system block size. For example, if `innodb_page_size=16K` and the file system block size is 4K, page data must compress to less than or equal to 12K to make hole punching possible.

## Hole Punch Size on Windows

On Windows systems, the underlying infrastructure for sparse files is based on NTFS compression. Hole punching size is the NTFS compression unit, which is 16 times the NTFS cluster size. Cluster sizes and their compression units are shown in the following table:

**Table 14.7 Windows NTFS Cluster Size and Compression Units**

Cluster Size	Compression Unit
512 Bytes	8 KB
1 KB	16 KB
2 KB	32 KB
4 KB	64 KB

Page compression on Windows systems only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the compression unit size.

The default NTFS cluster size is 4K, for which the compression unit size is 64K. This means that page compression has no benefit for an out-of-the box Windows NTFS configuration, as the maximum `innodb_page_size` is also 64K.

For page compression to work on Windows, the file system must be created with a cluster size smaller than 4K, and the `innodb_page_size` must be at least twice the size of the compression unit. For example, for page compression to work on Windows, you could build the file system with a cluster size of 512 Bytes (which has a compression unit of 8KB) and initialize [InnoDB](#) with an `innodb_page_size` value of 16K or greater.

## Enabling Page Compression

To enable page compression, specify the `COMPRESSION` attribute in the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (c1 INT) COMPRESSION="zlib";
```

You can also enable page compression in an `ALTER TABLE` statement. However, `ALTER TABLE ... COMPRESSION` only updates the tablespace compression attribute. Writes to the tablespace that occur after setting the new compression algorithm use the new setting, but to apply the new compression algorithm to existing pages, you must rebuild the table using `OPTIMIZE TABLE`.

```
ALTER TABLE t1 COMPRESSION="zlib";
```

```
OPTIMIZE TABLE t1;
```

## Disabling Page Compression

To disable page compression, set `COMPRESSION=None` using `ALTER TABLE`. Writes to the tablespace that occur after setting `COMPRESSION=None` no longer use page compression. To uncompress existing pages, you must rebuild the table using `OPTIMIZE TABLE` after setting `COMPRESSION=None`.

```
ALTER TABLE t1 COMPRESSION="None";
OPTIMIZE TABLE t1;
```

## Page Compression Metadata

Page compression metadata is found in the `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` table, in four columns that were added with the introduction of the Transparent Page Compression feature:

- `FS_BLOCK_SIZE`: The file system block size, which is the unit size used for hole punching.
- `FILE_SIZE`: The apparent size of the file, which represents the maximum size of the file, uncompressed.
- `ALLOCATED_SIZE`: The actual size of the file, which is the amount of space allocated on disk.
- `COMPRESSION`: The current tablespace setting for page compression (`Zlib`, `Lz4`, or `None`). A table may contain a mix of pages with different compression settings.

The `COMPRESSION` column displays incorrect data after a server restart (Bug #78197) and is removed in 5.7.10. Use `SHOW CREATE TABLE` to view the current page compression setting.

In the following example, page compression metadata for the `employees` table is retrieved from the `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` table.

```
# Create the employees table with Zlib page compression

CREATE TABLE employees (
  emp_no      INT          NOT NULL,
  birth_date  DATE         NOT NULL,
  first_name  VARCHAR(14)  NOT NULL,
  last_name   VARCHAR(16)  NOT NULL,
  gender      ENUM ('M','F') NOT NULL,
  hire_date   DATE         NOT NULL,
  PRIMARY KEY (emp_no)
) COMPRESSION="zlib";

# Insert data (not shown)

# Query page compression metadata in INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES

mysql> SELECT SPACE, NAME, FS_BLOCK_SIZE, FILE_SIZE, ALLOCATED_SIZE, COMPRESSION FROM
INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='employees/employees'\G
***** 1. row *****
SPACE: 45
NAME: employees/employees
FS_BLOCK_SIZE: 4096
FILE_SIZE: 23068672
ALLOCATED_SIZE: 19415040
COMPRESSION: Zlib
```

Page compression metadata for the `employees` table shows that `Zlib` compression is used. The apparent file size is 23068672 bytes while the actual file size (with page compression) is 19415040 bytes. The file system block size is 4096 bytes, which is the block size used for hole punching.

## Page Compression Limitations and Usage Notes

- Page compression is disabled if the file system block size (or compression unit size on Windows) \* 2 > `innodb_page_size`.

- Page compression is not supported for tables that reside in shared tablespaces, which include the system tablespace, the temporary table tablespace, and general tablespaces.
- Page compression is not supported for undo log tablespaces.
- Page compression is not supported for redo log pages.
- R-tree pages, which are used for spatial indexes, are not compressed.
- Pages that belong to compressed tables (`ROW_FORMAT=COMPRESSED`) are left as-is.
- During recovery, updated pages are written out in an uncompressed form.
- Loading a page-compressed tablespace on a server that does not support the compression algorithm that was used causes an I/O error.
- Before downgrading to an earlier version of MySQL that does not support page compression, uncompress the tables that use the page compression feature. To uncompress a table, run `ALTER TABLE ... COMPRESSION=None` and `OPTIMIZE TABLE`.
- Page-compressed tablespaces can be copied between Linux and Windows servers if the compression algorithm that was used is available on both servers.
- Preserving page compression when moving a page-compressed tablespace file from one host to another requires a utility that preserves sparse files.
- Better page compression may be achieved on Fusion-io hardware with NVMFS than on other platforms, as NVMFS is designed to take advantage of punch hole functionality.
- Using the page compression feature with a large InnoDB page size and relatively small file system block size could result in write amplification. For example, a maximum InnoDB page size of 64KB with a 4KB file system block size may improve compression but may also increase demand on the buffer pool, leading to increased I/O and potential write amplification.

## 14.7 InnoDB File-Format Management

As InnoDB evolves, data file formats that are not compatible with prior versions of InnoDB are sometimes required to support new features. To help manage compatibility in upgrade and downgrade situations, and systems that run different versions of MySQL, InnoDB uses named file formats. InnoDB currently supports two named file formats, [Antelope](#) and [Barracuda](#).

- [Antelope](#) is the original InnoDB file format, which previously did not have a name. It supports the `COMPACT` and `REDUNDANT` row formats for InnoDB tables.
- [Barracuda](#) is the newest file format. It supports all InnoDB row formats including the newer `COMPRESSED` and `DYNAMIC` row formats. The features associated with `COMPRESSED` and `DYNAMIC` row formats include compressed tables, off-page storage for long column data, and index key prefixes up to 3072 bytes (`innodb_large_prefix`). See [Section 14.8, “InnoDB Row Storage and Row Formats”](#).

This section discusses enabling file formats for new InnoDB tables, verifying compatibility of different file formats between MySQL releases, and identifying the file format in use.

InnoDB file format settings do not apply to tables stored in [general tablespaces](#) (introduced in MySQL 5.7.6). General tablespaces provide support for all row formats and associated features. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

### Note

The following file format configuration parameters have new default values as of MySQL 5.7.7:

- The `innodb_file_format` default value was changed to `Barracuda`. The previous default value was `Antelope`.
- The `innodb_large_prefix` default value was changed to `ON`. The previous default was `OFF`.

The following file format configuration parameters are deprecated in MySQL 5.7.7 and may be removed in a future release:

- `innodb_file_format`
- `innodb_file_format_check`
- `innodb_file_format_max`
- `innodb_large_prefix`

The file format configuration parameters were provided for creating tables compatible with earlier versions of `InnoDB` in MySQL 5.1. Now that MySQL 5.1 has reached the end of its product lifecycle, the parameters are no longer required. Future removal of the `innodb_file_format` parameter will require a new mechanism for managing compatibility of `InnoDB` tables and tablespaces among different versions of MySQL.

## 14.7.1 Enabling File Formats

The `innodb_file_format` configuration option defines the file format used when `InnoDB` tables are created in `file_per_table` tablespaces.

`Barracuda` is the default `innodb_file_format` setting as of MySQL 5.7.7. Prior to MySQL 5.7.7, the default file format is `Antelope`.

### Note

The `innodb_file_format` configuration option is deprecated and may be removed in a future release. For more information, see [Section 14.7, “InnoDB File-Format Management”](#).

You can set the value of `innodb_file_format` on the command line when you start `mysqld`, or in the option file (`my.cnf` on Unix, `my.ini` on Windows). You can also change it dynamically with a `SET GLOBAL` statement.

```
mysql> SET GLOBAL innodb_file_format=Barracuda;
Query OK, 0 rows affected (0.00 sec)
```

## Usage notes

- `ALTER TABLE` operations that recreate `InnoDB` tables use the current `innodb_file_format` setting.
- `InnoDB` file format settings do not apply to tables stored in `general tablespaces`. General tablespaces provide support for all row formats and associated features. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).
- As of MySQL 5.7.6, the `innodb_file_format` setting is not applicable when using the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE` to store a `DYNAMIC` table in the system tablespace.
- As of MySQL 5.7.9, the `innodb_file_format` setting is ignored when creating tables that use the `DYNAMIC` row format. For more information, see [Section 14.8.3, “DYNAMIC and COMPRESSED Row Formats”](#).

## 14.7.2 Verifying File Format Compatibility

InnoDB incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an old release of the MySQL server on InnoDB data files that use a newer file format. These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

### Backward Compatibility

You only need to consider backward file format compatibility when using a recent version of InnoDB (MySQL 5.5 and higher with InnoDB) alongside an older version (MySQL 5.1 or earlier, with the built-in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with an older version of InnoDB without risk of crashes, hangs, wrong results or corruptions. InnoDB includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with an old version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported, it cannot be accessed at all, even for read access.

The only way to “downgrade” an InnoDB tablespace to the earlier Antelope file format is to copy the data to a new table, in a tablespace that uses the earlier format.

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the `SHOW TABLE STATUS` command or querying the table `INFORMATION_SCHEMA.TABLES`. If the `Row_format` of the table is reported as `'Compressed'` or `'Dynamic'`, the tablespace containing the table supports the Barracuda format.

### Internal Details

Every InnoDB file-per-table tablespace (represented by a `*.ibd` file) is labeled with a file format identifier. The system tablespace (represented by the `ibdata` files) is tagged with the “highest” file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with `ROW_FORMAT=DYNAMIC`, updates the file header of the corresponding file-per-table `.ibd` file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support the Barracuda file format. To protect against anomalous behavior, InnoDB performs a compatibility check when the table is opened. (In many cases, the `ALTER TABLE` statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in [InnoDB Fast Index Creation](#).)

General tablespaces, which are also represented by a `*.ibd` file, support both Antelope and Barracuda file formats. For more information about general tablespaces, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

### Definition of ib-file set

To avoid confusion, for the purposes of this discussion we define the term “ib-file set” to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more `ibdata` files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.
- Zero or more single-table tablespaces (also called “file per table” files, named `*.ibd` files).
- InnoDB log files; usually two, `ib_logfile0` and `ib_logfile1`. Used for crash recovery and in backups.

An “ib-file set” does not include the corresponding `.frm` files that contain metadata about InnoDB tables. The `.frm` files are created and managed by MySQL, and can sometimes get out of sync with the internal metadata in InnoDB.

Multiple tables, even from more than one database, can be stored in a single “ib-file set”. (In MySQL, a “database” is a logical collection of tables, what other systems refer to as a “schema” or “catalog”.)

### 14.7.2.1 Compatibility Check When InnoDB Is Started

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a “fast shutdown” (i.e., `innodb_fast_shutdown` is greater than zero), there may be on-disk data structures (such as redo or undo entries, or doublewrite pages) that are in a “too-new” format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the “highest” file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file format tag are controlled by the configuration parameter `innodb_file_format_check`, which is `ON` by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` is `ON`, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a
file format that this version doesn't support
```

You can also set `innodb_file_format` to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the “high water mark” to the value you specify. The ability to set `innodb_file_format_check` will be useful (with future releases of InnoDB) if you manually “downgrade” all of the tables in an ib-file set (as described in [Downgrading the InnoDB Storage Engine](#)). You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.

In some limited circumstances, you might want to start the server and use an ib-file set that is in a new file format that is not supported by the software you are using. If you set the configuration parameter `innodb_file_format_check` to `OFF`, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a
file format that this version doesn't support
```

#### Note

This is a dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was a crash or “fast shutdown”. You should only set `innodb_file_format_check` to `OFF` if you are sure that the previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs.

The parameter `innodb_file_format_check` affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a “high water mark”, and as such it is increased after the server is started, if a table in a “higher” format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in [Section 14.7.2.2, “Compatibility Check When a Table Is Opened”](#). Any time the high water mark is updated, the value of `innodb_file_format_check` is updated as well, so the command `SELECT @@innodb_file_format_check;` displays the name of the latest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.

### 14.7.2.2 Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a “too new” data structure are encountered.

All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter `innodb_file_format` can prevent creating a new table that uses a specific file format, even if the file format is supported by a given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses a supported format.

Versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

```
ERROR 1146 (42S02): Table 'test.t1' doesn't exist
```

InnoDB also writes a message to the error log:

```
InnoDB: table test/t1: unknown table type 33
```

The table type should be equal to the tablespace flags, which contains the file format version as discussed in [Section 14.7.3, “Identifying the File Format in Use”](#).

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no way to ensure proper operations if a table in a newer file format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter `innodb_file_format_check` to `OFF`), the table-level checking described in this section still applies.

Users are *strongly* urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the MySQL 5.1 with the InnoDB Plugin. It may be possible to rebuild such tables to use the Antelope format.

## 14.7.3 Identifying the File Format in Use

If you enable a different [file format](#) using the `innodb_file_format` configuration option, the change only applies to newly created tables. Also, when you create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required to support the table's features. For example, if you enable the [Barracuda](#) file format, and create a new table that does not use the Dynamic or Compressed row format, the new tablespace that contains the table is tagged as using the [Antelope](#) file format .

It is easy to identify the file format used by a given table. The table uses the [Antelope](#) file format if the row format reported by `SHOW TABLE STATUS` is either `Compact` or `Redundant`. The table uses the [Barracuda](#) file format if the row format reported by `SHOW TABLE STATUS` is either `Compressed` or `Dynamic`.

```
mysql> SHOW TABLE STATUS\G
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 16384
      Data_free: 0
      Auto_increment: 1
      Create_time: 2014-11-03 13:32:10
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
```

You can also identify the file format used by a given table or tablespace using [InnoDB INFORMATION\\_SCHEMA](#) tables. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1'\G
***** 1. row *****
      TABLE_ID: 44
      NAME: test/t1
      FLAG: 1
      N_COLS: 6
      SPACE: 30
      FILE_FORMAT: Antelope
      ROW_FORMAT: Compact
      ZIP_PAGE_SIZE: 0

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='test/t1'\G
***** 1. row *****
      SPACE: 30
      NAME: test/t1
      FLAG: 0
      FILE_FORMAT: Antelope
      ROW_FORMAT: Compact or Redundant
      PAGE_SIZE: 16384
      ZIP_PAGE_SIZE: 0
```

## 14.7.4 Modifying the File Format

Each InnoDB tablespace file (with a name matching `*.ibd`) is tagged with the file format used to create its table and indexes. The way to modify the file format is to re-create the table and its indexes. The easiest way to recreate a table and its indexes is to use the following command on each table that you want to modify:

```
ALTER TABLE t ROW_FORMAT=format_name;
```

If you are modifying the file format to downgrade to an older MySQL version, there may be incompatibilities in table storage formats that require additional steps. For information about downgrading to a previous MySQL version, see [Section 2.11.2, “Downgrading MySQL”](#).

## 14.8 InnoDB Row Storage and Row Formats

This section discusses how InnoDB features such as table [compression](#), off-page storage of long variable-length column values, and large index key prefixes ([innodb\\_large\\_prefix](#)) are controlled by the row format of an [InnoDB](#) table. It also discusses considerations for choosing the right row format, and compatibility of row formats between MySQL releases.

### 14.8.1 Overview of InnoDB Row Storage

The storage for rows and associated columns affects performance for queries and DML operations. As more rows fit into a single disk [page](#), queries and index lookups can work faster, less cache memory is required in the InnoDB buffer pool, and less I/O is required to write out updated values for the numeric and short string columns.

The data in each InnoDB table is divided into [pages](#). The pages that make up each table are arranged in a tree data structure called a [B-tree index](#). Table data and [secondary indexes](#) both use this type of structure. The B-tree index that represents an entire table is known as the [clustered index](#), which is organized according to the [primary key](#) columns. The nodes of the index data structure contain the values of all the columns in that row (for the clustered index) or the index columns and the primary key columns (for secondary indexes).

Variable-length columns are an exception to this rule. Columns such as [BLOB](#) and [VARCHAR](#) that are too long to fit on a B-tree page are stored on separately allocated disk pages called [overflow pages](#). We call such columns [off-page columns](#). The values of these columns are stored in singly-linked lists of overflow pages, and each such column has its own list of one or more overflow pages. In some cases, all or a prefix of the long column value is stored in the B-tree, to avoid wasting storage and eliminating the need to read a separate page.

The following sections describe how to configure the row format of [InnoDB](#) tables to control how variable-length columns values are stored. Row format configuration also determines the availability of the [table compression](#) feature and the large index key prefix feature ([innodb\\_large\\_prefix](#)).

### 14.8.2 Specifying the Row Format for a Table

In MySQL 5.7.8 and earlier, rows are stored in [COMPACT](#) format by default. As of MySQL 5.7.9, the default row format is defined by [innodb\\_default\\_row\\_format](#), which has a default value of [DYNAMIC](#). The default row format is used when the [ROW\\_FORMAT](#) table option is not defined explicitly or when [ROW\\_FORMAT=DEFAULT](#) is specified.

The row format of a table can be defined explicitly using the [ROW\\_FORMAT](#) table option in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. For example:

```
CREATE TABLE t1 (c1 INT) ROW_FORMAT=DYNAMIC;
```

An explicitly defined [ROW\\_FORMAT](#) setting overrides the implicit default. Specifying [ROW\\_FORMAT=DEFAULT](#) is equivalent to using the implicit default.

The [innodb\\_default\\_row\\_format](#) option, introduced in MySQL 5.7.9, can be set dynamically:

```
mysql> SET GLOBAL innodb_default_row_format=DYNAMIC;
```

Valid [innodb\\_default\\_row\\_format](#) options include [DYNAMIC](#), [COMPACT](#), and [REDUNDANT](#). The [COMPRESSED](#) row format, which is not supported for use in the system tablespace, cannot be defined as the default. It can only be specified explicitly in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. Attempting to set [innodb\\_default\\_row\\_format](#) to [COMPRESSED](#) returns an error:

## Specifying the Row Format for a Table

```
mysql> SET GLOBAL innodb_default_row_format=COMPRESSED;
ERROR 1231 (42000): Variable 'innodb_default_row_format'
can't be set to the value of 'COMPRESSED'
```

Newly created tables use the row format defined by `innodb_default_row_format` when a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used. For example, the following `CREATE TABLE` statements use the row format defined by `innodb_default_row_format`.

```
CREATE TABLE t1 (c1 INT);
```

```
CREATE TABLE t2 (c1 INT) ROW_FORMAT=DEFAULT;
```

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`.

Table-rebuilding operations include `ALTER TABLE` operations that use `ALGORITHM=COPY` or `ALTER TABLE` operations that use `ALGORITHM=INPLACE` where table rebuilding is required. See [Table 14.8, “Summary of Online Status for DDL Operations”](#) for an overview of the online status of DDL operations. `OPTIMIZE TABLE` is also a table-rebuilding operation.

The following example demonstrates a table-rebuilding operation that silently changes the row format of a table created without an explicitly defined row format.

```
mysql> SELECT @@innodb_default_row_format;
+-----+
| @@innodb_default_row_format |
+-----+
| dynamic                      |
+-----+

mysql> CREATE TABLE t1 (c1 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
      TABLE_ID: 54
        NAME: test/t1
         FLAG: 33
        N_COLS: 4
         SPACE: 35
  FILE_FORMAT: Barracuda
   ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
   SPACE_TYPE: Single

mysql> SET GLOBAL innodb_default_row_format=COMPACT;

mysql> ALTER TABLE t1 ADD COLUMN (c2 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
      TABLE_ID: 55
        NAME: test/t1
         FLAG: 1
        N_COLS: 5
         SPACE: 36
  FILE_FORMAT: Antelope
   ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
   SPACE_TYPE: Single
```

Consider the following potential issues before changing the row format of existing tables from `REDUNDANT` or `COMPACT` to `DYNAMIC`.

- The `REDUNDANT` and `COMPACT` row format supports a maximum index key prefix length of 767 bytes whereas `DYNAMIC` and `COMPRESSED` row formats support an index key prefix length of 3072 bytes if the `innodb_large_prefix` configuration option is enabled. In a replication environment, if

`innodb_default_row_format` is set to `DYNAMIC` on the master and set to `COMPACT` on the slave, the following DDL statement, which does not explicitly define a row format, succeeds on the master but fails on the slave:

```
CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 VARCHAR(5000), KEY i1(c2(3070)));
```

For related information, see [Section 14.5.7, “Limits on InnoDB Tables”](#).

- Importing a table that does not explicitly define a row format results in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For more information, refer to the limitations outlined in [Section 14.4.6, “Copying File-Per-Table Tablespaces to Another Server”](#).

To view the row format of a table, issue a `SHOW TABLE STATUS` statement or query `INFORMATION_SCHEMA.TABLES`.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
```

The row format of an `InnoDB` table determines its physical row structure. See [Section 14.2.7.7, “Physical Row Structure”](#) for more information.

### 14.8.3 DYNAMIC and COMPRESSED Row Formats

When a table is created with a `DYNAMIC` or `COMPRESSED` row format, long column values are stored fully off-page, and the clustered index record contains only a 20-byte pointer to the overflow page. By comparison, the `COMPACT` row format stores up to the first 768 bytes of variable-length columns values in the clustered index record along with a 20-byte pointer to the overflow page.

Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long, `InnoDB` chooses the longest columns for off-page storage until the clustered index record fits on the `B-tree` page. `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

The `DYNAMIC` row format maintains the efficiency of storing the entire row in the index node if it fits (as do the `COMPACT` and `REDUNDANT` formats), but the `DYNAMIC` row format avoids the problem of filling `B-tree` nodes with a large number of data bytes of long columns. The `DYNAMIC` format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store all of the value off-page. With `DYNAMIC` format, shorter columns are likely to remain in the `B-tree` node, minimizing the number of overflow pages needed for any given row.

The `COMPRESSED` row format uses similar internal details for off-page storage as the `DYNAMIC` row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the `COMPRESSED` row format, the `KEY_BLOCK_SIZE` option controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For full details about the `COMPRESSED` row format, see [Section 14.6, “InnoDB Table and Page Compression”](#).

Both `DYNAMIC` and `COMPRESSED` row formats support index key prefixes up to 3072 bytes. This feature is controlled by the `innodb_large_prefix` configuration option, which is enabled by default as of MySQL 5.7.7. See the `innodb_large_prefix` option description for more information.

Tables that use the `COMPRESSED` row format can be created in [file\\_per\\_table](#) tablespaces or [general tablespaces](#) (introduced in MySQL 5.7.6). The system tablespace does not support the `COMPRESSED` row format. To store a `COMPRESSED` table in a file-per-table tablespace, `innodb_file_per_table` must be enabled and `innodb_file_format` must be set to `Barracuda`. The `innodb_file_per_table` and `innodb_file_format` configuration options are not applicable to general tablespaces. General tablespaces support all row formats with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes. For more information about general tablespaces, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

In MySQL 5.7.5 and earlier, tables that use the `DYNAMIC` row format can only be stored in `file_per_table` tablespaces, requiring that `innodb_file_per_table` be enabled and `innodb_file_format` be set to `Barracuda`.

As of MySQL 5.7.6, `DYNAMIC` tables can be stored in file-per-table tablespaces, general tablespaces, and the system tablespace. To store `DYNAMIC` tables in the system tablespace, you must use the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE`. The `innodb_file_per_table` and `innodb_file_format` configuration options are not applicable to general tablespaces, nor are they applicable when using the `TABLESPACE [=] innodb_system` table option to store `DYNAMIC` tables in the system tablespace.

As of MySQL 5.7.9, you can add a `DYNAMIC` table to the system tablespace by disabling `innodb_file_per_table` and using a regular `CREATE TABLE` or `ALTER TABLE` statement. The `innodb_file_format` setting is ignored. A `DYNAMIC` table always uses the `Barracuda` file format.

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format and therefore handle `CHAR` storage in the same way as the `COMPACT` row format. For more information, see [Section 14.2.7.7, “Physical Row Structure”](#).

## 14.8.4 COMPACT and REDUNDANT Row Formats

Early versions of `InnoDB` used an unnamed file format (now called `Antelope`) for database files. The `Antelope` file format supports the `COMPACT` or `REDUNDANT` row formats. With these row formats, `InnoDB` stores up to the first 768 bytes of variable-length columns (such as `BLOB` and `VARCHAR`) in the index record within the `B-tree` node, with the remainder stored on the overflow pages.

To preserve compatibility with earlier versions of `InnoDB`, `COMPACT` remained the default row format up to MySQL 5.7.8. As of MySQL 5.7.9, the default row format is `DYNAMIC`, which is defined by the `innodb_default_row_format` configuration option. See [Section 14.8.3, “DYNAMIC and COMPRESSED Row Formats”](#) for information about the `DYNAMIC` and `COMPRESSED` row formats.

With the `Antelope` file format, if the value of a column is 768 bytes or less, no overflow page is needed, and some savings in I/O may result, since the value is in the `B-tree` node. This works well for relatively short `BLOB`s, but may cause `B-tree` nodes to fill with data rather than key values, reducing their efficiency. Tables with many `BLOB` columns could cause `B-tree` nodes to become too full of data, and contain too few rows, making the entire index less efficient than if the rows were shorter or if the column values were stored off-page.

For information about the physical row structure of tables that use the `REDUNDANT` or `COMPACT` row format, see [Section 14.2.7.7, “Physical Row Structure”](#).

## 14.9 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The `ACID` design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, `InnoDB` tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a `fast shutdown`.

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as `InnoDB` tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.

- How to reorganize a table for optimal query performance.

## 14.9.1 InnoDB Disk I/O

InnoDB uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, InnoDB uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, InnoDB still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

### Read-Ahead

If InnoDB can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in InnoDB:

- In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

### Doublewrite Buffer

InnoDB uses a novel file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default (`innodb_doublewrite=ON`). It adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write (causing a [torn page](#) condition), InnoDB can later find a good copy of the page from the doublewrite buffer during recovery.

## 14.9.2 File Space Management

The data files that you define in the configuration file form the [InnoDB system tablespace](#). The files are logically concatenated to form the tablespace. There is no striping in use. You cannot define where within the tablespace your tables are allocated. In a newly created tablespace, InnoDB allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can turn on the `innodb_file_per_table` configuration option, which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by InnoDB within the system tablespace. For more information, see [Section 14.4.4, “InnoDB File-Per-Table Tablespaces”](#).

As of MySQL 5.7.6, you can also store tables in [general tablespaces](#). General tablespaces are shared tablespaces created using `CREATE TABLESPACE` syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

### Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database [pages](#). Every tablespace in a MySQL instance has the same [page size](#). By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB

---

or 4KB by specifying the `innodb_page_size` option when you create the MySQL instance. As of MySQL 5.7.6, you can also increase the page size to 32KB or 64KB. For more information, refer to the `innodb_page_size` documentation.

The pages are grouped into `extents` of size 1MB for pages up to 16KB in size (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). For a page size of 32KB, extent size is 2MB. For page size of 64KB, extent size is 4MB. The “files” inside a tablespace are called `segments` in InnoDB. (These segments are different from the `rollback segment`, which actually contains many tablespace segments.)

When a segment grows inside the tablespace, InnoDB allocates the first 32 pages to it one at a time. After that, InnoDB starts to allocate whole extents to the segment. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in InnoDB. One is for nonleaf nodes of the `B-tree`, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an InnoDB tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, InnoDB reports the extents that are definitely free in the tablespace. InnoDB always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, InnoDB contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the `purge` operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 14.2.3, “InnoDB Multi-Versioning”](#).)

To view information about the tablespace, query the `INNODB_SYS_TABLESPACES` table.

## How Pages Relate to Table Rows

The maximum row length, except for variable-length columns (`VARBINARY`, `VARCHAR`, `BLOB` and `TEXT`), is slightly less than half of a database page for 4KB, 8KB, 16KB, and 32KB `innodb_page_size` settings. For example, the maximum row length is about 8000 bytes for the default 16KB page size. For an `innodb_page_size` setting of 64KB, InnoDB restricts row size to about 16000 bytes. `LONGLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page. For a column chosen for off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored.

### 14.9.3 InnoDB Checkpoints

Making your `log files` very large may reduce disk I/O during `checkpointing`. It often makes sense to set the total size of the log files as large as the buffer pool or even larger. Although in the past large log files could make crash recovery take excessive time, starting with MySQL 5.5, performance enhancements to crash recovery make it possible to use large log files with fast startup after a crash. (Strictly speaking, this performance improvement is available for MySQL 5.1 with the InnoDB Plugin 1.0.7 and higher. It is with MySQL 5.5 that this improvement is available in the default InnoDB storage engine.)

## How Checkpoint Processing Works

InnoDB implements a [checkpoint](#) mechanism known as [fuzzy checkpointing](#). InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During [crash recovery](#), InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

### 14.9.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in [B-trees](#), and their [fill factor](#) may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” `ALTER TABLE` operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

You can also use `ALTER TABLE tbl_name FORCE` to perform a “null” alter operation that rebuilds the table.

As of MySQL 5.7.4, both `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use [online DDL \(ALGORITHM=COPY\)](#). For more information, see [Section 14.10.1, “Overview of Online DDL”](#).

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the InnoDB filesystem management algorithm guarantees that fragmentation in the index does not occur.

### 14.9.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when [truncating](#) an InnoDB table, the table must be stored in its own `.ibd` file. For a table to be stored in its own `.ibd` file, `innodb_file_per_table` must be enabled when the table is created. Additionally, there cannot be a [foreign key](#) constraint between the table being truncated and other tables, otherwise the `TRUNCATE TABLE` operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new `.ibd` file, and the freed space is returned to the operating system. This is in contrast to truncating InnoDB tables that are stored within the [InnoDB system tablespace](#) (tables created when `innodb_file_per_table=OFF`) and tables

stored in shared [general tablespaces](#), where only [InnoDB](#) can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that [physical backups](#) can be smaller. Truncating tables that are stored in the system tablespace (tables created when `innodb_file_per_table=OFF`) or in a general tablespace leaves blocks of unused space in the tablespace.

## 14.10 InnoDB and Online DDL

The [online DDL](#) feature enhances many types of `ALTER TABLE` operations to avoid table copying, blocking of [DML](#) operations while [DDL](#) is in progress, or both.

The [online DDL](#) feature has the following benefits:

- It improves responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours whenever you modify its indexes or column definitions is not practical.
- It lets you adjust the balance between performance and concurrency during the DDL operation, by choosing whether to block access to the table entirely (`LOCK=EXCLUSIVE` clause), allow queries but not DML (`LOCK=SHARED` clause), or allow full query and DML access to the table (`LOCK=NONE` clause). When you omit the `LOCK` clause or specify `LOCK=DEFAULT`, MySQL allows as much concurrency as possible depending on the type of operation.
- Performing changes in-place where possible, rather than creating a new copy of the table, avoids temporary increases in disk space usage and I/O overhead associated with copying the table and reconstructing secondary indexes.

### 14.10.1 Overview of Online DDL

Historically, many [DDL](#) operations on [InnoDB](#) tables were expensive. Many `ALTER TABLE` operations worked by creating a new, empty table defined with the requested table options and indexes, then copying the existing rows to the new table one-by-one, updating the indexes as the rows were inserted. After all rows from the original table were copied, the old table was dropped and the copy was renamed with the name of the original table.

MySQL 5.5, and MySQL 5.1 with the InnoDB Plugin, optimized `CREATE INDEX` and `DROP INDEX` to avoid the table-copying behavior. That feature was known as [Fast Index Creation](#). MySQL 5.6 enhanced many other types of `ALTER TABLE` operations to avoid copying the table. Another enhancement allowed `SELECT` queries and `INSERT`, `UPDATE`, and `DELETE` ([DML](#)) statements to proceed while the table is being altered. In MySQL 5.7, `ALTER TABLE RENAME INDEX` was also enhanced to avoid table copying. This combination of features is now known as [online DDL](#).

This mechanism also means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without any secondary indexes, then adding the secondary indexes after the data is loaded.

Although no syntax changes are required in the `CREATE INDEX` or `DROP INDEX` commands, some factors affect the performance, space usage, and semantics of this operation (see [Section 14.10.9](#), “[Limitations of Online DDL](#)”).

The online DDL enhancements in MySQL 5.6 improved many DDL operations that formerly required a table copy, blocked DML operations on the table, or both. [Table 14.8](#), “[Summary of Online Status for DDL Operations](#)” shows the variations of the `ALTER TABLE` statement and shows how the online DDL feature applies to each.

With the exception of `ALTER TABLE` partitioning clauses, online DDL operations for partitioned [InnoDB](#) tables follow the same rules that apply to regular [InnoDB](#) tables. For more information, see [Section 14.10.8](#), “[Online DDL for Partitioned InnoDB Tables](#)”.

- The “In-Place?” column shows which operations allow the `ALGORITHM=INPLACE` clause; the preferred value is “Yes”.
- The “Copies Table?” column shows which operations are able to avoid the expensive table-copying operation; the preferred value is “No”. This column is mostly the reverse of the “In-Place?” column, except that a few operations allow `ALGORITHM=INPLACE` but still involve some amount of table copying.
- The “Allows Concurrent DML?” column shows which operations can be performed fully online; the preferred value is “Yes”. You can specify `LOCK=NONE` to assert that full concurrency is allowed during the DDL, but MySQL automatically allows this level of concurrency when possible. When concurrent DML is allowed, concurrent queries are also always allowed.
- The “Allows Concurrent Queries?” column shows which DDL operations allow queries on the table while the operation is in progress; the preferred value is “Yes”. Concurrent query is allowed during all online DDL operations. It is shown with “Yes” listed for all cells, for reference purposes. You can specify `LOCK=SHARED` to assert that concurrent queries are allowed during the DDL, but MySQL automatically allows this level of concurrency when possible.
- The “Notes” column explains any exceptions to the “Yes/No” values of the other columns, such as when the answer depends on the setting of a configuration option or some other clause in the DDL statement. The values “Yes\*” and “No\*” indicate that an answer depends on these additional notes.

**Table 14.8 Summary of Online Status for DDL Operations**

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
<code>CREATE INDEX, ADD INDEX</code>	Yes*	No*	Yes	Yes	Some restrictions for <code>FULLTEXT</code> index; see next row.
<code>ADD FULLTEXT INDEX</code>	Yes	No*	No	Yes	Creating the first <code>FULLTEXT</code> index for a table involves a table copy, unless there is a user-supplied <code>FTS_DOC_ID</code> column. Subsequent <code>FULLTEXT</code> indexes on the same table can be created in-place.
<code>ADD SPATIAL INDEX</code>	Yes	No	No	Yes	In-place support was added in MySQL 5.7.5. Bulk load is not supported.
<code>RENAME INDEX</code>	Yes	No	Yes	Yes	Modifies <code>.frm</code> file only, not the data file.
<code>DROP INDEX</code>	Yes	No	Yes	Yes	Modifies <code>.frm</code> file only, not the data file.
<code>OPTIMIZE TABLE</code>	Yes	Yes	Yes	Yes	Uses <code>ALGORITHM=INPLACE</code> as of MySQL 5.7.4. <code>ALGORITHM=COPY</code> is used if <code>old_alter_table=1</code> or <code>mysqld --skip-new</code> option is enabled. <code>OPTIMIZE TABLE</code> using online DDL ( <code>ALGORITHM=INPLACE</code> ) is not supported for tables with <code>FULLTEXT</code> indexes.
Set default value for a column	Yes	No	Yes	Yes	Modifies <code>.frm</code> file only, not the data file.

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
Change <a href="#">auto-increment</a> value for a column	Yes	No	Yes	Yes	Modifies a value stored in memory, not the data file.
Add a <a href="#">foreign key constraint</a>	Yes*	No*	Yes	Yes	To avoid copying the table, disable <a href="#">foreign_key_checks</a> during constraint creation.
Drop a <a href="#">foreign key constraint</a>	Yes	No	Yes	Yes	The <a href="#">foreign_key_checks</a> option can be enabled or disabled.
Rename a column	Yes*	No*	Yes*	Yes	To allow concurrent DML, keep the same data type and only change the column name. Prior to MySQL 5.7.8, <a href="#">ALGORITHM=INPLACE</a> is supported for renaming a virtual generated column but not for renaming a stored generated column. As of MySQL 5.7.8, <a href="#">ALGORITHM=INPLACE</a> is not supported for renaming virtual or stored generated columns.
Add a column	Yes*	Yes*	Yes*	Yes	Concurrent DML is not allowed when adding an <a href="#">auto-increment</a> column. Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation. <a href="#">ALGORITHM=INPLACE</a> is supported for adding a virtual generated column but not for adding a stored generated column. Adding a virtual generated column does not require a table copy.
Drop a column	Yes	Yes*	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation. <a href="#">ALGORITHM=INPLACE</a> is supported for dropping a generated column. Dropping a virtual generated column does not require a table copy.
Reorder columns	Yes	Yes	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Change <a href="#">ROW_FORMAT</a> property	Yes	Yes	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
Change <a href="#">KEY_BLOCK_SIZE</a> property	Yes	Yes	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Make column <a href="#">NULL</a>	Yes	Yes	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Make column <a href="#">NOT NULL</a>	Yes*	Yes	Yes	Yes	<a href="#">STRICT_ALL_TABLES</a> or <a href="#">STRICT_TRANS_TABLES SQL_MODE</a> is required for the operation to succeed. The operation fails if the column contains NULL values. The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. For more information, see <a href="#">Section 13.1.6, "ALTER TABLE Syntax"</a> . Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.
Change data type of column	No*	Yes*	No	Yes	Exception: <a href="#">VARCHAR</a> size may be increased using online <a href="#">ALTER TABLE</a> . See <a href="#">InnoDB Online DDL Column Properties</a> for more information.
Add <a href="#">primary key</a>	Yes*	Yes	Yes	Yes	Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation. <a href="#">ALGORITHM=INPLACE</a> is not allowed under certain conditions if columns have to be converted to <a href="#">NOT NULL</a> . See <a href="#">Example 14.9, "Creating and Dropping the Primary Key"</a> .
Drop <a href="#">primary key</a> and add another	Yes	Yes	Yes	Yes	<a href="#">ALGORITHM=INPLACE</a> is only allowed when you add a new primary key in the same <a href="#">ALTER TABLE</a> ; the data is reorganized substantially, so it is still an expensive operation.
Drop <a href="#">primary key</a>	No	Yes	No	Yes	Restrictions apply when you drop a primary key without adding a new one in the same <a href="#">ALTER TABLE</a> statement.
Convert character set	No	Yes	No	Yes	Rebuilds the table if the new character encoding is different.

Operation	In-Place?	Copies Table?	Allows Concurrent DML?	Allows Concurrent Query?	Notes
Specify character set	No	Yes	No	Yes	Rebuilds the table if the new character encoding is different.
Rebuild with <code>FORCE</code> option	Yes	Yes	Yes	Yes	Uses <code>ALGORITHM=INPLACE</code> as of MySQL 5.7.4. <code>ALGORITHM=COPY</code> is used if <code>old_alter_table=1</code> or <code>mysqld --skip-new</code> option is enabled. Table rebuild using online DDL ( <code>ALGORITHM=INPLACE</code> ) is not supported for tables with <code>FULLTEXT</code> indexes.
Rebuild with “null” <code>ALTER TABLE ... ENGINE=INNODB</code>	Yes	Yes	Yes	Yes	Uses <code>ALGORITHM=INPLACE</code> as of MySQL 5.7.4. <code>ALGORITHM=COPY</code> is used if <code>old_alter_table=1</code> or <code>mysqld --skip-new</code> option is enabled. Table rebuild using online DDL ( <code>ALGORITHM=INPLACE</code> ) is not supported for tables with <code>FULLTEXT</code> indexes.
Set table-level <code>persistent statistics</code> options ( <code>STATS_PERSISTENT</code> , <code>STATS_AUTO_RECALC</code> <code>STATS_SAMPLE_PAGES</code> )	Yes	No	Yes	Yes	Modifies <code>.frm</code> file only, not the data file.

The following sections shows the basic syntax, and usage notes related to online DDL, for each of the major operations that can be performed with concurrent DML, in-place, or both:

### Secondary Indexes

- Create **secondary indexes**: `CREATE INDEX name ON table (col_list)` or `ALTER TABLE table ADD INDEX name (col_list)`. (Creating a `FULLTEXT` index still requires locking the table.)
- Drop **secondary indexes**: `DROP INDEX name ON table;` or `ALTER TABLE table DROP INDEX name`

Creating and dropping secondary indexes on `InnoDB` tables skips the table-copying behavior, the same as in MySQL 5.5 and MySQL 5.1 with the `InnoDB` Plugin.

In MySQL 5.6 and higher, the table remains available for read and write operations while the index is being created or dropped. The `CREATE INDEX` or `DROP INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table. Previously, modifying the table while an index is being created or dropped typically resulted in a **deadlock** that cancelled the `INSERT`, `UPDATE`, or `DELETE` statement on the table.

### Column Properties

- Set a default value for a column: `ALTER TABLE tbl ALTER COLUMN col SET DEFAULT literal` or `ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT`

The default values for columns are stored in the `.frm` file for the table, not the [InnoDB data dictionary](#).

- Changing the [auto-increment](#) value for a column: `ALTER TABLE table AUTO_INCREMENT=next_value;`

Especially in a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and you can restart the auto-increment sequence from 1.

- Renaming a column: `ALTER TABLE tbl CHANGE old_col_name new_col_name datatype`

When you keep the same data type and `[NOT] NULL` attribute, only changing the column name, this operation can always be performed online.

You can also rename a column that is part of a foreign key constraint. The foreign key definition is automatically updated to use the new column name. Renaming a column participating in a foreign key only works with the in-place mode of `ALTER TABLE`. If you use the `ALGORITHM=COPY` clause, or some other condition causes the command to use `ALGORITHM=COPY` behind the scenes, the `ALTER TABLE` statement will fail.

- Extending `VARCHAR` size using an in-place `ALTER TABLE` statement, as in this example:

```
ALTER TABLE t1 ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(255);
```

The number of length bytes required by a `VARCHAR` column must remain the same. For `VARCHAR` values of 0 to 255, one length byte is required to encode the value. For `VARCHAR` values of 256 bytes or more, two length bytes are required. As a result, in-place `ALTER TABLE` only supports increasing `VARCHAR` size from 0 to 255 bytes or increasing `VARCHAR` size from a value equal to or greater than 256 bytes. In-place `ALTER TABLE` does not support increasing `VARCHAR` size from less than 256 bytes to a value equal to or greater than 256 bytes. In this case, the number of required length bytes would change from 1 to 2, which is only supported by a table copy (`ALGORITHM=COPY`). For example, attempting to change `VARCHAR` column size from 255 to 256 using in-place `ALTER TABLE` would return an error:

```
ALTER TABLE t1 ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(256);
ERROR 0A000: ALGORITHM=INPLACE is not supported. Reason: Cannot change
column type INPLACE. Try ALGORITHM=COPY.
```

Decreasing `VARCHAR` size using in-place `ALTER TABLE` is not supported. Decreasing `VARCHAR` size requires a table copy (`ALGORITHM=COPY`).

## Foreign Keys

- Adding or dropping a [foreign key constraint](#):

```
ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1) REFERENCES tbl2(col2) referential_ac
ALTER TABLE tbl DROP FOREIGN KEY fk_name;
```

Dropping a foreign key can be performed online with the `foreign_key_checks` option enabled or disabled. Creating a foreign key online requires `foreign_key_checks` to be disabled.

If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the `CONSTRAINT` clause for each foreign key:

```
show create table table\G
```

Or, query the `information_schema.table_constraints` table and use the `constraint_name` and `constraint_type` columns to identify the foreign key names.

You can also drop a foreign key and its associated index in a single statement:

```
ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;
```

If **foreign keys** are already present in the table being altered (that is, it is a **child table** containing any `FOREIGN KEY ... REFERENCE` clauses), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:

- Concurrent DML is disallowed during online DDL operations on such child tables. (This restriction is being evaluated as a bug and might be lifted.)
- An `ALTER TABLE` on the child table could also wait for another transaction to commit, if a change to the parent table caused associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.

In the same way, if a table is the **parent table** in a foreign key relationship, even though it does not contain any `FOREIGN KEY` clauses, it could wait for the `ALTER TABLE` to complete if an `INSERT`, `UPDATE`, or `DELETE` statement caused an `ON UPDATE` or `ON DELETE` action in the child table.

## Notes on ALGORITHM=COPY

Any `ALTER TABLE` operation run with the `ALGORITHM=COPY` clause prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of `LOCK=SHARED` (allow queries but not DML). You can further restrict concurrency for such operations by specifying `LOCK=EXCLUSIVE` (prevent DML and queries).

## Concurrent DML but Table Copy Still Required

Some other `ALTER TABLE` operations allow concurrent DML but still require a table copy. However, the table copy for these operations is faster than it was in MySQL 5.5 and prior.

- Adding, dropping, or reordering columns.
- Adding or dropping a **primary key**.
- Changing the `ROW_FORMAT` or `KEY_BLOCK_SIZE` properties for a table.
- Changing the nullable status for a column.
- `OPTIMIZE TABLE`
- Rebuilding a table with the `FORCE` option
- Rebuilding a table using a “null” `ALTER TABLE ... ENGINE=INNODB` statement

## Maintaining CREATE TABLE Statements

As your database schema evolves with new columns, data types, constraints, indexes, and so on, keep your `CREATE TABLE` statements up to date with the latest table definitions. Even with the performance improvements of online DDL, it is more efficient to create stable database structures at the beginning, rather than creating part of the schema and then issuing `ALTER TABLE` statements afterward.

The main exception to this guideline is for **secondary indexes** on tables with large numbers of rows. It is typically most efficient to create the table with all details specified except the secondary indexes, load the data, then create the secondary indexes. You can use the same technique with **foreign keys** (load the data first, then set up the foreign keys) if you know the initial data is clean and do not need consistency checks during the loading process.

Whatever sequence of `CREATE TABLE`, `CREATE INDEX`, `ALTER TABLE`, and similar statements went into putting a table together, you can capture the SQL needed to reconstruct the current form of the table by issuing the statement `SHOW CREATE TABLE table\G` (uppercase `\G` required for tidy formatting). This output shows clauses such as numeric precision, `NOT NULL`, and `CHARACTER SET` that are sometimes added behind the scenes, and you might otherwise leave out when cloning the table on a new system or setting up foreign key columns with identical type.

## 14.10.2 Performance and Concurrency Considerations for Online DDL

[Online DDL](#) improves several aspects of MySQL operation, such as performance, concurrency, availability, and scalability:

- Because queries and [DML](#) operations on the table can proceed while the DDL is in progress, applications that access the table are more responsive. Reduced [locking](#) and waiting for other resources all throughout the MySQL server leads to greater scalability, even for operations not involving the table being altered.
- For in-place operations, by avoiding the disk I/O and CPU cycles to rebuild the table, you minimize the overall load on the database and maintain good performance and high throughput during the DDL operation.
- For in-place operations, because less data is read into the [buffer pool](#) than if all the data was copied, you avoid purging frequently accessed data from memory, which formerly could cause a temporary performance dip after a DDL operation.

If an online operation requires temporary files, [InnoDB](#) creates them in the temporary file directory, not the directory containing the original table. If this directory is not large enough to hold such files, you may need to set the `tmpdir` system variable to a different directory. (See [Section B.5.3.5](#), “Where MySQL Stores Temporary Files”.)

### Locking Options for Online DDL

While an [InnoDB](#) table is being changed by a DDL operation, the table may or may not be [locked](#), depending on the internal workings of that operation and the `LOCK` clause of the `ALTER TABLE` statement. By default, MySQL uses as little locking as possible during a DDL operation; you specify the clause either to make the locking more restrictive than it normally would be (thus limiting concurrent DML, or DML and queries), or to ensure that some expected degree of locking is allowed for an operation. If the `LOCK` clause specifies a level of locking that is not available for that specific kind of DDL operation, such as `LOCK=SHARED` or `LOCK=NONE` while creating or dropping a primary key, the clause works like an assertion, causing the statement to fail with an error. The following list shows the different possibilities for the `LOCK` clause, from the most permissive to the most restrictive:

- For DDL operations with `LOCK=NONE`, both queries and concurrent DML are allowed. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=NONE` if keeping the table fully available is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables involving customer signups or purchases, to avoid making those tables unavailable by mistakenly issuing an expensive `ALTER TABLE` statement.
- For DDL operations with `LOCK=SHARED`, any writes to the table (that is, DML operations) are blocked, but the data in the table can be read. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=SHARED` if keeping the table available for queries is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables in a data warehouse, where it is OK to delay data load operations until the DDL is finished, but queries cannot be delayed for long periods.
- For DDL operations with `LOCK=DEFAULT`, or with the `LOCK` clause omitted, MySQL uses the lowest level of locking that is available for that kind of operation, allowing concurrent queries, DML, or both wherever possible. This is the setting to use when making pre-planned, pre-tested changes that you know will not cause any availability problems based on the workload for that table.

- For DDL operations with `LOCK=EXCLUSIVE`, both queries and DML operations are blocked. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=EXCLUSIVE` if the primary concern is finishing the DDL in the shortest time possible, and it is OK to make applications wait when they try to access the table. You might also use `LOCK=EXCLUSIVE` if the server is supposed to be idle, to avoid unexpected accesses to the table.

An online DDL statement for an InnoDB table always waits for currently executing transactions that are accessing the table to `commit` or `roll back`, because it requires exclusive access to the table for a brief period while the DDL statement is being prepared. Likewise, it requires exclusive access to the table for a brief time before finishing. Thus, an online DDL statement waits for any transactions that are started while the DDL is in progress, and query or modify the table, to `commit` or `roll back` before the DDL completes.

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the old-style mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the ideal techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

A newly created InnoDB secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

## Performance of In-Place versus Table-Copying DDL Operations

The raw performance of an online DDL operation is largely determined by whether the operation is performed in-place, or requires copying and rebuilding the entire table. See [Table 14.8, “Summary of Online Status for DDL Operations”](#) to see what kinds of operations can be performed in-place, and any requirements for avoiding table-copy operations.

The performance speedup from in-place DDL applies to operations on secondary indexes, not to the primary key index. The rows of an InnoDB table are stored in a `clustered index` organized based on the `primary key`, forming what some database systems call an “index-organized table”. Because the table structure is so closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.
- The secondary index entries are pre-sorted, and so can be loaded in order.
- The change buffer is not used, because there are no random-access inserts into the secondary indexes.

To judge the relative performance of online DDL operations, you can run such operations on a big InnoDB table using current and earlier versions of MySQL. You can also run all the performance tests under the latest MySQL version, simulating the previous DDL behavior for the “before” results, by setting the `old_alter_table` system variable. Issue the statement `set old_alter_table=1` in the session, and measure DDL performance to record the “before” figures. Then `set old_alter_table=0` to re-enable the newer, faster behavior, and run the DDL operations again to record the “after” figures.

For a basic idea of whether a DDL operation does its changes in-place or performs a table copy, look at the “rows affected” value displayed after the command finishes. For example, here are lines you might see after doing different types of DDL operations:

- Changing the default value of a column (super-fast, does not affect the table data at all):

```
Query OK, 0 rows affected (0.07 sec)
```

- Adding an index (takes time, but `0 rows affected` shows that the table is not copied):

```
Query OK, 0 rows affected (21.42 sec)
```

- Changing the data type of a column (takes substantial time and does require rebuilding all the rows of the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

#### Note

Changing the data type of a column requires rebuilding all the rows of the table with the exception of changing `VARCHAR` size, which may be performed using online `ALTER TABLE`. See [InnoDB Online DDL Column Properties](#) for more information.

For example, before running a DDL operation on a big table, you might check whether the operation will be fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a tiny amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the “rows affected” value is zero or not. A non-zero value means the operation will require rebuilding the entire table, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replication slave server one at a time.

For a deeper understanding of the reduction in MySQL processing, examine the `performance_schema` and `INFORMATION_SCHEMA` tables related to `InnoDB` before and after DDL operations, to see the number of physical reads, writes, memory allocations, and so on.

### 14.10.3 SQL Syntax for Online DDL

Typically, you do not need to do anything special to enable `online DDL` when using the `ALTER TABLE` statement for `InnoDB` tables. See [Table 14.8, “Summary of Online Status for DDL Operations”](#) for the kinds of DDL operations that can be performed in-place, allowing concurrent DML, or both. Some variations require particular combinations of configuration settings or `ALTER TABLE` clauses.

You can control the various aspects of a particular online DDL operation by using the `LOCK` and `ALGORITHM` clauses of the `ALTER TABLE` statement. These clauses come at the end of the statement, separated from the table and column specifications by commas. The `LOCK` clause is useful for fine-tuning the degree of concurrent access to the table. The `ALGORITHM` clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues with existing DDL code. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, specify a clause on the `ALTER TABLE` statement such as `LOCK=NONE` (allow both reads and writes) or `LOCK=SHARED` (allow reads). The operation halts immediately if the requested level of concurrency is not available.
- To compare performance, run one statement with `ALGORITHM=INPLACE` and another with `ALGORITHM=COPY`, as an alternative to setting the `old_alter_table` configuration option.
- To avoid tying up the server with an `ALTER TABLE` operation that copies the table, include `ALGORITHM=INPLACE`. The statement halts immediately if it cannot use the in-place mechanism.

See [Table 14.8, “Summary of Online Status for DDL Operations”](#) for a list of the DDL operations that can or cannot be performed in-place.

See [Section 14.10.2, “Performance and Concurrency Considerations for Online DDL”](#) for more details about the `LOCK` clause. For full examples of using online DDL, see [Section 14.10.5, “Examples of Online DDL”](#).

## 14.10.4 Combining or Separating DDL Statements

Before the introduction of [online DDL](#), it was common practice to combine many DDL operations into a single `ALTER TABLE` statement. Because each `ALTER TABLE` statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex `ALTER TABLE` for each slightly different scenario.

For DDL operations that can be done in-place, as shown in [Table 14.8, “Summary of Online Status for DDL Operations”](#), now you can separate them into individual `ALTER TABLE` statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),
CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```
ALTER TABLE t1 ADD INDEX i1(c1);
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.
- Operations that cannot be performed in-place, that is, that still copy and rebuild the table.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

## 14.10.5 Examples of Online DDL

Here are code examples showing some operations whose performance, concurrency, and scalability are improved by the latest [online DDL](#) enhancements.

- [Example 14.1, “Schema Setup Code for Online DDL Experiments”](#) sets up tables named `BIG_TABLE` and `SMALL_TABLE` used in the subsequent examples.
- [Example 14.2, “Speed and Efficiency of CREATE INDEX and DROP INDEX”](#) illustrates the performance aspects of creating and dropping indexes.
- [Example 14.3, “Concurrent DML During CREATE INDEX and DROP INDEX”](#) shows queries and DML statements running during a `DROP INDEX` operation.
- [Example 14.4, “Renaming a Column”](#) demonstrates the speed improvement for renaming a column, and shows the care needed to keep the data type precisely the same when doing the rename operation.

- [Example 14.5, “Dropping Foreign Keys”](#) demonstrates how foreign keys work with online DDL. Because two tables are involved in foreign key operations, there are extra locking considerations. Thus, tables with foreign keys sometimes have restrictions for online DDL operations.
- [Example 14.6, “Changing Auto-Increment Value”](#) demonstrates how auto-increment columns work with online DDL. Tables with auto-increment columns sometimes have restrictions for online DDL operations.
- [Example 14.7, “Controlling Concurrency with the LOCK Clause”](#) demonstrates the options to permit or restrict concurrent queries and DML operations while an online DDL operation is in progress. It shows the situations when the DDL statement might wait, or the concurrent transaction might wait, or the concurrent transaction might cancel a DML statement due to a deadlock error.
- [Example 14.8, “Schema Setup Code for Online DDL Experiments”](#) demonstrates creating and dropping multiple indexes in a single statement, which can be more efficient than using a separate statement for each index operation.
- [Example 14.9, “Creating and Dropping the Primary Key”](#) demonstrates how it is more efficient to define a [primary key](#) when creating the table, and relatively expensive to add one later.

### Example 14.1 Schema Setup Code for Online DDL Experiments

Here is the code that sets up the initial tables used in these demonstrations:

```

/*
Setup code for the online DDL demonstration:
- Set up some config variables.
- Create 2 tables that are clones of one of the INFORMATION_SCHEMA tables
  that always has some data. The "small" table has a couple of thousand rows.
  For the "big" table, keep doubling the data until it reaches over a million rows.
- Set up a primary key for the sample tables, since we are demonstrating InnoDB aspects.
*/

set autocommit = 0;
set foreign_key_checks = 1;
set global innodb_file_per_table = 1;
set old_alter_table=0;
prompt mysql:

use test;

\! echo "Setting up 'small' table:"
drop table if exists small_table;
create table small_table as select * from information_schema.columns;
alter table small_table add id int unsigned not null primary key auto_increment;
select count(id) from small_table;

\! echo "Setting up 'big' table:"
drop table if exists big_table;
create table big_table as select * from information_schema.columns;
show create table big_table\G

insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
commit;

alter table big_table add id int unsigned not null primary key auto_increment;
select count(id) from big_table;

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

## Examples of Online DDL

```
Setting up 'small' table:
Query OK, 0 rows affected (0.01 sec)

Query OK, 1678 rows affected (0.13 sec)

### Example 14.2 Speed and Efficiency of CREATE INDEX and DROP INDEX

Here is a sequence of statements demonstrating the relative speed of `CREATE INDEX` and `DROP INDEX` statements. For a small table, the elapsed time is less than a second whether we use the fast or slow technique, so we look at the “rows affected” output to verify which operations can avoid the table rebuild. For a large table, the difference in efficiency is obvious because skipping the table rebuild saves substantial time.

```

\! clear

\! echo "=== Create and drop index (small table, new/fast technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/small_table.ibd
create index i_dtyp_small on small_table (data_type), algorithm=inplace;
\! echo "Data size after index created: "
\! du -k data/test/small_table.ibd
drop index i_dtyp_small on small_table, algorithm=inplace;

-- Compare against the older slower DDL.

\! echo "=== Create and drop index (small table, old/slow technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/small_table.ibd
create index i_dtyp_small on small_table (data_type), algorithm=copy;
\! echo "Data size after index created: "
\! du -k data/test/small_table.ibd
drop index i_dtyp_small on small_table, algorithm=copy;

-- In the above example, we examined the "rows affected" number,
-- ideally looking for a zero figure. Let's try again with a larger
-- sample size, where we'll see that the actual time taken can
-- vary significantly.

\! echo "=== Create and drop index (big table, new/fast technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/big_table.ibd
create index i_dtyp_big on big_table (data_type), algorithm=inplace;
\! echo "Data size after index created: "
\! du -k data/test/big_table.ibd
drop index i_dtyp_big on big_table, algorithm=inplace;

\! echo "=== Create and drop index (big table, old/slow technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/big_table.ibd
create index i_dtyp_big on big_table (data_type), algorithm=copy;
\! echo "Data size after index created: "
\! du -k data/test/big_table.ibd

```

```
drop index i_dtyp_big on big_table, algorithm=copy;
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```
Query OK, 0 rows affected (0.00 sec)

=== Create and drop index (small table, new/fast technique) ===

Data size (kilobytes) before index created:
384 data/test/small_table.ibd

348160 data/test/big_table.ibd
Query OK, 1718272 rows affected (46.59 sec)
Records: 1718272 Duplicates: 0 Warnings: 0
```

### Example 14.3 Concurrent DML During CREATE INDEX and DROP INDEX

Here are some snippets of code that are run in separate `mysql` sessions connected to the same database, to illustrate DML statements (insert, update, or delete) running at the same time as `CREATE INDEX` and `DROP INDEX`.

```
/*
CREATE INDEX statement to run against a table while
insert/update/delete statements are modifying the
column being indexed.
```

```

*/

-- Run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

use test;
create index i_concurrent on big_table(table_name);

/*
DROP INDEX statement to run against a table while
insert/update/delete statements are modifying the
column being indexed.
*/

-- Run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

use test;
drop index i_concurrent on big_table;

/*
Some queries and insert/update/delete statements to run against a table
while an index is being created or dropped. Previously, these operations
would have stalled during the index create/drop period and possibly
timed out or deadlocked.
*/

-- Run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

-- In the test instance, that column has about 1.7M rows, with 136 different values.
-- Sample values: COLUMNS (20480), ENGINES (6144), EVENTS (24576), FILES (38912),
-- TABLES (21504), VIEWS (10240).

set autocommit = 0;
use test;

select distinct character_set_name from big_table where table_name = 'FILES';
delete from big_table where table_name = 'FILES';
select distinct character_set_name from big_table where table_name = 'FILES';

-- I'll issue the final rollback interactively, not via script,
-- the better to control the timing.
-- rollback;

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

mysql: source concurrent_ddl_create.sql
Database changed
Query OK, 0 rows affected (1 min 25.15 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql: source concurrent_ddl_drop.sql
Database changed
Query OK, 0 rows affected (24.98 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql: source concurrent_dml.sql
Query OK, 0 rows affected (0.00 sec)

Database changed
+-----+
| character_set_name |
+-----+
| NULL               |
| utf8               |
+-----+
2 rows in set (0.32 sec)

```

```
Query OK, 38912 rows affected (1.84 sec)

Empty set (0.01 sec)

mysql: rollback;
Query OK, 0 rows affected (1.05 sec)
```

### Example 14.4 Renaming a Column

Here is a demonstration of using `ALTER TABLE` to rename a column. We use the new, fast DDL mechanism to change the name, then the old, slow DDL mechanism (with `old_alter_table=1`) to restore the original column name.

Notes:

- Because the syntax for renaming a column also involves re-specifying the data type, be careful to specify exactly the same data type to avoid a costly table rebuild. In this case, we checked the output of `show create table table\G` and copied any clauses such as `CHARACTER SET` and `NOT NULL` from the original column definition.
- Again, renaming a column for a small table is fast enough that we need to examine the “rows affected” number to verify that the new DDL mechanism is more efficient than the old one. With a big table, the difference in elapsed time makes the improvement obvious.

```
/*
Run through a sequence of 'rename column' statements.
Because this operation involves only metadata, not table data,
it is fast for big and small tables, with new or old DDL mechanisms.
*/

\! clear

\! echo "Rename column (fast technique, small table):"
alter table small_table change `IS_NULLABLE` `NULLABLE` varchar(3) character
  set utf8 not null, algorithm=inplace;
\! echo "Rename back to original name (slow technique):"
alter table small_table change `NULLABLE` `IS_NULLABLE` varchar(3) character
  set utf8 not null, algorithm=copy;

\! echo "Rename column (fast technique, big table):"
alter table big_table change `IS_NULLABLE` `NULLABLE` varchar(3) character
  set utf8 not null, algorithm=inplace;
\! echo "Rename back to original name (slow technique):"
alter table big_table change `NULLABLE` `IS_NULLABLE` varchar(3) character
  set utf8 not null, algorithm=copy;
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```
Rename column (fast technique, small table):
Query OK, 0 rows affected (0.05 sec)

Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

Rename back to original name (slow technique):
Query OK, 0 rows affected (0.00 sec)

Query OK, 1678 rows affected (0.35 sec)
Records: 1678 Duplicates: 0 Warnings: 0

Rename column (fast technique, big table):
Query OK, 0 rows affected (0.00 sec)

Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0

Rename back to original name (slow technique):
```

```
Query OK, 0 rows affected (0.00 sec)

Query OK, 1718272 rows affected (1 min 0.00 sec)
Records: 1718272 Duplicates: 0 Warnings: 0

Query OK, 0 rows affected (0.00 sec)
```

### Example 14.5 Dropping Foreign Keys

Here is a demonstration of foreign keys, including improvement to the speed of dropping a foreign key constraint.

```
/*
Demonstrate aspects of foreign keys that are or aren't affected by the DDL improvements.
- Create a new table with only a few values to serve as the parent table.
- Set up the 'small' and 'big' tables as child tables using a foreign key.
- Verify that the ON DELETE CASCADE clause makes changes ripple from parent to child tables.
- Drop the foreign key constraints, and optionally associated indexes. (This is the operation that is s
*/

\! clear

-- Make sure foreign keys are being enforced, and allow
-- rollback after doing some DELETES that affect both
-- parent and child tables.
set foreign_key_checks = 1;
set autocommit = 0;

-- Create a parent table, containing values that we know are already present
-- in the child tables.
drop table if exists schema_names;
create table schema_names (id int unsigned not null primary key auto_increment, schema_name
    varchar(64) character set utf8 not null, index i_schema (schema_name)) as select distinct
    table_schema schema_name from small_table;

show create table schema_names\G
show create table small_table\G
show create table big_table\G

-- Creating the foreign key constraint still involves a table rebuild when foreign_key_checks=1,
-- as illustrated by the "rows affected" figure.
alter table small_table add constraint small_fk foreign key i_table_schema (table_schema)
    references schema_names(schema_name) on delete cascade;
alter table big_table add constraint big_fk foreign key i_table_schema (table_schema)
    references schema_names(schema_name) on delete cascade;

show create table small_table\G
show create table big_table\G

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- big_table is the parent table.
-- schema_names is the parent table.
-- big_table is the child table.
-- (One row in the parent table can have many "children" in the child table.)
-- Changes to the parent table can ripple through to the child table.
-- For example, removing the value 'test' from schema_names.schema_name will
-- result in the removal of 20K or so rows from big_table.

delete from schema_names where schema_name = 'test';

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- Because we've turned off autocommit, we can still get back those deleted rows
-- if the DELETE was issued by mistake.
rollback;
```

## Examples of Online DDL

```
select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- All of the cross-checking between parent and child tables would be
-- deadly slow if there wasn't the requirement for the corresponding
-- columns to be indexed!

-- But we can get rid of the foreign key using a fast operation
-- that doesn't rebuild the table.
-- If we didn't specify a constraint name when setting up the foreign key, we would
-- have to find the auto-generated name such as 'big_table_ibfk_1' in the
-- output from 'show create table'.

-- For the small table, drop the foreign key and the associated index.
-- Having an index on a small table is less critical.

\! echo "DROP FOREIGN KEY and INDEX from small_table:"
alter table small_table drop foreign key small_fk, drop index small_fk;

-- For the big table, drop the foreign key and leave the associated index.
-- If we are still doing queries that reference the indexed column, the index is
-- very important to avoid a full table scan of the big table.
\! echo "DROP FOREIGN KEY from big_table:"
alter table big_table drop foreign key big_fk;

show create table small_table\G
show create table big_table\G
```

```

### Example 14.6 Changing Auto-Increment Value

Here is an illustration of increasing the [auto-increment](#) lower limit for a table column, demonstrating how this operation now avoids a table rebuild, plus other facts about [InnoDB](#) auto-increment columns.

```

/*
If this script is run after foreign_key.sql, the schema_names table is
already set up. But to allow this script to run multiple times without
running into duplicate ID errors, we set up the schema_names table
all over again.
*/

\! clear

\! echo "=== Adjusting the Auto-Increment Limit for a Table ==="
\! echo

drop table if exists schema_names;
create table schema_names (id int unsigned not null primary key auto_increment,
  schema_name varchar(64) character set utf8 not null, index i_schema (schema_name))
  as select distinct table_schema schema_name from small_table;

\! echo "Initial state of schema_names table."
\! echo "AUTO_INCREMENT is included in SHOW CREATE TABLE output."
\! echo "Note how MySQL reserved a block of IDs."
\! echo "Only 4 IDs are needed in this transaction. The next inserted values get IDs 8 and 9."

```

```

show create table schema_names\G
select * from schema_names order by id;

\! echo "Inserting even a tiny amount of data can produce gaps in the ID sequence."
insert into schema_names (schema_name) values ('eight'), ('nine');

\! echo "Bumping auto-increment lower limit to 20 (fast mechanism):"
alter table schema_names auto_increment=20, algorithm=inplace;

\! echo "Inserting 2 rows that should get IDs 20 and 21:"
insert into schema_names (schema_name) values ('foo'), ('bar');
commit;

\! echo "Bumping auto-increment lower limit to 30 (slow mechanism):"
alter table schema_names auto_increment=30, algorithm=copy;

\! echo "Inserting 2 rows that should get IDs 30 and 31:"
insert into schema_names (schema_name) values ('bletch'),('baz');
commit;

select * from schema_names order by id;

\! echo "Final state of schema_names table."
\! echo "AUTO_INCREMENT value shows the next inserted row would get ID=32."
show create table schema_names\G

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

=== Adjusting the Auto-Increment Limit for a Table ===

### Example 14.7 Controlling Concurrency with the LOCK Clause

This example shows how to use the `LOCK` clause of the `ALTER TABLE` statement to allow or deny concurrent access to the table while an online DDL operation is in progress. The clause has settings that allow queries and DML statements (`LOCK=NONE`), just queries (`LOCK=SHARED`), or no concurrent access at all (`LOCK=EXCLUSIVE`).

In one session, we run a succession of `ALTER TABLE` statements to create and drop an index, using different values for the `LOCK` clause to see what happens with waiting or deadlocking in either session. We are using the same `BIG_TABLE` table as in previous examples, starting with approximately 1.7 million rows. For illustration purposes, we will index and query the `IS_NULLABLE` column. (Although in real life it would be silly to make an index for a tiny column with only 2 distinct values.)

```

mysql: desc big_table;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| TABLE_CATALOG | varchar(512) | NO | | | |
| TABLE_SCHEMA | varchar(64) | NO | | | |
| TABLE_NAME | varchar(64) | NO | | | |
| COLUMN_NAME | varchar(64) | NO | | | |
| ORDINAL_POSITION | bigint(21) unsigned | NO | | 0 | |
| COLUMN_DEFAULT | longtext | YES | | NULL | |
+-----+-----+-----+-----+-----+-----+

```

```

| IS_NULLABLE          | varchar(3)          | NO |      |      |      |
+-----+-----+-----+-----+-----+-----+
21 rows in set (0.14 sec)

mysql: alter table big_table add index i1(is_nullable);
Query OK, 0 rows affected (20.71 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.02 sec)

mysql: alter table big_table add index i1(is_nullable), lock=exclusive;
Query OK, 0 rows affected (19.44 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.03 sec)

mysql: alter table big_table add index i1(is_nullable), lock=shared;
Query OK, 0 rows affected (16.71 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.05 sec)

mysql: alter table big_table add index i1(is_nullable), lock=none;
Query OK, 0 rows affected (12.26 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.01 sec)

... repeat statements like the above while running queries ...
... and DML statements at the same time in another session ...

```

Nothing dramatic happens in the session running the DDL statements. Sometimes, an `ALTER TABLE` takes unusually long because it is waiting for another transaction to finish, when that transaction modified the table during the DDL or queried the table before the DDL:

```

mysql: alter table big_table add index i1(is_nullable), lock=none;

Query OK, 0 rows affected (59.27 sec)

mysql: -- The previous ALTER took so long because it was waiting for all the concurrent
mysql: -- transactions to commit or roll back.

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (41.05 sec)

mysql: -- Even doing a SELECT on the table in the other session first causes
mysql: -- the ALTER TABLE above to stall until the transaction
mysql: -- surrounding the SELECT is committed or rolled back.

```

Here is the log from another session running concurrently, where we issue queries and DML statements against the table before, during, and after the DDL operations shown in the previous listings. This first listing shows queries only. We expect the queries to be allowed during DDL operations using `LOCK=NONE` or `LOCK=SHARED`, and for the query to wait until the DDL is finished if the `ALTER TABLE` statement includes `LOCK=EXCLUSIVE`.

```

mysql: show variables like 'autocommit';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| autocommit    | ON    |
+-----+-----+
1 row in set (0.01 sec)

mysql: -- A trial query before any ADD INDEX in the other session:
mysql: -- Note: because autocommit is enabled, each
mysql: -- transaction finishes immediately after the query.
mysql: select distinct is_nullable from big_table;

```

```

+-----+
| is_nullable |
+-----+
| NO          |
| YES        |
+-----+
2 rows in set (4.49 sec)

mysql: -- Index is being created with LOCK=EXCLUSIVE on the ALTER statement.
mysql: -- The query waits until the DDL is finished before proceeding.
mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES        |
+-----+

2 rows in set (17.26 sec)

mysql: -- Index is being created with LOCK=SHARED on the ALTER statement.
mysql: -- The query returns its results while the DDL is in progress.
mysql: -- The same thing happens with LOCK=NONE on the ALTER statement.
mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES        |
+-----+

2 rows in set (3.11 sec)

mysql: -- Once the index is created, and with no DDL in progress,
mysql: -- queries referencing the indexed column are very fast:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+

1 row in set (0.20 sec)

mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO          |
| YES        |
+-----+

2 rows in set (0.00 sec)

```

Now in this concurrent session, we run some transactions including DML statements, or a combination of DML statements and queries. We use `DELETE` statements to illustrate predictable, verifiable changes to the table. Because the transactions in this part can span multiple statements, we run these tests with `autocommit` turned off.

```

mysql: set global autocommit = off;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Count the rows that will be involved in our DELETE statements:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+

1 row in set (0.95 sec)

mysql: -- After this point, any DDL statements back in the other session
mysql: -- stall until we commit or roll back.

```

```
mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.14 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (1.04 sec)

mysql: rollback;
Query OK, 0 rows affected (0.09 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+
1 row in set (0.93 sec)

mysql: -- OK, now we're going to try that during index creation with LOCK=NONE.
mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.21 sec)

mysql: -- We expect that now there will be 400000 'YES' rows left:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (1.25 sec)

mysql: -- In the other session, the ALTER TABLE is waiting before finishing,
mysql: -- because _this_ transaction hasn't committed or rolled back yet.
mysql: rollback;
Query OK, 0 rows affected (0.11 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+
1 row in set (0.19 sec)

mysql: -- The ROLLBACK left the table in the same state we originally found it.
mysql: -- Now let's make a permanent change while the index is being created,
mysql: -- again with ALTER TABLE ... , LOCK=NONE.
mysql: -- First, commit so the DROP INDEX in the other shell can finish;
mysql: -- the previous SELECT started a transaction that accessed the table.
mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Now we add the index back in the other shell, then issue DML in this one
mysql: -- while the DDL is running.
mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.23 sec)

mysql: commit;
Query OK, 0 rows affected (0.01 sec)

mysql: -- In the other shell, the ADD INDEX has finished.
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
```

## Examples of Online DDL

```
1 row in set (0.19 sec)

mysql: -- At the point the new index is finished being created, it contains entries
mysql: -- only for the 400000 'YES' rows left when all concurrent transactions are finished.
mysql:
mysql: -- Now we will run a similar test, while ALTER TABLE ... , LOCK=SHARED is running.
mysql: -- We expect a query to complete during the ALTER TABLE, but for the DELETE
mysql: -- to run into some kind of issue.
mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- As expected, the query returns results while the LOCK=SHARED DDL is running:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (2.07 sec)

mysql: -- The DDL in the other session is not going to finish until this transaction
mysql: -- is committed or rolled back. If we tried a DELETE now and it waited because
mysql: -- of LOCK=SHARED on the DDL, both transactions would wait forever (deadlock).
mysql: -- MySQL detects this condition and cancels the attempted DML statement.
mysql: delete from big_table where is_nullable = 'YES' limit 100000;
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
mysql: -- The transaction here is still going, so in the other shell, the ADD INDEX operation
mysql: -- is waiting for this transaction to commit or roll back.
mysql: rollback;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Now let's try issuing a query and some DML, on one line, while running
mysql: -- ALTER TABLE ... , LOCK=EXCLUSIVE in the other shell.
mysql: -- Notice how even the query is held up until the DDL is finished.
mysql: -- By the time the DELETE is issued, there is no conflicting access
mysql: -- to the table and we avoid the deadlock error.
mysql: select count(*) from big_table where is_nullable = 'YES'; delete from big_table
      where is_nullable = 'YES' limit 100000;
+-----+
| count(*) |
+-----+
| 400000 |
+-----+

1 row in set (15.98 sec)

Query OK, 100000 rows affected (2.81 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 300000 |
+-----+
1 row in set (0.17 sec)

mysql: rollback;
Query OK, 0 rows affected (1.36 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (0.19 sec)

mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Next, we try ALTER TABLE ... , LOCK=EXCLUSIVE in the other session
mysql: -- and only issue DML, not any query, in the concurrent transaction here.
```

```
mysql: delete from big_table where is_nullable = 'YES' limit 100000;
Query OK, 100000 rows affected (16.37 sec)

mysql: -- That was OK because the ALTER TABLE did not have to wait for the transaction
mysql: -- here to complete. The DELETE in this session waited until the index was ready.
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 300000 |
+-----+
1 row in set (0.16 sec)

mysql: commit;
Query OK, 0 rows affected (0.00 sec)
```

In the preceding example listings, we learned that:

- The `LOCK` clause for `ALTER TABLE` is set off from the rest of the statement by a comma.
- Online DDL operations might wait before starting, until any prior transactions that access the table are committed or rolled back.
- Online DDL operations might wait before completing, until any concurrent transactions that access the table are committed or rolled back.
- While an online DDL operation is running, concurrent queries are relatively straightforward, as long as the `ALTER TABLE` statement uses `LOCK=NONE` or `LOCK=SHARED`.
- Pay attention to whether `autocommit` is turned on or off. If it is turned off, be careful to end transactions in other sessions (even just queries) before performing DDL operations on the table.
- With `LOCK=SHARED`, concurrent transactions that mix queries and DML could encounter deadlock errors and have to be restarted after the DDL is finished.
- With `LOCK=NONE`, concurrent transactions can freely mix queries and DML. The DDL operation waits until the concurrent transactions are committed or rolled back.
- With `LOCK=EXCLUSIVE`, concurrent transactions can freely mix queries and DML, but those transactions wait until the DDL operation is finished before they can access the table.

#### Example 14.8 Schema Setup Code for Online DDL Experiments

You can create multiple indexes on a table with one `ALTER TABLE` statement. This is relatively efficient, because the clustered index of the table needs to be scanned only once (although the data is sorted separately for each new index). For example:

```
CREATE TABLE T1(A INT PRIMARY KEY, B INT, C CHAR(1)) ENGINE=InnoDB;
INSERT INTO T1 VALUES (1,2,'a'), (2,3,'b'), (3,2,'c'), (4,3,'d'), (5,2,'e');
COMMIT;
ALTER TABLE T1 ADD INDEX (B), ADD UNIQUE INDEX (C);
```

The above statements create table `T1` with the primary key on column `A`, insert several rows, then build two new indexes on columns `B` and `C`. If there were many rows inserted into `T1` before the `ALTER TABLE` statement, this approach is much more efficient than creating all the secondary indexes before loading the data.

Because dropping InnoDB secondary indexes also does not require any copying of table data, it is equally efficient to drop multiple indexes with a single `ALTER TABLE` statement or multiple `DROP INDEX` statements:

```
ALTER TABLE T1 DROP INDEX B, DROP INDEX C;
```

or:

```
DROP INDEX B ON T1;
DROP INDEX C ON T1;
```

### Example 14.9 Creating and Dropping the Primary Key

Restructuring the [clustered index](#) for an [InnoDB](#) table always requires copying the table data. Thus, it is best to define the [primary key](#) when you create a table, rather than issuing `ALTER TABLE ... ADD PRIMARY KEY` later, to avoid rebuilding the table.

Defining a [PRIMARY KEY](#) later causes the data to be copied, as in the following example:

```
CREATE TABLE T2 (A INT, B INT);
INSERT INTO T2 VALUES (NULL, 1);
ALTER TABLE T2 ADD PRIMARY KEY (B);
```

When you create a [UNIQUE](#) or [PRIMARY KEY](#) index, MySQL must do some extra work. For [UNIQUE](#) indexes, MySQL checks that the table contains no duplicate values for the key. For a [PRIMARY KEY](#) index, MySQL also checks that none of the [PRIMARY KEY](#) columns contains a [NULL](#).

When you add a primary key using the [ALGORITHM=COPY](#) clause, MySQL actually converts [NULL](#) values in the associated columns to default values: 0 for numbers, the empty string for character-based columns and BLOBs, and 0000-00-00 00:00:00 for [DATETIME](#). This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using [ALGORITHM=INPLACE](#) is only allowed when the [SQL\\_MODE](#) setting includes the [strict\\_trans\\_tables](#) or [strict\\_all\\_tables](#) flags; when the [SQL\\_MODE](#) setting is strict, `ADD PRIMARY KEY ... , ALGORITHM=INPLACE` is allowed, but the statement can still fail if the requested primary key columns contain any [NULL](#) values. The [ALGORITHM=INPLACE](#) behavior is more standard-compliant.

The following examples show the different possibilities for the `ADD PRIMARY KEY` clause. With the [ALGORITHM=COPY](#) clause, the operation succeeds despite the presence of [NULL](#) values in the primary key columns; the data is silently changed, which could cause problems.

```
mysql> CREATE TABLE add_pk_via_copy (c1 INT, c2 VARCHAR(10), c3 DATETIME);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO add_pk_via_copy VALUES (1, 'a', '2014-11-03 11:01:37'), (NULL, NULL, NULL);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE add_pk_via_copy ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=COPY;
Query OK, 2 rows affected, 3 warnings (0.07 sec)
Records: 2  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'c1' at row 2 |
| Warning | 1265 | Data truncated for column 'c2' at row 2 |
| Warning | 1265 | Data truncated for column 'c3' at row 2 |
+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT * FROM add_pk_via_copy;
+-----+-----+-----+
| c1 | c2 | c3 |
+-----+-----+-----+
| 0 |  | 0000-00-00 00:00:00 |
| 1 | a | 2014-11-03 11:01:37 |
+-----+-----+-----+
```

```
+-----+-----+-----+
2 rows in set (0.00 sec)
```

With the `ALGORITHM=INPLACE` clause, the operation could fail for different reasons, because this setting considers data integrity a high priority: the statement gives an error if the `SQL_MODE` setting is not “strict” enough, or if the primary key columns contain any `NULL` values. Once we address both of those requirements, the `ALTER TABLE` operation succeeds.

```
mysql> CREATE TABLE add_pk_via_inplace (c1 INT, c2 VARCHAR(10), c3 DATETIME);
Query OK, 0 rows affected (0.02 sec)

mysql> INSERT INTO add_pk_via_inplace VALUES (1,'a','2014-11-03 11:01:37'),(NULL,NULL,NULL);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM add_pk_via_inplace;
+-----+-----+-----+
| c1   | c2   | c3                                     |
+-----+-----+-----+
| 1    | a    | 2014-11-03 11:01:37                 |
| NULL | NULL | NULL                                 |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE add_pk_via_inplace ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason: cannot silently convert NULL
values, as required in this SQL_MODE. Try ALGORITHM=COPY.

mysql> SET sql_mode = 'strict_trans_tables';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE add_pk_via_inplace ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=INPLACE;
ERROR 1138 (22004): Invalid use of NULL value
mysql> DELETE FROM add_pk_via_inplace WHERE c1 IS NULL OR c2 IS NULL OR c3 IS NULL;
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM add_pk_via_inplace;
+-----+-----+-----+
| c1   | c2   | c3                                     |
+-----+-----+-----+
| 1    | a    | 2014-11-03 11:01:37                 |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> ALTER TABLE add_pk_via_inplace ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=INPLACE;
Query OK, 0 rows affected (0.09 sec)

```

If you create a table without a primary key, InnoDB chooses one for you, which can be the first `UNIQUE` key defined on `NOT NULL` columns, or a system-generated key. To avoid any uncertainty and the potential space requirement for an extra hidden column, specify the `PRIMARY KEY` clause as part of the `CREATE TABLE` statement.

## 14.10.6 Implementation Details of Online DDL

Each `ALTER TABLE` operation for an InnoDB table is governed by several aspects:

- Whether there is any change to the physical representation of the table, or whether it purely a change to metadata that can be done without touching the table itself.
- Whether the volume of data in the table stays the same, increases, or decreases.
- Whether a change in table data involves the clustered index, secondary indexes, or both.

- Whether there are any [foreign key](#) relationships between the table being altered and some other table. The mechanics differ depending on whether the [foreign\\_key\\_checks](#) configuration option is enabled or disabled.
- Whether the table is partitioned. Partitioning clauses of [ALTER TABLE](#) are turned into low-level operations involving one or more tables, and those operations follow the regular rules for online DDL.
- Whether the table data must be copied, whether the table can be reorganized “in-place”, or a combination of both.
- Whether the table contains any [auto-increment](#) columns.
- What degree of [locking](#) is required, either by the nature of the underlying database operations, or a [LOCK](#) clause that you specify in the [ALTER TABLE](#) statement.

This section explains how these factors affect the different kinds of [ALTER TABLE](#) operations on [InnoDB](#) tables.

## Error Conditions for Online DDL

Here are the primary reasons why an online DDL operation could fail:

- If a [LOCK](#) clause specifies a low degree of locking ([SHARED](#) or [NONE](#)) that is not compatible with the particular type of DDL operation.
- If a timeout occurs while waiting to get an [exclusive lock](#) on the table, which is needed briefly during the initial and final phases of the DDL operation.
- If the [tmpdir](#) file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation.
- If the [ALTER TABLE](#) takes so long, and concurrent DML modifies the table so much, that the size of the temporary online log exceeds the value of the [innodb\\_online\\_alter\\_log\\_max\\_size](#) configuration option. This condition causes a [DB\\_ONLINE\\_LOG\\_TOO\\_BIG](#) error.
- If concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert [NULL](#) values into a column while creating a [primary key](#) index on that column. The changes made by the concurrent DML take precedence, and the [ALTER TABLE](#) operation is effectively [rolled back](#).

Although the configuration option [innodb\\_file\\_per\\_table](#) has a dramatic effect on the representation for an [InnoDB](#) table, all online DDL operations work equally well whether that option is enabled or disabled, and whether the table is physically located in its own [.ibd file](#) or inside the [system tablespace](#).

InnoDB has two types of indexes: the [clustered index](#) representing all the data in the table, and optional [secondary indexes](#) to speed up queries. Since the clustered index contains the data values in its B-tree nodes, adding or dropping a clustered index does involve copying the data, and creating a new copy of the table. A secondary index, however, contains only the index key and the value of the primary key. This type of index can be created or dropped without copying the data in the clustered index. Because each secondary index contains copies of the primary key values (used to access the clustered index when needed), when you change the definition of the primary key, all secondary indexes are recreated as well.

Dropping a secondary index is simple. Only the internal InnoDB system tables and the MySQL data dictionary tables are updated to reflect the fact that the index no longer exists. InnoDB returns the storage used for the index to the tablespace that contained it, so that new indexes or additional table rows can use the space.

To add a secondary index to an existing table, InnoDB scans the table, and sorts the rows using memory buffers and temporary files in order by the values of the secondary index key columns. The B-tree is then built in key-value order, which is more efficient than inserting rows into an index in random order. Because the B-tree nodes are split when they fill, building the index in this way results in a higher fill-factor for the index, making it more efficient for subsequent access.

## Primary Key and Secondary Key Indexes

Historically, the MySQL server and InnoDB have each kept their own metadata about table and index structures. The MySQL server stores this information in `.frm files` that are not protected by a transactional mechanism, while InnoDB has its own `data dictionary` as part of the `system tablespace`. If a DDL operation was interrupted by a crash or other unexpected event partway through, the metadata could be left inconsistent between these two locations, causing problems such as startup errors or inability to access the table that was being altered. Now that InnoDB is the default storage engine, addressing such issues is a high priority. These enhancements to DDL operations reduce the window of opportunity for such issues to occur.

### 14.10.7 How Crash Recovery Works with Online DDL

Although no data is lost if the server crashes while an `ALTER TABLE` statement is executing, the `crash recovery` process is different for `clustered indexes` and `secondary indexes`.

If the server crashes while creating an InnoDB secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the `ALTER TABLE` or `CREATE INDEX` statement.

When a crash occurs during the creation of an InnoDB clustered index, recovery is more complicated, because the data in the table must be copied to an entirely new clustered index. Remember that all InnoDB tables are stored as clustered indexes.

MySQL creates the new clustered index by copying the existing data from the original InnoDB table to a temporary table that has the desired index structure. Once the data is completely copied to this temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

If a system crash occurs while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario.

### 14.10.8 Online DDL for Partitioned InnoDB Tables

With the exception of `ALTER TABLE` partitioning clauses, online DDL operations for partitioned InnoDB tables follow the same rules that apply to regular InnoDB tables. Online DDL rules are outlined in [Table 14.8, “Summary of Online Status for DDL Operations”](#).

`ALTER TABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned InnoDB tables, and are only allowed in conjunction with `ALGORITHM=DEFAULT` and `LOCK=DEFAULT`.

If you use an `ALTER TABLE` partitioning clause in an `ALTER TABLE` statement, the partitioned table will be “re-partitioned” using the `ALTER TABLE COPY` algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table will include any changes applied by the `ALTER TABLE` statement and the table data will be copied into the new table structure.

If you do not change the table's partitioning using `ALTER TABLE` partitioning clauses or perform any other partition management in your `ALTER TABLE` statement, `ALTER TABLE` will use the `INPLACE` algorithm on each table partition. Be aware, however, that when `INPLACE ALTER TABLE`

operations are performed on each partition, there will be increased demand on system resources due to operations being performed on multiple partitions.

Even though partitioning clauses of the `ALTER TABLE` statement do not go through the same internal online DDL API as regular non-partitioned `InnoDB` tables, MySQL still attempts to minimize data copying and locking where possible:

- `ADD PARTITION` and `DROP PARTITION` for tables partitioned by `RANGE` or `LIST` do not copy any existing data.
- `TRUNCATE PARTITION` does not copy any existing data, for all types of partitioned tables.
- Concurrent queries are allowed during `ADD PARTITION` and `COALESCE PARTITION` for tables partitioned by `HASH` or `LIST`. MySQL copies the data while holding a shared lock.
- For `REORGANIZE PARTITION`, `REBUILD PARTITION`, or `ADD PARTITION` or `COALESCE PARTITION` for a table partitioned by `LINEAR HASH` or `LIST`, concurrent queries are allowed. Data from the affected partitions is copied while holding a shared metadata (read) lock at the table level.

#### Note

Full-text search (FTS) and foreign keys are not supported by `InnoDB` partitioned tables. For more information, see [Section 12.9.5, “Full-Text Restrictions”](#) and [Section 18.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

## 14.10.9 Limitations of Online DDL

Take the following limitations into account when running online DDL operations:

- During an online DDL operation that copies the table, files are written to the temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by the `--tmpdir` configuration variable). Each temporary file is large enough to hold one column in the new table or index, and each one is removed as soon as it is merged into the final table or index.
- The table is copied, rather than using Fast Index Creation when you create an index on a `TEMPORARY TABLE`. This has been reported as MySQL Bug #39833.
- `InnoDB` handles error cases when users attempt to drop indexes needed for foreign keys. See [Section 14.18.5, “InnoDB Error Codes”](#) for information related to error 1553.
- The `ALTER TABLE` clause `LOCK=NONE` is not allowed if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.
- During each online DDL `ALTER TABLE` statement, regardless of the `LOCK` clause, there are brief periods at the beginning and end requiring an `exclusive lock` on the table (the same kind of lock specified by the `LOCK=EXCLUSIVE` clause). Thus, an online DDL operation might wait before starting if there is a long-running transaction performing inserts, updates, deletes, or `SELECT ... FOR UPDATE` on that table; and an online DDL operation might wait before finishing if a similar long-running transaction was started while the `ALTER TABLE` was in progress.
- When running an online `ALTER TABLE` operation, the thread that runs the `ALTER TABLE` operation will apply an “online log” of DML operations that were run concurrently on the same table from other connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (`ERROR 1062 (23000): Duplicate entry`), even if the duplicate entry is only temporary and would be reverted by a later entry in the “online log”. This is similar to the idea of a foreign key constraint check in `InnoDB` in which constraints must hold during a transaction.
- `OPTIMIZE TABLE` for an `InnoDB` table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. Prior to 5.7.4, there is no `online DDL` support for this operation. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. As of 5.7.4, `OPTIMIZE TABLE` is

supported with the addition of [online DDL](#) support for rebuilding regular and partitioned [InnoDB](#) tables. For additional information, see [Section 14.10.1, “Overview of Online DDL”](#).

- [InnoDB](#) tables created before MySQL 5.6 do not support `ALTER TABLE ... ALGORITHM=INPLACE` for tables that include temporal columns (`DATE`, `DATETIME` or `TIMESTAMP`) and have not been rebuilt using `ALTER TABLE ... ALGORITHM=COPY`. In this case, an `ALTER TABLE ... ALGORITHM=INPLACE` operation returns the following error:

```
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
```

- These limitations are generally applicable to online DDL operations on large tables where table copying is involved:
  - There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.
  - Progress monitoring capability for online DDL operations is limited until MySQL 5.7.6, which introduces Performance Schema stage events for monitoring `ALTER TABLE` progress. See [Section 14.13.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#).
  - Rollback of an online DDL operation can be expensive should the operation fail.
  - Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the master before it is run on the slave. Also, DML that was processed concurrently on the master is only processed on the slave after the DDL operation on the slave is completed (Bug #73196).
  - An online `ALTER TABLE` operation can cause a server exit if the operation uses all of the available disk space on the file system where the data directory (`datadir`) resides (Bug #77497). To avoid this problem, ensure that there is enough disk space to accommodate operations that copy the table. During these operations, MySQL writes temporary sort files to the temporary directory (`--tmpdir`).

For additional information related to running online DDL operations on large tables, see [Section 14.10.2, “Performance and Concurrency Considerations for Online DDL”](#).

## 14.11 InnoDB Startup Options and System Variables

- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable the [InnoDB](#) adaptive hash index, you can use `--innodb_adaptive_hash_index` or `--skip-innodb_adaptive_hash_index` on the command line, or `innodb_adaptive_hash_index` or `skip-innodb_adaptive_hash_index` in an option file.
- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.
- Many system variables can be changed at runtime (see [Section 5.1.5.2, “Dynamic System Variables”](#)).
- For information about `GLOBAL` and `SESSION` variable scope modifiers, refer to the `SET` statement documentation.
- Certain options control the locations and layout of the [InnoDB](#) data files. [Section 14.3, “InnoDB Configuration”](#) explains how to use these options.
- Some options, which you might not use initially, help tune [InnoDB](#) performance characteristics based on machine capacity and your database [workload](#).

- For more information on specifying options and system variables, see [Section 4.2.3, “Specifying Program Options”](#).

## InnoDB Command Options

- `--ignore-builtin-innodb`

<b>Deprecated</b>	5.5.22	
<b>Command-Line Format</b>	<code>--ignore-builtin-innodb</code>	
<b>System Variable</b>	<b>Name</b>	<code>ignore_builtin_innodb</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>

In MySQL 5.1, this option caused the server to behave as if the built-in `InnoDB` were not present, which enabled `InnoDB Plugin` to be used instead. In MySQL 5.7, `InnoDB` is the default storage engine and `InnoDB Plugin` is not used, so this option is ignored.

- `--innodb[=value]`

<b>Deprecated</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb[=<i>value</i>]</code>	
<b>Permitted Values</b>	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>ON</code>
	<b>Valid Values</b>	<code>OFF</code>
		<code>ON</code>
	<code>FORCE</code>	

Controls loading of the `InnoDB` storage engine, if the server was compiled with `InnoDB` support. This option has a tristate format, with possible values of `OFF`, `ON`, or `FORCE`. See [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

To disable `InnoDB`, use `--innodb=OFF` or `--skip-innodb`. In this case, because the default storage engine is `InnoDB`, the server will not start unless you also use `--default-storage-`

`engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and `TEMPORARY` tables.

As of MySQL 5.7.5, the `InnoDB` storage engine can no longer be disabled, and the `--innodb=OFF` and `--skip-innodb` options are deprecated and have no effect. Their use results in a warning. These options will be removed in a future MySQL release.

- `--innodb-status-file`

<b>Command-Line Format</b>	<code>--innodb-status-file</code>	
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Controls whether `InnoDB` creates a file named `innodb_status.pid` in the MySQL data directory. If enabled, `InnoDB` periodically writes the output of `SHOW ENGINE INNODB STATUS` to this file.

By default, the file is not created. To create it, start `mysqld` with the `--innodb-status-file=1` option. The file is deleted during normal shutdown.

- `--skip-innodb`

Disable the `InnoDB` storage engine. See the description of `--innodb`.

## InnoDB System Variables

- `daemon_memcached_enable_binlog`

<b>Command-Line Format</b>	<code>--daemon_memcached_enable_binlog=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>daemon_memcached_enable_binlog</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>false</code>

See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option.

- `daemon_memcached_engine_lib_name`

<b>Command-Line Format</b>	<code>--daemon_memcached_engine_lib_name=library</code>	
<b>System Variable</b>	<b>Name</b>	<code>daemon_memcached_engine_lib_name</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>innodb_engine.so</code>

Specifies the shared library that implements the `InnoDB memcached` plugin.

See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option.

- `daemon_memcached_engine_lib_path`

<b>Command-Line Format</b>	<code>--daemon_memcached_engine_lib_path=directory</code>	
<b>System Variable</b>	<b>Name</b>	<code>daemon_memcached_engine_lib_path</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>directory name</code>
	<b>Default</b>	<code>NULL</code>

The path of the directory containing the shared library that implements the `InnoDB memcached` plugin. The default value is `NULL`, representing the MySQL plugin directory. You should not need to modify this parameter unless specifying a different storage engine `memcached` plugin that is located outside of the MySQL plugin directory.

See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option.

- `daemon_memcached_option`

<b>Command-Line Format</b>	<code>--daemon_memcached_option=options</code>	
<b>System Variable</b>	<b>Name</b>	<code>daemon_memcached_option</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	

Used to pass space-separated `memcached` options to the underlying `memcached` memory object caching daemon on startup. For example, you might change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.

See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option. For information about `memcached` options, refer to the `memcached` man page.

- `daemon_memcached_r_batch_size`

<b>Command-Line Format</b>	<code>--daemon_memcached_r_batch_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>daemon_memcached_r_batch_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>1</code>

Specifies how many `memcached` read operations (`get`) to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_w_batch_size`.

This value is set to 1 by default, so that any changes made to the table through SQL statements are immediately visible to the `memcached` operations. You might increase it to reduce the overhead from frequent commits on a system where the underlying table is only being accessed through the

`memcached` interface. If you set the value too large, the amount of undo or redo data could impose some storage overhead, as with any long-running transaction.

See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option.

- `daemon_memcached_w_batch_size`

<b>Command-Line Format</b>	<code>--daemon_memcached_w_batch_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>daemon_memcached_w_batch_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>1</code>

Specifies how many `memcached` write operations, such as `add`, `set`, or `incr`, to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_r_batch_size`.

This value is set to 1 by default, on the assumption that any data being stored is important to preserve in case of an outage and should immediately be committed. When storing non-critical data, you might increase this value to reduce the overhead from frequent commits; but then the last  $N-1$  uncommitted write operations could be lost in case of a crash.

See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option.

- `ignore_builtin_innodb`

<b>Deprecated</b>	5.5.22	
<b>Command-Line Format</b>	<code>--ignore-builtin-innodb</code>	
<b>System Variable</b>	<b>Name</b>	<code>ignore_builtin_innodb</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>

See the description of `--ignore-builtin-innodb` under “InnoDB Command Options” earlier in this section.

- `innodb_adaptive_flushing`

<b>Command-Line Format</b>	<code>--innodb_adaptive_flushing=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_adaptive_flushing</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

Specifies whether to dynamically adjust the rate of flushing `dirty pages` in the `InnoDB buffer pool` based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity.

This setting is enabled by default. See [Section 14.3.3.2, “Configuring the Rate of InnoDB Buffer Pool Flushing”](#) for more information. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_adaptive_flushing_lwm`

<b>Command-Line Format</b>	<code>--innodb_adaptive_flushing_lwm=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_adaptive_flushing_lwm</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>10</code>
	<b>Min Value</b>	<code>0</code>
	<b>Max Value</b>	<code>70</code>

Low water mark representing percentage of [redo log](#) capacity at which [adaptive flushing](#) is enabled.

- `innodb_adaptive_hash_index`

<b>Command-Line Format</b>	<code>--innodb_adaptive_hash_index=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_adaptive_hash_index</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

Whether the [InnoDB adaptive hash index](#) is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable [adaptive hash indexing](#) to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See [Section 14.2.7.6, “Adaptive Hash Indexes”](#) for details.

This variable is enabled by default. You can modify this parameter using the `SET GLOBAL` statement, without restarting the server. Changing the setting requires the `SUPER` privilege. You can also use `--skip-innodb_adaptive_hash_index` at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- `innodb_adaptive_hash_index_parts`

<b>Introduced</b>	5.7.8	
<b>Command-Line Format</b>	<code>--innodb_adaptive_hash_index_parts=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_adaptive_hash_index_parts</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	numeric
	<b>Default</b>	8
	<b>Min Value</b>	1
	<b>Max Value</b>	512

Partitions the adaptive hash index search system. Each index is bound to a specific partition, with each partition protected by a separate latch.

Prior to MySQL 5.7.8, the adaptive hash index search system was protected by a single latch (`btr_search_latch`) which could become a point of contention. With the introduction of the `innodb_adaptive_hash_index_parts` option, the search system is partitioned into 8 parts by default. The maximum setting is 512.

For related information, see [Section 14.2.7.6, “Adaptive Hash Indexes”](#).

- `innodb_adaptive_max_sleep_delay`

<b>Command-Line Format</b>	<code>--innodb_adaptive_max_sleep_delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_adaptive_max_sleep_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	150000
	<b>Min Value</b>	0
	<b>Max Value</b>	1000000

Allows InnoDB to automatically adjust the value of `innodb_thread_sleep_delay` up or down according to the current workload. Any non-zero value enables automated, dynamic adjustment of the `innodb_thread_sleep_delay` value, up to the maximum value specified in the `innodb_adaptive_max_sleep_delay` option. The value represents the number of microseconds. This option can be useful in busy systems, with greater than 16 InnoDB threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see [Section 14.3.6, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_additional_mem_pool_size`

<b>Deprecated</b>	5.6.3	
<b>Removed</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_additional_mem_pool_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_additional_mem_pool_size</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	8388608
	<b>Min Value</b>	2097152
	<b>Max Value</b>	4294967295

The size in bytes of a memory pool InnoDB uses to store [data dictionary](#) information and other internal data structures. The more tables you have in your application, the more memory you allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB.

This variable relates to the InnoDB internal memory allocator, which is unused if `innodb_use_sys_malloc` is enabled.

`innodb_additional_mem_pool_size` was deprecated in MySQL 5.6.3 and removed in MySQL 5.7.4.

- `innodb_api_bk_commit_interval`

<b>Command-Line Format</b>	<code>--innodb_api_bk_commit_interval=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_api_bk_commit_interval</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	5
	<b>Min Value</b>	1
	<b>Max Value</b>	1073741824

How often to auto-commit idle connections that use the InnoDB `memcached` interface, in seconds. See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option.

- `innodb_api_disable_rowlock`

<b>Command-Line Format</b>	<code>--innodb_api_disable_rowlock=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_api_disable_rowlock</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Use this variable to disable row locks when `InnoDB memcached` performs DML operations. By default, `innodb_api_disable_rowlock` is set to `OFF` which means that `memcached` requests row locks for get and set operations. When `innodb_api_disable_rowlock` is set to `ON`, `memcached` requests a table lock instead of row locks.

The `innodb_api_disable_rowlock` option is not dynamic. It must be specified on the `mysqld` command line or entered in the MySQL configuration file. Configuration takes effect when the plugin is installed, which you do each time the MySQL server is started.

- `innodb_api_enable_binlog`

<b>Command-Line Format</b>	<code>--innodb_api_enable_binlog=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_api_enable_binlog</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Lets you use the `InnoDB memcached` plugin with the MySQL `binary log`. See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option.

- `innodb_api_enable_md1`

<b>Command-Line Format</b>	<code>--innodb_api_enable_md1=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_api_enable_md1</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Locks the table used by the `InnoDB memcached` plugin, so that it cannot be dropped or altered by `DDL` through the SQL interface. See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option.

- `innodb_api_trx_level`

<b>Command-Line Format</b>	<code>--innodb_api_trx_level=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_api_trx_level</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>0</code>

Lets you control the transaction `isolation level` on queries processed by the `memcached` interface. See [Section 14.17, “InnoDB Integration with memcached”](#) for usage details for this option. The constants corresponding to the familiar names are:

- 0 = `READ UNCOMMITTED`
- 1 = `READ COMMITTED`
- 2 = `REPEATABLE READ`
- 3 = `SERIALIZABLE`
- `innodb_autoextend_increment`

<b>Command-Line Format</b>	<code>--innodb_autoextend_increment=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_autoextend_increment</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	64
	<b>Min Value</b>	1
	<b>Max Value</b>	1000

The increment size (in MB) for extending the size of an auto-extend [InnoDB system tablespace](#) file when it becomes full. The default value is 64. This variable does not affect file-per-table (`.ibd`) data files that are created if you use `innodb_file_per_table=1`, or general tablespace `.ibd` data files. Those files are auto-extending regardless of the value of `innodb_autoextend_increment`. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- `innodb_autoinc_lock_mode`

<b>Command-Line Format</b>	<code>--innodb_autoinc_lock_mode=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_autoinc_lock_mode</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	1
	<b>Valid Values</b>	0
		1
2		

The [lock mode](#) to use for generating [auto-increment](#) values. The permissible values are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively. [Section 14.5.5, “AUTO\\_INCREMENT Handling in InnoDB”](#), describes the characteristics of these modes.

This variable has a default of 1 (“consecutive” lock mode).

- `innodb_background_drop_list_empty`

<b>Introduced</b>	5.7.10
-------------------	--------

<b>Command-Line Format</b>	<code>--innodb_background_drop_list_empty=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_background_drop_list_empty</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Enabling the `innodb_background_drop_list_empty` debug option helps avoid test case failures by delaying table creation until the background drop list is empty. For example, if test case A places table `t1` on the background drop list, test case B waits until the background drop list is empty before creating table `t1`.

- `innodb_buffer_pool_chunk_size`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_buffer_pool_chunk_size</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_chunk_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	134217728
	<b>Min Value</b>	1048576
	<b>Max Value</b>	<code>innodb_buffer_pool_size / innodb_buffer_pool_instances</code>

`innodb_buffer_pool_chunk_size` defines the chunk size for online InnoDB buffer pool resizing operations.

As of MySQL 5.7.5, the `innodb_buffer_pool_size` parameter is dynamic, which allows you to resize the buffer pool without restarting the server. To avoid copying all buffer pool pages during resizing operations, the operation is performed in “chunks”. Chunk size is defined by `innodb_buffer_pool_chunk_size`. By default, `innodb_buffer_pool_chunk_size` is 128MB (134217728 bytes). The number of pages contained in a chunk depends on the value of `innodb_page_size`. `innodb_buffer_pool_chunk_size` can be increased or decreased in units of 1MB (1048576 bytes).

The following conditions apply when altering the `innodb_buffer_pool_chunk_size` value:

- If `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.
- Buffer pool size must always be a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than current buffer pool size. The adjustment occurs when the buffer pool is initialized.

**Important**

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can automatically increase the size of the buffer pool. Before you change `innodb_buffer_pool_chunk_size`, calculate the effect it will have on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

See [Section 14.3.3.7, “Resizing the InnoDB Buffer Pool Online”](#) for more information.

- `innodb_buffer_pool_dump_at_shutdown`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_dump_at_shutdown=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_dump_at_shutdown</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Specifies whether to record the pages cached in the InnoDB [buffer pool](#) when the MySQL server is shut down, to shorten the [warmup](#) process at the next restart. Typically used in combination with `innodb_buffer_pool_load_at_startup`. The `innodb_buffer_pool_dump_pct` option defines the percentage of most recently used buffer pool pages to dump.

Both `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` are enabled by default as of MySQL 5.7.7.

For related information, see [Section 14.3.3.5, “Preloading the InnoDB Buffer Pool for Faster Restart”](#).

- `innodb_buffer_pool_dump_now`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_dump_now=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_dump_now</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Immediately records the pages cached in the InnoDB [buffer pool](#). Typically used in combination with `innodb_buffer_pool_load_now`.

For related information, see [Section 14.3.3.5, “Preloading the InnoDB Buffer Pool for Faster Restart”](#).

- `innodb_buffer_pool_dump_pct`

<b>Introduced</b>	5.7.2	
<b>Command-Line Format</b>	<code>--innodb_buffer_pool_dump_pct=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_dump_pct</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	100
	<b>Min Value</b>	1
	<b>Max Value</b>	100
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	25
	<b>Min Value</b>	1
	<b>Max Value</b>	100

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100. Prior to MySQL 5.7.7, the default value is 100 (dump all pages). As of MySQL 5.7.7, the default value is 25. For example, if there are 4 buffer pools with 100 pages each, and `innodb_buffer_pool_dump_pct` is set to 25, the 25 most recently used pages from each buffer pool are dumped.

The change to the `innodb_buffer_pool_dump_pct` default value in MySQL 5.7.7 coincides with default value changes for `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup`, which are both enabled by default as of MySQL 5.7.7.

- `innodb_buffer_pool_filename`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_filename=file</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_filename</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>file name</code>
	<b>Default</b>	<code>ib_buffer_pool</code>

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`. Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is located in the `InnoDB` data directory.

For related information, see [Section 14.3.3.5, “Preloading the InnoDB Buffer Pool for Faster Restart”](#).

- `innodb_buffer_pool_instances`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_instances=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_instances</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b> (Windows, 32-bit platforms)	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>(autosized)</code>
	<b>Min Value</b>	1
	<b>Max Value</b>	64
<b>Permitted Values (Other)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	8 (or 1 if <code>innodb_buffer_pool_size &lt; 1GB</code> )
	<b>Min Value</b>	1
	<b>Max Value</b>	64

The number of regions that the [InnoDB buffer pool](#) is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, [flush lists](#), [LRUs](#), and all other data structures connected to a buffer pool, and is protected by its own buffer pool [mutex](#).

This option takes effect only when you set the `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

The default value in on 32-bit Windows systems depends on the value of `innodb_buffer_pool_size`, as described below:

- If `innodb_buffer_pool_size` is greater than 1.3GB, the default for `innodb_buffer_pool_instances` is `innodb_buffer_pool_size/128MB`, with individual memory allocation requests for each chunk. 1.3GB was chosen as the boundary at which there is significant risk for 32-bit Windows to be unable to allocate the contiguous address space needed for a single buffer pool.
- Otherwise, the default is 1.

On all other platforms, the default value is 8 when `innodb_buffer_pool_size` is greater than or equal to 1GB. Otherwise, the default is 1.

- `innodb_buffer_pool_load_abort`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_load_abort=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_load_abort</code>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Interrupts the process of restoring InnoDB [buffer pool](#) contents triggered by `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`.

For related information, see [Section 14.3.3.5, “Preloading the InnoDB Buffer Pool for Faster Restart”](#).

- `innodb_buffer_pool_load_at_startup`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_load_at_startup=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_load_at_startup</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Specifies that, on MySQL server startup, the InnoDB [buffer pool](#) is automatically [warmed up](#) by loading the same pages it held at an earlier time. Typically used in combination with `innodb_buffer_pool_dump_at_shutdown`.

Both `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` are enabled by default as of MySQL 5.7.7.

For related information, see [Section 14.3.3.5, “Preloading the InnoDB Buffer Pool for Faster Restart”](#).

- `innodb_buffer_pool_load_now`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_load_now=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_buffer_pool_load_now</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Immediately [warms up](#) the [InnoDB buffer pool](#) by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

For related information, see [Section 14.3.3.5, “Preloading the InnoDB Buffer Pool for Faster Restart”](#).

- `innodb_buffer_pool_size`

<b>Command-Line Format</b>	<code>--innodb_buffer_pool_size=#</code>	
----------------------------	--	--

<b>System Variable (&lt;= 5.7.4)</b>	<b>Name</b>	<code>innodb_buffer_pool_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>System Variable (&gt;= 5.7.5)</b>	<b>Name</b>	<code>innodb_buffer_pool_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (32-bit platforms)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	134217728
	<b>Min Value</b>	5242880
	<b>Max Value</b>	$2^{32}-1$
<b>Permitted Values (64-bit platforms)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	134217728
	<b>Min Value</b>	5242880
	<b>Max Value</b>	$2^{64}-1$

The size in bytes of the [buffer pool](#), the memory area where [InnoDB](#) caches table and index data. The default value is 128MB. The maximum value depends on the CPU architecture; the maximum is 4294967295 ( $2^{32}-1$ ) on 32-bit systems and 18446744073709551615 ( $2^{64}-1$ ) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting `innodb_buffer_pool_instances` to a value greater than 1 can improve the scalability on a busy server.

The larger you set the `innodb_buffer_pool_size` value, the less disk I/O is needed to access the same data in tables more than once. On a dedicated database server, you might set this to up to 80% of the machine physical memory size. Be prepared to scale back this value if these other issues occur:

- Competition for physical memory might cause paging in the operating system.
- [InnoDB](#) reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified size.
- The address space must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On large installations, this initialization time might be significant. For example, on a modern Linux x86\_64 server, initialization of a 10GB buffer pool takes approximately 6 seconds. See [Section 8.10.1, “The InnoDB Buffer Pool”](#).

As of MySQL 5.7.5, `innodb_buffer_pool_size` can be set dynamically, which allows you to resize the buffer pool without restarting the server. The resizing operation is performed chunks. Chunk size is configurable using the `innodb_buffer_pool_chunk_size` configuration option. The `innodb_buffer_pool_resize_status` status variable reports the status of the resizing operation. See [Section 14.3.3.7, “Resizing the InnoDB Buffer Pool Online”](#) for more information.

- `innodb_change_buffer_max_size`

<b>Command-Line Format</b>	<code>--innodb_change_buffer_max_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_change_buffer_max_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>25</code>
	<b>Min Value</b>	<code>0</code>
	<b>Max Value</b>	<code>50</code>

Maximum size for the InnoDB [change buffer](#), as a percentage of the total size of the [buffer pool](#). You might increase this value for a MySQL server with heavy insert, update, and delete activity, or decrease it for a MySQL server with unchanging data used for reporting. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_change_buffering`

<b>Command-Line Format</b>	<code>--innodb_change_buffering=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_change_buffering</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>all</code>
	<b>Valid Values</b>	<code>none</code>
		<code>inserts</code>
		<code>deletes</code>
		<code>changes</code>
<code>purges</code>		
<code>all</code>		

Whether InnoDB performs [change buffering](#), an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. The permitted values are described in the following table. For more information, see [Section 14.3.5, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

**Table 14.10 Permitted Values for `innodb_change_buffering`**

Value	Description
<code>none</code>	Do not buffer any operations.
<code>inserts</code>	Buffer insert operations.
<code>deletes</code>	Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation.
<code>changes</code>	Buffer inserts and delete-marking operations.

Value	Description
<code>purges</code>	Buffer the physical deletion operations that happen in the background.
<code>all</code>	The default. Buffer inserts, delete-marking operations, and purges.

- `innodb_change_buffering_debug`

<b>Command-Line Format</b>	<code>--innodb_change_buffering_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_change_buffering_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>0</code>
	<b>Max Value</b>	<code>2</code>

Sets a debug flag for InnoDB change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes a crash at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_checksum_algorithm`

<b>Command-Line Format</b>	<code>--innodb_checksum_algorithm=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_checksum_algorithm</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>innodb</code>
	<b>Valid Values</b>	<code>innodb</code>
		<code>crc32</code>
		<code>none</code>
		<code>strict_innodb</code>
<code>strict_crc32</code>		
<code>strict_none</code>		
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>crc32</code>
	<b>Valid Values</b>	<code>innodb</code>
		<code>crc32</code>
		<code>none</code>
		<code>strict_innodb</code>
<code>strict_crc32</code>		
<code>strict_none</code>		

Specifies how to generate and verify the `checksum` stored in each disk block of each `InnoDB` `tablespace`.

The default value for `innodb_checksum_algorithm` was changed from `innodb` to `crc32` in MySQL 5.6.6, but switched back to `innodb` in 5.6.7 for improved compatibility of `InnoDB` data files during a downgrade to an earlier MySQL version, and for use with `MySQL Enterprise Backup`. The limitations encountered included:

- `.ibd` files containing CRC32 checksums could cause problems downgrading to MySQL versions prior to 5.6.3. MySQL 5.6.3 and up recognizes either the new or old checksum values for the block as correct when reading the block from disk, ensuring that data blocks are compatible during upgrade and downgrade regardless of the algorithm setting. If data written with new checksum values is processed by a level of MySQL earlier than 5.6.3, it could be reported as corrupted.
- Versions of `MySQL Enterprise Backup` up to 3.8.0 do not support backing up tablespaces that use CRC32 checksums. `MySQL Enterprise Backup` adds CRC32 checksum support in 3.8.1, with some limitations. Refer to the `MySQL Enterprise Backup` 3.8.1 Change History for more information.

As of MySQL 5.7.7, `crc32` is once again the default value for `innodb_checksum_algorithm`.

`innodb_checksum_algorithm` replaced the `innodb_checksums` option in MySQL 5.6.3. The following values were provided for compatibility, up to and including MySQL 5.7.6:

- `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=innodb`.
- `innodb_checksums=OFF` is the same as `innodb_checksum_algorithm=none`.

As of MySQL 5.7.7, with a default `innodb_checksum_algorithm` value of `crc32`, `innodb_checksums=ON` is now the same as `innodb_checksum_algorithm=crc32`. `innodb_checksums=OFF` is still the same as `innodb_checksum_algorithm=none`.

To avoid conflicts, remove references to `innodb_checksums` from your configuration file and MySQL startup scripts.

The value `innodb` is backward-compatible with all versions of MySQL. The value `crc32` uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 32 bits at a time, which is faster the `innodb` checksum algorithm, which scans blocks 8 bits at a time. The value `none` writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablespace can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once any blocks in a tablespace are modified to use the `crc32` algorithm, the associated tables cannot be read by earlier versions of MySQL.

The `strict_*` forms work the same as `innodb`, `crc32`, and `none`, except that `InnoDB` halts if it encounters a mix of checksum values in the same tablespace. You can only use these options in a completely new instance, to set up all tablespaces for the first time. The `strict_*` settings are somewhat faster, because they do not need to compute both new and old checksum values to accept both during disk reads.

#### Note

As of MySQL 5.7.8, `InnoDB` no longer halts if it encounters a *valid* non-matching checksum. Instead, a message is printed to the error log and the page is accepted as valid if it matches an `innodb`, `crc32` or `none` checksum.

The following table illustrates the difference between the `none`, `innodb`, and `crc32` option values, and their `strict_*` counterparts. `none`, `innodb`, and `crc32` write the specified type checksum value

into each data block, but for compatibility accept any of the other checksum values when verifying a block during a read operation. The `strict_` form of each parameter only recognizes one kind of checksum, which makes verification faster but requires that all InnoDB data files in an instance be created under the identical `innodb_checksum_algorithm` value.

**Table 14.11 Allowed Settings for `innodb_checksum_algorithm`**

Value	Generated checksum (when writing)	Allowed checksums (when reading)
none	A constant number.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
crc32	A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
strict_none	A constant number	Only the checksum generated by <code>none</code> .
strict_innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Only the checksum generated by <code>innodb</code> .
strict_crc32	A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist.	Only the checksum generated by <code>crc32</code> .

- `innodb_checksums`

<b>Deprecated</b>	5.6.3	
<b>Command-Line Format</b>	<code>--innodb_checksums</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_checksums</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

InnoDB can use `checksum` validation on all tablespace pages read from the disk to ensure extra fault tolerance against hardware faults or corrupted data files. This validation is enabled by default. Under specialized circumstances (such as when running benchmarks) this extra safety feature can be disabled with `--skip-innodb-checksums`. You can specify the method of calculating the checksum with `innodb_checksum_algorithm`.

In MySQL 5.6.3 and higher, `innodb_checksums` is deprecated, replaced by `innodb_checksum_algorithm`.

Prior to MySQL 5.7.7, `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=innodb`. As of MySQL 5.7.7, the `innodb_checksum_algorithm` default value is `crc32`, and `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=crc32`. `innodb_checksums=OFF` is the same as `innodb_checksum_algorithm=none`.

It is recommended that you remove any `innodb_checksums` options from your configuration files and startup scripts, to avoid conflicts with `innodb_checksum_algorithm`.

`innodb_checksums=OFF` automatically sets `innodb_checksum_algorithm=none`.  
`innodb_checksums=ON` is ignored and overridden by any other setting for `innodb_checksum_algorithm`.

- `innodb_cmp_per_index_enabled`

<b>Command-Line Format</b>	<code>--innodb_cmp_per_index_enabled=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_cmp_per_index_enabled</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF
	<b>Valid Values</b>	OFF
		ON

Enables per-index compression-related statistics in the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because these statistics can be expensive to gather, only enable this option on development, test, or slave instances during performance tuning related to [InnoDB compressed](#) tables.

- `innodb_commit_concurrency`

<b>Command-Line Format</b>	<code>--innodb_commit_concurrency=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_commit_concurrency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	1000

The number of [threads](#) that can [commit](#) at the same time. A value of 0 (the default) permits any number of [transactions](#) to commit simultaneously.

The value of `innodb_commit_concurrency` cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- `innodb_compress_debug`

<b>Introduced</b>	5.7.8	
<b>Command-Line Format</b>	<code>--innodb_compress_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_compress_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	none
	<b>Valid Values</b>	none
		zlib
lz4		
		lz4hc

Compresses all tables using a specified compression algorithm without having to define a `COMPRESSION` attribute for each table. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_compression_failure_threshold_pct`

<b>Command-Line Format</b>	<code>--innodb_compression_failure_threshold_pct=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_compression_failure_threshold_pct</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	5
	<b>Min Value</b>	0
	<b>Max Value</b>	100

Sets the cutoff point at which MySQL begins adding padding within `compressed` pages to avoid expensive `compression failures`. A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

For more information, see [Section 14.6.1.6, “Compression for OLTP Workloads”](#).

- `innodb_compression_level`

<b>Command-Line Format</b>	<code>--innodb_compression_level=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_compression_level</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	6
	<b>Min Value</b>	0
	<b>Max Value</b>	9

Specifies the level of zlib compression to use for `InnoDB compressed` tables and indexes.

For more information, see [Section 14.6.1.6, “Compression for OLTP Workloads”](#).

- `innodb_compression_pad_pct_max`

<b>Command-Line Format</b>	<code>--innodb_compression_pad_pct_max=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_compression_pad_pct_max</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	50
	<b>Min Value</b>	0
	<b>Max Value</b>	75

Specifies the maximum percentage that can be reserved as free space within each compressed page, allowing room to reorganize the data and modification log within the page when a compressed table or index is updated and the data might be recompressed. Only applies when `innodb_compression_failure_threshold_pct` is set to a non-zero value, and the rate of compression failures passes the cutoff point.

For more information, see [Section 14.6.1.6, “Compression for OLTP Workloads”](#).

- `innodb_concurrency_tickets`

<b>Command-Line Format</b>	<code>--innodb_concurrency_tickets=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_concurrency_tickets</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	5000
	<b>Min Value</b>	1
	<b>Max Value</b>	4294967295

Determines the number of threads that can enter InnoDB concurrently. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is permitted to enter InnoDB, it is given a number of “free tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave InnoDB freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter InnoDB. The default value is 5000.

With a small `innodb_concurrency_tickets` value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small `innodb_concurrency_tickets` value is that large transactions must loop through the queue many times before they can complete, which extends the length of time required to complete their task.

With a large `innodb_concurrency_tickets` value, large transactions spend less time waiting for a position at the end of the queue (controlled by `innodb_thread_concurrency`) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their

task. The disadvantage of a large `innodb_concurrency_tickets` value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a non-zero `innodb_thread_concurrency` value, you may need to adjust the `innodb_concurrency_tickets` value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the `TRX_CONCURRENCY_TICKETS` column of the `INFORMATION_SCHEMA.INNODB_TRX` table.

For more information, see [Section 14.3.6, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_create_intrinsic`

<b>Introduced</b>	5.7.5	
<b>Removed</b>	5.7.6	
<b>Command-Line Format</b>	<code>--innodb_create_intrinsic=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_create_intrinsic</code>
	<b>Variable Scope</b>	Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

When `innodb_create_intrinsic` is enabled, `CREATE TEMPORARY TABLE` creates “optimized temporary tables” instead of normal temporary tables.

An optimized temporary table is a lightweight subclass of temporary table that excludes certain functionality and benefits from optimizations that makes it faster than a normal temporary table. Like normal temporary tables, optimized temporary tables are only visible to the current connection, and are dropped when the connection is terminated. Unlike normal temporary tables, optimized temporary tables are operational when `InnoDB` is in read-only mode.

Row format `COMPRESSED` is not supported. If you attempt to create a compressed optimized temporary table, the `innodb_create_intrinsic=ON` setting is ignored and `InnoDB` creates a normal temporary table.

Optimized temporary table metadata is not available in the `INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO` table.

Undo logging is disabled for optimized temporary tables, which means that rollback is also not supported.

Atomicity for optimized temporary tables is supported at the row-level, not at the statement level.

Statistics generated by the same workload may differ for intrinsic temporary tables compared to normal temporary tables, as optimized temporary tables may use a different algorithm to complete certain types of operations.

`innodb_create_intrinsic` was removed in MySQL 5.7.6.

- `innodb_data_file_path`

<b>Command-Line Format</b>	<code>--innodb_data_file_path=name</code>
----------------------------	---

<b>System Variable</b>	<b>Name</b>	<code>innodb_data_file_path</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>ibdata1:12M:autoextend</code>

The paths to individual [InnoDB data files](#) and their sizes. The full directory path to each data file is formed by concatenating `innodb_data_home_dir` to each path specified here. The file sizes are specified KB, MB or GB (1024MB) by appending `K`, `M` or `G` to the size value. If specifying data file size in kilobytes (KB), do so in multiples of 1024. Otherwise, KB values are rounded off to nearest megabyte (MB) boundary. The sum of the sizes of the files must be at least slightly larger than 10MB. If you do not specify `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on those operating systems that support big files. You can also [use raw disk partitions as data files](#). For detailed information on configuring [InnoDB tablespace](#) files, see [Section 14.3, “InnoDB Configuration”](#).

As of MySQL 5.7.8, the following minimum file sizes are enforced for the *first* system tablespace data file (`ibdata1`) to ensure that there is enough space for doublewrite buffer blocks (Bug #20972309):

- For an `innodb_page_size` value of 16KB or less, the minimum data file size is 3MB.
- For an `innodb_page_size` value of 32KB, the minimum data file size is 6MB.
- For an `innodb_page_size` value of 64KB, the minimum data file size is 12MB.
- `innodb_data_home_dir`

<b>Command-Line Format</b>	<code>--innodb_data_home_dir=dir_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_data_home_dir</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>directory name</code>

The common part of the directory path for all [InnoDB data files](#) in the [system tablespace](#). This setting does not affect the location of [file-per-table](#) tablespaces when `innodb_file_per_table` is enabled. The default value is the MySQL `data` directory. If you specify the value as an empty string, you can use absolute file paths in `innodb_data_file_path`.

- `innodb_default_row_format`

<b>Introduced</b>	5.7.9	
<b>Command-Line Format</b>	<code>--innodb_default_row_format=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_default_row_format</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>enumeration</code>

	<b>Default</b>	DYNAMIC
	<b>Valid Values</b>	DYNAMIC
		COMPACT
		REDUNDANT

The `innodb_default_row_format` option, introduced in MySQL 5.7.9, defines the default row format for InnoDB tables (including user-created InnoDB temporary tables). The default setting is `DYNAMIC`. Other permitted values are `COMPACT` and `REDUNDANT`. The `COMPRESSED` row format, which is not supported for use in the system tablespace, cannot be defined as the default.

Newly created tables use the row format defined by `innodb_default_row_format` when a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used.

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`. For more information, see [Section 14.8.2, “Specifying the Row Format for a Table”](#).

Internal InnoDB temporary tables created by the server to process queries use the `DYNAMIC` row format, regardless of the `innodb_default_row_format` setting.

In MySQL 5.7.8 and earlier, the default row format is `COMPACT`.

- `innodb_disable_sort_file_cache`

<b>Command-Line Format</b>	<code>--innodb_disable_sort_file_cache=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_disable_sort_file_cache</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

If enabled, this variable disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of `O_DIRECT`.

- `innodb_disable_resize_buffer_pool_debug`

<b>Introduced</b>	5.7.6	
<b>Command-Line Format</b>	<code>--innodb_disable_resize_buffer_pool_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_disable_resize_buffer_pool_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Disables resizing of the InnoDB buffer pool. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_doublewrite`

## InnoDB System Variables

<b>Command-Line Format</b>	<code>--innodb-doublewrite</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_doublewrite</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

If this variable is enabled (the default), InnoDB stores all data twice, first to the `doublewrite` buffer, then to the actual `data files`. This variable can be turned off with `--skip-innodb_doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

- `innodb_fast_shutdown`

<b>Command-Line Format</b>	<code>--innodb_fast_shutdown[=#]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_fast_shutdown</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>1</code>
	<b>Valid Values</b>	<code>0</code>
		<code>1</code>
	<code>2</code>	

The InnoDB shutdown mode. If the value is 0, InnoDB does a `slow shutdown`, a full `purge` and a change buffer merge before shutting down. If the value is 1 (the default), InnoDB skips these operations at shutdown, a process known as a `fast shutdown`. If the value is 2, InnoDB flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the `crash recovery` operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- `innodb_fil_make_page_dirty_debug`

<b>Command-Line Format</b>	<code>--innodb_fil_make_page_dirty_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_fil_make_page_dirty_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>

	<b>Default</b>	0
	<b>Max Value</b>	2**32-1

By default, setting `innodb_fil_make_page_dirty_debug` to the ID of a tablespace immediately dirties the first page of the tablespace. If `innodb_saved_page_number_debug` is set to a non-default value, setting `innodb_fil_make_page_dirty_debug` dirties the specified page. The `innodb_fil_make_page_dirty_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_file_format`

<b>Deprecated</b>	5.7.7	
<b>Command-Line Format</b>	<code>--innodb_file_format=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_file_format</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	string
	<b>Default</b>	Antelope
	<b>Valid Values</b>	Antelope Barracuda
<b>Permitted Values (&gt;= 5.7.7)</b>	<b>Type</b>	string
	<b>Default</b>	Barracuda
	<b>Valid Values</b>	Antelope Barracuda

The `file format` to use for new InnoDB tables. Currently, `Antelope` and `Barracuda` are supported. This setting only applies to tables that have their own `file-per-table tablespace`, so for it to have an effect, `innodb_file_per_table` must be enabled. The `Barracuda` file format is required to use `Compressed` or `Dynamic` row formats and associated features such as `compression`, off-page storage for large variable-length columns, and large index key prefixes (see `innodb_large_prefix`). This restriction does not apply to tables stored in general tablespaces. For more information, see [Section 14.4.9, “InnoDB General Tablespaces”](#).

Be aware that `ALTER TABLE` operations that recreate InnoDB tables (`ALGORITHM=COPY`) in file-per-table tablespaces will use the current `innodb_file_format` setting (the conditions outlined above still apply).

The `innodb_file_format` default value was changed to `Barracuda` in MySQL 5.7.7. This change allows `Compressed` or `Dynamic` row formats to be used for tables stored in file-per-table tablespaces.

The `innodb_file_format` option is also deprecated in MySQL 5.7.7, and will be removed in a future release. The purpose of the `innodb_file_format` option was to allow users to downgrade to the built-in version of InnoDB in MySQL 5.1. Now that MySQL 5.1 has reached the end of its product lifecycle, downgrade support provided by this option is no longer necessary.

- `innodb_file_format_check`

<b>Deprecated</b>	5.7.7	
<b>Command-Line Format</b>	<code>--innodb file format check=#</code>	

<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_file_format_check</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

This variable can be set to 1 or 0 at server startup to enable or disable whether InnoDB checks the [file format](#) tag in the [system tablespace](#) (for example, [Antelope](#) or [Barracuda](#)). If the tag is checked and is higher than that supported by the current version of InnoDB, an error occurs and InnoDB does not start. If the tag is not higher, InnoDB sets the value of [innodb\\_file\\_format\\_max](#) to the file format tag.

**Note**

Despite the default value sometimes being displayed as `ON` or `OFF`, always use the numeric values 1 or 0 to turn this option on or off in your configuration file or command line.

The [innodb\\_file\\_format\\_check](#) option is deprecated in MySQL 5.7.7 together with the [innodb\\_file\\_format](#) option. Both options will be removed in a future release.

- [innodb\\_file\\_format\\_max](#)

<b>Deprecated</b>	5.7.7	
<b>Command-Line Format</b>	<code>--innodb_file_format_max=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_file_format_max</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	<a href="#">Antelope</a>
	<b>Valid Values</b>	<a href="#">Antelope</a> <a href="#">Barracuda</a>

At server startup, InnoDB sets the value of this variable to the [file format](#) tag in the [system tablespace](#) (for example, [Antelope](#) or [Barracuda](#)). If the server creates or opens a table with a “higher” file format, it sets the value of [innodb\\_file\\_format\\_max](#) to that format.

The [innodb\\_file\\_format\\_max](#) option is deprecated in MySQL 5.7.7 together with the [innodb\\_file\\_format](#) option. Both options will be removed in a future release.

- [innodb\\_file\\_per\\_table](#)

<b>Command-Line Format</b>	<code>--innodb_file_per_table</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_file_per_table</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean

	<b>Default</b>	ON
--	----------------	----

When `innodb_file_per_table` is enabled (the default in 5.6.6 and higher), InnoDB stores the data and indexes for each newly created table in a separate `.ibd file`, rather than in the system tablespace. The storage for these InnoDB tables is reclaimed when the tables are dropped or truncated. This setting enables several other InnoDB features, such as table [compression](#). See [Section 14.4.4, “InnoDB File-Per-Table Tablespaces”](#) for details about such features as well as advantages and disadvantages of using per-table tablespaces.

Be aware that enabling `innodb_file_per_table` also means that an `ALTER TABLE` operation will move InnoDB table from the system tablespace to an individual `.ibd file` in cases where `ALTER TABLE` recreates the table (`ALGORITHM=COPY`). An exception to this rule is for tables that were placed in the system tablespace using the `TABLESPACE=innodb_system` option with `CREATE TABLE` or `ALTER TABLE`. These tables are unaffected by the `innodb_file_per_table` setting and can only be moved to file-per-table tablespaces using `ALTER TABLE ... TABLESPACE=innodb_file_per_table`.

When `innodb_file_per_table` is disabled, InnoDB stores the data for all tables and indexes in the `ibdata files` that make up the [system tablespace](#). This setting reduces the performance overhead of filesystem operations for operations such as `DROP TABLE` or `TRUNCATE TABLE`. It is most appropriate for a server environment where entire storage devices are devoted to MySQL data. Because the system tablespace never shrinks, and is shared across all databases in an [instance](#), avoid loading huge amounts of temporary data on a space-constrained system when `innodb_file_per_table=OFF`. Set up a separate instance in such cases, so that you can drop the entire instance to reclaim the space.

By default, `innodb_file_per_table` is enabled as of MySQL 5.6.6, disabled before that. Consider disabling it if backward compatibility with MySQL 5.5 or 5.1 is a concern. This will prevent `ALTER TABLE` from moving InnoDB tables from the system tablespace to individual `.ibd files`.

`innodb_file_per_table` is dynamic and can be set `ON` or `OFF` using `SET GLOBAL`. You can also set this parameter in the MySQL [configuration file](#) (`my.cnf` or `my.ini`) but this requires shutting down and restarting the server.

Dynamically changing the value of this parameter requires the `SUPER` privilege and immediately affects the operation of all connections.

- `innodb_fill_factor`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_fill_factor=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_fill_factor</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	100
	<b>Min Value</b>	10
	<b>Max Value</b>	100

As of MySQL 5.7.5, InnoDB performs a bulk load when creating or rebuilding indexes. This method of index creation is known as a “sorted index build”.

`innodb_fill_factor` defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. For example, setting `innodb_fill_factor` to 80 reserves 20 percent of the space on each B-tree page for future index growth. Actual percentages may vary. The `innodb_fill_factor` setting is interpreted as a hint rather than a hard limit.

As of MySQL 5.7.8, an `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth (MySQL Bug #74325).

`innodb_fill_factor` applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for `TEXT` or `BLOB` entries.

For more information, see [Section 14.2.7.8, “Sorted Index Builds”](#).

- `innodb_flush_log_at_timeout`

<b>System Variable</b>	<b>Name</b>	<code>innodb_flush_log_at_timeout</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	1
	<b>Min Value</b>	1
	<b>Max Value</b>	2700

Write and flush the logs every *N* seconds. `innodb_flush_log_at_timeout` was introduced in MySQL 5.6.6. It allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. Prior to MySQL 5.6.6, flushing frequency was once per second. The default setting for `innodb_flush_log_at_timeout` is also once per second.

- `innodb_flush_log_at_trx_commit`

<b>Command-Line Format</b>	<code>--innodb_flush_log_at_trx_commit[=#]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_flush_log_at_trx_commit</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	1
	<b>Valid Values</b>	0
		1
	2	

Controls the balance between strict `ACID` compliance for `commit` operations, and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value, but then you can lose up to a second of transactions in a crash.

- The default value of 1 is required for full ACID compliance. With this value, the contents of the [InnoDB log buffer](#) are written out to the [log file](#) at each transaction commit and the log file is [flushed](#) to disk.
- With a value of 0, the contents of the [InnoDB log buffer](#) are written to the log file approximately once per second and the log file is flushed to disk. No writes from the log buffer to the log file are performed at transaction commit. Once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions with any `mysqld` process crash.
- With a value of 2, the contents of the [InnoDB log buffer](#) are written to the log file after each transaction commit and the log file is flushed to disk approximately once per second. Once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions in an operating system crash or a power outage.
- As of MySQL 5.6.6, [InnoDB log flushing frequency](#) is controlled by `innodb_flush_log_at_timeout`, which allows you to set log flushing frequency to *N* seconds (where *N* is 1 ... 2700, with a default value of 1). However, any `mysqld` process crash can erase up to *N* seconds of transactions.
- DDL changes and other internal [InnoDB](#) activities flush the [InnoDB log](#) independent of the `innodb_flush_log_at_trx_commit` setting.
- [InnoDB's crash recovery](#) works regardless of the `innodb_flush_log_at_trx_commit` setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses [InnoDB](#) with transactions:

- If binary logging is enabled, set `sync_binlog=1`.
- Always set `innodb_flush_log_at_trx_commit=1`.

**Caution**

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt [InnoDB](#) data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command `hdparm` to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor.

- [innodb\\_flush\\_method](#)

<b>Command-Line Format</b>	<code>--innodb_flush_method=name</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_flush_method</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (Unix)</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>NULL</code>

	<b>Valid Values</b>	fsync O_DSYNC littlesync nosync O_DIRECT O_DIRECT_NO_FSYNC
<b>Permitted Values</b> (Windows)	<b>Type</b>	string
	<b>Default</b>	NULL
	<b>Valid Values</b>	async_unbuffered
		unbuffered

Defines the method used to flush data to the InnoDB data files and log files, which can affect I/O throughput.

If `innodb_flush_method=NULL` on a Unix-like system, the `fsync` option is used by default. If `innodb_flush_method=NULL` on Windows, the `async_unbuffered` option is used by default.

The `innodb_flush_method` options for Unix-like systems include:

- `fsync`: InnoDB uses the `fsync()` system call to flush both the data and log files. `fsync` is the default setting.
- `O_DSYNC`: InnoDB uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. InnoDB does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.
- `littlesync`: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- `nosync`: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- `O_DIRECT`: InnoDB uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.
- `O_DIRECT_NO_FSYNC`: InnoDB uses `O_DIRECT` during flushing I/O, but skips the `fsync()` system call afterwards. This setting is suitable for some types of file systems but not others. For example, it is not suitable for XFS. If you are not sure whether the file system you use requires an `fsync()`, for example to preserve all file metadata, use `O_DIRECT` instead. This option was introduced in MySQL 5.6.7 (Bug #11754304, Bug #45892).

The `innodb_flush_method` options for Windows systems include:

- `async_unbuffered`: InnoDB uses Windows asynchronous I/O and non-buffered I/O. `async_unbuffered` is the default setting on Windows systems.
- `normal`: InnoDB uses a simulated asynchronous I/O and buffered I/O.
- `unbuffered`: InnoDB uses a simulated asynchronous I/O and non-buffered I/O.

How each settings affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `InnoDB_data_fsyncs` status variable to see the overall number of `fsync()` calls for each setting. The mix of read and write operations in your workload can affect

how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the InnoDB buffer pool and the operating system's file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value or `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see [Section 8.5.8, "Optimizing InnoDB Disk I/O"](#).

- `innodb_flush_neighbors`

<b>Command-Line Format</b>	<code>--innodb_flush_neighbors</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_flush_neighbors</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	1
	<b>Valid Values</b>	0
		1
	2	

Specifies whether [flushing](#) a page from the InnoDB [buffer pool](#) also flushes other [dirty pages](#) in the same [extent](#).

- The default value of 1 flushes contiguous dirty pages in the same extent from the buffer pool.
- A setting of 0 turns `innodb_flush_neighbors` off and no other dirty pages are flushed from the buffer pool.
- A setting of 2 flushes dirty pages in the same extent from the buffer pool.

When the table data is stored on a traditional [HDD](#) storage device, flushing such [neighbor pages](#) in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on [SSD](#), seek time is not a significant factor and you can turn this setting off to spread out the write operations. For general I/O tuning advice, see [Section 8.5.8, "Optimizing InnoDB Disk I/O"](#).

- `innodb_flush_sync`

<b>Introduced</b>	5.7.8	
<b>Command-Line Format</b>	<code>--innodb_flush_sync=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_flush_sync</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

The `innodb_flush_sync` parameter, which is enabled by default, causes the `innodb_io_capacity` setting to be ignored for bursts of I/O activity that occur at [checkpoints](#). To adhere to the limit on InnoDB background I/O activity defined by the `innodb_io_capacity` setting, disable `innodb_flush_sync`.

- `innodb_flushing_avg_loops`

<b>Command-Line Format</b>	<code>--innodb_flushing_avg_loops=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_flushing_avg_loops</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>30</code>
	<b>Min Value</b>	<code>1</code>
	<b>Max Value</b>	<code>1000</code>

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly [adaptive flushing](#) responds to changing [workloads](#). Increasing the value makes the rate of [flush](#) operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

- `innodb_force_load_corrupted`

<b>Command-Line Format</b>	<code>--innodb_force_load_corrupted</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_force_load_corrupted</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Lets InnoDB load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, turn this setting back off and restart the server.

- `innodb_force_recovery`

<b>Command-Line Format</b>	<code>--innodb_force_recovery=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_force_recovery</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>0</code>
	<b>Min Value</b>	<code>0</code>
	<b>Max Value</b>	<code>6</code>

The [crash recovery](#) mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about `innodb_force_recovery`, see [Section 14.18.2, “Forcing InnoDB Recovery”](#).

**Warning**

Only set this variable to a value greater than 0 in an emergency situation, so that you can start InnoDB and dump your tables. As a safety measure, InnoDB prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. Also, as of 5.7.3, an `innodb_force_recovery` setting of 4 or greater places InnoDB into read-only mode.

These restrictions may cause replication administration commands to fail with an error, as replication options such as `--relay-log-info-repository=TABLE` and `--master-info-repository=TABLE` store information in tables in InnoDB.

- `innodb_ft_aux_table`

<b>Command-Line Format</b>	<code>--innodb_ft_aux_table=#</code> ( $\geq 5.7.2$ )	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_aux_table</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>string</code>

Specifies the qualified name of an InnoDB table containing a `FULLTEXT` index. This variable is intended for diagnostic purposes.

After you set this variable to a name in the format `db_name/table_name`, the `INFORMATION_SCHEMA` tables `INNODB_FT_INDEX_TABLE`, `INNODB_FT_INDEX_CACHE`, `INNODB_FT_CONFIG`, `INNODB_FT_DELETED`, and `INNODB_FT_BEING_DELETED` will show information about the search index for the specified table.

- `innodb_ft_cache_size`

<b>Command-Line Format</b>	<code>--innodb_ft_cache_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_cache_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	8000000
	<b>Min Value</b>	1600000
	<b>Max Value</b>	80000000

The memory allocated, in bytes, for the InnoDB `FULLTEXT` search index cache, which holds a parsed document in memory while creating an InnoDB `FULLTEXT` index. Index inserts and updates are only committed to disk when the `innodb_ft_cache_size` size limit is reached.

`innodb_ft_cache_size` defines the cache size on a per table basis. To set a global limit for all tables, see `innodb_ft_total_cache_size`.

- `innodb_ft_enable_diag_print`

<b>Command-Line Format</b>	<code>--innodb_ft_enable_diag_print=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_enable_diag_print</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and will not be of interest to most users. Output is printed to the error log and includes information such as:

- FTS index sync progress (when the FTS cache limit is reached). For example:

```
FTS SYNC for table test, deleted count: 100 size: 10000 bytes
SYNC words: 100
```

- FTS optimize progress. For example:

```
FTS start optimize test
FTS_OPTIMIZE: optimize "mysql"
FTS_OPTIMIZE: processed "mysql"
```

- FTS index build progress. For example:

```
Number of doc processed: 1000
```

- For FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:

```
FTS Search Processing time: 1 secs: 100 millisc: row(s) 10000
Full Search Memory: 245666 (bytes), Row: 10000
```

- `innodb_ft_enable_stopword`

<b>Command-Line Format</b>	<code>--innodb_ft_enable_stopword=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_enable_stopword</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Specifies that a set of [stopwords](#) is associated with an InnoDB FULLTEXT index at the time the index is created. If the `innodb_ft_user_stopword_table` option is set, the stopwords are taken from that table. Else, if the `innodb_ft_server_stopword_table` option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

- `innodb_ft_max_token_size`

<b>Command-Line Format</b>	<code>--innodb_ft_max_token_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_max_token_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	84
	<b>Min Value</b>	10
	<b>Max Value</b>	84
<b>Permitted Values (&lt;= 5.7.2)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	84
	<b>Min Value</b>	10
	<b>Max Value</b>	252
<b>Permitted Values (&gt;= 5.7.3)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	84
	<b>Min Value</b>	10
	<b>Max Value</b>	84

Maximum character length of words that are stored in an InnoDB `FULLTEXT` index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

- `innodb_ft_min_token_size`

<b>Command-Line Format</b>	<code>--innodb_ft_min_token_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_min_token_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	3
	<b>Min Value</b>	0
	<b>Max Value</b>	16

Minimum length of words that are stored in an InnoDB `FULLTEXT` index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common word that are unlikely to be significant in a search context, such as the English words “a” and “to”. For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

- `innodb_ft_num_word_optimize`

<b>Command-Line Format</b>	<code>--innodb_ft_num_word_optimize=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_num_word_optimize</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>2000</code>

Number of words to process during each `OPTIMIZE TABLE` operation on an InnoDB FULLTEXT index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of `OPTIMIZE TABLE` statements, each picking up where the last left off.

- `innodb_ft_result_cache_limit`

<b>Introduced</b>	5.7.2	
<b>Command-Line Format</b>	<code>--innodb_ft_result_cache_limit=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_result_cache_limit</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&gt;= 5.7.4)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>2000000000</code>
	<b>Min Value</b>	<code>1000000</code>
	<b>Max Value</b>	<code>2**32-1</code>
<b>Permitted Values (Unix, 32-bit platforms, &gt;= 5.7.2, &lt;= 5.7.3)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>2000000000</code>
	<b>Min Value</b>	<code>1000000</code>
	<b>Max Value</b>	<code>2**32-1</code>
<b>Permitted Values (Unix, 64-bit platforms, &gt;= 5.7.2, &lt;= 5.7.3)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>2000000000</code>
	<b>Min Value</b>	<code>1000000</code>
	<b>Max Value</b>	<code>2**64-1</code>
<b>Permitted Values (Windows, &gt;= 5.7.2, &lt;= 5.7.3)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>2000000000</code>
	<b>Min Value</b>	<code>1000000</code>

	<b>Max Value</b>	2**32-1
--	------------------	---------

The [InnoDB FULLTEXT](#) search (FTS) query result cache limit (defined in bytes) per FTS query or per thread. Intermediate and final [InnoDB](#) FTS query results are handled in memory. Use [innodb\\_ft\\_result\\_cache\\_limit](#) to place a size limit on the [InnoDB](#) FTS query result cache to avoid excessive memory consumption in case of very large [InnoDB](#) FTS query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when an FTS query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

As of MySQL 5.7.4, the maximum value of [innodb\\_ft\\_result\\_cache\\_limit](#) for all platform types and platform bit sizes is 2\*\*32-1. Bug #71554.

- [innodb\\_ft\\_server\\_stopword\\_table](#)

<b>Command-Line Format</b>	<code>--innodb_ft_server_stopword_table=db_name/table_name</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_ft_server_stopword_table</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	NULL

This option is used to specify your own [InnoDB FULLTEXT](#) index stopword list for all [InnoDB](#) tables. To configure your own stopword list for a specific [InnoDB](#) table, use [innodb\\_ft\\_user\\_stopword\\_table](#).

Set [innodb\\_ft\\_server\\_stopword\\_table](#) to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopword table must exist before you configure [innodb\\_ft\\_server\\_stopword\\_table](#). [innodb\\_ft\\_enable\\_stopword](#) must be enabled and [innodb\\_ft\\_server\\_stopword\\_table](#) option must be configured before you create the [FULLTEXT](#) index.

The stopword table must be an [InnoDB](#) table, containing a single [VARCHAR](#) column named `VALUE`.

For more information, see [Section 12.9.4, “Full-Text Stopwords”](#).

- [innodb\\_ft\\_sort\\_pll\\_degree](#)

<b>Command-Line Format</b>	<code>--innodb_ft_sort_pll_degree=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_ft_sort_pll_degree</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	2
	<b>Min Value</b>	1
	<b>Max Value</b>	32

Number of threads used in parallel to index and tokenize text in an `InnoDB FULLTEXT` index, when building a `search index`. See `innodb_sort_buffer_size` for additional usage information.

- `innodb_ft_total_cache_size`

<b>Introduced</b>	5.7.2	
<b>Command-Line Format</b>	<code>--innodb_ft_total_cache_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_total_cache_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>640000000</code>
	<b>Min Value</b>	<code>320000000</code>
	<b>Max Value</b>	<code>1600000000</code>

The total memory allocated, in bytes, for the `InnoDB FULLTEXT` search index cache for all tables. Creating numerous tables, each with a full-text search index, could consume a significant portion of available memory. `innodb_ft_total_cache_size`, defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a force sync is triggered.

- `innodb_ft_user_stopword_table`

<b>Command-Line Format</b>	<code>--innodb_ft_user_stopword_table=db_name/table_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_ft_user_stopword_table</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>string</code>
	<b>Default</b>	<code>NULL</code>

This option is used to specify your own `InnoDB FULLTEXT` index stopwords list on a specific table. To configure your own stopwords list for all `InnoDB` tables, use `innodb_ft_server_stopword_table`.

Set `innodb_ft_user_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopwords table must exist before you configure `innodb_ft_user_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_user_stopword_table` must be configured before you create the `FULLTEXT` index.

The stopwords table must be an `InnoDB` table, containing a single `VARCHAR` column named `VALUE`.

For more information, see [Section 12.9.4, “Full-Text Stopwords”](#).

- `innodb_io_capacity`

<b>Command-Line Format</b>	<code>--innodb_io_capacity=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_io_capacity</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	<code>integer</code>
	<b>Default</b>	200
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{32}-1$
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	<code>integer</code>
	<b>Default</b>	200
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{64}-1$

The `innodb_io_capacity` parameter sets an upper limit on the I/O activity performed by the InnoDB background tasks, such as flushing pages from the buffer pool and merging data from the change buffer. The default value is 200. For busy systems capable of higher I/O rates, you can set a higher value at server startup, to help the server handle the background maintenance work associated with a high rate of row changes.

The `innodb_io_capacity` limit is a total limit for all buffer pool instances. When dirty pages are flushed, the `innodb_io_capacity` limit is divided equally among buffer pool instances.

As of MySQL 5.7.2, the `innodb_io_capacity` setting is also used to limit the number of buffer pool load operations per second when there is other I/O activity being performed by InnoDB background tasks.

For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to the former default of 100.

This parameter should be set to approximately the number of I/O operations that the system can perform per second. Ideally, keep this setting as low as practical, but not so low that these background activities fall behind. If the value is too high, data is removed from the buffer pool and insert buffer too quickly to provide significant benefit from the caching.

The value represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that could perform about 100 IOPS. The current default of 200 reflects that modern storage devices are capable of much higher I/O rates.

In general, you can increase the value as a function of the number of drives used for InnoDB I/O, particularly fast drives capable of high numbers of IOPS. For example, systems that use multiple disks or solid-state disks for InnoDB are likely to benefit from the ability to control this parameter.

Although you can specify a very high number, in practice such large values have little if any benefit; for example, a value of one million would be considered very high.

You can set the `innodb_io_capacity` value to any number 100 or greater to a maximum defined by `innodb_io_capacity_max`. The default value is 200. You can set the value of this parameter

in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

The `innodb_flush_sync` configuration option, introduced in MySQL 5.7.8, causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. `innodb_flush_sync` is enabled by default.

See [Section 14.3.8, “Configuring the InnoDB Master Thread I/O Rate”](#) for more information about the `innodb_io_capacity` setting. For general information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_io_capacity_max`

<b>Command-Line Format</b>	<code>--innodb_io_capacity_max=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_io_capacity_max</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (32-bit platforms)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>see description</code>
	<b>Min Value</b>	<code>2000</code>
	<b>Max Value</b>	<code>2**32-1</code>
<b>Permitted Values (Unix, 64-bit platforms)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>see description</code>
	<b>Min Value</b>	<code>2000</code>
	<b>Max Value</b>	<code>2**64-1</code>
<b>Permitted Values (Windows, 64-bit platforms)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>2000</code>
	<b>Min Value</b>	<code>2000</code>
	<b>Max Value</b>	<code>2**32-1</code>

The limit up to which InnoDB is allowed to extend the `innodb_io_capacity` setting in case of emergency. If you specify an `innodb_io_capacity` setting at startup and do not specify a value for `innodb_io_capacity_max`, the `innodb_io_capacity_max` value defaults to twice the value of `innodb_io_capacity`, with a lower limit of 2000. 2000 is also the initial default `innodb_io_capacity_max` configuration value.

The `innodb_io_capacity_max` setting is a total limit for all buffer pool instances.

For a brief period during MySQL 5.6 development, this variable was known as `innodb_max_io_capacity`.

- `innodb_large_prefix`

<b>Deprecated</b>	<code>5.7.7</code>
<b>Command-Line Format</b>	<code>--innodb_large_prefix</code>

<b>System Variable</b>	<b>Name</b>	<code>innodb_large_prefix</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (<= 5.7.6)	<b>Type</b>	boolean
	<b>Default</b>	OFF
<b>Permitted Values</b> (>= 5.7.7)	<b>Type</b>	boolean
	<b>Default</b>	ON

When this option is enabled, index key prefixes longer than 767 bytes (up to 3072 bytes) are allowed for InnoDB tables that use the `DYNAMIC` and `COMPRESSED` row formats. See [Section 14.5.7, “Limits on InnoDB Tables”](#) for the relevant maximums associated with index key prefixes under various settings.

For tables using the `REDUNDANT` and `COMPACT` row formats, this option does not affect the allowed index key prefix length.

`innodb_large_prefix` is enabled by default in MySQL 5.7.7. This change coincides with the default value change for `innodb_file_format`, which is set to `Barracuda` by default in MySQL 5.7.7. Together, these default value changes allow larger index key prefixes to be created when using `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`. If either option is set to a non-default value, index key prefixes larger than 767 bytes are silently truncated.

`innodb_large_prefix` is deprecated in MySQL 5.7.7, and will be removed in a future release. `innodb_large_prefix` was introduced in MySQL 5.5 to allow users to disable large index key prefixes for compatibility with earlier versions of MySQL and InnoDB that do not support large index key prefixes.

- `innodb_limit_optimistic_insert_debug`

<b>Command-Line Format</b>	<code>--innodb_limit_optimistic_insert_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_limit_optimistic_insert_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	$2^{32}-1$

Limits the number of records per B-tree page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_lock_wait_timeout`

<b>Command-Line Format</b>	<code>--innodb_lock_wait_timeout=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_lock_wait_timeout</code>

	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	50
	<b>Min Value</b>	1
	<b>Max Value</b>	1073741824

The length of time in seconds an [InnoDB transaction](#) waits for a [row lock](#) before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another [InnoDB](#) transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is [rolled back](#) (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option. See also [Section 14.18.4, “InnoDB Error Handling”](#).

You might decrease this value for highly interactive applications or [OLTP](#) systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to [InnoDB](#) row locks only. A MySQL [table lock](#) does not happen inside [InnoDB](#) and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to [deadlocks](#), because [InnoDB](#) detects them immediately and rolls back one of the deadlocked transactions.

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires the `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- `innodb_locks_unsafe_for_binlog`

<b>Deprecated</b>	5.6.3	
<b>Command-Line Format</b>	<code>--innodb_locks_unsafe_for_binlog</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_locks_unsafe_for_binlog</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

This variable affects how [InnoDB](#) uses [gap locking](#) for searches and index scans. As of MySQL 5.6.3, `innodb_locks_unsafe_for_binlog` is deprecated and will be removed in a future MySQL release.

Normally, InnoDB uses an algorithm called next-key locking that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record *R* in an index, another session cannot insert a new index record in the gap immediately before *R* in the index order. See [Section 14.2.2.4, “InnoDB Record, Gap, and Next-Key Locks”](#).

By default, the value of `innodb_locks_unsafe_for_binlog` is 0 (disabled), which means that gap locking is enabled: InnoDB uses next-key locks for searches and index scans. To enable the variable, set it to 1. This causes gap locking to be disabled: InnoDB uses only index-record locks for searches and index scans.

Enabling `innodb_locks_unsafe_for_binlog` does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effect of enabling `innodb_locks_unsafe_for_binlog` is similar to but not identical to setting the transaction isolation level to `READ COMMITTED`:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.
- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`. For additional details about the effect of isolation level on gap locking, see [Section 13.3.6, “SET TRANSACTION Syntax”](#).

Enabling `innodb_locks_unsafe_for_binlog` may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session can insert a new row into the table. Consequently, if you were to execute the same `SELECT` again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, InnoDB does not guarantee serializability. Therefore, if `innodb_locks_unsafe_for_binlog` is enabled, InnoDB guarantees at most an isolation level of `READ COMMITTED`. (Conflict serializability is still guaranteed.) For additional information about phantoms, see [Section 14.2.2.5, “Avoiding the Phantom Problem Using Next-Key Locking”](#).

Enabling `innodb_locks_unsafe_for_binlog` has additional effects:

- For `UPDATE` or `DELETE` statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.
- For `UPDATE` statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 14.2.7.2, “Clustered and Secondary Indexes”](#)).

Suppose that one client performs an `UPDATE` using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an `UPDATE` by executing these statements following those of the first client:

```
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As `InnoDB` executes each `UPDATE`, it first acquires an exclusive lock for each row, and then determines whether to modify it. If `InnoDB` does not modify the row and `innodb_locks_unsafe_for_binlog` is enabled, it releases the lock. Otherwise, `InnoDB` retains the lock until the end of the transaction. This affects transaction processing as follows.

If `innodb_locks_unsafe_for_binlog` is disabled, the first `UPDATE` acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `innodb_locks_unsafe_for_binlog` is enabled, the first `UPDATE` acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, `InnoDB` does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

- `innodb_log_buffer_size`

<b>Command-Line Format</b>	<code>--innodb_log_buffer_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_log_buffer_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.5)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>8388608</code>
	<b>Min Value</b>	<code>262144</code>
	<b>Max Value</b>	<code>4294967295</code>
<b>Permitted Values (&gt;= 5.7.6)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>16777216</code>
	<b>Min Value</b>	<code>1048576</code>
	<b>Max Value</b>	<code>4294967295</code>

The size in bytes of the buffer that InnoDB uses to write to the [log files](#) on disk. The default value changed from 8MB to 16MB in 5.7.6 with the introduction of 32k and 64k `innodb_page_size` values. A large [log buffer](#) enables large [transactions](#) to run without a need to write the log to disk before the transactions [commit](#). Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_log_checksum_algorithm`

<b>Introduced</b>	5.7.8	
<b>Removed</b>	5.7.9	
<b>Command-Line Format</b>	<code>--innodb_log_checksum_algorithm=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_log_checksum_algorithm</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&gt;= 5.7.8)</b>	<b>Type</b>	<code>enumeration</code>
	<b>Default</b>	<code>innodb</code>
	<b>Valid Values</b>	<code>innodb</code>
		<code>crc32</code>
		<code>none</code>
		<code>strict_innodb</code>
<code>strict_crc32</code>		
<code>strict_none</code>		

This configuration option was removed in MySQL 5.7.9 and replaced by `innodb_log_checksums`.

Specifies how to generate and verify the [checksum](#) stored in each redo log disk block. [innodb\\_log\\_checksum\\_algorithm](#) supports same algorithms as [innodb\\_checksum\\_algorithm](#). Previously, only the [innodb](#) algorithm was supported for redo log disk blocks. [innodb\\_log\\_checksum\\_algorithm=innodb](#) is the default setting.

The [strict\\_\\*](#) forms work the same as [innodb](#), [crc32](#), and [none](#), except that InnoDB halts if it encounters a mix of checksum values in the same redo log. You can only use these options in a completely new instance. The [strict\\_\\*](#) settings are somewhat faster, because they do not need to compute both new and old checksum values to accept both during disk reads.

The following table illustrates the difference between the [none](#), [innodb](#), and [crc32](#) option values, and their [strict\\_\\*](#) counterparts. [none](#), [innodb](#), and [crc32](#) write the specified type checksum value into each data block, but for compatibility accept any of the other checksum values when verifying a block during a read operation. The [strict\\_\\*](#) form of each parameter only recognizes one kind of checksum, which makes verification faster but requires that all InnoDB redo logs in an instance be created under the identical [innodb\\_log\\_checksum\\_algorithm](#) value.

**Table 14.12 Allowed Settings for [innodb\\_log\\_checksum\\_algorithm](#)**

Value	Generated checksum (when writing)	Allowed checksums (when reading)
none	A constant number.	Any of the checksums generated by <a href="#">none</a> , <a href="#">innodb</a> , or <a href="#">crc32</a> .
innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Any of the checksums generated by <a href="#">none</a> , <a href="#">innodb</a> , or <a href="#">crc32</a> .
crc32	A checksum calculated using the <a href="#">crc32</a> algorithm, possibly done with a hardware assist.	Any of the checksums generated by <a href="#">none</a> , <a href="#">innodb</a> , or <a href="#">crc32</a> .
strict_none	A constant number	Only the checksum generated by <a href="#">none</a> .
strict_innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Only the checksum generated by <a href="#">innodb</a> .
strict_crc32	A checksum calculated using the <a href="#">crc32</a> algorithm, possibly done with a hardware assist.	Only the checksum generated by <a href="#">crc32</a> .

- [innodb\\_log\\_checksums](#)

<b>Introduced</b>	5.7.9	
<b>Command-Line Format</b>	<code>--innodb_log_checksums=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_log_checksums</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<a href="#">boolean</a>
	<b>Default</b>	ON

Enables or disables checksums for redo log pages. [innodb\\_log\\_checksums](#) replaces [innodb\\_log\\_checksum\\_algorithm](#), which was removed in MySQL 5.7.9.

`innodb_log_checksums=ON` enables the CRC-32C checksum algorithm for redo log pages. When `innodb_log_checksums` is disabled, the contents of the redo log page checksum field are ignored.

Checksums on the redo log header page and redo log checkpoint pages are never disabled.

- `innodb_log_compressed_pages`

<b>Command-Line Format</b>	<code>--innodb_log_compressed_pages=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_log_compressed_pages</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Specifies whether images of [re-compressed pages](#) are stored in [InnoDB redo logs](#).

- `innodb_log_file_size`

<b>Command-Line Format</b>	<code>--innodb_log_file_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_log_file_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.10)</b>	<b>Type</b>	integer
	<b>Default</b>	50331648
	<b>Min Value</b>	1048576
	<b>Max Value</b>	512GB / <code>innodb_log_files_in_group</code>
<b>Permitted Values (&gt;= 5.7.11)</b>	<b>Type</b>	integer
	<b>Default</b>	50331648
	<b>Min Value</b>	4194304
	<b>Max Value</b>	512GB / <code>innodb_log_files_in_group</code>

The size in bytes of each [log file](#) in a [log group](#). The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, would allow you to approach the limit but not exceed it. The default value is 48MB. Sensible values range from 1MB to 1/*N*-th of the size of the [buffer pool](#), where *N* is the number of log files in the group. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. Larger log files also make [crash recovery](#) slower, although improvements to recovery performance in MySQL 5.5 and higher make the log file size less of a consideration. For general I/O tuning advice, see [Section 8.5.8, "Optimizing InnoDB Disk I/O"](#).

- `innodb_log_files_in_group`

<b>Command-Line Format</b>	<code>--innodb_log_files_in_group=#</code>
----------------------------	--

## InnoDB System Variables

<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_log_files_in_group</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<a href="#">integer</a>
	<b>Default</b>	2
	<b>Min Value</b>	2
	<b>Max Value</b>	100

The number of [log files](#) in the [log group](#). InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2. The location of these files is specified by [innodb\\_log\\_group\\_home\\_dir](#). The combined size of log files ([innodb\\_log\\_file\\_size](#) \* [innodb\\_log\\_files\\_in\\_group](#)) can be up to 512GB.

- [innodb\\_log\\_group\\_home\\_dir](#)

<b>Command-Line Format</b>	<code>--innodb_log_group_home_dir=dir_name</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_log_group_home_dir</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<a href="#">directory name</a>

The directory path to the InnoDB [redo log](#) files, whose number is specified by [innodb\\_log\\_files\\_in\\_group](#). If you do not specify any InnoDB log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Their size is given by the size of the [innodb\\_log\\_file\\_size](#) system variable.

- [innodb\\_log\\_write\\_ahead\\_size](#)

<b>Introduced</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_log_write_ahead_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_log_write_ahead_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<a href="#">integer</a>
	<b>Default</b>	8192
	<b>Min Value</b>	512 (log file block size)
	<b>Max Value</b>	Equal to <a href="#">innodb_page_size</a>

The write-ahead block size for the redo log, in bytes. To avoid “read-on-write”, set [innodb\\_log\\_write\\_ahead\\_size](#) to match the operating system or file system cache block size. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file

system due to a mismatch between write-ahead block size for redo logs and operating system or file system cache block size.

Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size ( $2^n$ ). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to `innodb_page_size`. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` value is truncated to the `innodb_page_size` value.

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size will result in “read-on-write”. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

- `innodb_lru_scan_depth`

<b>Command-Line Format</b>	<code>--innodb_lru_scan_depth=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_lru_scan_depth</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (32-bit platforms)	<b>Type</b>	<code>integer</code>
	<b>Default</b>	1024
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{32}-1$
<b>Permitted Values</b> (64-bit platforms)	<b>Type</b>	<code>integer</code>
	<b>Default</b>	1024
	<b>Min Value</b>	100
	<b>Max Value</b>	$2^{64}-1$

A parameter that influences the algorithms and heuristics for the `flush` operation for the InnoDB buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU list the `page_cleaner` thread scans looking for `dirty pages` to flush. This is a background operation performed once a second. If you have spare I/O capacity under a typical workload, increase the value. If a write-intensive workload saturates your I/O capacity, decrease the value, especially if you have a large buffer pool. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_dirty_pages_pct`

<b>Command-Line Format</b>	<code>--innodb_max_dirty_pages_pct=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_dirty_pages_pct</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b> (<= 5.7.4)	<b>Type</b>	<code>numeric</code>
	<b>Default</b>	75

	<b>Min Value</b>	0
	<b>Max Value</b>	99
<b>Permitted Values (&gt;= 5.7.5)</b>	<b>Type</b>	numeric
	<b>Default</b>	75
	<b>Min Value</b>	0
	<b>Max Value</b>	99.99

InnoDB tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed this value. The default value is 75.

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 14.3.3.2, “Configuring the Rate of InnoDB Buffer Pool Flushing”](#).

For additional information about this variable, see [Section 14.3.3.6, “Tuning InnoDB Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_dirty_pages_pct_lwm`

<b>Command-Line Format</b>	<code>--innodb_max_dirty_pages_pct_lwm=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_dirty_pages_pct_lwm</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.4)</b>	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	99
<b>Permitted Values (&gt;= 5.7.5)</b>	<b>Type</b>	numeric
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	99.99

Low water mark representing percentage of dirty pages where preflushing is enabled to control the dirty page ratio. The default of 0 disables the pre-flushing behavior entirely. For additional information about this variable, see [Section 14.3.3.6, “Tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_max_purge_lag`

<b>Command-Line Format</b>	<code>--innodb_max_purge_lag=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_purge_lag</code>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

This variable controls how to delay `INSERT`, `UPDATE`, and `DELETE` operations when `purge` operations are lagging (see [Section 14.2.3, “InnoDB Multi-Versioning”](#)). The default value is 0 (no delays).

The InnoDB transaction system maintains a list of transactions that have index records delete-marked by `UPDATE` or `DELETE` operations. The length of this list represents the `purge_lag` value. When `purge_lag` exceeds `innodb_max_purge_lag`, each `INSERT`, `UPDATE`, and `DELETE` operation is delayed.

To prevent excessive delays in extreme situations where `purge_lag` becomes huge, you can put a cap on the amount of delay by setting the `innodb_max_purge_lag_delay` configuration option. The delay is computed at the beginning of a purge batch.

A typical setting for a problematic workload might be 1 million, assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged InnoDB table rows.

The lag value is displayed as the history list length in the `TRANSACTIONS` section of InnoDB Monitor output. For example, if the output includes the following lines, the lag value is 20:

```
-----
TRANSACTIONS
-----
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_purge_lag_delay`

<b>Command-Line Format</b>	<code>--innodb_max_purge_lag_delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_purge_lag_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	

Specifies the maximum delay in milliseconds for the delay imposed by the `innodb_max_purge_lag` configuration option. Any non-zero value represents an upper limit on

the delay period computed from the formula based on the value of `innodb_max_purge_lag`. The default of zero means that there is no upper limit imposed on the delay interval.

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_undo_log_size`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_max_undo_log_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_max_undo_log_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	1073741824
	<b>Min Value</b>	10485760
	<b>Max Value</b>	$2^{*64}-1$

`innodb_max_undo_log_size` defines a threshold size for undo tablespaces. If an undo tablespace exceeds the threshold, it can be marked for truncation when `innodb_undo_log_truncate` is enabled. The default value is 1024 MiB (1073741824 bytes).

For more information, see [Section 14.4.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_merge_threshold_set_all_debug`

<b>Introduced</b>	5.7.6	
<b>Command-Line Format</b>	<code>--innodb_merge_threshold_set_all_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_merge_threshold_set_all_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	50
	<b>Min Value</b>	1
	<b>Max Value</b>	50

Overrides the current `MERGE_THRESHOLD` setting with the specified value for all indexes that are currently in the dictionary cache. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option. For related information, see [Section 14.3.12, “Configuring the Merge Threshold for Index Pages”](#).

- `innodb_monitor_disable`

<b>Command-Line Format</b>	<code>--innodb_monitor_disable=[counter module pattern all]</code>
----------------------------	--

<b>System Variable</b>	<b>Name</b>	<code>innodb_monitor_disable</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>string</code>

Turns off one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 20.30.20](#), “The `INFORMATION_SCHEMA.INNODB_METRICS` Table”.

As of MySQL 5.7.8, `innodb_monitor_disable='latch'` disables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.5.15](#), “`SHOW ENGINE Syntax`”.

- `innodb_monitor_enable`

<b>Command-Line Format</b>	<code>--innodb_monitor_enable=[counter module pattern all]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_monitor_enable</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>string</code>

Turns on one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 20.30.20](#), “The `INFORMATION_SCHEMA.INNODB_METRICS` Table”.

As of MySQL 5.7.8, `innodb_monitor_enable='latch'` enables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.5.15](#), “`SHOW ENGINE Syntax`”.

- `innodb_monitor_reset`

<b>Command-Line Format</b>	<code>--innodb_monitor_reset=[counter module pattern all]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_monitor_reset</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>string</code>

Resets to zero the count value for one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 20.30.20](#), “The `INFORMATION_SCHEMA.INNODB_METRICS` Table”.

As of MySQL 5.7.8, `innodb_monitor_reset='latch'` resets statistics reported by `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.5.15](#), “`SHOW ENGINE Syntax`”.

- `innodb_monitor_reset_all`

<b>Command-Line Format</b>	<code>--innodb_monitor_reset_all=[counter module pattern all]</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_monitor_reset_all</code>
	<b>Variable Scope</b>	Global

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	string

Resets all values (minimum, maximum, and so on) for one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 20.30.20, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

- [innodb\\_numa\\_interleave](#)

<b>Introduced</b>	5.7.9	
<b>Command-Line Format</b>	<code>--innodb_numa_interleave=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_numa_interleave</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Enables the NUMA interleave memory policy for allocation of the [InnoDB](#) buffer pool. When [innodb\\_numa\\_interleave](#) is enabled, the NUMA memory policy is set to `MPOL_INTERLEAVE` for the `mysqld` process. After the [InnoDB](#) buffer pool is allocated, the NUMA memory policy is set back to `MPOL_DEFAULT`. For the [innodb\\_numa\\_interleave](#) option to be available, MySQL must be compiled on a NUMA-enabled system.

- [innodb\\_old\\_blocks\\_pct](#)

<b>Command-Line Format</b>	<code>--innodb_old_blocks_pct=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_old_blocks_pct</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	37
	<b>Min Value</b>	5
	<b>Max Value</b>	95

Specifies the approximate percentage of the [InnoDB](#) buffer pool used for the old block [sublist](#). The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with [innodb\\_old\\_blocks\\_time](#). See [Section 14.3.3.3, “Making the Buffer Pool Scan Resistant”](#) for more information. See [Section 8.10.1, “The InnoDB Buffer Pool”](#) for information about buffer pool management, such as the [LRU](#) algorithm and [eviction](#) policies.

- [innodb\\_old\\_blocks\\_time](#)

<b>Command-Line Format</b>	<code>--innodb_old_blocks_time=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_old_blocks_time</a>

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	1000
	<b>Min Value</b>	0
	<b>Max Value</b>	$2^{*}32-1$

Non-zero values protect against the [buffer pool](#) being filled up by data that is referenced only for a brief period, such as during a [full table scan](#). Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds (ms) a block inserted into the old [sublist](#) must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many ms after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000.

This variable is often used in combination with [innodb\\_old\\_blocks\\_pct](#). See [Section 14.3.3.3, “Making the Buffer Pool Scan Resistant”](#) for more information. See [Section 8.10.1, “The InnoDB Buffer Pool”](#) for information about buffer pool management, such as the [LRU](#) algorithm and [eviction](#) policies.

- [innodb\\_online\\_alter\\_log\\_max\\_size](#)

<b>Command-Line Format</b>	<code>--innodb_online_alter_log_max_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_online_alter_log_max_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	134217728
	<b>Min Value</b>	65536
	<b>Max Value</b>	$2^{*}64-1$

Specifies an upper limit on the size of the temporary log files used during [online DDL](#) operations for [InnoDB](#) tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of [innodb\\_sort\\_buffer\\_size](#), up to the maximum specified by [innodb\\_online\\_alter\\_log\\_max\\_size](#). If any temporary log file exceeds the upper size limit, the `ALTER TABLE` operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also causes a longer period at the end of the DDL operation when the table is locked to apply the data from the log.

- `innodb_open_files`

<b>Command-Line Format</b>	<code>--innodb_open_files=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_open_files</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	-1 (autosized)
	<b>Min Value</b>	10
	<b>Max Value</b>	4294967295

This variable is relevant only if you use multiple [InnoDB tablespaces](#). It specifies the maximum number of `.ibd` files that MySQL can keep open at one time. The minimum value is 10. The default value is 300 if `innodb_file_per_table` is not enabled, and the higher of 300 and `table_open_cache` otherwise.

The file descriptors used for `.ibd` files are for [InnoDB](#) tables only. They are independent of those specified by the `--open-files-limit` server option, and do not affect the operation of the table cache. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_optimize_fulltext_only`

<b>Command-Line Format</b>	<code>--innodb_optimize_fulltext_only=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_optimize_fulltext_only</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Changes the way the `OPTIMIZE TABLE` statement operates on [InnoDB](#) tables. Intended to be enabled temporarily, during maintenance operations for [InnoDB](#) tables with `FULLTEXT` indexes.

By default, `OPTIMIZE TABLE` reorganizes the data in the [clustered index](#) of the table. When this option is enabled, `OPTIMIZE TABLE` skips this reorganization of the table data, and instead processes the newly added, deleted, and updated token data for a `FULLTEXT` index, See [Section 14.2.7.3, “InnoDB FULLTEXT Indexes”](#) for more information about `FULLTEXT` indexes for [InnoDB](#) tables.

- `innodb_optimize_point_storage`

<b>Introduced</b>	5.7.5	
<b>Removed</b>	5.7.6	
<b>Command-Line Format</b>	<code>--innodb_optimize_point_storage=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_optimize_point_storage</code>
	<b>Variable Scope</b>	Session
		2172

	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Enable this variable before creating a column of type `POINT` to store the `POINT` data type internally as variable-length `BLOB` data.

This variable was removed in MySQL 5.7.6.

- `innodb_page_cleaners`

<b>Introduced</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_page_cleaners=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_page_cleaners</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.7)</b>	<b>Type</b>	integer
	<b>Default</b>	1
	<b>Min Value</b>	1
	<b>Max Value</b>	64
<b>Permitted Values (&gt;= 5.7.8)</b>	<b>Type</b>	integer
	<b>Default</b>	4
	<b>Min Value</b>	1
	<b>Max Value</b>	64

The number of page cleaner threads that flush dirty pages from buffer pool instances. The page cleaner threads perform flush list and LRU flushing. A single page cleaner thread was introduced in MySQL 5.6.2 to offload buffer pool flushing work from the `InnoDB` master thread. As of MySQL 5.7.4, `InnoDB` provides support for multiple page cleaner threads. A value of 1 maintains the pre-MYSQL 5.7.4 configuration in which there is a single page cleaner thread. When there are multiple page cleaner threads, buffer pool flushing tasks for each buffer pool instance are dispatched to idle page cleaner threads. The `innodb_page_cleaners` default value was changed from 1 to 4 in MySQL 5.7.8. If the number of page cleaner threads exceeds the number of buffer pool instances, `innodb_page_cleaners` is automatically set to the same value as `innodb_buffer_pool_instances`.

If your workload is write-IO bound (when flushing dirty pages from buffer pool instances to data files) and if your system hardware has available capacity, increasing the number of page cleaner threads may help improve write-IO throughput.

Multi-threaded page cleaner support is extended to shutdown and recovery phases in MySQL 5.7.5.

As of MySQL 5.7.6, the `setpriority()` system call is used on Linux platforms (where it is supported and where the `mysqld` execution user is authorized) to give `page_cleaner` threads priority over other MySQL/`InnoDB` threads to help page flushing keep pace with the current workload. `mysqld` execution user authorization can be configured in `/etc/security/limits.conf`. For

example, if `mysqld` is run under the `mysql` user, you might authorize the `mysql` user by adding lines similar to the following to `/etc/security/limits.conf`:

```
mysql          hard    nice    -20
mysql          soft    nice    -20
```

Refer to your Linux operating system documentation for more information.

- `innodb_page_size`

<b>Command-Line Format</b>	<code>--innodb_page_size=#k</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_page_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.5)</b>	<b>Type</b>	enumeration
	<b>Default</b>	16384
	<b>Valid Values</b>	4k
		8k
		16k
		4096
8192		
16384		
<b>Permitted Values (&gt;= 5.7.6)</b>	<b>Type</b>	enumeration
	<b>Default</b>	16384
	<b>Valid Values</b>	4k
		8k
		16k
		32k
		64k
		4096
		8192
		16384
32768		
65536		

Specifies the [page size](#) for all [InnoDB tablespaces](#) in a MySQL [instance](#). This value is set when the instance is created and remains constant afterwards. You can specify page size using the values 64k, 32k, 16k (the default), 8k, or 4k. Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

**Note**

Support for 32k and 64k page sizes was added in MySQL 5.7.6. For both 32k and 64k page sizes, the maximum row length is about 16000 bytes. `ROW_FORMAT=COMPRESSED` is not supported when `innodb_page_size` is set to 32KB or 64KB. For `innodb_page_size=32k`, extent size is 2MB. For `innodb_page_size=64k`, extent size is 4MB. `innodb_log_buffer_size`

should be set to at least 16M (which is the default as of MySQL 5.7.6) when using 32k or 64k page sizes.

The default page size of 16KB and larger is appropriate for a wide range of [workloads](#), particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for [OLTP](#) workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages might also be efficient with [SSD](#) storage devices, which typically use small block sizes. Keeping the [InnoDB](#) page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

The minimum file size for the first system tablespace data file (`ibdata1`) differs depending on the `innodb_page_size` value. See the `innodb_data_file_path` option description for more information.

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_print_all_deadlocks`

<b>Command-Line Format</b>	<code>--innodb_print_all_deadlocks=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_print_all_deadlocks</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

When this option is enabled, information about all [deadlocks](#) in [InnoDB](#) user transactions is recorded in the `mysqld` error log. Otherwise, you see information about only the last deadlock, using the `SHOW ENGINE INNODB STATUS` command. An occasional [InnoDB](#) deadlock is not necessarily an issue, because [InnoDB](#) detects the condition immediately, and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are happening if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue [DML](#) or `SELECT ... FOR UPDATE` statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

- `innodb_purge_batch_size`

<b>Command-Line Format</b>	<code>--innodb_purge_batch_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_purge_batch_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	300
	<b>Min Value</b>	1
	<b>Max Value</b>	5000

The granularity of changes, expressed in units of [redo log](#) records, that trigger a [purge](#) operation, flushing the changed [buffer pool](#) blocks to disk. This option is intended for tuning performance in combination with the setting `innodb_purge_threads=n`, and typical users do not need to modify it.

- `innodb_purge_threads`

<b>Command-Line Format</b>	<code>--innodb_purge_threads=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_purge_threads</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.7)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	1
	<b>Min Value</b>	1
	<b>Max Value</b>	32
<b>Permitted Values (&gt;= 5.7.8)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	4
	<b>Min Value</b>	1
	<b>Max Value</b>	32

The number of background threads devoted to the InnoDB [purge](#) operation. A minimum value of 1 signifies that the purge operation is always performed by background threads, never as part of the [master thread](#). Running the purge operation in one or more background threads helps reduce internal contention within InnoDB, improving scalability. Increasing the value to greater than 1 creates that many separate purge threads, which can improve efficiency on systems where [DML](#) operations are performed on multiple tables. The maximum is 32.

The `innodb_purge_threads` default value was changed from 1 to 4 in MySQL 5.7.8.

- `innodb_purge_rseg_truncate_frequency`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_purge_rseg_truncate_frequency=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_purge_rseg_truncate_frequency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	128
	<b>Min Value</b>	1
	<b>Max Value</b>	128

`innodb_purge_rseg_truncate_frequency` defines the frequency with which the purge system frees rollback segments. An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. Reducing the `innodb_purge_rseg_truncate_frequency` value increases the frequency with which the purge thread frees rollback segments. The default value is 128.

`innodb_purge_rseg_truncate_frequency` is intended for use with `innodb_undo_log_truncate`. For more information, see [Section 14.4.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_random_read_ahead`

<b>Command-Line Format</b>	<code>--innodb_random_read_ahead=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_random_read_ahead</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Enables the random [read-ahead](#) technique for optimizing InnoDB I/O.

See [Section 14.3.3.1, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for details about the performance considerations for the different types of read-ahead requests. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_ahead_threshold`

<b>Command-Line Format</b>	<code>--innodb_read_ahead_threshold=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_read_ahead_threshold</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>56</code>
	<b>Min Value</b>	<code>0</code>
	<b>Max Value</b>	<code>64</code>

Controls the sensitivity of linear [read-ahead](#) that InnoDB uses to prefetch pages into the [buffer pool](#). If InnoDB reads at least `innodb_read_ahead_threshold` pages sequentially from an [extent](#) (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. A value of 0 disables read-ahead. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through this read-ahead mechanism, and how many of them are evicted from the buffer pool without ever being accessed, can be useful to help fine-tune the `innodb_read_ahead_threshold` parameter. As of MySQL 5.5, `SHOW ENGINE INNODB STATUS` output displays counter information from the `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted` global status variables. These variables indicate

the number of pages brought into the [buffer pool](#) by read-ahead requests, and the number of such pages [evicted](#) from the buffer pool without ever being accessed respectively. These counters provide global values since the last server restart.

`SHOW ENGINE INNODB STATUS` also shows the rate at which the read-ahead pages are read in and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of `SHOW ENGINE INNODB STATUS` and are displayed in the [BUFFER POOL AND MEMORY](#) section of the output.

See [Section 14.3.3.1, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_io_threads`

<b>Command-Line Format</b>	<code>--innodb_read_io_threads=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_read_io_threads</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	4
	<b>Min Value</b>	1
	<b>Max Value</b>	64

The number of I/O threads for read operations in [InnoDB](#). The default value is 4. Its counterpart for write threads is `innodb_write_io_threads`. See [Section 14.3.7, “Configuring the Number of Background InnoDB I/O Threads”](#) for more information. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

**Note**

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

- `innodb_read_only`

<b>Command-Line Format</b>	<code>--innodb_read_only=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_read_only</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	OFF

Starts the server in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. See [Section 14.3.2, “Configuring InnoDB for Read-Only Operation”](#) for usage instructions.

- `innodb_replication_delay`

<b>Command-Line Format</b>	<code>--innodb_replication_delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_replication_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

The replication thread delay (in ms) on a slave server if `innodb_thread_concurrency` is reached.

- `innodb_rollback_on_timeout`

<b>Command-Line Format</b>	<code>--innodb_rollback_on_timeout</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_rollback_on_timeout</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	OFF

In MySQL 5.7, **InnoDB rolls back** only the last statement on a transaction timeout by default. If `--innodb_rollback_on_timeout` is specified, a transaction timeout causes **InnoDB** to abort and roll back the entire transaction.

- `innodb_rollback_segments`

<b>Command-Line Format</b>	<code>--innodb_rollback_segments=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_rollback_segments</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	128
	<b>Min Value</b>	1

## InnoDB System Variables

	<b>Max Value</b>	128
--	------------------	-----

Defines how many of the [rollback segments](#) in the [system tablespace](#) are used for InnoDB [transactions](#). This setting, while still valid, is replaced by `innodb_undo_logs`.

- [innodb\\_saved\\_page\\_number\\_debug](#)

<b>Command-Line Format</b>	<code>--innodb_saved_page_number_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_saved_page_number_debug</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	0
	<b>Max Value</b>	$2^{23}-1$

Saves a page number. Setting the `innodb_fil_make_page_dirty_debug` option dirties the page defined by `innodb_saved_page_number_debug`. The `innodb_saved_page_number_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- [innodb\\_sort\\_buffer\\_size](#)

<b>Command-Line Format</b>	<code>--innodb_sort_buffer_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<a href="#">innodb_sort_buffer_size</a>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	1048576
	<b>Min Value</b>	65536
	<b>Max Value</b>	67108864

Specifies the size of sort buffers used for sorting data during creation of an [InnoDB](#) index. The size specified defines the amount of data filled in memory for an internal sort and written out to disk, which can be referred to as a “run”. During the merge phase, pairs of buffers of the specified size are “read in” and merged. The larger the setting, the fewer “runs” and merges there are, which is important to understand from a tuning perspective.

This sort area is only used for merge sorts during index creation, not during later index maintenance operations. Buffers are deallocated when index creation completes.

The value of this option also controls the amount by which the temporary log file is extended, to record concurrent DML during [online DDL](#) operations.

Before this setting was made configurable, the size was hardcoded to 1048576 bytes (1MB), and that value remains the default.

During an `ALTER TABLE` or `CREATE TABLE` statement that creates an index, 3 buffers are allocated, each with a size defined by this option. Additionally, auxiliary pointers are allocated to rows in the sort buffer so that the sort can run on pointers (as opposed to moving rows during the sort operation).

For a typical sort operation, a formula such as this can be used to estimate memory consumption:

```
(6 /*FTS_NUM_AUX_INDEX*/ * (3*@@global.innodb_sort_buffer_size)
+ 2 * number_of_partitions * number_of_secondary_indexes_created
* (@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)*/)
* 8 /*64-bit sizeof *buf->tuples*/)
```

`"@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)"` indicates the maximum tuples held. `"2 * (@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)*/) * 8 /*64-bit size of *buf->tuples*/"` indicates auxiliary pointers allocated.

**Note**

For 32-bit, multiply by 4 instead of 8.

For parallel sorts on a full-text index, multiply by the `innodb_ft_sort_pll_degree` setting:

```
(6 /*FTS_NUM_AUX_INDEX*/ * @@global.innodb_ft_sort_pll_degree)
```

- `innodb_spin_wait_delay`

<b>Command-Line Format</b>	<code>--innodb_spin_wait_delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_spin_wait_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	6
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

The maximum delay between polls for a `spin` lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. The default value is 6. See [Section 14.3.9, “Configuring Spin Lock Polling”](#) for more information.

- `innodb_stats_auto_recalc`

<b>Command-Line Format</b>	<code>--innodb_stats_auto_recalc=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_auto_recalc</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes

<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	ON

Causes InnoDB to automatically recalculate [persistent statistics](#) after the data in a table is changed substantially. The threshold value is currently 10% of the rows in the table. This setting applies to tables created when the `innodb_stats_persistent` option is enabled, or where the clause `STATS_PERSISTENT=1` is enabled by a `CREATE TABLE` or `ALTER TABLE` statement. The amount of data sampled to produce the statistics is controlled by the `innodb_stats_persistent_sample_pages` configuration option.

For additional information about `innodb_stats_auto_recalc`, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_method`

<b>Command-Line Format</b>	<code>--innodb_stats_method=name</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_method</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	enumeration
	<b>Default</b>	<code>nulls_equal</code>
	<b>Valid Values</b>	<code>nulls_equal</code>
		<code>nulls_unequal</code>
	<code>nulls_ignored</code>	

How the server treats `NULL` values when collecting [statistics](#) about the distribution of index values for InnoDB tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all `NULL` index values are considered equal and form a single value group that has a size equal to the number of `NULL` values. For `nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

- `innodb_stats_on_metadata`

<b>Command-Line Format</b>	<code>--innodb_stats_on_metadata</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_on_metadata</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

When this variable is enabled, InnoDB updates [statistics](#) when metadata statements such as `SHOW TABLE STATUS` or when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Leaving this setting disabled can improve access speed for schemas that have a large number of

tables or indexes. It can also improve the stability of [execution plans](#) for queries that involve [InnoDB](#) tables.

To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=mode`, where *mode* is either `ON` or `OFF` (or `1` or `0`). Changing this setting requires the `SUPER` privilege and immediately affects the operation of all connections.

This variable is disabled by default.

- `innodb_stats_persistent`

<b>Command-Line Format</b>	<code>--innodb_stats_persistent=setting</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_persistent</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>
	<b>Valid Values</b>	<code>OFF</code>
		<code>ON</code>
<code>0</code>		
	<code>1</code>	

Specifies whether [InnoDB](#) index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in [query execution plans](#). This setting is stored with each table when the table is created. You can set `innodb_stats_persistent` at the global level before creating a table, or use the `STATS_PERSISTENT` clause of the `CREATE TABLE` and `ALTER TABLE` statements to override the system-wide setting and configure persistent statistics for individual tables.

For more information about this option, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_persistent_sample_pages`

<b>Command-Line Format</b>	<code>--innodb_stats_persistent_sample_pages=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_persistent_sample_pages</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>20</code>

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O during the execution of `ANALYZE TABLE` for an [InnoDB](#) table. For additional information, see [Section 14.3.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

**Note**

Setting a high value for `innodb_stats_persistent_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages that will be accessed, see [Section 14.3.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

This option only applies when the `innodb_stats_persistent` setting is turned on for a table; when that option is turned off for a table, the `innodb_stats_transient_sample_pages` setting applies instead.

- `innodb_stats_sample_pages`

<b>Deprecated</b>	5.6.3	
<b>Command-Line Format</b>	<code>--innodb_stats_sample_pages=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_sample_pages</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	8
	<b>Min Value</b>	1
	<b>Max Value</b>	$2^{64}-1$

Deprecated, use `innodb_stats_transient_sample_pages` instead.

- `innodb_stats_transient_sample_pages`

<b>Command-Line Format</b>	<code>--innodb_stats_transient_sample_pages=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_stats_transient_sample_pages</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	8

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. The default value is 8. Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O when opening an InnoDB table or recalculating statistics. For additional information, see [Section 14.3.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

**Note**

Setting a high value for `innodb_stats_transient_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages that will be accessed, see [Section 14.3.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

This option only applies when the `innodb_stats_persistent` setting is turned off for a table; when this option is turned on for a table, the `innodb_stats_persistent_sample_pages` setting applies instead. Takes the place of the `innodb_stats_sample_pages` option. See [Section 14.3.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#) for more information.

- `innodb_status_output`

<b>Introduced</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_status_output</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_status_output</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Enables or disables periodic output for the standard `InnoDB` Monitor. Also used in combination with `innodb_status_output_locks` to enable or disable periodic output for the `InnoDB` Lock Monitor. See [Section 14.14, “InnoDB Monitors”](#) for additional information.

- `innodb_status_output_locks`

<b>Introduced</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_status_output_locks</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_status_output_locks</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

Enables or disables the `InnoDB` Lock Monitor. When enabled, the `InnoDB` Lock Monitor prints additional information about locks in `SHOW ENGINE INNODB STATUS` output and in periodic output printed to the MySQL error log. Periodic output for the `InnoDB` Lock Monitor is printed as part of the standard `InnoDB` Monitor output. The standard `InnoDB` Monitor must therefore be enabled for the `InnoDB` Lock Monitor to print data to the MySQL error log periodically. See [Section 14.14, “InnoDB Monitors”](#) for more information.

- `innodb_strict_mode`

<b>Command-Line Format</b>	<code>--innodb_strict_mode=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_strict_mode</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&lt;= 5.7.6)</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

<b>Permitted Values</b> (>= 5.7.7)	<b>Type</b>	boolean
	<b>Default</b>	ON

When `innodb_strict_mode` is ON, InnoDB returns errors rather than warnings for certain conditions. As of MySQL 5.7.7, the default value is ON.

**Strict mode** helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When `innodb_strict_mode` is ON, InnoDB raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE`, `CREATE INDEX`, and `OPTIMIZE TABLE` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses on `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is OFF, InnoDB ignores conflicting clauses and creates the table or index, with only a warning in the message log. The resulting table might have different behavior than you intended, such as having no compression when you tried to create a compressed table. When `innodb_strict_mode` is ON, such problems generate an immediate error and the table or index is not created, avoiding a troubleshooting session later.

You can turn `innodb_strict_mode` ON or OFF on the command line when you start `mysqld`, or in the **configuration file** `my.cnf` or `my.ini`. You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either ON or OFF. Changing the GLOBAL setting requires the SUPER privilege and affects the operation of all clients that subsequently connect. Any client can change the SESSION setting for `innodb_strict_mode`, and the setting affects only that client.

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 13.1.15, "CREATE TABLESPACE Syntax"](#).

- `innodb_support_xa`

<b>Deprecated</b>	5.7.10	
<b>Command-Line Format</b>	<code>--innodb_support_xa</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_support_xa</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	TRUE

Enables InnoDB support for two-phase commit in XA transactions, causing an extra disk flush for transaction preparation. This setting is the default. The XA mechanism is used internally and is essential for any server that has its binary log turned on and is accepting changes to its data from more than one thread. If you turn it off, transactions can be written to the binary log in a different order from the one in which the live database is committing them. This can produce different data when the binary log is replayed in disaster recovery or on a replication slave. Do not turn it off on a

replication master server unless you have an unusual setup where only one thread is able to change data.

`innodb_support_xa` is deprecated and will be removed in a future MySQL release. InnoDB support for two-phase commit in XA transactions is always enabled as of MySQL 5.7.10. Disabling `innodb_support_xa` is no longer permitted as it makes replication unsafe and prevents performance gains associated with binary log group commit.

- `innodb_sync_array_size`

<b>Command-Line Format</b>	<code>--innodb_sync_array_size=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_sync_array_size</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	1
	<b>Min Value</b>	1
	<b>Max Value</b>	1024

Splits an internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing this option value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.

- `innodb_sync_spin_loops`

<b>Command-Line Format</b>	<code>--innodb_sync_spin_loops=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_sync_spin_loops</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	30
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended. The default value is 30.

- `innodb_sync_debug`

<b>Introduced</b>	5.7.8	
<b>Command-Line Format</b>	<code>--innodb_sync_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_sync_debug</code>

## InnoDB System Variables

	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Enables sync debug checking for the `InnoDB` storage engine. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

Prior to MySQL 5.7.8, enabling `InnoDB` sync debug checking required that the Debug Sync facility be enabled using the `ENABLE_DEBUG_SYNC` CMake option. This requirement was removed in MySQL 5.7.8 with the introduction of the `innodb_sync_debug` configuration option.

- `innodb_table_locks`

<b>Command-Line Format</b>	<code>--innodb_table_locks</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_table_locks</code>
	<b>Variable Scope</b>	Global, Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	TRUE

If `autocommit = 0`, `InnoDB` honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of `innodb_table_locks` is 1, which means that `LOCK TABLES` causes `InnoDB` to lock a table internally if `autocommit = 0`.

In MySQL 5.7, `innodb_table_locks = 0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- `innodb_temp_data_file_path`

<b>Introduced</b>	5.7.1	
<b>Command-Line Format</b>	<code>--innodb_temp_data_file_path=file</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_temp_data_file_path</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	string
	<b>Default</b>	<code>ibtmp1:12M:autoextend</code>

Specifies the path, file name, and file size for `InnoDB` temporary table tablespace data files. The full directory path for a file is formed by concatenating `innodb_data_home_dir` to the path specified by `innodb_temp_data_file_path`. File size is specified in KB, MB, or GB (1024MB) by appending `K`, `M`, or `G` to the size value. The sum of the sizes of the files must be slightly larger than 12MB. If you do not specify `innodb_temp_data_file_path`, the default behavior is to create a single auto-extending temporary table tablespace data file, slightly larger than 12MB, named `ibtmp1`. The size limit of individual files is determined by your operating system. You can set the

file size to more than 4GB on operating systems that support big files. Use of raw disk partitions for temporary table tablespace data files is not supported.

The name of a [InnoDB](#) temporary table tablespace data file cannot be the same as the name of a [InnoDB](#) data file. Any inability or error creating a temporary table tablespace data file is treated as fatal and server startup will be refused. The temporary table tablespace has a dynamically generated space ID, which can change on each server restart.

The [InnoDB](#) temporary table tablespace is shared by all non-compressed [InnoDB](#) temporary tables. Compressed [InnoDB](#) temporary tables reside in per-table tablespace files, which are located in the temporary file directory defined by `tmpdir`.

Metadata about active [InnoDB](#) temporary tables if found in the `INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO`.

- `innodb_tmpdir`

<b>Introduced</b>	5.7.11	
<b>Command-Line Format</b>	<code>--innodb_tmpdir=path</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_tmpdir</code>
	<b>Variable Scope</b>	Session
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>directory name</code>
	<b>Default</b>	<code>NULL</code>

The `innodb_tmpdir` option is used to define an alternate directory for temporary files that are created during online `ALTER TABLE` operations.

A valid value is any directory path other than the MySQL data directory path. If the value is `NULL` (the default), temporary files are created in the location defined by the MySQL `tmpdir` option. If a directory is specified, existence of the directory and permissions are only checked when the `innodb_tmpdir` setting is configured using a `SET` statement. If a symlink is provided in a directory string, the symlink is resolved and stored as an absolute path. The path should not exceed 512 bytes. An online `ALTER TABLE` operation reports an error if `innodb_tmpdir` is set to an invalid directory. `innodb_tmpdir` overrides the MySQL `tmpdir` setting but only for online `ALTER TABLE` operations.

The `FILE` privilege is required to configure `innodb_tmpdir`.

The `innodb_tmpdir` option was introduced to help avoid overflowing a temporary file directory located on a `tmpfs` file system. Such overflows could occur as a result of large temporary files created during online `ALTER TABLE` operations.

- `innodb_thread_concurrency`

<b>Command-Line Format</b>	<code>--innodb_thread_concurrency=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_thread_concurrency</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>0</code> 2189

	<b>Min Value</b>	0
	<b>Max Value</b>	1000

InnoDB tries to keep the number of operating system threads concurrently inside InnoDB less than or equal to the limit given by this variable (InnoDB uses operating system threads to process user transactions). Once the number of threads reaches this limit, additional threads are placed into a wait state within a “First In, First Out” (FIFO) queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The range of this variable is 0 to 1000. A value of 0 (the default) is interpreted as infinite concurrency (no concurrency checking). Disabling thread concurrency checking enables InnoDB to create as many threads as it needs. A value of 0 also disables the `queries inside InnoDB` and `queries in queue counters` in the `ROW OPERATIONS` section of `SHOW ENGINE INNODB STATUS` output.

Consider setting this variable if your MySQL instance shares CPU resources with other applications, or if your workload or number of concurrent users is growing. The correct setting depends on workload, computing environment, and the version of MySQL that you are running. You will need to test a range of values to determine the setting that provides the best performance. `innodb_thread_concurrency` is a dynamic variable, which allows you to experiment with different settings on a live test system. If a particular setting performs poorly, you can quickly set `innodb_thread_concurrency` back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is less than 64, set `innodb_thread_concurrency=0`.
- If your workload is consistently heavy or occasionally spikes, start by setting `innodb_thread_concurrency=128`, and lowering the value to 96, 80, 64, and so on, until you find the number of threads that provides the best performance. For example, suppose your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or even 200. You find that performance is stable at 80 concurrent users but starts to show a regression above this number. In this case, you would set `innodb_thread_concurrency=80` to avoid impacting performance.
- If you do not want InnoDB to use more than a certain number of vCPUs for user threads (20 vCPUs for example), set `innodb_thread_concurrency` to this number (or possibly lower, depending on performance results). If your goal is to isolate MySQL from other applications, you may consider binding the `mysqld` process exclusively to the vCPUs. Be aware, however, that exclusive binding could result in non-optimal hardware usage if the `mysqld` process is not consistently busy. In this case, you might bind the `mysqld` process to the vCPUs but also allow other applications to use some or all of the vCPUs.

#### Note

From an operating system perspective, using a resource management solution (if available) to manage how CPU time is shared among applications may be preferable to binding the `mysqld` process. For example, you could assign 90% of vCPU time to a given application while other critical process *are not* running, and scale that value back to 40% when other critical processes *are* running.

- `innodb_thread_concurrency` values that are too high can cause performance regression due to increased contention on system internals and resources.

- In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of vCPUs.
- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

For related information, see [Section 14.3.6, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_trx_purge_view_update_only_debug`

<b>Command-Line Format</b>	<code>--innodb_trx_purge_view_update_only_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_trx_purge_view_update_only_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	boolean
	<b>Default</b>	OFF

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_trx_rseg_n_slots_debug`

<b>Command-Line Format</b>	<code>--innodb_trx_rseg_n_slots_debug=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_trx_rseg_n_slots_debug</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	integer
	<b>Default</b>	0
	<b>Max Value</b>	1024

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function which looks for a free slot for an undo log segment. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_thread_sleep_delay`

<b>Command-Line Format</b>	<code>--innodb_thread_sleep_delay=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_thread_sleep_delay</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values (&gt;= 5.7.4)</b>	<b>Type</b>	integer
	<b>Default</b>	10000

	<b>Min Value</b>	0
	<b>Max Value</b>	1000000
<b>Permitted Values</b> (32-bit platforms, <= 5.7.3)	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	4294967295
<b>Permitted Values</b> (64-bit platforms, <= 5.7.3)	<b>Type</b>	integer
	<b>Default</b>	10000
	<b>Min Value</b>	0
	<b>Max Value</b>	18446744073709551615

How long **InnoDB** threads sleep before joining the **InnoDB** queue, in microseconds. The default value is 10000. A value of 0 disables sleep. In MySQL 5.6.3 and higher, you can set the configuration option `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and **InnoDB** automatically adjusts `innodb_thread_sleep_delay` up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

For more information, see [Section 14.3.6, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_undo_directory`

<b>Command-Line Format</b>	<code>--innodb_undo_directory=dir_name</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_undo_directory</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b> (<= 5.7.7)	<b>Type</b>	directory name
	<b>Default</b>	.
<b>Permitted Values</b> (>= 5.7.8)	<b>Type</b>	directory name

The path where **InnoDB** creates separate tablespaces for the undo logs. Typically used to place undo logs on a different storage device. Used in conjunction with `innodb_undo_logs` and `innodb_undo_tablespaces`, which determine the disk layout of the undo logs outside the **system tablespace**.

Prior to MySQL 5.7.8, the `innodb_undo_directory` default value is “.”, which represents the same directory where **InnoDB** creates its other log files by default. As of MySQL 5.7.8, there is no default value (it is NULL). If a path is not specified, undo tablespaces are created in the MySQL data directory, as defined by `datadir`.

For more information about configuring separate tablespaces for undo logs, see [Section 14.4.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_undo_log_truncate`

<b>Introduced</b>	5.7.5	
<b>Command-Line Format</b>	<code>--innodb_undo_log_truncate=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_undo_log_truncate</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>OFF</code>

When you enable `innodb_undo_log_truncate`, undo tablespaces that exceed the threshold value defined by `innodb_max_undo_log_size` are marked for truncation. Only undo logs that reside in undo tablespaces can be truncated. Truncation of undo logs that reside in the system tablespace is not supported. For truncation to occur, there must be at least two undo tablespaces and two redo-enabled undo logs configured to use the undo tablespaces. This means that `innodb_undo_tablespaces` must be set to a value equal to or greater than 2, and `innodb_undo_logs` must be set to a value equal to or greater than 35.

The `innodb_purge_rseg_truncate_frequency` configuration option can be used to expedite truncation of undo tablespaces.

For more information, see [Section 14.4.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_undo_logs`

<b>Command-Line Format</b>	<code>--innodb_undo_logs=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_undo_logs</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	Yes
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	<code>128</code>
	<b>Min Value</b>	<code>0</code>
	<b>Max Value</b>	<code>128</code>

Defines the number of undo logs (otherwise referred to as [rollback segments](#)) used by InnoDB. The `innodb_undo_logs` option replaces `innodb_rollback_segments`.

As of MySQL 5.7.2, 32 undo logs are reserved for use by temporary tables and are hosted in the temporary table tablespace (`ibtmp1`). To allocate additional undo logs for data-modifying transactions that generate undo records, `innodb_undo_logs` must be set to a value greater than 32 if undo logs are stored in the system tablespace only. If you have configured separate undo tablespaces, `innodb_undo_logs` must be set to a value greater than 33 to allocate additional undo logs for data-modifying transactions. Each undo log can host up to a maximum of 1024 transactions.

Although you can increase or decrease the number of undo logs used by InnoDB, the number of undo logs physically present in the system never decreases. Thus you might start with a low value for this parameter and gradually increase it, to avoid allocating undo logs that

are not required. If `innodb_undo_logs` is not set, it defaults to the maximum value of 128. For the total number of available undo logs, rather than the number of active ones, see the `InnoDB_available_undo_logs` status variable.

For more information about undo logs, see [Section 14.2.3, “InnoDB Multi-Versioning”](#). For information about configuring separate tablespaces for undo logs, see [Section 14.4.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_undo_tablespaces`

<b>Command-Line Format</b>	<code>--innodb_undo_tablespaces=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_undo_tablespaces</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values (&lt;= 5.7.7)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	126
<b>Permitted Values (&gt;= 5.7.8)</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	0
	<b>Min Value</b>	0
	<b>Max Value</b>	95

The number of `tablespace` files that the `undo logs` are divided between. By default, all undo logs are part of the `system tablespace`, and the system tablespace always contains one undo tablespace in addition to those configured by `innodb_undo_tablespaces`.

Because undo logs can become large during long-running transactions, having undo logs in multiple tablespaces reduces the maximum size of any one tablespace. The undo tablespace files are created in the location defined by `innodb_undo_directory`, with names in the form of `undoN`, where `N` is a sequential series of integers (including leading zeros). The default size of an undo tablespace file is 10M. The number of `innodb_undo_tablespaces` must be set prior to initializing `InnoDB`. Attempting to restart `InnoDB` with a greater number of undo tablespaces than you specified when you first created the database will result in a failed start and an error stating that `InnoDB` did not find the expected number of undo tablespaces.

As MySQL 5.7.2, 32 of 128 undo logs were reserved for temporary tables, as described in [Section 14.2.6, “InnoDB Temporary Table Undo Logs”](#). One undo log is always allocated to the system tablespace, which leaves 95 undo logs available for undo tablespaces. This change effectively reduced the `innodb_undo_tablespaces` maximum limit from 126 to 95, and in MySQL 5.7.8, the `innodb_undo_tablespaces` maximum value was officially reduced to 95.

For information about configuring separate tablespaces for undo logs, see [Section 14.4.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_use_native_aio`

<b>Command-Line Format</b>	<code>--innodb_use_native_aio=#</code>
----------------------------	--

<b>System Variable</b>	<b>Name</b>	<code>innodb_use_native_aio</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to touch this option, because it is enabled by default.

As of MySQL 5.5, the [asynchronous I/O](#) capability that [InnoDB](#) has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in the output of the command `SHOW ENGINE INNODB STATUS\G`.

Running with a large number of [InnoDB](#) I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

However, if a problem with the asynchronous I/O subsystem in the OS prevents [InnoDB](#) from starting, you can start the server with `innodb_use_native_aio=0` disabled (use `innodb_use_native_aio=0` in the option file). This option may also be turned off automatically during startup if [InnoDB](#) detects a potential problem such as a combination of `tmpdir` location, `tmpfs` filesystem, and Linux kernel that does not support AIO on `tmpfs`.

- [innodb\\_use\\_sys\\_malloc](#)

<b>Deprecated</b>	5.6.3	
<b>Removed</b>	5.7.4	
<b>Command-Line Format</b>	<code>--innodb_use_sys_malloc=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_use_sys_malloc</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>boolean</code>
	<b>Default</b>	<code>ON</code>

Whether [InnoDB](#) uses the operating system memory allocator (`ON`) or its own (`OFF`). The default value is `ON`. See [Section 14.3.4, “Configuring the Memory Allocator for InnoDB”](#) for more information.

`innodb_use_sys_malloc` was deprecated in MySQL 5.6.3 and removed in MySQL 5.7.4.

- [innodb\\_version](#)

The [InnoDB](#) version number. In 5.7, the separate numbering for [InnoDB](#) does not apply and this value is the same as for the `version` variable.

- [innodb\\_write\\_io\\_threads](#)

<b>Command-Line Format</b>	<code>--innodb_write_io_threads=#</code>	
<b>System Variable</b>	<b>Name</b>	<code>innodb_write_io_threads</code>
	<b>Variable Scope</b>	Global
	<b>Dynamic Variable</b>	No
<b>Permitted Values</b>	<b>Type</b>	<code>integer</code>
	<b>Default</b>	4
	<b>Min Value</b>	1
	<b>Max Value</b>	64

The number of I/O threads for write operations in InnoDB. The default value is 4. Its counterpart for read threads is `innodb_read_io_threads`. See [Section 14.3.7, “Configuring the Number of Background InnoDB I/O Threads”](#) for more information. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

#### Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

You should also take into consideration the value of `sync_binlog`, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

## 14.12 InnoDB INFORMATION\_SCHEMA Tables

This section provides information and usage examples for InnoDB INFORMATION\_SCHEMA tables.

InnoDB INFORMATION\_SCHEMA tables provide metadata, status information, and statistics about various aspects of the InnoDB storage engine. You can view a list of InnoDB INFORMATION\_SCHEMA tables by issuing a `SHOW TABLES` statement on the INFORMATION\_SCHEMA database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see [Section 20.30, “INFORMATION\\_SCHEMA Tables for InnoDB”](#). For general information regarding the MySQL INFORMATION\_SCHEMA database, see [Chapter 20, INFORMATION\\_SCHEMA Tables](#).

### 14.12.1 InnoDB INFORMATION\_SCHEMA Tables about Compression

There are two pairs of InnoDB INFORMATION\_SCHEMA tables about compression that can provide insight into how well compression is working overall:

- `INNODB_CMP` and `INNODB_CMP_RESET` contain information about the number of compression operations and the amount of time spent performing compression.
- `INNODB_CMPMEM` and `INNODB_CMP_RESET` contain information about the way memory is allocated for compression.

### 14.12.1.1 INNODB\_CMP and INNODB\_CMP\_RESET

The `INNODB_CMP` and `INNODB_CMP_RESET` tables contain status information about operations related to compressed tables, which are described in [Section 14.6, “InnoDB Table and Page Compression”](#). The `PAGE_SIZE` column reports the compressed [page size](#).

These two tables have identical contents, but reading from `INNODB_CMP_RESET` resets the statistics on compression and uncompression operations. For example, if you archive the output of `INNODB_CMP_RESET` every 60 minutes, you see the statistics for each hourly period. If you monitor the output of `INNODB_CMP` (making sure never to read `INNODB_CMP_RESET`), you see the cumulated statistics since InnoDB was started.

For the table definition, see [Section 20.30.1, “The INFORMATION\\_SCHEMA INNODB\\_CMP and INNODB\\_CMP\\_RESET Tables”](#).

### 14.12.1.2 INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables contain status information about compressed pages that reside in the buffer pool. Please consult [Section 14.6, “InnoDB Table and Page Compression”](#) for further information on compressed tables and the use of the buffer pool. The `INNODB_CMP` and `INNODB_CMP_RESET` tables should provide more useful statistics on compression.

#### Internal Details

InnoDB uses a [buddy allocator](#) system to manage memory allocated to [pages of various sizes](#), from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables have identical contents, but reading from `INNODB_CMPMEM_RESET` resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of `INNODB_CMPMEM_RESET`, it would show the hourly statistics. If you never read `INNODB_CMPMEM_RESET` and monitored the output of `INNODB_CMPMEM` instead, it would show the cumulated statistics since InnoDB was started.

For the table definition, see [Section 20.30.3, “The INFORMATION\\_SCHEMA INNODB\\_CMPMEM and INNODB\\_CMPMEM\\_RESET Tables”](#).

### 14.12.1.3 Using the Compression Information Schema Tables

#### Example 14.10 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see [Section 14.6, “InnoDB Table and Page Compression”](#), `INNODB_CMP`, `INNODB_CMP_PER_INDEX`, and `INNODB_CMPMEM`).

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMP` under a light [workload](#). The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns `COMPRESS_TIME` and `UNCOMPRESS_TIME` are zero.

page size	compress ops	compress ops ok	compress time	uncompress ops	uncompress time
1024	0	0	0	0	0
2048	0	0	0	0	0
4096	0	0	0	0	0
8192	1048	921	0	61	0
16384	0	0	0	0	0

According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the `buffer pool`. The only other allocated block size is 64 bytes. The smallest `PAGE_SIZE` in `INNODB_CMPMEM` is used for block descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMPMEM` under a light `workload`. Some memory is unusable due to fragmentation of the memory allocator for compressed pages: `SUM(PAGE_SIZE*PAGES_FREE)=6784`. This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of `SUM(PAGE_SIZE*RELOCATION_OPS)` bytes has consumed less than a second (`SUM(RELOCATION_TIME)=0`).

page size	pages used	pages free	relocation ops	relocation time
64	5910	0	2436	0
128	0	1	0	0
256	0	0	0	0
512	0	1	0	0

## 14.12.2 InnoDB INFORMATION\_SCHEMA Transaction and Locking Tables

Three `InnoDB INFORMATION_SCHEMA` tables make it easy to monitor transactions and diagnose possible locking problems. The three tables are `INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`.

- `INNODB_TRX`: Contains information about every transaction currently executing inside `InnoDB`, including whether the transaction is waiting for a lock, when the transaction started, and the particular SQL statement the transaction is executing.
- `INNODB_LOCKS`: Each transaction in `InnoDB` that is waiting for another transaction to release a lock (`INNODB_TRX.TRX_STATE='LOCK WAIT'`) is blocked by exactly one “blocking lock request”. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. The waiting or blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, `INNODB_LOCKS` contains one row that describes each lock the transaction has requested, and for which it is waiting. `INNODB_LOCKS` also contains one row for each lock that is blocking another transaction, whatever the state of the transaction that holds the lock (`'RUNNING'`, `'LOCK WAIT'`, `'ROLLING BACK'` or `'COMMITTING'`). The lock that is blocking a transaction is always held in a mode (read vs. write, shared vs. exclusive) incompatible with the mode of requested lock.
- `INNODB_LOCK_WAITS`: Using this table, you can tell which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each *blocked* transaction, indicating the lock it has requested and any locks that are blocking that request. The `REQUESTED_LOCK_ID` refers to the lock that a transaction is requesting, and the `BLOCKING_LOCK_ID` refers to the lock (held by another transaction) that is preventing the first transaction from proceeding. For any given blocked transaction, all rows in `INNODB_LOCK_WAITS` have the same value for `REQUESTED_LOCK_ID` and different values for `BLOCKING_LOCK_ID`.

### 14.12.2.1 Usage Examples for InnoDB Transaction and Locking Tables

#### Example 14.11 Identifying Blocking Transactions

It is sometimes helpful to be able to identify which transaction is blocking another. You can use the [INFORMATION\\_SCHEMA](#) tables to find out which transaction is waiting for another, and which resource is being requested.

Suppose you have the following scenario, with three users running concurrently. Each user (or session) corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these users have issued the following commands, but none has yet committed its transaction:

- User A:

```
BEGIN;
SELECT a FROM t FOR UPDATE;
SELECT SLEEP(100);
```

- User B:

```
SELECT b FROM t FOR UPDATE;
```

- User C:

```
SELECT c FROM t FOR UPDATE;
```

In this scenario, you can use this query to see who is waiting for whom:

```
SELECT r.trx_id waiting_trx_id,
       r.trx_mysql_thread_id waiting_thread,
       r.trx_query waiting_query,
       b.trx_id blocking_trx_id,
       b.trx_mysql_thread_id blocking_thread,
       b.trx_query blocking_query
FROM   information_schema.innodb_lock_waits w
INNER JOIN information_schema.innodb_trx b ON
        b.trx_id = w.blocking_trx_id
INNER JOIN information_schema.innodb_trx r ON
        r.trx_id = w.requesting_trx_id;
```

waiting trx id	waiting thread	waiting query	blocking trx id	blocking thread	blocking query
A4	6	SELECT b FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A4	6	SELECT b FROM t FOR UPDATE

In the above result, you can identify users by the “waiting query” or “blocking query”. As you can see:

- User B (trx id 'A4', thread 6) and User C (trx id 'A5', thread 7) are both waiting for User A (trx id 'A3', thread 5).
- User C is waiting for User B as well as User A.

You can see the underlying data in the tables [INNODB\\_TRX](#), [INNODB\\_LOCKS](#), and [INNODB\\_LOCK\\_WAITS](#).

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_TRX`.

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
A3	RUNNING	2008-01-15 16:44:54	NULL	NULL	2	5	SELECT SLEEP(100)
A4	LOCK WAIT	2008-01-15 16:45:09	A4:1:3:2	2008-01-15 16:45:09	2	6	SELECT b FROM t FOR UPDATE
A5	LOCK WAIT	2008-01-15 16:45:14	A5:1:3:2	2008-01-15 16:45:14	2	7	SELECT c FROM t FOR UPDATE

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCKS`.

A5:1:3:2	A5	X	RECORD	`test`.`t`	`PRIMARY`	1	3	2	0x0200

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_LOCK_WAITS`.

requesting trx id	requested lock id	blocking trx id	blocking lock id
A4	A4:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A4	A4:1:3:2

#### Example 14.12 More Complex Example of Transaction Data in Information Schema Tables

Sometimes you would like to correlate the internal `InnoDB` locking information with session-level information maintained by MySQL. For example, you might like to know, for a given `InnoDB` transaction ID, the corresponding MySQL session ID and name of the user that may be holding a lock, and thus blocking another transaction.

The following output from the `INFORMATION_SCHEMA` tables is taken from a somewhat loaded system.

As can be seen in the following tables, there are several transactions running.

The following `INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables shows that:

- Transaction `77F` (executing an `INSERT`) is waiting for transactions `77E`, `77D` and `77B` to commit.
- Transaction `77E` (executing an `INSERT`) is waiting for transactions `77D` and `77B` to commit.
- Transaction `77D` (executing an `INSERT`) is waiting for transaction `77B` to commit.
- Transaction `77B` (executing an `INSERT`) is waiting for transaction `77A` to commit.
- Transaction `77A` is running, currently executing `SELECT`.
- Transaction `E56` (executing an `INSERT`) is waiting for transaction `E55` to commit.
- Transaction `E55` (executing an `INSERT`) is waiting for transaction `19C` to commit.
- Transaction `19C` is running, currently executing an `INSERT`.

Note that there may be an inconsistency between queries shown in the two tables `INNODB_TRX.TRX_QUERY` and `PROCESSLIST.INFO`. The current transaction ID for a thread, and the

query being executed in that transaction, may be different in these two tables for any given thread. See [Potential Inconsistency with PROCESSLIST Data](#) for an explanation.

The following table shows the contents of `INFORMATION_SCHEMA.PROCESSLIST` in a system running a heavy [workload](#).

ID	USER	HOST	DB	COMMAND	TIME	STATE	INFO
384	root	localhost	test	Query	10	update	insert into t2 values ...
257	root	localhost	test	Query	3	update	insert into t2 values ...
130	root	localhost	test	Query	0	update	insert into t2 values ...
61	root	localhost	test	Query	1	update	insert into t2 values ...
8	root	localhost	test	Query	1	update	insert into t2 values ...
4	root	localhost	test	Query	0	preparing	SELECT * FROM processlist
2	root	localhost	test	Sleep	566		NULL

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_TRX` in a system running a heavy [workload](#).

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
77F	LOCK WAIT	2008-01-15 13:10:16	77F:806	2008-01-15 13:10:16	1	876	insert into t09 (D, B, C) values ...

#### 14.12.2.2 INNODB\_LOCKS and INNODB\_LOCK\_WAITS Data

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or rollback. If a transaction is not waiting for a lock, it is in a 'RUNNING' state. If a transaction is waiting for a lock, it is in a 'LOCK WAIT' state.

The `INNODB_LOCKS` table holds one or more rows for each 'LOCK WAIT' transaction, indicating any lock requests that are preventing its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The `INNODB_LOCK_WAITS` table shows which locks already held by a transaction are blocking locks requested by other transactions.

### 14.12.2.3 Data Persistence and Consistency for InnoDB Transaction and Locking Tables

The data exposed by the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`) represent a glimpse into fast-changing data. This is not like other (user) tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly.

For performance reasons, and to minimize the chance of misleading `JOINS` between the InnoDB transaction and locking `INFORMATION_SCHEMA` tables, InnoDB collects the required transaction and locking information into an intermediate buffer whenever a `SELECT` on any of the tables is issued. This buffer is refreshed only if more than 0.1 seconds has elapsed since the last time the buffer was read. The data needed to fill the three tables is fetched atomically and consistently and is saved in this global internal buffer, forming a point-in-time “snapshot”. If multiple table accesses occur within 0.1 seconds (as they almost certainly do when MySQL processes a join among these tables), then the same snapshot is used to satisfy the query.

A correct result is returned when you `JOIN` any of these tables together in a single query, because the data for the three tables comes from the same snapshot. Because the buffer is not refreshed with every query of any of these tables, if you issue separate queries against these tables within a tenth of a second, the results are the same from query to query. On the other hand, two separate queries of the same or different tables issued more than a tenth of a second apart may see different results, since the data come from different snapshots.

Because InnoDB must temporarily stall while the transaction and locking data is collected, too frequent queries of these tables can negatively impact performance as seen by other users.

As these tables contain sensitive information (at least `INNODB_LOCKS.LOCK_DATA` and `INNODB_TRX.TRX_QUERY`), for security reasons, only the users with the `PROCESS` privilege are allowed to `SELECT` from them.

#### Potential Inconsistency with `PROCESSLIST` Data

As described in [Section 14.12.2.3, “Data Persistence and Consistency for InnoDB Transaction and Locking Tables”](#), the data that fills the InnoDB transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS` and `INNODB_LOCK_WAITS`) is fetched automatically and saved to an intermediate buffer that provides a “point-in-time” snapshot. The data across all three tables is consistent when queried from the same snapshot. However, the underlying data changes so fast that similar glimpses at other, similarly fast-changing data, may not be in synchrony. Thus, you should be careful when comparing data in the InnoDB transaction and locking tables with data in the `PROCESSLIST` table. The data from the `PROCESSLIST` table does not come from the same snapshot as the data about locking and transactions. Even if you issue a single `SELECT` (joining `INNODB_TRX` and `PROCESSLIST`, for example), the content of those tables is generally not consistent. `INNODB_TRX` may reference rows that are not present in `PROCESSLIST` or the currently executing SQL query of a transaction, shown in `INNODB_TRX.TRX_QUERY` may differ from the one in `PROCESSLIST.INFO`.

### 14.12.3 InnoDB INFORMATION\_SCHEMA System Tables

You can extract metadata about schema objects managed by InnoDB using InnoDB `INFORMATION_SCHEMA` system tables. This information comes from the InnoDB internal system tables (also referred to as the InnoDB data dictionary), which cannot be queried directly like regular

InnoDB tables. Traditionally, you would get this type of information using the techniques from [Section 14.14, “InnoDB Monitors”](#), setting up InnoDB monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` command. The InnoDB INFORMATION\_SCHEMA table interface allows you to query this data using SQL.

With the exception of `INNODB_SYS_TABLESTATS`, for which there is no corresponding internal system table, InnoDB INFORMATION\_SCHEMA system tables are populated with data read directly from internal InnoDB system tables rather than from metadata that is cached in memory.

InnoDB INFORMATION\_SCHEMA system tables include the tables listed below.

`INNODB_SYS_DATAFILES` and `INNODB_SYS_TABLESPACES` were added in MySQL 5.6.6 with the introduction of support for the `DATA DIRECTORY='directory'` clause of the `CREATE TABLE` statement, which allows InnoDB file-per-table tablespaces (`.ibd` files) to be created in a location outside the MySQL data directory.

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_SYS%';
+-----+
| Tables_in_information_schema (INNODB_SYS%) |
+-----+
| INNODB_SYS_DATAFILES                       |
| INNODB_SYS_TABLESTATS                     |
| INNODB_SYS_FOREIGN                         |
| INNODB_SYS_COLUMNS                         |
| INNODB_SYS_INDEXES                         |
| INNODB_SYS_FIELDS                          |
| INNODB_SYS_TABLESPACES                     |
| INNODB_SYS_FOREIGN_COLS                    |
| INNODB_SYS_TABLES                          |
+-----+
```

The table names are indicative of the type of data provided:

- `INNODB_SYS_TABLES` provides metadata about InnoDB tables, equivalent to the information in the `SYS_TABLES` table in the InnoDB data dictionary.
- `INNODB_SYS_COLUMNS` provides metadata about InnoDB table columns, equivalent to the information in the `SYS_COLUMNS` table in the InnoDB data dictionary.
- `INNODB_SYS_INDEXES` provides metadata about InnoDB indexes, equivalent to the information in the `SYS_INDEXES` table in the InnoDB data dictionary.
- `INNODB_SYS_FIELDS` provides metadata about the key columns (fields) of InnoDB indexes, equivalent to the information in the `SYS_FIELDS` table in the InnoDB data dictionary.
- `INNODB_SYS_TABLESTATS` provides a view of low-level status information about InnoDB tables that is derived from in-memory data structures. There is no corresponding internal InnoDB system table.
- `INNODB_SYS_DATAFILES` provides data file path information for InnoDB file-per-table and general tablespaces, equivalent to information in the `SYS_DATAFILES` table in the InnoDB data dictionary.
- `INNODB_SYS_TABLESPACES` provides metadata about InnoDB file-per-table and general tablespaces, equivalent to the information in the `SYS_TABLESPACES` table in the InnoDB data dictionary.
- `INNODB_SYS_FOREIGN` provides metadata about foreign keys defined on InnoDB tables, equivalent to the information in the `SYS_FOREIGN` table in the InnoDB data dictionary.
- `INNODB_SYS_FOREIGN_COLS` provides metadata about the columns of foreign keys that are defined on InnoDB tables, equivalent to the information in the `SYS_FOREIGN_COLS` table in the InnoDB data dictionary.

InnoDB INFORMATION\_SCHEMA system tables can be joined together through fields such as `TABLE_ID`, `INDEX_ID`, and `SPACE`, allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the [InnoDB INFORMATION\\_SCHEMA](#) documentation for information about the columns of each table.

### Example 14.13 InnoDB INFORMATION\_SCHEMA System Tables

This example uses a simple table (`t1`) with a single index (`i1`) to demonstrate the type of metadata found in the [InnoDB INFORMATION\\_SCHEMA](#) system tables.

1. Create a test database and table `t1`:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE t1 (
  col1 INT,
  col2 CHAR(10),
  col3 VARCHAR(10))
ENGINE = InnoDB;

mysql> CREATE INDEX i1 ON t1(col1);
```

2. After creating the table `t1`, query `INNODB_SYS_TABLES` to locate the metadata for `test/t1`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G

***** 1. row *****
      TABLE_ID: 71
        NAME: test/t1
         FLAG: 1
        N_COLS: 6
         SPACE: 57
  FILE_FORMAT: Antelope
  ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
      ...
```

Table `t1` has a `TABLE_ID` of 71. The `FLAG` field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by InnoDB (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). The ID of the table's `SPACE` is 57 (a value of 0 would indicate that the table resides in the system tablespace). The `FILE_FORMAT` is Antelope, and the `ROW_FORMAT` is Compact. `ZIP_PAGE_SIZE` only applies to tables with a `Compressed` row format.

3. Using the `TABLE_ID` information from `INNODB_SYS_TABLES`, query the `INNODB_SYS_COLUMNS` table for information about the table's columns.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71 \G

***** 1. row *****
TABLE_ID: 71
  NAME: col1
   POS: 0
  MTYPE: 6
 PRTYPE: 1027
   LEN: 4

***** 2. row *****
TABLE_ID: 71
  NAME: col2
   POS: 1
  MTYPE: 2
 PRTYPE: 524542
   LEN: 10

***** 3. row *****
TABLE_ID: 71
  NAME: col3
   POS: 2
  MTYPE: 1
 PRTYPE: 524303
   LEN: 10
```

In addition to the `TABLE_ID` and column `NAME`, `INNODB_SYS_COLUMNS` provides the ordinal position (`POS`) of each column (starting from 0 and incrementing sequentially), the column `MTYPE` or “main type” (6 = INT, 2 = CHAR, 1 = VARCHAR), the `PRTYPE` or “precise type” (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (`LEN`).

- Using the `TABLE_ID` information from `INNODB_SYS_TABLES` once again, query `INNODB_SYS_INDEXES` for information about the indexes associated with table `t1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 71 \G
***** 1. row *****
INDEX_ID: 111
NAME: GEN_CLUST_INDEX
TABLE_ID: 71
TYPE: 1
N_FIELDS: 0
PAGE_NO: 3
SPACE: 57
MERGE_THRESHOLD: 50
***** 2. row *****
INDEX_ID: 112
NAME: i1
TABLE_ID: 71
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
MERGE_THRESHOLD: 50
```

`INNODB_SYS_INDEXES` returns data for two indexes. The first index is `GEN_CLUST_INDEX`, which is a clustered index created by `InnoDB` if the table does not have a user-defined clustered index. The second index (`i1`) is the user-defined secondary index.

The `INDEX_ID` is an identifier for the index that is unique across all databases in an instance. The `TABLE_ID` identifies the table that the index is associated with. The index `TYPE` value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The `N_FIELDS` value is the number of fields that comprise the index. `PAGE_NO` is the root page number of the index B-tree, and `SPACE` is the ID of the tablespace where the index resides. A non-zero value indicates that the index does not reside in the system tablespace. `MERGE_THRESHOLD` defines a percentage threshold value for the amount of data in an index page. If the amount of data in an index page falls below this value (the default is 50%) when a row is deleted or when a row is shortened by an update operation, `InnoDB` attempts to merge the index page with a neighboring index page.

- Using the `INDEX_ID` information from `INNODB_SYS_INDEXES`, query `INNODB_SYS_FIELDS` for information about the fields of index `i1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS where INDEX_ID = 112 \G
***** 1. row *****
INDEX_ID: 112
NAME: coll
POS: 0
```

`INNODB_SYS_FIELDS` provides the `NAME` of the indexed field and its ordinal position within the index. If the index (`i1`) had been defined on multiple fields, `INNODB_SYS_FIELDS` would provide metadata for each of the indexed fields.

- Using the `SPACE` information from `INNODB_SYS_TABLES`, query `INNODB_SYS_TABLESPACES` table for information about the table's tablespace.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 57 \G
***** 1. row *****
SPACE: 57
NAME: test/t1
FLAG: 0
FILE_FORMAT: Antelope
```

```

ROW_FORMAT: Compact or Redundant
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0

```

In addition to the [SPACE ID](#) of the tablespace and the [NAME](#) of the associated table, [INNODB\\_SYS\\_TABLESPACES](#) provides tablespace [FLAG](#) data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace [FILE\\_FORMAT](#), [ROW\\_FORMAT](#), [PAGE\\_SIZE](#), and [ZIP\\_PAGE\\_SIZE](#) data ([ZIP\\_PAGE\\_SIZE](#) is applicable to tablespaces with a [Compressed](#) row format).

- Using the [SPACE](#) information from [INNODB\\_SYS\\_TABLES](#) once again, query [INNODB\\_SYS\\_DATAFILES](#) for the location of the tablespace data file.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57 \G
***** 1. row *****
SPACE: 57
PATH: ./test/t1.ibd

```

The datafile is located in the `test` directory under MySQL's `data` directory. If a [file-per-table](#) tablespace were created in a location outside the MySQL data directory using the [DATA DIRECTORY](#) clause of the [CREATE TABLE](#) statement, the tablespace [PATH](#) would be a fully qualified directory path.

- As a final step, insert a row into table `t1` ([TABLE\\_ID](#) = 71) and view the data in the [INNODB\\_SYS\\_TABLESTATS](#) table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an [InnoDB](#) table. This information is derived from in-memory data structures. There is no corresponding internal [InnoDB](#) system table.

```

mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71 \G
***** 1. row *****
      TABLE_ID: 71
          NAME: test/t1
STATS_INITIALIZED: Initialized
      NUM_ROWS: 1
  CLUST_INDEX_SIZE: 1
  OTHER_INDEX_SIZE: 0
  MODIFIED_COUNTER: 1
      AUTOINC: 0
      REF_COUNT: 1

```

The [STATS\\_INITIALIZED](#) field indicates whether or not statistics have been collected for the table. [NUM\\_ROWS](#) is the current estimated number of rows in the table. The [CLUST\\_INDEX\\_SIZE](#) and [OTHER\\_INDEX\\_SIZE](#) fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The [MODIFIED\\_COUNTER](#) value shows the number of rows modified by DML operations and cascade operations from foreign keys. The [AUTOINC](#) value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table `t1`, so the value is 0. The [REF\\_COUNT](#) value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.

#### Example 14.14 Foreign Key INFORMATION\_SCHEMA System Tables

The [INNODB\\_SYS\\_FOREIGN](#) and [INNODB\\_SYS\\_FOREIGN\\_COLS](#) tables provide data about foreign key relationships. This example uses a parent table and child table with a foreign key relationship to demonstrate the data found in the [INNODB\\_SYS\\_FOREIGN](#) and [INNODB\\_SYS\\_FOREIGN\\_COLS](#) tables.

- Create the test database with parent and child tables:

```

mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE parent (id INT NOT NULL,
-> PRIMARY KEY (id)) ENGINE=INNODB;

```

```
mysql> CREATE TABLE child (id INT, parent_id INT,
-> INDEX par_ind (parent_id),
-> CONSTRAINT fk1
-> FOREIGN KEY (parent_id) REFERENCES parent(id)
-> ON DELETE CASCADE) ENGINE=INNODB;
```

2. After the parent and child tables are created, query `INNODB_SYS_FOREIGN` and locate the foreign key data for the `test/child` and `test/parent` foreign key relationship:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN \G
***** 1. row *****
      ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
  N_COLS: 1
   TYPE: 1
```

Metadata includes the foreign key `ID` (`fk1`), which is named for the `CONSTRAINT` that was defined on the child table. The `FOR_NAME` is the name of the child table where the foreign key is defined. `REF_NAME` is the name of the parent table (the “referenced” table). `N_COLS` is the number of columns in the foreign key index. `TYPE` is a numerical value representing bit flags that provide additional information about the foreign key column. In this case, the `TYPE` value is 1, which indicates that the `ON DELETE CASCADE` option was specified for the foreign key. See the `INNODB_SYS_FOREIGN` table definition for more information about `TYPE` values.

3. Using the foreign key `ID`, query `INNODB_SYS_FOREIGN_COLS` to view data about the columns of the foreign key.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1' \G
***** 1. row *****
      ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
      POS: 0
```

`FOR_COL_NAME` is the name of the foreign key column in the child table, and `REF_COL_NAME` is the name of the referenced column in the parent table. The `POS` value is the ordinal position of the key field within the foreign key index, starting at zero.

### Example 14.15 Joining InnoDB INFORMATION\_SCHEMA System Tables

This example demonstrates joining three `InnoDB INFORMATION_SCHEMA` system tables (`INNODB_SYS_TABLES`, `INNODB_SYS_TABLESPACES`, and `INNODB_SYS_TABLESTATS`) to gather file format, row format, page size, and index size information about tables in the employees sample database.

The following table name aliases are used to shorten the query string:

- `INFORMATION_SCHEMA.INNODB_SYS_TABLES: a`
- `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES: b`
- `INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS: c`

An `IF()` control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using `ZIP_PAGE_SIZE` rather than `PAGE_SIZE`. `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE`, which are reported in bytes, are divided by `1024*1024` to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the `ROUND()` function.

```
mysql> SELECT a.NAME, a.FILE_FORMAT, a.ROW_FORMAT,
@page_size :=
  IF(a.ROW_FORMAT='Compressed',
    b.ZIP_PAGE_SIZE, b.PAGE_SIZE)
  AS page_size,
ROUND((@page_size * c.CLUST_INDEX_SIZE)
```

```

    /(1024*1024)) AS pk_mb,
    ROUND((@page_size * c.OTHER_INDEX_SIZE)
    /(1024*1024)) AS secidx_mb
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES a
INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES b on a.NAME = b.NAME
INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS c on b.NAME = c.NAME
WHERE a.NAME LIKE 'employees/%'
ORDER BY a.NAME DESC;

```

NAME	FILE_FORMAT	ROW_FORMAT	page_size	pk_mb	secidx_mb
employees/titles	Antelope	Compact	16384	20	11
employees/salaries	Antelope	Compact	16384	91	33
employees/employees	Antelope	Compact	16384	15	0
employees/dept_manager	Antelope	Compact	16384	0	0
employees/dept_emp	Antelope	Compact	16384	12	10
employees/departments	Antelope	Compact	16384	0	0

### 14.12.4 InnoDB INFORMATION\_SCHEMA FULLTEXT Index Tables

With the introduction of [FULLTEXT](#) index support for [InnoDB](#) tables in MySQL 5.6.4, the following tables were added to the [INFORMATION\\_SCHEMA](#) database:

```

mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_FT%';
+-----+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_FT%) |
+-----+-----+
| INNODB_FT_CONFIG |
| INNODB_FT_BEING_DELETED |
| INNODB_FT_DELETED |
| INNODB_FT_DEFAULT_STOPWORD |
| INNODB_FT_INDEX_TABLE |
| INNODB_FT_INDEX_CACHE |
+-----+-----+

```

#### Table Overview

- [INNODB\\_FT\\_CONFIG](#): Displays metadata about the [FULLTEXT](#) index and associated processing for an [InnoDB](#) table.
- [INNODB\\_FT\\_BEING\\_DELETED](#): Provides a snapshot of the [INNODB\\_FT\\_DELETED](#) table that is only used during an [OPTIMIZE TABLE](#) maintenance operation. When [OPTIMIZE TABLE](#) is run, the [INNODB\\_FT\\_BEING\\_DELETED](#) table is emptied, and DOC\_IDs are removed from the [INNODB\\_FT\\_DELETED](#) table. Because the contents of [INNODB\\_FT\\_BEING\\_DELETED](#) typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running [OPTIMIZE TABLE](#) on tables with [FULLTEXT](#) indexes, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).
- [INNODB\\_FT\\_DELETED](#): Records rows that are deleted from the [FULLTEXT](#) index for an [InnoDB](#) table. To avoid expensive index reorganization during DML operations for an [InnoDB FULLTEXT](#) index, the information about newly deleted words is stored separately, filtered out of search results when you perform a text search, and removed from the main search index only when you run [OPTIMIZE TABLE](#).
- [INNODB\\_FT\\_DEFAULT\\_STOPWORD](#): Holds a list of [stopwords](#) that are used by default when creating a [FULLTEXT](#) index.

For information about the [INNODB\\_FT\\_DEFAULT\\_STOPWORD](#) table, see [Section 12.9.4, “Full-Text Stopwords”](#).

- [INNODB\\_FT\\_INDEX\\_TABLE](#): Contains data about the inverted index used to process text searches against the [FULLTEXT](#) index.
- [INNODB\\_FT\\_INDEX\\_CACHE](#): Contains token information about newly inserted rows in a [FULLTEXT](#) index. To avoid expensive index reorganization during DML operations, the information about newly

indexed words is stored separately, and combined with the main search index only when `OPTIMIZE TABLE` is run, when the server is shut down, or when the cache size exceeds a limit defined by `innodb_ft_cache_size` or `innodb_ft_total_cache_size`.

### Note

With the exception of the `INNODB_FT_DEFAULT_STOPWORD` table, you must set the `innodb_ft_aux_table` configuration variable to the name of the table (`database_name/table_name`) that contains the `FULLTEXT` index. Otherwise, the InnoDB `FULLTEXT` index `INFORMATION_SCHEMA` tables appear empty.

### Example 14.16 InnoDB FULLTEXT Index INFORMATION\_SCHEMA Tables

This example uses a table with a `FULLTEXT` index to demonstrate the data contained in the `FULLTEXT` index `INFORMATION_SCHEMA` tables.

1. Create a table with a `FULLTEXT` index and insert some data:

```
mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;

INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');
```

2. Set the `innodb_ft_aux_table` variable to the name of the table with the `FULLTEXT` index. If this variable is not set, the InnoDB `FULLTEXT` `INFORMATION_SCHEMA` tables appear empty, with the exception of the `INNODB_FT_DEFAULT_STOPWORD` table.

```
SET GLOBAL innodb_ft_aux_table = 'test/articles';
```

3. Query the `INNODB_FT_INDEX_CACHE` table, which shows information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the `FULLTEXT` index cache until `OPTIMIZE TABLE` is run (or until the server is shutdown or cache limits are exceeded).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
+-----+-----+-----+-----+-----+-----+
| WORD          | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+-----+-----+-----+-----+-----+-----+
| 1001          | 5            | 5           | 1         | 5      | 0       |
| after        | 3            | 3           | 1         | 3      | 22      |
| comparison    | 6            | 6           | 1         | 6      | 44      |
| configured    | 7            | 7           | 1         | 7      | 20      |
| database     | 2            | 6           | 2         | 2      | 31      |
+-----+-----+-----+-----+-----+-----+
```

4. Enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE` on the table that contains the `FULLTEXT` index. This operation flushes the contents of the `FULLTEXT` index cache to the main `FULLTEXT` index. `innodb_optimize_fulltext_only` changes the way the `OPTIMIZE TABLE` statement operates on InnoDB tables, and is intended to be enabled temporarily, during maintenance operations on InnoDB tables with `FULLTEXT` indexes.

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> OPTIMIZE TABLE articles;
```

Table	Op	Msg_type	Msg_text
test.articles	optimize	status	OK

- Query the `INNOODB_FT_INDEX_TABLE` table to view information about data in the main `FULLTEXT` index, including information about the data that was just flushed from the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNOODB_FT_INDEX_TABLE LIMIT 5;
```

WORD	FIRST_DOC_ID	LAST_DOC_ID	DOC_COUNT	DOC_ID	POSITION
1001	5	5	1	5	0
after	3	3	1	3	22
comparison	6	6	1	6	44
configured	7	7	1	7	20
database	2	6	2	2	31

The `INNOODB_FT_INDEX_CACHE` table is now empty since the `OPTIMIZE TABLE` operation flushed the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNOODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

- Delete some records from the `test/articles` table.

```
mysql> DELETE FROM test.articles WHERE id < 4;
Query OK, 3 rows affected (0.11 sec)
```

- Query the `INNOODB_FT_DELETED` table. This table records rows that are deleted from the `FULLTEXT` index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run `OPTIMIZE TABLE`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNOODB_FT_DELETED;
```

DOC_ID
2
3
4

- Run `OPTIMIZE TABLE` to remove the deleted records.

```
mysql> OPTIMIZE TABLE articles;
```

Table	Op	Msg_type	Msg_text
test.articles	optimize	status	OK

The `INNOODB_FT_DELETED` table should now appear empty.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNOODB_FT_DELETED;
Empty set (0.00 sec)
```

- Query the `INNOODB_FT_CONFIG` table. This table contains metadata about the `FULLTEXT` index and related processing:
  - `optimize_checkpoint_limit` is the number of seconds after which an `OPTIMIZE TABLE` run will stop.
  - `synced_doc_id` is the next `DOC_ID` to be issued.
  - `stopword_table_name` is the `database/table` name for a user-defined stopword table. This field appears empty if there is no user-defined stopword table.

- `use_stopword` indicates whether or not a stopwords table is used, which is defined when the `FULLTEXT` index is created.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY                | VALUE |
+-----+-----+
| optimize_checkpoint_limit | 180   |
| synced_doc_id       | 8     |
| stopwords_table_name |       |
| use_stopword        | 1     |
+-----+-----+
```

## 14.12.5 InnoDB INFORMATION\_SCHEMA Buffer Pool Tables

The `InnoDB INFORMATION_SCHEMA` buffer pool tables provide buffer pool status information and metadata about the pages within the `InnoDB` buffer pool. The tables were introduced in MySQL 5.6.2 and later backported to MySQL 5.5 (in MySQL 5.5.28) and MySQL 5.1 (in MySQL 5.1.66).

The `InnoDB INFORMATION_SCHEMA` buffer pool tables include those listed below:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
+-----+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_BUFFER%) |
+-----+-----+
| INNODB_BUFFER_PAGE_LRU                        |
| INNODB_BUFFER_PAGE                           |
| INNODB_BUFFER_POOL_STATS                     |
+-----+-----+
```

### Table Overview

- `INNODB_BUFFER_PAGE`: Holds information about each page in the `InnoDB` buffer pool.
- `INNODB_BUFFER_PAGE_LRU`: Holds information about the pages in the `InnoDB` buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The `INNODB_BUFFER_PAGE_LRU` table has the same columns as the `INNODB_BUFFER_PAGE` table, except that the `INNODB_BUFFER_PAGE_LRU` table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.
- `INNODB_BUFFER_POOL_STATS`: Provides buffer pool status information. Much of the same information is provided by `SHOW ENGINE INNODB STATUS` output, or may be obtained using `InnoDB` buffer pool server status variables.

#### Warning

Querying the `INNODB_BUFFER_PAGE` table or `INNODB_BUFFER_PAGE_LRU` table can introduce significant performance overhead. Do not query these tables on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

#### Example 14.17 Querying System Data in the `INNODB_BUFFER_PAGE` Table

This query provides an approximate count of pages that contain system data by excluding pages where the `TABLE_NAME` value is either `NULL` or includes a slash “/” or period “.” in the table name, which indicates a user-defined table.

```
SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-----+
| COUNT(*) |
+-----+
|      1516 |
+-----+
```

```
+-----+
```

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```
SELECT
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)
) AS system_pages,
(
SELECT COUNT(*)
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
) AS total_pages,
(
SELECT ROUND((system_pages/total_pages) * 100)
) AS system_page_percentage;
+-----+-----+-----+
| system_pages | total_pages | system_page_percentage |
+-----+-----+-----+
|           295 |          8192 |                   4 |
+-----+-----+-----+
```

The type of system data in the buffer pool can be determined by querying the `PAGE_TYPE` value. For example, the following query returns eight distinct `PAGE_TYPE` values among the pages that contain system data:

```
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-----+
| PAGE_TYPE |
+-----+
| SYSTEM    |
| IBUF_BITMAP |
| UNKNOWN   |
| FILE_SPACE_HEADER |
| INODE     |
| UNDO_LOG  |
| ALLOCATED |
+-----+
```

#### Example 14.18 Querying User Data in the INNODB\_BUFFER\_PAGE Table

This query provides an approximate count of pages containing user data by counting pages where the `TABLE_NAME` value is `NOT NULL` and `NOT LIKE '%INNODB_SYS_TABLES%'`.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND TABLE_NAME NOT LIKE '%INNODB_SYS_TABLES%';
+-----+
| COUNT(*) |
+-----+
|       7897 |
+-----+
```

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```
mysql> SELECT
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
) AS user_pages,
(
SELECT COUNT(*)
FROM information_schema.INNODB_BUFFER_PAGE
) AS total_pages,
(
SELECT ROUND((user_pages/total_pages) * 100)
) AS user_page_percentage;
+-----+-----+-----+
| user_pages | total_pages | user_page_percentage |
+-----+-----+-----+
|       7897 |          8192 |                   96 |
+-----+-----+-----+
```

This query identifies user-defined tables with pages in the buffer pool:

```
mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
AND TABLE_NAME NOT LIKE '`mysql`.`innodb_%`;
+-----+
| TABLE_NAME |
+-----+
| `employees`.`salaries` |
| `employees`.`employees` |
+-----+
```

#### Example 14.19 Querying Index Data in the INNODB\_BUFFER\_PAGE Table

For information about index pages, query the `INDEX_NAME` column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the `emp_no` index that is defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = '`employees`.`salaries`;
+-----+-----+-----+
| INDEX_NAME | Pages | Total Data (MB) |
+-----+-----+-----+
| emp_no     | 1609 | 25               |
+-----+-----+-----+
```

This query returns the number of pages and total data size of pages for all indexes defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME = '`employees`.`salaries`
GROUP BY INDEX_NAME;
+-----+-----+-----+
| INDEX_NAME | Pages | Total Data (MB) |
+-----+-----+-----+
| emp_no     | 1608 | 25               |
| PRIMARY   | 6086 | 95               |
+-----+-----+-----+
```

#### Example 14.20 Querying LRU\_POSITION Data in the INNODB\_BUFFER\_PAGE\_LRU Table

The `INNODB_BUFFER_PAGE_LRU` table holds information about the pages in the InnoDB buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for `INNODB_BUFFER_PAGE`, except this table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the `employees.employees` table.

```
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
WHERE TABLE_NAME='`employees`.`employees`' AND LRU_POSITION < 3072;
+-----+
| COUNT(LRU_POSITION) |
+-----+
| 548                  |
+-----+
```

#### Example 14.21 Querying the INNODB\_BUFFER\_POOL\_STATS Table

The `INNODB_BUFFER_POOL_STATS` table provides information similar to `SHOW ENGINE INNODB STATUS` and InnoDB buffer pool status variables.

```
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
```

```
***** 1. row *****
      POOL_ID: 0
      POOL_SIZE: 8192
      FREE_BUFFERS: 1
      DATABASE_PAGES: 8173
      OLD_DATABASE_PAGES: 3014
      MODIFIED_DATABASE_PAGES: 0
      PENDING_DECOMPRESS: 0
      PENDING_READS: 0
      PENDING_FLUSH_LRU: 0
      PENDING_FLUSH_LIST: 0
      PAGES_MADE_YOUNG: 15907
      PAGES_NOT_MADE_YOUNG: 3803101
      PAGES_MADE_YOUNG_RATE: 0

```

For comparison, `SHOW ENGINE INNODB STATUS` output and InnoDB buffer pool status variable output is shown below, based on the same data set.

For more information about `SHOW ENGINE INNODB STATUS` output, see [Section 14.14.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

```
mysql> SHOW ENGINE INNODB STATUS \G
...
-----
BUFFER POOL AND MEMORY
-----
Total large memory allocated 137428992
Dictionary memory allocated 579084
Buffer pool size      8192
Free buffers          1
Database pages        8173
Old database pages    3014
Modified db pages     0
Pending reads         0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 15907, not young 3803101
0.00 youngs/s, 0.00 non-youngs/s
Pages read 3270, created 13176, written 15109
0.00 reads/s, 0.00 creates/s, 0.00 writes/s
No buffer pool page gets since the last printout
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead 0.00/s
LRU len: 8173, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
...
-----
```

For status variable descriptions, see [Section 5.1.6, “Server Status Variables”](#).

```
mysql> SHOW STATUS LIKE 'Innodb_buffer%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_dump_status | not started |
| Innodb_buffer_pool_load_status | not started |
+-----+-----+
```

## 14.12.6 InnoDB INFORMATION\_SCHEMA Metrics Table

The `INNODB_METRICS` table, introduced in MySQL 5.6.2, consolidates all InnoDB performance and resource-related counters into a single `INFORMATION_SCHEMA` table.

The columns of the `INNODB_METRICS` table are shown in the following example. For a description of each column, see [Section 20.30.20, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
  SUBSYSTEM: dml
      COUNT: 46273
   MAX_COUNT: 46273
   MIN_COUNT: NULL
   AVG_COUNT: 492.2659574468085
  COUNT_RESET: 46273
MAX_COUNT_RESET: 46273
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
  TIME_ENABLED: 2014-11-28 16:07:53
  TIME_DISABLED: NULL
  TIME_ELAPSED: 94
   TIME_RESET: NULL
      STATUS: enabled
      TYPE: status_counter
  COMMENT: Number of rows inserted
```

## Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following configuration options:

- `innodb_monitor_enable`: Enables one or more counters.

```
SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_disable`: Disables one or more counters.

```
SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset`: Resets the count value for one or more counters to zero.

```
SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset_all`: Resets all values for one or more counters. A counter must be disabled before using `innodb_monitor_reset_all`.

```
SET GLOBAL innodb_monitor_reset_all = [counter-name|module_name|pattern|all];
```

You can also enable counters and counter modules at startup using the MySQL server configuration file. For example, to enable the `log` module, `metadata_table_handles_opened` and

`metadata_table_handles_closed` counters, enter the following line in the `[mysqld]` section of your `my.cnf` configuration file.

```
[mysqld]
innodb_monitor_enable = module_recovery,metadata_table_handles_opened,metadata_table_handles_closed
```

When enabling multiple counters or modules in your configuration file, you must specify the `innodb_monitor_enable` configuration option followed by counter and module names separated by a comma, as shown in the example above. Only the `innodb_monitor_enable` option can be used in your configuration file. The `disable` and `reset` configuration options are only supported on the command line.

### Note

Because each counter imposes some degree of runtime overhead on the server, typically you enable more counters on test and development servers during experimentation and benchmarking, and only enable counters on production servers to diagnose known issues or monitor aspects that are likely to be bottlenecks for a particular server and workload.

## Counters

The counters represented in the `INNODB_METRICS` table are subject to change, so for the most up-to-date list, query a running MySQL server. The list below shows counters that are available as of MySQL 5.7.6.

Counters that are enabled by default correspond to those used by `SHOW ENGINE INNODB STATUS`. Counters used by `SHOW ENGINE INNODB STATUS` are always “on” at a system level but you can disable these counters for the `INNODB_METRICS` table, as required. Also, counter status is not persistent. Unless specified otherwise, counters revert to their default enabled or disabled status when the server is restarted.

If you run programs that would be affected by additions or changes to the `INNODB_METRICS` table, it is recommended that you review releases notes and query the `INNODB_METRICS` table for the new release prior to upgrading.

```
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
```

## Counter Modules

The module names correspond to, but are not identical to, the values from the [SUBSYSTEM](#) column of the [INNODB\\_METRICS](#) table. Rather enabling, disabling, or resetting counters individually, you can use

module names to quickly enable, disable, or reset all counters for a particular subsystem. For example, use `module_dml` to enable all counters associated with the `dml` subsystem.

```
mysql> SET GLOBAL innodb_monitor_enable = module_dml;

mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE subsystem = 'dml';
+-----+-----+-----+
| name      | subsystem | status |
+-----+-----+-----+
| dml_reads | dml       | enabled |
| dml_inserts | dml      | enabled |
| dml_deletes | dml      | enabled |
| dml_updates | dml      | enabled |
+-----+-----+-----+
```

Here are the values you can use for `module_name` with the `innodb_monitor_enable` and related configuration options, along with the corresponding `SUBSYSTEM` names:

- `module_metadata` (subsystem = `metadata`)
- `module_lock` (subsystem = `lock`)
- `module_buffer` (subsystem = `buffer`)
- `module_buf_page` (subsystem = `buffer_page_io`)
- `module_os` (subsystem = `os`)
- `module_trx` (subsystem = `transaction`)
- `module_purge` (subsystem = `purge`)
- `module_compress` (subsystem = `compression`)
- `module_file` (subsystem = `file_system`)
- `module_index` (subsystem = `index`)
- `module_adaptive_hash` (subsystem = `adaptive_hash_index`)
- `module_ibuf_system` (subsystem = `change_buffer`)
- `module_srv` (subsystem = `server`)
- `module_ddl` (subsystem = `ddl`)
- `module_dml` (subsystem = `dml`)
- `module_log` (subsystem = `recovery`)
- `module_icp` (subsystem = `icp`)

#### Example 14.22 Working with INNODB\_METRICS Table Counters

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the `INNODB_METRICS` table.

1. Create a simple `InnoDB` table:

```
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)
```

2. Enable the `dml_inserts` counter.

```
mysql> SET GLOBAL innodb_monitor_enable = dml_inserts;
Query OK, 0 rows affected (0.01 sec)
```

A description of the `dml_inserts` counter can be found in the `COMMENT` column of the `INNODB_METRICS` table:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts";
+-----+-----+
| NAME          | COMMENT                                |
+-----+-----+
| dml_inserts  | Number of rows inserted              |
+-----+-----+
```

- Query the `INNODB_METRICS` table for the `dml_inserts` counter data. Because no DML operations have been performed, the counter values are zero or NULL. The `TIME_ENABLED` and `TIME_ELAPSED` values indicate when the counter was last enabled and how many seconds have elapsed since this time.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
      SUBSYSTEM: dml
      COUNT: 0
      MAX_COUNT: 0
      MIN_COUNT: NULL
      AVG_COUNT: 0
      COUNT_RESET: 0
      MAX_COUNT_RESET: 0
      MIN_COUNT_RESET: NULL
      AVG_COUNT_RESET: NULL
      TIME_ENABLED: 2014-12-04 14:18:28
      TIME_DISABLED: NULL
      TIME_ELAPSED: 28
      TIME_RESET: NULL
      STATUS: enabled
      TYPE: status_counter
      COMMENT: Number of rows inserted
```

- Insert three rows of data into the table.

```
mysql> INSERT INTO t1 values(1);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(2);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(3);
Query OK, 1 row affected (0.00 sec)
```

- Query the `INNODB_METRICS` table again for the `dml_inserts` counter data. A number of counter values have now incremented including `COUNT`, `MAX_COUNT`, `AVG_COUNT`, and `COUNT_RESET`. Refer to the `INNODB_METRICS` table definition for descriptions of these values.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
      SUBSYSTEM: dml
      COUNT: 3
      MAX_COUNT: 3
      MIN_COUNT: NULL
      AVG_COUNT: 0.046153846153846156
      COUNT_RESET: 3
      MAX_COUNT_RESET: 3
      MIN_COUNT_RESET: NULL
      AVG_COUNT_RESET: NULL
      TIME_ENABLED: 2014-12-04 14:18:28
      TIME_DISABLED: NULL
      TIME_ELAPSED: 65
      TIME_RESET: NULL
```

```

STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted

```

- Reset the `dml_inserts` counter, and query the `INNODB_METRICS` table again for the `dml_inserts` counter data. The “%\_RESET” values that were reported previously, such as `COUNT_RESET` and `MAX_RESET`, are set back to zero. Values such as `COUNT`, `MAX_COUNT`, and `AVG_COUNT`, which cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```

mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
     SUBSYSTEM: dml
        COUNT: 3
     MAX_COUNT: 3
     MIN_COUNT: NULL
     AVG_COUNT: 0.03529411764705882
     COUNT_RESET: 0
  MAX_COUNT_RESET: 0
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: 0
     TIME_ENABLED: 2014-12-04 14:18:28
     TIME_DISABLED: NULL
     TIME_ELAPSED: 85
     TIME_RESET: 2014-12-04 14:19:44
        STATUS: enabled
         TYPE: status_counter
        COMMENT: Number of rows inserted

```

- To reset all counter values, you must first disable the counter. Disabling the counter sets the `STATUS` value to `disabled`.

```

mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
     SUBSYSTEM: dml
        COUNT: 3
     MAX_COUNT: 3
     MIN_COUNT: NULL
     AVG_COUNT: 0.030612244897959183
     COUNT_RESET: 0
  MAX_COUNT_RESET: 0
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: 0
     TIME_ENABLED: 2014-12-04 14:18:28
     TIME_DISABLED: 2014-12-04 14:20:06
     TIME_ELAPSED: 98
     TIME_RESET: NULL
        STATUS: disabled
         TYPE: status_counter
        COMMENT: Number of rows inserted

```

### Note

Wildcard match is supported for counter and module names. For example, instead of specifying the full `dml_inserts` counter name, you can specify “`dml_i%`”. You can also enable, disable, or reset multiple counters or modules at once using a wildcard match. For example, specify “`dml_%`” to enable, disable, or reset all counters that begin with “`dml_%`”.

- After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```
mysql> SET GLOBAL innodb_monitor_reset_all = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
     SUBSYSTEM: dml
        COUNT: 0
     MAX_COUNT: NULL
     MIN_COUNT: NULL
     AVG_COUNT: NULL
    COUNT_RESET: 0
  MAX_COUNT_RESET: NULL
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: NULL
      TIME_ENABLED: NULL
      TIME_DISABLED: NULL
      TIME_ELAPSED: NULL
      TIME_RESET: NULL
        STATUS: disabled
         TYPE: status_counter
      COMMENT: Number of rows inserted
```

## 14.12.7 InnoDB INFORMATION\_SCHEMA Temporary Table Information Table

The `INNODB_TEMP_TABLE_INFO` table, introduced in MySQL 5.7.1, provides users with a snapshot of active InnoDB temporary tables. The table contains metadata about all user and system-created temporary tables that are active within a given InnoDB instance with the exception of optimized temporary tables that are used internally by InnoDB.

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_TEMP%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_TEMP%) |
+-----+
| INNODB_TEMP_TABLE_INFO                       |
+-----+
```

For the table definition, see [Section 20.30.27, “The INFORMATION\\_SCHEMA INNODB\\_TEMP\\_TABLE\\_INFO Table”](#).

### Example 14.23 INNODB\_TEMP\_TABLE\_INFO

This example demonstrates characteristics of the `INNODB_TEMP_TABLE_INFO` table.

1. Create a simple InnoDB temporary table with a single column:

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)
```

2. Query the `INNODB_TEMP_TABLE_INFO` table to view the temporary table's metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 194
         NAME: #sql7a79_1_0
        N_COLS: 4
         SPACE: 182
  PER_TABLE_TABLESPACE: FALSE
        IS_COMPRESSED: FALSE
```

The `TABLE_ID` is a unique identifier for the temporary table. The `NAME` column displays the system-generated name for the temporary table, which is prefixed with “#sql”. The number of columns (`N_COLS`) is 4 rather than 1 because InnoDB always creates three hidden table columns (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). `PER_TABLE_TABLESPACE` and `IS_COMPRESSED` only report `TRUE` for compressed temporary tables.

3. Create a compressed temporary table. Before you do so, ensure that `innodb_file_format` is set to `Barracuda`, which is required to create tables with a compressed row format.

```
mysql> SET GLOBAL innodb_file_format="Barracuda";
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TEMPORARY TABLE t2 (c1 INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)
```

4. Query the `INNODB_TEMP_TABLE_INFO` table again.

```
mysql> CREATE TEMPORARY TABLE t2 (c1 INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 195
        NAME: #sql7a79_1_1
        N_COLS: 4
        SPACE: 183
PER_TABLE_TABLESPACE: TRUE
      IS_COMPRESSED: TRUE
***** 2. row *****
      TABLE_ID: 194
        NAME: #sql7a79_1_0
        N_COLS: 4
        SPACE: 182
PER_TABLE_TABLESPACE: FALSE
      IS_COMPRESSED: FALSE
```

`PER_TABLE_TABLESPACE` and `IS_COMPRESSED` report `TRUE` for the compressed temporary table. The `SPACE` ID for the compressed temporary table is different because compressed temporary tables are created in separate per-table tablespaces. Non-compressed temporary tables share a single tablespace (`ibtmp1`, by default) and report the same `SPACE` ID.

5. Restart MySQL and query the `INNODB_TEMP_TABLE_INFO` table.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
Empty set (0.00 sec)
```

An empty set is returned because the `INNODB_TEMP_TABLE_INFO` table and the data within it are not persisted to disk on server shutdown.

6. Create a new temporary table.

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)
```

7. Query the `INNODB_TEMP_TABLE_INFO` table to view the temporary table's metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 196
        NAME: #sql7b0e_1_0
        N_COLS: 4
        SPACE: 184
PER_TABLE_TABLESPACE: FALSE
      IS_COMPRESSED: FALSE
```

The `SPACE` ID is new because it is dynamically generated on server restart.

## 14.12.8 Retrieving InnoDB Tablespace Metadata from INFORMATION\_SCHEMA.FILES

As of MySQL 5.7.8, the `INFORMATION_SCHEMA.FILES` table provides metadata about all InnoDB tablespace types including `file-per-table tablespaces`, `general tablespaces`, the `system tablespace`, `temporary table tablespaces`, and `undo tablespaces` (if present).

This section provides [InnoDB](#)-specific usage examples. For more information about data provided by the `INFORMATION_SCHEMA.FILES` table, see [Section 20.8](#), “The `INFORMATION_SCHEMA.FILES` Table”.

### Note

The `INNODB_SYS_TABLESPACES` and `INNODB_SYS_DATAFILES` tables also provide metadata about [InnoDB](#) tablespaces, but data is limited to file-per-table and general tablespaces.

This query retrieves metadata about the [InnoDB](#) system tablespace from fields of the `INFORMATION_SCHEMA.FILES` table that are pertinent to [InnoDB](#) tablespaces. `INFORMATION_SCHEMA.FILES` fields that are not relevant to [InnoDB](#) always return `NULL`, and are excluded from the query.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS,
TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS ENGINE
FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME LIKE 'innodb_system' \G
***** 1. row *****
      FILE_ID: 0
      FILE_NAME: ./ibdata1
      FILE_TYPE: TABLESPACE
TABLESPACE_NAME: innodb_system
      FREE_EXTENTS: 0
      TOTAL_EXTENTS: 12
      EXTENT_SIZE: 1048576
      INITIAL_SIZE: 12582912
      MAXIMUM_SIZE: NULL
      AUTOEXTEND_SIZE: 67108864
      DATA_FREE: 4194304
      ENGINE: NORMAL
```

This query retrieves the `FILE_ID` (equivalent to the space ID) and the `FILE_NAME` (which includes path information) for [InnoDB](#) file-per-table and general tablespaces. File-per-table and general tablespaces have a `.ibd` file extension.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%.ibd%' ORDER BY FILE_ID;
+-----+-----+
| FILE_ID | FILE_NAME |
+-----+-----+
| 2 | ./mysql/plugin.ibd |
| 3 | ./mysql/servers.ibd |
| 4 | ./mysql/help_topic.ibd |
| 5 | ./mysql/help_category.ibd |
| 6 | ./mysql/help_relation.ibd |
| 7 | ./mysql/help_keyword.ibd |
| 8 | ./mysql/time_zone_name.ibd |
| 9 | ./mysql/time_zone.ibd |
| 10 | ./mysql/time_zone_transition.ibd |
| 11 | ./mysql/time_zone_transition_type.ibd |
| 12 | ./mysql/time_zone_leap_second.ibd |
| 13 | ./mysql/innodb_table_stats.ibd |
| 14 | ./mysql/innodb_index_stats.ibd |
| 15 | ./mysql/slave_relay_log_info.ibd |
| 16 | ./mysql/slave_master_info.ibd |
| 17 | ./mysql/slave_worker_info.ibd |
| 18 | ./mysql/gtid_executed.ibd |
| 19 | ./mysql/server_cost.ibd |
| 20 | ./mysql/engine_cost.ibd |
| 21 | ./sys/sys_config.ibd |
| 23 | ./test/t1.ibd |
| 26 | /home/user/test/test/t2.ibd |
+-----+-----+
```

This query retrieves the `FILE_ID` and `FILE_NAME` for [InnoDB](#) temporary table tablespaces. Temporary table tablespace file names are prefixed by `ibtmp`.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
```

```
WHERE FILE_NAME LIKE '%ibtmp%';
+-----+-----+
| FILE_ID | FILE_NAME |
+-----+-----+
|      22 | ./ibtmp1  |
+-----+-----+
```

Similarly, InnoDB undo tablespace file names are prefixed by `undo`. The following query returns the `FILE_ID` and `FILE_NAME` for InnoDB undo tablespaces, if separate undo tablespaces are configured.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%undo%';
```

## 14.13 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see [Chapter 21, MySQL Performance Schema](#).

You can profile certain internal InnoDB operations using the MySQL Performance Schema feature. This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be generally familiar with how to use the [Performance Schema feature](#). For example, you should know how to enable instruments and consumers, and how to query `performance_schema` tables to retrieve data. For an introductory overview, see [Section 21.1, “Performance Schema Quick Start”](#).
- You should be familiar with Performance Schema instruments that are available for InnoDB. To view InnoDB-related instruments, you can query the `setup_instruments` table for instrument names that contain `'innodb'`.

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE '%innodb%';
+-----+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+-----+
| wait/synch/mutex/innodb/commit_cond_mutex | NO      | NO    |
| wait/synch/mutex/innodb/innobase_share_mutex | NO      | NO    |
| wait/synch/mutex/innodb/autoinc_mutex      | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_mutex     | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_zip_mutex | NO      | NO    |
| wait/synch/mutex/innodb/cache_last_read_mutex | NO      | NO    |
| wait/synch/mutex/innodb/dict_foreign_err_mutex | NO      | NO    |
| wait/synch/mutex/innodb/dict_sys_mutex     | NO      | NO    |
| wait/synch/mutex/innodb/recalc_pool_mutex   | NO      | NO    |
| wait/synch/mutex/innodb/file_format_max_mutex | NO      | NO    |
| ...                                        |         |       |
| wait/io/file/innodb/innodb_data_file       | YES     | YES   |
| wait/io/file/innodb/innodb_log_file        | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file       | YES     | YES   |
| stage/innodb/alter table (end)             | YES     | YES   |
| stage/innodb/alter table (flush)           | YES     | YES   |
| stage/innodb/alter table (insert)          | YES     | YES   |
| stage/innodb/alter table (log apply index)  | YES     | YES   |
| stage/innodb/alter table (log apply table)  | YES     | YES   |
| stage/innodb/alter table (merge sort)      | YES     | YES   |
| stage/innodb/alter table (read PK and internal sort) | YES     | YES   |
| stage/innodb/buffer pool load              | YES     | YES   |
| memory/innodb/buf_buf_pool                 | NO      | NO    |
| memory/innodb/dict_stats_bg_recalc_pool_t  | NO      | NO    |
| memory/innodb/dict_stats_index_map_t       | NO      | NO    |
| memory/innodb/dict_stats_n_diff_on_level   | NO      | NO    |
| memory/innodb/other                         | NO      | NO    |
| memory/innodb/row_log_buf                  | NO      | NO    |
```

```

| memory/innodb/row_merge_sort | NO | NO |
| memory/innodb/std | NO | NO |
| memory/innodb/sync_debug_latches | NO | NO |
| memory/innodb/trx_sys_t:rw_trx_ids | NO | NO |
...
+-----+-----+-----+
155 rows in set (0.00 sec)

```

For additional information about the instrumented [InnoDB](#) objects, you can query Performance Schema [instances tables](#), which provide additional information about instrumented objects. Instance tables relevant to [InnoDB](#) include:

- The [mutex\\_instances](#) table
- The [rwlock\\_instances](#) table
- The [cond\\_instances](#) table
- The [file\\_instances](#) table

**Note**

Mutexes and RW-locks related to the [InnoDB](#) buffer pool are not included in this coverage; the same applies to the output of the [SHOW ENGINE INNODB MUTEX](#) command.

For example, to view information about instrumented [InnoDB](#) file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```

mysql> SELECT * FROM file_instances WHERE EVENT_NAME LIKE '%innodb%'\G
***** 1. row *****
FILE_NAME: /path/to/mysql-5.7/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
***** 2. row *****
FILE_NAME: /path/to/mysql-5.7/data/ib_logfile0
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 3. row *****
FILE_NAME: /path/to/mysql-5.7/data/ib_logfile1
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 4. row *****
FILE_NAME: /path/to/mysql-5.7/data/mysql/engine_cost.ibd
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
...

```

- You should be familiar with [performance\\_schema](#) tables that store [InnoDB](#) event data. Tables relevant to [InnoDB](#)-related events include:
  - The [Wait Event](#) tables, which store wait events.
  - The [Summary](#) tables, which provide aggregated information for terminated events over time. Summary tables include [file I/O summary tables](#), which aggregate information about I/O operations.
  - [Stage Event](#) tables, which store event data for [InnoDB ALTER TABLE](#) and buffer pool load operations. For more information, see [Section 14.13.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#), and [Monitoring Buffer Pool Load Progress Using Performance Schema](#).

If you are only interested in [InnoDB](#)-related objects, use the clause [WHERE EVENT\\_NAME LIKE '%innodb%'](#) or [WHERE NAME LIKE '%innodb%'](#) (as required) when querying these tables.

## 14.13.1 Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema

As of MySQL 5.7.6, you can monitor `ALTER TABLE` progress for InnoDB tables using [Performance Schema](#).

There are seven stage events that represent different phases of `ALTER TABLE`. Each stage event reports a running total of `WORK_COMPLETED` and `WORK_ESTIMATED` for the overall `ALTER TABLE` operation as it progresses through its different phases. `WORK_ESTIMATED` is calculated using a formula that takes into account all of the work that `ALTER TABLE` performs, and may be revised during `ALTER TABLE` processing. `WORK_COMPLETED` and `WORK_ESTIMATED` values are an abstract representation of all of the work performed by `ALTER TABLE`.

In order of occurrence, `ALTER TABLE` stage events include:

- `stage/innodb/alter table (read PK and internal sort)`: This stage is active when `ALTER TABLE` is in the reading-primary-key phase. It starts with `WORK_COMPLETED=0` and `WORK_ESTIMATED` set to the estimated number of pages in the primary key. When the stage is completed, `WORK_ESTIMATED` is updated to the actual number of pages in the primary key.
- `stage/innodb/alter table (merge sort)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (insert)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (log apply index)`: This stage includes the application of DML log generated while `ALTER TABLE` was running.
- `stage/innodb/alter table (flush)`: Before this stage begins, `WORK_ESTIMATED` is updated with a more accurate estimate, based on the length of the flush list.
- `stage/innodb/alter table (log apply table)`: This stage includes the application of concurrent DML log generated while `ALTER TABLE` was running. The duration of this phase depends on the extent of table changes. This phase is instant if no concurrent DML was run on the table.
- `stage/innodb/alter table (end)`: Includes any remaining work that appeared after the flush phase, such as reapplying DML that was executed on the table while `ALTER TABLE` was running.

### Note

InnoDB `ALTER TABLE` stage events do not currently account for the addition of spatial indexes.

## ALTER TABLE Monitoring Example Using Performance Schema

The following example demonstrates how to enable the `stage/innodb/alter table%` stage event instruments and related consumer tables to monitor `ALTER TABLE` progress. For information about Performance Schema stage event instruments and related consumers, see [Section 21.9.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/alter%` instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES' WHERE NAME LIKE 'stage/innodb/alter%';
Query OK, 7 rows affected (0.00 sec)
Rows matched: 7  Changed: 7  Warnings: 0
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES' WHERE NAME LIKE '%stages%';
Query OK, 3 rows affected (0.00 sec)
```

```
Rows matched: 3  Changed: 3  Warnings: 0
```

- Run an `ALTER TABLE` operation. In this example, a `middle_name` column is added to the `employees` table of the `employees` sample database.

```
mysql> ALTER TABLE employees.employees ADD COLUMN middle_name varchar(14) AFTER first_name;
Query OK, 0 rows affected (9.27 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

- Check the progress of the `ALTER TABLE` operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on which `ALTER TABLE` phase is currently in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column provides an estimate of the remaining work.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_current;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter table (read PK and internal sort) | 280 | 1245 |
+-----+-----+-----+
1 row in set (0.01 sec)
```

The `events_stages_current` table returns an empty set if the `ALTER TABLE` operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter table (read PK and internal sort) | 886 | 1213 |
| stage/innodb/alter table (flush) | 1213 | 1213 |
| stage/innodb/alter table (log apply table) | 1597 | 1597 |
| stage/innodb/alter table (end) | 1597 | 1597 |
| stage/innodb/alter table (log apply table) | 1981 | 1981 |
+-----+-----+-----+
5 rows in set (0.00 sec)
```

As shown above, the `WORK_ESTIMATED` value was revised during `ALTER TABLE` processing. The estimated work after completion of the initial stage is 1213. When `ALTER TABLE` processing completed, `WORK_ESTIMATED` was set to the actual value, which is 1981.

## 14.13.2 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For InnoDB mutexes that are instrumented, mutex waits can be monitored using [Performance Schema](#). Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable InnoDB mutex wait instruments, how to enable associated consumers, and how to query wait event data.

- To view available InnoDB mutex wait instruments, query the Performance Schema `setup_instruments` table, as shown below. All InnoDB mutex wait instruments are disabled by default.

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%wait/synch/mutex/innodb%';
+-----+-----+-----+
| NAME | ENABLED | TIMED |
+-----+-----+-----+
| wait/synch/mutex/innodb/commit_cond_mutex | NO | NO |
+-----+-----+-----+
```

wait/synch/mutex/innodb/innobase_share_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_mutex	NO	NO
wait/synch/mutex/innodb/cache_last_read_mutex	NO	NO
wait/synch/mutex/innodb/dict_foreign_err_mutex	NO	NO
wait/synch/mutex/innodb/dict_sys_mutex	NO	NO
wait/synch/mutex/innodb/recalc_pool_mutex	NO	NO
wait/synch/mutex/innodb/file_format_max_mutex	NO	NO
wait/synch/mutex/innodb/fil_system_mutex	NO	NO
wait/synch/mutex/innodb/flush_list_mutex	NO	NO
wait/synch/mutex/innodb/fts_bg_threads_mutex	NO	NO
wait/synch/mutex/innodb/fts_delete_mutex	NO	NO
wait/synch/mutex/innodb/fts_optimize_mutex	NO	NO
wait/synch/mutex/innodb/fts_doc_id_mutex	NO	NO
wait/synch/mutex/innodb/log_flush_order_mutex	NO	NO
wait/synch/mutex/innodb/hash_table_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_bitmap_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex	NO	NO
wait/synch/mutex/innodb/log_sys_mutex	NO	NO
wait/synch/mutex/innodb/page_zip_stat_per_index_mutex	NO	NO
wait/synch/mutex/innodb/purge_sys_pq_mutex	NO	NO
wait/synch/mutex/innodb/recv_sys_mutex	NO	NO
wait/synch/mutex/innodb/recv_writer_mutex	NO	NO
wait/synch/mutex/innodb/redo_rseg_mutex	NO	NO
wait/synch/mutex/innodb/noredoreg_mutex	NO	NO
wait/synch/mutex/innodb/rw_lock_list_mutex	NO	NO
wait/synch/mutex/innodb/rw_lock_mutex	NO	NO
wait/synch/mutex/innodb/srv_dict_tmpfile_mutex	NO	NO
wait/synch/mutex/innodb/srv_innodb_monitor_mutex	NO	NO
wait/synch/mutex/innodb/srv_misc_tmpfile_mutex	NO	NO
wait/synch/mutex/innodb/srv_monitor_file_mutex	NO	NO
wait/synch/mutex/innodb/buf_dblwr_mutex	NO	NO
wait/synch/mutex/innodb/trx_undo_mutex	NO	NO
wait/synch/mutex/innodb/trx_pool_mutex	NO	NO
wait/synch/mutex/innodb/trx_pool_manager_mutex	NO	NO
wait/synch/mutex/innodb/srv_sys_mutex	NO	NO
wait/synch/mutex/innodb/lock_mutex	NO	NO
wait/synch/mutex/innodb/lock_wait_mutex	NO	NO
wait/synch/mutex/innodb/trx_mutex	NO	NO

wait/synch/mutex/innodb/rtr_active_mutex	NO	NO
wait/synch/mutex/innodb/rtr_match_mutex	NO	NO
wait/synch/mutex/innodb/rtr_path_mutex	NO	NO
wait/synch/mutex/innodb/rtr_ssn_mutex	NO	NO
wait/synch/mutex/innodb/trx_sys_mutex	NO	NO
wait/synch/mutex/innodb/zip_pad_mutex	NO	NO

49 rows in set (0.02 sec)

- Some [InnoDB](#) mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all [InnoDB](#) mutex instances are instrumented and enabled, add the following `performance-schema-instrument` rule to your MySQL configuration file:

```
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all [InnoDB](#) mutexes, you can disable specific instruments by adding additional `performance-schema-instrument` rules to your MySQL configuration file. For example, to disable [InnoDB](#) mutex wait event instruments related to full-text search, add the following rule:

```
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

**Note**

Rules with a longer prefix such as `wait/synch/mutex/innodb/fts%` take precedence over rules with shorter prefixes such as `wait/synch/mutex/innodb/%`.

After adding the `performance-schema-instrument` rules to your configuration file, restart the server. All the InnoDB mutexes except for those related to full text search are enabled. To verify, query the `setup_instruments` table. The `ENABLED` and `TIMED` columns should be set to `YES` for the instruments that you enabled.

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	YES	YES
wait/synch/mutex/innodb/innobase_share_mutex	YES	YES
wait/synch/mutex/innodb/autoinc_mutex	YES	YES
...		
wait/synch/mutex/innodb/zip_pad_mutex	YES	YES

```
49 rows in set (0.00 sec)
```

3. Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```
mysql> UPDATE performance_schema.setup_consumers SET enabled = 'YES'
WHERE name like 'events_waits%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0
```

You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	NO
events_waits_current	YES
events_waits_history	YES
events_waits_history_long	YES
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES

```
15 rows in set (0.00 sec)
```

4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
shell> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10 --number-of-queries=1000
--number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long`

tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- `COUNT_STAR`

The number of summarized wait events.

- `SUM_TIMER_WAIT`

The total wait time of the summarized timed wait events.

- `MIN_TIMER_WAIT`

The minimum wait time of the summarized timed wait events.

- `AVG_TIMER_WAIT`

The average wait time of the summarized timed wait events.

- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (`EVENT_NAME`), the number of wait events (`COUNT_STAR`), and the total wait time for the events for that instrument (`SUM_TIMER_WAIT`). Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events (`COUNT_STAR`). You can adjust the `ORDER BY` clause to order the data by total wait time.

```
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
FROM performance_schema.events_waits_summary_global_by_event_name
WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
ORDER BY COUNT_STAR DESC;
```

EVENT_NAME	COUNT_STAR	SUM_TIMER_WAIT_MS
wait/synch/mutex/innodb/os_mutex	78831	10.3283
wait/synch/mutex/innodb/log_sys_mutex	41488	6510.3233
wait/synch/mutex/innodb/trx_sys_mutex	29770	1107.9687
wait/synch/mutex/innodb/lock_mutex	24212	104.0724
wait/synch/mutex/innodb/trx_mutex	22756	1.9421
wait/synch/mutex/innodb/rseg_mutex	20333	3.6220
wait/synch/mutex/innodb/dict_sys_mutex	13422	2.2284
wait/synch/mutex/innodb/mutex_list_mutex	12694	344.1164
wait/synch/mutex/innodb/fil_system_mutex	9208	0.9542
wait/synch/mutex/innodb/rw_lock_list_mutex	8304	0.1794
wait/synch/mutex/innodb/trx_undo_mutex	6190	0.6801
wait/synch/mutex/innodb/buf_pool_mutex	2869	29.4623
wait/synch/mutex/innodb/innobase_share_mutex	2005	0.1349
wait/synch/mutex/innodb/flush_list_mutex	1274	0.1300
wait/synch/mutex/innodb/file_format_max_mutex	1016	0.0469
wait/synch/mutex/innodb/purge_sys_bh_mutex	1004	0.0326
wait/synch/mutex/innodb/buf_dblwr_mutex	640	0.0437
wait/synch/mutex/innodb/log_flush_order_mutex	437	0.0510
wait/synch/mutex/innodb/recv_sys_mutex	394	0.0202
wait/synch/mutex/innodb/srv_sys_mutex	169	0.5259
wait/synch/mutex/innodb/lock_wait_mutex	154	0.1172
wait/synch/mutex/innodb/ibuf_mutex	9	0.0027
wait/synch/mutex/innodb/srv_innodb_monitor_mutex	2	0.0009
wait/synch/mutex/innodb/ut_list_mutex	1	0.0001
wait/synch/mutex/innodb/recv_writer_mutex	1	0.0005

25 rows in set (0.01 sec)

**Note**

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the `events_waits_summary_global_by_event_name` table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```

## 14.14 InnoDB Monitors

[InnoDB](#) monitors provide information about the [InnoDB](#) internal state. This information is useful for performance tuning.

### 14.14.1 InnoDB Monitor Types

There are four types of [InnoDB](#) monitors:

- The standard [InnoDB](#) Monitor displays the following types of information:
  - Table and record locks held by each active transaction.
  - Lock waits of a transaction.
  - Semaphore waits of threads.
  - Pending file I/O requests.
  - Buffer pool statistics.
  - Purge and change buffer merge activity of the main [InnoDB](#) thread.
- The [InnoDB](#) Lock Monitor prints additional lock information as part of the standard [InnoDB](#) Monitor output.
- The [InnoDB](#) Tablespace Monitor prints a list of file segments in the shared tablespace and validates the tablespace allocation data structures.
- The [InnoDB](#) Table Monitor prints the contents of the [InnoDB](#) internal data dictionary.

**Note**

The Tablespace Monitor and Table Monitor were deprecated in MySQL 5.6.3 and have been removed in MySQL 5.7.4. For the Tablespace Monitor, equivalent functionality will be introduced before the GA release of MySQL 5.7. For the Table Monitor, equivalent information can be obtained from [InnoDB INFORMATION\\_SCHEMA](#) tables.

For additional information about [InnoDB](#) monitors, see:

- Mark Leith: [InnoDB Table and Tablespace Monitors](#)

### 14.14.2 Enabling InnoDB Monitors

When you enable [InnoDB](#) monitors for periodic output, [InnoDB](#) writes their output to the `mysqld` server standard error output (`stderr`). In this case, no output is sent to clients. When switched on, [InnoDB](#) monitors print data about every 15 seconds. Server output usually is directed to the error log (see [Section 5.2.2, “The Error Log”](#)). This data is useful in performance tuning. On Windows, start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

InnoDB sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. InnoDB removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb-status-file=1` is set.

InnoDB monitors should be enabled only when you actually want to see monitor information because output generation does result in some performance decrement. Also, if you enable monitor output, your error log may become quite large if you forget to disable it later.

#### Note

To assist with troubleshooting, InnoDB temporarily enables standard InnoDB Monitor output under certain conditions. For more information, see [Section 14.18, “InnoDB Troubleshooting”](#).

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
=====
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT
=====
```

The header for the standard InnoDB Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

Enabling an InnoDB monitor for periodic output involves using a `CREATE TABLE` statement to create a specially named InnoDB table that is associated with the monitor. For example, to enable the standard InnoDB Monitor, you would create an InnoDB table named `innodb_monitor`.

Using `CREATE TABLE` syntax is just a way to pass a command to the InnoDB engine through MySQL's SQL parser. The only things that matter are the table name and that it be an InnoDB table. The structure of the table is not relevant. If you shut down the server, the monitor does not restart automatically when you restart the server. Drop the monitor table and issue a new `CREATE TABLE` statement to start the monitor.

#### Note

The `CREATE TABLE` method of enabling InnoDB monitors was removed in MySQL 5.7.4. Use the `innodb_status_output` and `innodb_status_output_locks` system variables to enable the standard InnoDB Monitor and InnoDB Lock Monitor.

The `PROCESS` privilege is required to enable and disable InnoDB Monitors.

## Enabling the Standard InnoDB Monitor

Prior to MySQL 5.7.4, enable the standard InnoDB Monitor for periodic output by creating the `innodb_monitor` table:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

To disable the standard InnoDB Monitor, drop the table:

```
DROP TABLE innodb_monitor;
```

As of MySQL 5.7.4, enable the standard InnoDB Monitor by setting the `innodb_status_output` system variable to `ON`.

```
set GLOBAL innodb_status_output=ON;
```

To disable the standard InnoDB Monitor, set `innodb_status_output` to `OFF`.

When you shut down the server, the `innodb_status_output` variable is set to the default `OFF` value.

## Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard InnoDB Monitor for periodic output, you can obtain standard InnoDB Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

`SHOW ENGINE INNODB STATUS` output also includes InnoDB Lock Monitor data if the InnoDB Lock Monitor is enabled.

## Enabling the InnoDB Lock Monitor

Prior to MySQL 5.7.4, enable the InnoDB Lock Monitor for periodic output by creating the `innodb_lock_monitor` table:

```
CREATE TABLE innodb_lock_monitor (a INT) ENGINE=INNODB;
```

To disable the InnoDB Lock Monitor, drop the table:

```
DROP TABLE innodb_lock_monitor;
```

InnoDBLock Monitor data is printed with the standard InnoDB Monitor output. Both the InnoDB standard Monitor and InnoDB Lock Monitor must be enabled to have InnoDBLock Monitor data printed periodically.

As of MySQL 5.7.4, you can also enable the InnoDB Lock Monitor by setting the `innodb_status_output_locks` system variable to `ON`. As with the `CREATE TABLE` method for enabling InnoDB Monitors, both the InnoDB standard Monitor and InnoDB Lock Monitor must be enabled to have InnoDBLock Monitor data printed periodically:

```
set GLOBAL innodb_status_output=ON;
set GLOBAL innodb_status_output_locks=ON;
```

When you shut down the server, the `innodb_status_output` and `innodb_status_output_locks` variables are set to the default `OFF` value.

To disable the InnoDB Lock Monitor, set `innodb_status_output_locks` to `OFF`. Set `innodb_status_output` to `OFF` to also disable the standard InnoDB Monitor.

### Note

To enable the InnoDB Lock Monitor for `SHOW ENGINE INNODB STATUS` output, you are only required to enable `innodb_status_output_locks`.

## Enabling the InnoDB Tablespace Monitor

To enable the InnoDB Tablespace Monitor for periodic output, create the `innodb_tablespace_monitor` table:

```
CREATE TABLE innodb_tablespace_monitor (a INT) ENGINE=INNODB;
```

To disable the standard InnoDB Tablespace Monitor, drop the table:

```
DROP TABLE innodb_tablespace_monitor;
```

**Note**

The Tablespace Monitor was removed in MySQL 5.7.4. InnoDB tablespace metadata can be obtained from [INFORMATION\\_SCHEMA](#) tables.

**Enabling the InnoDB Table Monitor**

To enable the [InnoDB Table Monitor](#) for periodic output, create the `innodb_table_monitor` table:

```
CREATE TABLE innodb_table_monitor (a INT) ENGINE=INNODB;
```

To disable the [InnoDB Table Monitor](#), drop the table:

```
DROP TABLE innodb_table_monitor;
```

**Note**

The Tablespace Monitor was removed in MySQL 5.7.4. InnoDB tablespace metadata can be obtained from [INFORMATION\\_SCHEMA](#) tables.

**14.14.3 InnoDB Standard Monitor and Lock Monitor Output**

The Lock Monitor is the same as the standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the standard [InnoDB Monitor](#) and [InnoDB Lock Monitor](#), that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Example InnoDB Monitor output (as of MySQL 5.7.6):

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
  Type: InnoDB
  Name:
  Status:
=====

END OF INNODB MONITOR OUTPUT
=====
```

Standard [InnoDB](#) Monitor output is limited to 1MB when produced using the [SHOW ENGINE INNODB STATUS](#) statement. This limit does not apply to output written to the server's error output.

Some notes on the output sections:

### Status

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time `InnoDB` Monitor output was printed.

#### BACKGROUND THREAD

The `srv_master_thread` lines shows work done by the main background thread.

#### SEMAPHORES

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside `InnoDB`. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the `innodb_thread_concurrency` system variable smaller than the default value might help in such situations. The `Spin rounds per wait` line shows the number of spinlock rounds per OS wait for a mutex.

The line that reports mutex spin waits, rounds, and OS waits information was removed from `SHOW ENGINE INNODB STATUS` output in MySQL 5.7.8. Mutex metrics are reported by `SHOW ENGINE INNODB MUTEX`.

#### LATEST FOREIGN KEY ERROR

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

#### LATEST DETECTED DEADLOCK

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction `InnoDB` decided to roll back to break the deadlock. The lock modes reported in this section are explained in [Section 14.2.2.1, “InnoDB Lock Modes”](#).

#### TRANSACTIONS

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

#### FILE I/O

This section provides information about threads that `InnoDB` uses to perform various types of I/O. The first few of these are dedicated to general `InnoDB` processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See [Section 14.11, “InnoDB Startup Options and System Variables”](#).

#### INSERT BUFFER AND ADAPTIVE HASH INDEX

This section shows the status of the `InnoDB` insert buffer (also referred to as the `change buffer`) and the adaptive hash index.

Change buffer status information includes:

- `size`: The number of pages used within the change buffer. Change buffer size is equal to `seg size - (1 + free list len)`. The `1 +` value represents the change buffer header page.
- `free list len`: The number of pages free within the change buffer.

- `seg size`: The size of the change buffer, in pages.
- `merges`: The total number of change buffer merges.
- `merged operations - insert`: The number of inserted records merged.
- `merged operations - delete mark`: The number of deleted records merged.
- `merged operations - delete`: The number of purge records merged.
- `discarded operations - insert`: The number of insert merge operations discarded.
- `discarded operations - delete mark`: The number of delete merge operations discarded.
- `discarded operations - delete`: The number of purge merge operations discarded.

For related information, see [Section 14.2.7.5, “Change Buffer”](#).

Adaptive hash index status information includes:

- `Hash table size`: The total number of array cells allocated to the adaptive hash index.
- `node heap has # buffer(s)`: The total number of pages allocated to the adaptive hash index.
- `hash searches/s`: The per second average of searches satisfied by the adaptive hash index.
- `non-hash searches/s`: The per second average of searches not satisfied by the adaptive hash index.

For related information, see [Section 14.2.7.6, “Adaptive Hash Indexes”](#).

## LOG

This section displays information about the [InnoDB](#) log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which [InnoDB](#) last took a checkpoint. (See [Section 14.9.3, “InnoDB Checkpoints”](#).) The section also displays information about pending writes and write performance statistics.

## BUFFER POOL AND MEMORY

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For additional information about the operation of the buffer pool, see [Section 8.10.1, “The InnoDB Buffer Pool”](#).

## ROW OPERATIONS

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

### 14.14.4 InnoDB Tablespace Monitor Output

#### Note

The Tablespace Monitor was removed in MySQL 5.7.4. InnoDB tablespace metadata can be obtained from [INFORMATION\\_SCHEMA](#) tables.

The [InnoDB](#) Tablespace Monitor prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. The Tablespace Monitor does not describe file-per-table tablespaces created with the `innodb_file_per_table` option.

Example [InnoDB](#) Tablespace Monitor output:

```

=====

NUMBER of file segments: 73
Validating tablespace
Validation ok
-----
END OF INNODB TABLESPACE MONITOR OUTPUT
=====

```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.

In this example using the default [page size](#), the tablespace consists of database pages that are 16KB each. The pages are grouped into [extents](#) of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```

FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845

```

Overall tablespace information includes these values:

- [id](#): The tablespace ID. A value of 0 refers to the shared tablespace.
- [size](#): The current tablespace size in pages.
- [free limit](#): The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.
- [free extents](#): The number of free extents.
- [not full frag extents](#), [used pages](#): The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.
- [full frag extents](#): The number of completely full fragment extents.
- [first seg id not used](#): The first unused segment ID.

Individual segment information has this format:

```
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
fragm pages 32; free extents 0; not full extents 0; pages 0
```

Segment information includes these values:

**id**: The segment ID.

**space**, **page**: The tablespace number and page within the tablespace where the segment “inode” is located. A tablespace number of 0 indicates the shared tablespace. InnoDB uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (**id**, **res**, and so forth) are derived from information in the inode.

**res**: The number of pages allocated (reserved) for the segment.

**used**: The number of allocated pages in use by the segment.

**full ext**: The number of extents allocated for the segment that are completely used.

**fragm pages**: The number of initial pages that have been allocated to the segment.

**free extents**: The number of extents allocated for the segment that are completely unused.

**not full extents**: The number of extents allocated for the segment that are partially used.

**pages**: The number of pages used within the not-full extents.

When a segment grows, it starts as a single page, and InnoDB allocates the first pages for it one at a time, up to 32 pages (this is the **fragm pages** value). After that, InnoDB allocates complete extents. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1; pages 14
```

It is possible for a segment that has extents allocated to it to have a **fragm pages** value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

## 14.14.5 InnoDB Table Monitor Output

### Note

The InnoDB Table Monitor was removed in MySQL 5.7.4. Equivalent information can be obtained from InnoDB INFORMATION\_SCHEMA tables. See [Section 20.30, “INFORMATION\\_SCHEMA Tables for InnoDB”](#).

The InnoDB Table Monitor prints the contents of the InnoDB internal data dictionary.

The output contains one section per table. The **SYS\_FOREIGN** and **SYS\_FOREIGN\_COLS** sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created InnoDB table. Suppose that the following two tables have been created in the **test** database:

```
CREATE TABLE parent
(
  par_id INT NOT NULL,
```

```

fname      CHAR(20),
lname      CHAR(20),
PRIMARY KEY (par_id),
UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
  par_id     INT NOT NULL,
  child_id  INT NOT NULL,
  name       VARCHAR(40),
  birth      DATE,
  weight     DECIMAL(10,2),
  misc_info  VARCHAR(255),
  last_update TIMESTAMP,
  PRIMARY KEY (par_id, child_id),
  INDEX (name),
  FOREIGN KEY (par_id) REFERENCES parent (par_id)
  ON DELETE CASCADE
  ON UPDATE CASCADE
) ENGINE = INNODB;

```

Then the Table Monitor output will look something like this (reformatted slightly):

```

=====
090420 12:09:32 INNODB TABLE MONITOR OUTPUT

-----
END OF INNODB TABLE MONITOR OUTPUT
=====

```

For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in `db_name/tbl_name` format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.

The `COLUMNS` part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such as `DB_ROW_ID` (row ID), `DB_TRX_ID` (transaction ID), and `DB_ROLL_PTR` (a pointer to the rollback/undo data).

- `DATA_xxx`: These symbols indicate the data type. There may be multiple `DATA_xxx` symbols for a given column.
- `prtype`: The column's "precise" type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the `innobase/include/data0type.h` source file.
- `len`: The column length in bytes.

Each `INDEX` part of the table section provides the name and characteristics of one table index:

- `name`: The index name. If the name is `PRIMARY`, the index is a primary key. If the name is `GEN_CLUST_INDEX`, the index is the clustered index that is created automatically if the table definition doesn't include a primary key or non-`NULL` unique index. See [Section 14.2.7.2, "Clustered and Secondary Indexes"](#).
- `id`: The index ID.
- `fields`: The number of fields in the index, as a value in `m/n` format:
  - `m` is the number of user-defined columns; that is, the number of columns you would see in the index definition in a `CREATE TABLE` statement.
  - `n` is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For

a secondary index, the total includes the columns from the primary key that are not part of the secondary index.

- `uniq`: The number of leading fields that are enough to determine index values uniquely.
- `type`: The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), will have a `type` value of 3. An index with a `type` value of 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.
- `root page`: The index root page number.
- `appr. key vals`: The approximate index cardinality.
- `leaf pages`: The approximate number of leaf pages in the index.
- `size pages`: The approximate total number of pages in the index.
- `FIELDS`: The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal `DB_ROW_ID` (row ID) field. `DB_TRX_ID` and `DB_ROLL_PTR` are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the `FOREIGN KEY` definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

## 14.15 InnoDB Backup and Recovery

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these techniques, alone or in combination: [hot backup](#) with MySQL Enterprise Backup; [cold backup](#) by copying files while the MySQL server is shut down; [physical backup](#) for fast operation (especially for restore); [logical backup](#) with `mysqldump` for smaller data volumes or to record the structure of schema objects.

### Hot Backups

The `mysqlbackup` command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including `InnoDB` and `MyISAM` tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `mysqlbackup` is copying `InnoDB` tables, reads and writes to both `InnoDB` and `MyISAM` tables can continue. During the copying of `MyISAM` tables, reads (but not writes) to those tables are permitted. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with MySQL's binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see [Section 25.2, "MySQL Enterprise Backup Overview"](#).

### Cold Backups

If you can shut down your MySQL server, you can make a binary backup that consists of all files used by `InnoDB` to manage its tables. Use the following procedure:

1. Do a [slow shutdown](#) of the MySQL server and make sure that it stops without errors.
2. Copy all `InnoDB` data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all the `.frm` files for `InnoDB` tables to a safe place.
4. Copy all `InnoDB` log files (`ib_logfile` files) to a safe place.
5. Copy your `my.cnf` configuration file or files to a safe place.

## Alternative Backup Types

In addition to making binary backups as just described, regularly make dumps of your tables with `mysqldump`. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option for making a consistent snapshot without locking out other clients. See [Section 7.3.1, “Establishing a Backup Policy”](#).

Replication works with `InnoDB` tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

## Performing Recovery

To recover your `InnoDB` database to the present from the time at which the binary backup was made, you must run your MySQL server with binary logging turned on, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

To recover from a crash of your MySQL server, the only requirement is to restart it. `InnoDB` automatically checks the logs and performs a roll-forward of the database to the present. `InnoDB` automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, `mysqld` displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rollback of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` SQL statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption. You can use the Tablespace Monitor to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of `InnoDB` consistency problems, see [Section 14.18.2, “Forcing InnoDB Recovery”](#) for steps to start the instance in a diagnostic mode where you can dump the data.

## 14.15.1 The InnoDB Recovery Process

InnoDB crash recovery consists of several steps:

- Applying the **redo log**: Redo log application is the first step and is performed during initialization, before accepting any connections. If all changes were flushed from the **buffer pool** to the **tablespaces** (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, the redo log application can be skipped. If the redo log files are missing at startup, InnoDB skips the redo log application.

Removing redo logs to speed up the recovery process is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered an option after a clean shutdown is performed, with `innodb_fast_shutdown` set to 0 or 1.

- **Rolling back incomplete transactions**: Any transactions that were active at the time of crash or **fast shutdown**. The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

You cannot cancel transactions that are in the process of being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start InnoDB with an `innodb_force_recovery` setting of 3 or greater. See [Section 14.18.2, “Forcing InnoDB Recovery”](#) for more information.

- **Change buffer merge**: Applying changes from the change buffer (part of the **system tablespace**) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.
- **Purge**: Deleting delete-marked records that are no longer visible for any active transaction.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, InnoDB attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, InnoDB rolls back any transactions that were not committed or in `XA PREPARE` state when the server crashed. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is needed from the DBA. If a hardware failure or severe system error corrupted InnoDB data, MySQL might refuse to start. In that case, see [Section 14.18.2, “Forcing InnoDB Recovery”](#) for the steps to troubleshoot such an issue.

For information about the binary log and InnoDB crash recovery, see [Section 5.2.4, “The Binary Log”](#).

## 14.15.2 Tablespace Discovery During Crash Recovery

If, during crash recovery, InnoDB encounters redo logs written after the last log checkpoint, redo logs must be applied to tablespace files that have changed since the last log checkpoint.

Prior to MySQL 5.7.5, tablespace files were referenced in redo logs by a `space_id`, which is a numeric identifier. In the file system, however, **file-per-table** tablespaces are known by a `*.ibd` file name, which required that InnoDB construct a “space\_id-filename” map in order to apply the redo logs. To construct a map, InnoDB would traverse the data directory, reading the first page of each `*.ibd` file. This process could result in unnecessary downtime for MySQL instances with numerous `*.ibd` files.

In MySQL 5.6.6, the introduction of support for the `CREATE TABLE DATA DIRECTORY` clause for **file-per-table** tablespaces further complicated “tablespace discovery”. The `DATA DIRECTORY` enhancement introduced `.isl` files as placeholders that point to the actual location of `*.ibd` files.

In MySQL 5.7.5, instead of reading the first page of all `$datadir/*/*.ibd` files and checking the contents of `$datadir/*/*.isl` files before applying redo logs, a new redo log record type (`MLOG_FILE_NAME`) identifies tablespaces that have been modified since the last checkpoint. Benefits of the `MLOG_FILE_NAME` redo log record type include:

- Elimination of file system scans prior to redo log application. The `MLOG_FILE_NAME` redo log record provides the information necessary to identify tablespaces that have changed since the last checkpoint.
- Only `*.ibd` files modified since the last checkpoint are accessed.
- `*.ibd` files that are not attached to the InnoDB instance are ignored when redo logs are applied.
- InnoDB no longer silently discards redo log records for missing `*.ibd` files unless there is an `MLOG_FILE_DELETE` record in the redo log. For example, if a file rename fails, resulting in a “missing” `*.ibd` file, you can manually rename the file and restart crash recovery. Missing `*.ibd` files are ignored in `innodb_force_recovery` mode.
- The entire redo log is read from the last checkpoint to the detected logical end of the log. If tablespace files that are referenced in the scanned portion of the redo log are missing, startup is refused, avoiding potential version mismatch failures during redo log processing.
- Failure scenarios related to inconsistent `*.isl` files are eliminated. `*.isl` files are now only used after redo log apply, when opening tables.

In MySQL 5.7.6, two discovery searches for tablespaces were added with the introduction of InnoDB general tablespaces.

- The first search traverses `SYS_TABLESPACES` and related entries in `SYS_DATAFILES`, in the internal data dictionary. All previously created general tablespaces are opened, including general tablespaces that are empty.
- The second search traverses `SYS_TABLES`, in the internal data dictionary. For tables with a SPACE ID greater than 0, the SPACE ID is looked up in `SYS_DATAFILES` to ensure that the tablespace is opened.

## 14.16 InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, make a copy of the InnoDB tablespace and the log files, as well as the `.frm` files of the InnoDB tables, and move the copies to the slave. If the `innodb_file_per_table` option is enabled, copy the `.ibd` files as well. For the proper procedure to do this, see [Section 14.15, “InnoDB Backup and Recovery”](#).

To make a new slave without taking down the master or an existing slave, use the [MySQL Enterprise Backup](#) product. If you can shut down the master or an existing slave, take a [cold backup](#) of the InnoDB tablespaces and log files and use that to set up a slave.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

**Replication and CASCADE.** Cascading actions for InnoDB tables on the master are replicated on the slave *only* if the tables sharing the foreign key relation use InnoDB on both the master and slave. This is true whether you are using statement-based or row-based replication. Suppose that you

have started replication, and then create two tables on the master using the following `CREATE TABLE` statements:

```
CREATE TABLE fc1 (
  i INT PRIMARY KEY,
  j INT
) ENGINE = InnoDB;

CREATE TABLE fc2 (
  m INT PRIMARY KEY,
  n INT,
  FOREIGN KEY ni (n) REFERENCES fc1 (i)
  ON DELETE CASCADE
) ENGINE = InnoDB;
```

Suppose that the slave does not have `InnoDB` support enabled. If this is the case, then the tables on the slave are created, but they use the `MyISAM` storage engine, and the `FOREIGN KEY` option is ignored. Now we insert some rows into the tables on the master:

```
master> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2 Duplicates: 0 Warnings: 0

master> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

At this point, on both the master and the slave, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```
master> SELECT * FROM fc1;
+----+-----+
| i  | j    |
+----+-----+
| 1  | 1    |
| 2  | 2    |
+----+-----+
2 rows in set (0.00 sec)

master> SELECT * FROM fc2;
+----+-----+
| m  | n    |
+----+-----+
| 1  | 1    |
| 2  | 2    |
| 3  | 1    |
+----+-----+
3 rows in set (0.00 sec)

slave> SELECT * FROM fc1;
+----+-----+
| i  | j    |
+----+-----+
| 1  | 1    |
| 2  | 2    |
+----+-----+
2 rows in set (0.00 sec)

slave> SELECT * FROM fc2;
+----+-----+
| m  | n    |
+----+-----+
| 1  | 1    |
| 2  | 2    |
| 3  | 1    |
+----+-----+
3 rows in set (0.00 sec)
```

Now suppose that you perform the following `DELETE` statement on the master:

```
master> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)
```

Due to the cascade, table `fc2` on the master now contains only 1 row:

```
master> SELECT * FROM fc2;
+----+----+
| m | n |
+----+----+
| 2 | 2 |
+----+----+
1 row in set (0.00 sec)
```

However, the cascade does not propagate on the slave because on the slave the `DELETE` for `fc1` deletes no rows from `fc2`. The slave's copy of `fc2` still contains all of the rows that were originally inserted:

```
slave> SELECT * FROM fc2;
+----+----+
| m | n |
+----+----+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+----+----+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the `InnoDB` storage engine, which means that none of the changes are logged.

## 14.17 InnoDB Integration with memcached

The `memcached` daemon is frequently used as an in-memory caching layer in front of a MySQL database server. With the introduction of the `InnoDB memcached` plugin, MySQL now allows direct access to `InnoDB` tables using the `memcached` protocol and client libraries.

The `InnoDB memcached` plugin provides an integrated `memcached` daemon that can automatically store and retrieve data from `InnoDB` tables, turning the MySQL server into a fast “key-value store”. Instead of formulating queries in SQL, you can perform simple get, set, and increment operations that avoid the performance overhead of SQL parsing and constructing a query optimization plan. You can also access the same `InnoDB` tables through SQL for convenience, complex queries, bulk operations, application compatibility, and other strengths of traditional database software.

This “NoSQL-style” interface uses the `memcached` API to speed up database operations, letting `InnoDB` handle memory caching using its `buffer pool` mechanism. Data modified through `memcached` operations such as `ADD`, `SET`, `INCR` are stored to disk, using `InnoDB` mechanisms such as `change buffering`, the `doublewrite buffer`, and `crash recovery`. The combination of `memcached` simplicity and `InnoDB` reliability and consistency provides users with the best of both worlds, as explained in [Section 14.17.1, “Benefits of the InnoDB / memcached Combination”](#). For architectural details about how the components fit together, see [Section 14.17.2, “Architecture of InnoDB and memcached Integration”](#).

### 14.17.1 Benefits of the InnoDB / memcached Combination

This section outlines advantages of the `memcached` interface to `InnoDB` tables introduced in [Section 14.17, “InnoDB Integration with memcached”](#). The combination of `InnoDB` tables and `memcached` offers advantages over using either by themselves:

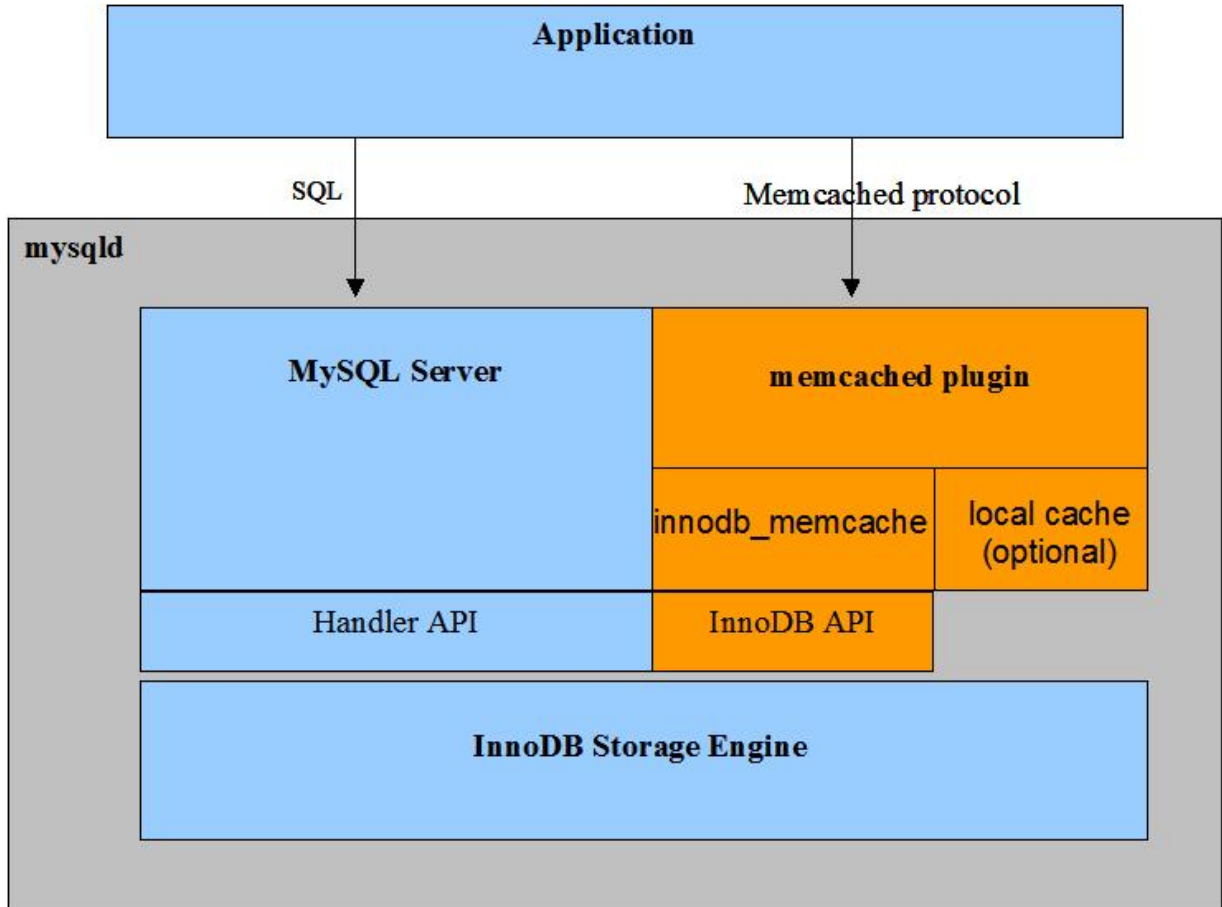

- Direct access to the `InnoDB` storage engine avoids the parsing and planning overhead of SQL.

- Running `memcached` in the same process space as the MySQL server avoids the network overhead of passing requests back and forth.
- Data that is written using the `memcached` protocol is transparently written to an `InnoDB` table, without going through the MySQL SQL layer. You can control the frequency of writes to achieve higher raw performance when updating non-critical data.
- Data that is requested through the `memcached` protocol is transparently queried from an `InnoDB` table, without going through the MySQL SQL layer.
- Subsequent requests for the same data is served from the `InnoDB` buffer pool. The buffer pool handles the in-memory caching. You can tune the performance of data-intensive operations using the familiar `InnoDB` configuration options.
- Data can be unstructured or structured, depending on the type of application. You can make an all-new table for the data, or map the NoSQL-style processing to one or more existing tables.
- `InnoDB` can handle composing and decomposing multiple column values into a single `memcached` item value, reducing the amount of string parsing and concatenation required in your application. For example, you might store a string value `2 | 4 | 6 | 8` in the `memcached` cache, and `InnoDB` splits that value based on a separator character, then stores the result into four numeric columns.
- The transfer between memory and disk is handled automatically, simplifying application logic.
- Data is stored in a MySQL database to protect against crashes, outages, and corruption.
- You can still access the underlying table through SQL, for reporting, analysis, ad hoc queries, bulk loading, multi-step transactional computations, set operations such as union and intersection, and other operations well suited to the expressiveness and flexibility of SQL.
- You can ensure high availability of the NoSQL data by using this feature on a `master server` in combination with MySQL replication.
- The integration of `memcached` with MySQL provides a painless way to make the in-memory data persistent, so you can use it for more significant kinds of data. You can put more `add`, `incr`, and similar write operations into your application, without worrying that the data could disappear at any moment. You can stop and start the `memcached` server without losing updates made to the cached data. To guard against unexpected outages, you can take advantage of `InnoDB` crash recovery, replication, and backup procedures.
- The way `InnoDB` does fast `primary key` lookups is a natural fit for `memcached` single-item queries. The direct, low-level database access path used by the `memcached` plugin is much more efficient for key-value lookups than equivalent SQL queries.
- The serialization features of `memcached`, which can turn complex data structures, binary files, or even code blocks into storeable strings, offer a simple way to get such objects into a database.
- Because you can access the underlying data through SQL, you can produce reports, search or update across multiple keys, and call functions such as `AVG()` and `MAX()` on the `memcached` data. All of these operations are expensive or complicated with the standalone `memcached`.
- You do not need to manually load data into `memcached` at startup. As particular keys are requested by an application, the values are retrieved from the database automatically, and cached in memory using the `InnoDB` `buffer pool`.
- Because `memcached` consumes relatively little CPU, and its memory footprint is easy to control, it can run comfortably alongside a MySQL instance on the same system.
- Because data consistency is enforced by the mechanisms used for regular `InnoDB` tables, you do not have to worry about stale `memcached` data or fallback logic to query the database in the case of a missing key.

## 14.17.2 Architecture of InnoDB and memcached Integration

This section describes how the `memcached` daemon is integrated into the MySQL Server.

When integrated with MySQL Server, `memcached` is implemented as a MySQL plugin daemon, accessing the `InnoDB` storage engine directly and bypassing the SQL layer:

Features provided in the current release:

- `memcached` as a daemon plugin of `mysqld`: both `mysqld` and `memcached` run in the same process space, with very low latency access to data.
- Direct access to `InnoDB` tables, bypassing the SQL parser, the optimizer, and even the Handler API layer.
- Standard `memcached` protocols, both the text-based protocol and the binary protocol. The `InnoDB` + `memcached` combination passes all 55 compatibility tests from the `memcapable` command.
- Multi-column support: you can map multiple columns into the “value” part of the key/value store, with column values delimited by a user-specified separator character.
- By default, you use the `memcached` protocol to read and write data directly to `InnoDB`, and let MySQL manage the in-memory caching through the `InnoDB` **buffer pool**. The default settings represent the combination of high reliability with the fewest surprises for database applications. For example, the default settings avoid uncommitted data on the database side, or stale data returned for `memcached get` requests.
- Advanced users can configure the system as a traditional `memcached` server, with all data cached only in the `memcached` default engine (memory), or use a combination of the “`memcached` default engine” (memory caching) and the `InnoDB` `memcached` engine (`InnoDB` as backend persistent storage).
- You can control how often data is passed back and forth between `InnoDB` and `memcached` operations through the `innodb_api_bk_commit_interval`,

`daemon_memcached_r_batch_size`, and `daemon_memcached_w_batch_size` configuration options. Both the batch size options default to a value of 1 for maximum reliability.

- You can specify `memcached` configuration options through the MySQL configuration variable `daemon_memcached_option`. For example, you might change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.
- A configuration option `innodb_api_trx_level` lets you control the transaction `isolation level` on queries processed by the `memcached` interface. Although `memcached` has no concept of `transactions`, you might use this property to control how soon `memcached` sees changes caused by SQL statements, if you issue `DML` statements on the same table that `memcached` interfaces with. By default, it is set to `READ UNCOMMITTED`.
- Another configuration option is `innodb_api_enable_md1`. “MDL” stands for “metadata locking”. This basically locks the table from the MySQL level, so that the mapped table cannot be dropped or altered by `DDL` through the SQL interface. Without the lock, the table can be dropped from MySQL layer, but will be kept in the InnoDB storage until `memcached` or any other user stops using it.

## Differences Between Using memcached Standalone or with InnoDB

MySQL users might already be familiar with using `memcached` along with MySQL, as described in [Section 16.3, “Using MySQL with memcached”](#). This section describes the similarities and differences between the information in that section, and when using the `InnoDB` integration features of the `memcached` that is built into MySQL. The link at the start of each item goes to the associated information about the traditional `memcached` server.

- **Installation:** Because the `memcached` library comes with the MySQL server, installation and setup are straightforward. You run a SQL script to set up a table for `memcached` to use, issue a one-time `install plugin` statement to enable `memcached`, and add to the MySQL configuration file or startup script any desired `memcached` options, for example to use a different port. You might still install the regular `memcached` distribution to get the additional utilities such as `memcp`, `memcat`, and `memcapable`.
- **Deployment:** It is typical to run large numbers of low-capacity `memcached` servers. Because the `InnoDB + memcached` combination has a 1:1 ratio between database and `memcached` servers, the typical deployment involves a smaller number of moderate or high-powered servers, machines that were already running MySQL. The benefit of this server configuration is more for improving the efficiency of each individual database server than in tapping into unused memory or distributing lookups across large numbers of servers. In the default configuration, very little memory is used for `memcached`, and the in-memory lookups are served from the `InnoDB buffer pool`, which automatically caches the most recently used and most frequently used data. As in a traditional MySQL server instance, keep the value of the `innodb_buffer_pool_size` configuration option as high as practical (without causing paging at the OS level), so that as much of the workload as possible is done in memory.
- **Expiry:** By default (that is, with the caching policy `innodb_only`), the latest data from the `InnoDB` table is always returned, so the expiry options have no practical effect. If you change the caching policy to `caching` or `cache-only`, the expiry options work as usual, but requested data might be stale if it was updated in the underlying table before it expires from the memory cache.
- **Namespaces:** `memcached` is like a single giant directory, where to keep files from conflicting with each other you might give them elaborate names with prefixes and suffixes. The integrated `InnoDB / memcached` server lets you use these same naming conventions for keys, with one addition. Key names of the format `@@table_id.key.table_id` are decoded to reference a specific a table, using mapping data from the `innodb_memcache.containers` table. The `key` is looked up in or written to the specified table.

The `@@` notation only works for individual calls to the `get`, `add`, and `set` functions, not the others such as `incr` or `delete`. To designate the default table for all subsequent `memcached` operations

within a session, perform a `get` request using the `@@` notation and a table ID, but without the key portion. For example:

```
get @@table_x
```

Subsequent `get`, `set`, `incr`, `delete` and other operations use the table designated by `table_x` in the `innodb_memcache.containers.name` column.

- **Hashing and distribution:** The default configuration, with the caching policy `innodb_only`, is suitable for the traditional deployment configuration where all data is available on all servers, such as a set of replication slave servers.

If you physically divide the data, as in a sharded configuration, you can split the data across several machines running the `InnoDB` and `memcached` combined server, and use the traditional `memcached` hashing mechanism to route requests to a particular machine. On the MySQL side, typically you would let all the data be inserted by `add` requests to `memcached` so the appropriate values were stored in the database on the appropriate server.

These types of deployment best practices are still being codified.

- **Memory usage:** By default (with the caching policy `innodb_only`), the `memcached` protocol passes information back and forth with `InnoDB` tables, and the fixed-size `InnoDB` buffer pool handles the in-memory lookups rather than `memcached` memory usage growing and shrinking. Relatively little memory is used on the `memcached` side.

If you switch the caching policy to `caching` or `cache-only`, the normal rules of `memcached` memory usage apply. Memory for the `memcached` data values is allocated in terms of “slabs”. You can control the slab size and maximum memory used for `memcached`.

Either way, you can monitor and troubleshoot the integrated `memcached` daemon using the familiar `statistics` system, accessed through the standard protocol, for example over a `telnet` session. Because extra utilities are not included with the integrated daemon, to use the `memcached-tool script`, install a full `memcached` distribution.

- **Thread usage:** MySQL threads and `memcached` threads must co-exist on the same server, so any limits imposed on threads by the operating system apply to this total number.
- **Log usage:** Because the `memcached` daemon is run alongside the MySQL server and writes to `stderr`, the `-v`, `-vv`, and `-vvv` options for logging write their output to the MySQL `error log`.
- **memcached operations:** All the familiar operations such as `get`, `set`, `add`, and `delete` are available. Serialization (that is, the exact string format to represent complex data structures) depends on the language interface.
- **Using memcached as a MySQL front end:** That is what the `InnoDB` integration with `memcached` is all about. Putting these components together improves the performance of your application. Making `InnoDB` handle data transfers between memory and disk simplifies the logic of your application.
- **Utilities:** The MySQL server includes the `libmemcached` library but not the additional command-line utilities. To get the commands such as `memcp`, `memcat`, and `memcapable` commands, install a full `memcached` distribution. When `memrm` and `memflush` remove items from the cache, they are also removed from the underlying `InnoDB` table.
- **Programming interfaces:** You can access the MySQL server through the `InnoDB` and `memcached` combination using the same language as always: `C` and `C++`, `Java`, `Perl`, `Python`, `PHP`, and `Ruby`. Specify the server hostname and port as with any other `memcached` server. By default, the integrated `memcached` server listens on the same port as usual, `11211`. You can use both the `text` and `binary protocols`. You can customize the `behavior` of the `memcached` functions at runtime.

Serialization (that is, the exact string format to represent complex data structures) depends on the language interface.

- **Frequently asked questions:** MySQL has had an extensive [memcached](#) FAQ for several releases. In MySQL 5.7, the answers are largely the same, except that using [InnoDB](#) tables as a storage medium for [memcached](#) data means that you can use this combination for more write-intensive applications than before, rather than as a read-only cache.

For a more detailed look at the workings of this feature, see [Section 14.17.7, “Internals of the InnoDB memcached Plugin”](#).

### 14.17.3 Getting Started with InnoDB Memcached Plugin

This section describes the steps to activate the [InnoDB / memcached](#) integration on a MySQL Server. Because the [memcached](#) daemon is tightly integrated with the MySQL Server to avoid network traffic and minimize latency, you perform this process on each MySQL instance that uses this feature.

#### Note

Before setting up the [memcached](#) interface for any data, consult [Section 14.17.4, “Security Considerations for the InnoDB memcached Plugin”](#) to understand the security procedures needed to prevent unauthorized access.

#### 14.17.3.1 Prerequisites for the InnoDB memcached Plugin

Before you set up the plugin and the internal tables, verify that your server has the required prerequisite software.

##### Platform Support

The [memcached](#) Daemon Plugin is only supported on Linux, Solaris, and OS X platforms.

##### Software Prerequisites

You must have [libevent](#) installed, since it is required by [memcached](#). The way to get this library is different if you use the MySQL installer or build from source:

- If you installed using the MySQL installer, the [libevent](#) library is not included in the installation. Use the installation method for your operating system to install [libevent](#) 1.4.3 or later: for example, depending on the operating system, you might use the command [apt-get](#), [yum](#), or [port install](#). For example, on Ubuntu Linux:

```
sudo apt-get install libevent-dev
```

- If you install from a source code release, [libevent](#) 1.4.3 is bundled with the package and is located at the top level of the MySQL source code directory. If you use this bundled version of [libevent](#), no action is required. If you want to use a local system version of [libevent](#) you must build MySQL with the [-DWITH\\_LIBEVENT](#) build option set to [system](#) or [yes](#).

##### Prerequisites When Building MySQL from Source

When you build MySQL server, you must build with [-DWITH\\_INNO\\_DB\\_MEMCACHED=ON](#). This build option generates two shared libraries in the MySQL plugin directory ([plugin\\_dir](#)) that are required to run [InnoDB memcached](#):

- [libmemcached.so](#): the [memcached](#) daemon plugin to MySQL.
- [innodb\\_engine.so](#): an [InnoDB](#) API plugin to [memcached](#).

#### 14.17.3.2 Installing and Configuring the InnoDB memcached Plugin

##### Setting Up Required Tables

To configure the `memcached` plugin so it can interact with `InnoDB` tables, run the `innodb_memcached_config.sql` configuration script to install the necessary tables used behind the scenes:

```
mysql> source MYSQL_HOME/share/innodb_memcached_config.sql
```

This is a one-time operation. The tables remain in place if you later disable and re-enable the `memcached` support. For information about the layout and purpose of these tables, see [Section 14.17.7, “Internals of the InnoDB memcached Plugin”](#).

### Installing the Daemon Plugin

To activate the daemon plugin, use the `install plugin` statement, just as when installing any other MySQL plugin:

```
mysql> install plugin daemon_memcached soname "libmemcached.so";
```

Once the plugin is installed this way, it is automatically activated each time the MySQL server is booted or restarted.

### Disabling the Daemon Plugin

When making major changes to the plugin configuration, you might need to turn off the plugin. To do so, issue the following statement:

```
mysql> uninstall plugin daemon_memcached;
```

To re-enable it, issue the preceding `install plugin` statement again. All the previous configuration settings, internal tables, and data are preserved when the plugin is restarted this way.

For additional information about enabling and disabling plugins, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

### Specifying memcached Configuration Options

If you have any `memcached` specific configuration parameters, specify them on the `mysqld` command line or enter them in the MySQL configuration file, encoded in the argument to the `daemon_memcached_option` MySQL configuration option. The `memcached` configuration options take effect when the plugin is installed, which you do each time the MySQL server is started.

For example, to make `memcached` listen on port 11222 instead of the default port 11211, add `-p11222` to the MySQL configuration option `daemon_memcached_option`:

```
mysqld .... --daemon_memcached_option="-p11222"
```

You can add other `memcached` command line options to the `daemon_memcached_option` string. The other configuration options are:

- `daemon_memcached_engine_lib_name` (default `innodb_engine.so`)
- `daemon_memcached_engine_lib_path` (default `NULL`, representing the plugin directory).
- `daemon_memcached_r_batch_size`, batch commit size for read operations (`get`). It specifies after how many `memcached` read operations the system automatically does a `commit`. By default,

this is set to 1 so that every `get` request can access the very latest committed data in the `InnoDB` table, whether the data was updated through `memcached` or by SQL. When its value is greater than 1, the counter for read operations is incremented once for every `get` call. The `flush_all` call resets both the read and write counters.

- `daemon_memcached_w_batch_size`, batch commit for any write operations (`set`, `replace`, `append`, `prepend`, `incr`, `decr`, and so on) By default, this is set as 1, so that no uncommitted data is lost in case of an outage, and any SQL queries on the underlying table can access the very latest data. When its value is greater than 1, the counter for write operations is incremented once for every `add`, `set`, `incr`, `decr`, and `delete` call. The `flush_all` call resets both the read and write counters.

By default, you do not need to change anything with the first two configuration options. Those options allow you to load any other storage engine for `memcached` (such as the NDB `memcached` engine).

Again, please note that you will have these configuration parameters in your MySQL configuration file or MySQL boot command line. They take effect when you load the `memcached` plugin.

## Summary

Now you have everything set up. You can directly interact with InnoDB tables through the `memcached` interface. To verify that the feature is working properly, see [Section 14.17.3.3, “Verifying the InnoDB and memcached Setup”](#).

### 14.17.3.3 Verifying the InnoDB and memcached Setup

Now that everything is set up, you can experiment with the InnoDB and `memcached` combination:

Here is an example using the Unix, Linux, or OS X command shell:

```
# Point memcached-related commands at the memcached attached to the mysqld process.
export MEMCACHED_SERVERS=127.0.0.1:11211
# Store the contents of a modestly sized text file in memcached, with the data passed
# to MySQL and stored in a table. The key is the basename of the file, 'mime.types'.
memcp /etc/apache2/mime.types
# Retrieve the data we just stored, from the memory cache.
memcat mime.types
```

Here is an example using `telnet` to send `memcached` commands and receive results through the ASCII protocol:

```
telnet 127.0.0.1 11211
set all 10 0 9
123456789
STORED
get all
VALUE all 0 9
123456789
END
quit
```

To prove that all the same data has been stored in MySQL, connect to the MySQL server and issue:

```
mysql> select * from test.demo_test;
```

Now, shut down the MySQL server, which also shuts off the integrated `memcached` server. Further attempts to access the `memcached` data now fail with a connection error. Normally, the `memcached` data would disappear at this point, and you would write application logic to load the data back into

memory when `memcached` was restarted. But the MySQL / `memcached` integration automates this process:

- Restart the MySQL server.
- Now any `memcat` commands or `get` operations once again return the key/value pairs you stored in the earlier `memcached` session. When a key is requested and the associated value is not already in the memory cache, it is automatically queried from the MySQL table, by default `test.demo_test`.

## 14.17.4 Security Considerations for the InnoDB memcached Plugin

### Caution

Consult this section before deploying the `InnoDB memcached` plugin on any production servers, or even test servers if the MySQL instance contains any sensitive information.

Because `memcached` does not use an authentication mechanism by default, and the optional SASL authentication is not as strong as traditional DBMS security measures, make sure to keep only non-sensitive data in the MySQL instance using the `InnoDB memcached` plugin, and wall off any servers using this configuration from potential intruders. Do not allow `memcached` access to such servers from the Internet, only from within a firewalled intranet, ideally from a subnet whose membership you can restrict.

### 14.17.4.1 Password-Protecting the memcached Interface through SASL

SASL support gives you the capability to protect your MySQL database from unauthenticated access through `memcached` clients. This section explains the steps to enable this option. The steps to enable such support are almost identical to those you would do to enable SASL for a traditional `memcached` server.

#### Background Info

SASL stands for “Simple Authentication and Security Layer”, a standard for adding authentication support to connection-based protocols. `memcached` added SASL support starting in its 1.4.3 release.

SASL authentication is only supported with the binary protocol.

For the InnoDB + `memcached` combination, the table that stores the `memcached` data must be registered in the `container` system table. And `memcached` clients can only access such a registered table. Even though the DBA can add access restrictions on a table that is registered with the `memcached` plugin, they have no control over who can access it through `memcached` applications. This is why we provide a means (through SASL) to control who can access `InnoDB` tables associated with the `memcached` plugin.

The following section shows how to build, enable, and test an SASL-enabled `InnoDB memcached` plugin.

#### Steps to Build and Enable SASL in InnoDB Memcached Plugin

By default, SASL-enabled `InnoDB memcached` is not included in the release package, since it relies on building `memcached` with SASL libraries. To enable this feature, download the MySQL source and rebuild the `InnoDB memcached` plugin after downloading the SASL libraries:

1. First, get the SASL development and utility libraries. For example, on Ubuntu, you can get these libraries through:

```
sudo apt-get -f install libsasl2-2 sasl2-bin libsasl2-2 libsasl2-dev libsasl2-modules
```

2. Then build the `InnoDB memcached` plugin (shared libraries) with SASL capability, by adding `ENABLE_MEMCACHED_SASL=1` to the `cmake` options. In addition, `memcached` provides a simple

cleartext password support, which is easier to use for testing. To enable this, set the option `ENABLE_MEMCACHED_SASL_PWDB=1`.

Overall, you will add following three options to the `cmake`:

```
cmake ... -DWITH_INNO_DB_MEMCACHED=1
-DENABLE_MEMCACHED_SASL=1 -DENABLE_MEMCACHED_SASL_PWDB=1
```

3. The third step is to install the [InnoDB memcached](#) plugin as before, as explained in [Section 14.17.3, “Getting Started with InnoDB Memcached Plugin”](#).
4. As previously mentioned, `memcached` provides a simple cleartext password support through SASL, which will be used for this demo.
  - a. Create a user named `testname` and its password as `testpasswd` in a file:

```
echo "testname:testpasswd:::::" >/home/jy/memcached-sasl-db
```

- b. Let `memcached` know about it by setting the environment variable `MEMCACHED_SASL_PWDB`:

```
export MEMCACHED_SASL_PWDB=/home/jy/memcached-sasl-db
```

- c. Also tell `memcached` that it is a cleartext password:

```
echo "mech_list: plain" > /home/jy/work2/msasl/clients/memcached.conf
export SASL_CONF_PATH=/home/jy/work2/msasl/clients
```

5. Then reboot the server, and add a `daemon_memcached_option` option `-S` to enable SASL:

```
mysqld ... --daemon_memcached_option="-S"
```

6. Now the setup is complete. To test it, you might need an SASL-enabled client, such as this [SASL-enabled libmemcached](#).

```
memcp --servers=localhost:11211 --binary --username=testname
--password=testpasswd myfile.txt

memcat --servers=localhost:11211 --binary --username=testname
--password=testpasswd myfile.txt
```

Without appropriate user name or password, the above operation is rejected with the error message `memcache error AUTHENTICATION FAILURE`. Otherwise, the operation succeed. You can also examine the cleartext password set in the `memcached-sasl-db` file to verify it.

There are other methods to test SASL authentication with `memcached`. But the one described above is the most straightforward.

## 14.17.5 Writing Applications for the InnoDB memcached Interface

Typically, writing an application for the [InnoDB memcached](#) interface involves some degree of rewriting or adapting existing code that uses MySQL or the `memcached` API:

- Instead of many `memcached` servers running on low-powered machines, you have the same number of `memcached` servers as MySQL servers, running on relatively high-powered machines with substantial disk storage and memory. You might reuse some existing code that works with the `memcached` API, but some adaptation is likely needed due to the different server configuration.

- The data stored through this interface all goes into `VARCHAR`, `TEXT`, or `BLOB` columns, and must be converted to do numeric operations. You can do the conversion on the application side, or by using the `CAST()` function in queries.
- Coming from a database background, you might be used to general-purpose SQL tables with many columns. The tables accessed by the `memcached` code likely have only a few or even just a single column holding data values.
