- You might adapt parts of your application that do single-row queries, inserts, updates, or deletes, to squeeze more performance out of critical sections of code. Both `queries` (read) and `DML` (write) operations can be substantially faster when performed through the `memcached` interface. The speedup for writes is typically greater than the speedup for reads, so you might focus on adapting the code that performs logging or records interactive choices on a web site.

The following sections explore these aspects in more detail.

### 14.17.5.1 Adapting an Existing MySQL Schema for a memcached Application

Consider these aspects of `memcached` applications when adapting an existing MySQL schema or application to use the `memcached` interface:

- `memcached` keys cannot contain spaces or newlines, because those characters are used as separators in the ASCII protocol. If you are using lookup values that contain spaces, transform or hash them into values without spaces before using them as keys in calls to `add()`, `set()`, `get()` and so on. Although theoretically those characters are allowed in keys in programs that use the binary protocol, you should always restrict the characters used in keys to ensure compatibility with a broad range of clients.
- If you have a short numeric `primary key` column in an `InnoDB` table, you can use that as the unique lookup key for `memcached` by converting the integer to a string value. If the `memcached` server is being used for more than one application, or with more than one `InnoDB` table, consider modifying the name to make sure it is unique. For example, you might prepend the table name, or the database name and the table name, before the numeric value.

#### Note

As of MySQL 5.7.3, the `InnoDB memcached` plugin supports inserts and reads on mapped `InnoDB` tables that have an `INTEGER` defined as the primary key.

- You cannot use a partitioned table for data queried or stored through the `memcached` interface.
- The `memcached` protocol passes numeric values around as strings. To store numeric values in the underlying `InnoDB` table, for example to implement counters that can be used in SQL functions such as `SUM()` or `AVG()`:
  - Use `VARCHAR` columns with enough characters to hold all the digits of the largest expected number (and additional characters if appropriate for the negative sign, decimal point, or both).
  - In any query that performs arithmetic using the column values, use the `CAST()` function to convert from string to integer or other numeric type. For example:

```
-- Alphabetic entries are returned as zero.
select cast(c2 as unsigned integer) from demo_test;
-- Since there could be numeric values of 0, can't disqualify them.
-- Test the string values to find the ones that are integers, and average only those.
select avg(cast(c2 as unsigned integer)) from demo_test
  where c2 between '0' and '9999999999';
-- Views let you hide the complexity of queries. The results are already converted;
-- no need to repeat conversion functions and WHERE clauses each time.
create view numbers as select c1 key, cast(c2 as unsigned integer) val
  from demo_test where c2 between '0' and '9999999999';
select sum(val) from numbers;
```

Note that any alphabetic values in the result set are turned into 0 by the call to `CAST()`. When using functions such as `AVG()` that depend on the number of rows in the result set, include `WHERE` clauses to filter out any non-numeric values.

- If the `InnoDB` column you use as a key can be longer than 250 bytes, hash it to a value that is less than 250 bytes.
- To use an existing table with the `memcached` interface, define an entry for it in the `innodb_memcache.containers` table. To make that the table the default for all requests relayed through `memcached`, specify the value `default` in the `name` column, then restart the MySQL server to make that change take effect. If you are using multiple tables for different classes of `memcached` data, set up multiple entries in the `innodb_memcache.containers` table with `name` values of your choosing, then issue a `memcached` request of the form `get @@name` or `set @@name` within the application to switch the table used for subsequent requests through the `memcached` API.

For an example of using a table other than the predefined `test.demo_test` table, see [Example 14.24, “Specifying the Table and Column Mapping for an InnoDB + memcached Application”](#). For the required layout and meaning of the columns in such a table, see [Section 14.17.7, “Internals of the InnoDB memcached Plugin”](#).

- To use multiple MySQL column values with `memcached` key/value pairs, in the `innodb_memcache.containers` entry associated with the MySQL table, specify in the `value_columns` field several column names separated by comma, semicolon, space, or pipe characters; for example, `col1,col2,col3` or `col1|col2|col3`.

Concatenate the column values into a single string using the pipe character as a separator, before passing that string to `memcached add` or `set` calls. The string is unpacked automatically into the various columns. Each `get` call returns a single string with the column values, also delimited by the pipe separator character. you unpack those values using the appropriate syntax depending on your application language.

#### Example 14.24 Specifying the Table and Column Mapping for an InnoDB + memcached Application

Here is an example showing how to use your own table for a MySQL application going through the `InnoDB memcached` plugin for data manipulation.

First, we set up a table to hold some country data: the population, area in metric units, and 'R' or 'L' indicating if people drive on the right or on the left.

```
use test;

CREATE TABLE `multicol` (
  `country` varchar(128) NOT NULL DEFAULT '',
  `population` varchar(10) DEFAULT NULL,
  `area_sq_km` varchar(9) DEFAULT NULL,
  `drive_side` varchar(1) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  `c4` bigint(20) unsigned DEFAULT NULL,
  `c5` int(11) DEFAULT NULL,
  PRIMARY KEY (`country`),
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

Now we make a descriptor for this table so that the `InnoDB memcached` plugin knows how to access it:

- The sample entry in the `CONTAINERS` table has a `name` column 'aaa'; we set up another identifier 'bbb'. If we made a single master table for all `memcached` applications to use, we would make the ID 'default' and skip the @@ requests to switch tables.
- We specify the `test.multicol` table. The schema name is stored in one column and the table name is stored in another column.

- The key column will be our unique `country` value. That column was specified as the primary key when we created the table above, so we also specify the index name `'PRIMARY'` here.
- Rather than a single column to hold a composite data value, we will divide the data among three table columns, so we specify a comma-separated list of those columns that will be used when storing or retrieving values.
- And for the flags, expire, and CAS values, we specify corresponding columns based on the settings from the sample table `demo.test`. These values are typically not significant in applications using the `InnoDB memcached` plugin, because MySQL keeps the data synchronized and there is no need to worry about data expiring or being stale.

```
insert into innodb_memcache.containers
  (name,db_schema,db_table,key_columns,value_columns,flags,cas_column,
  expire_time_column,unique_idx_name_on_key)
values
  ('bbb','test','multicol','country','population,area_sq_km,drive_side',
  'c3','c4','c5','PRIMARY');

commit;
```

Here is a sample Python program showing how we would access this table from a program:

- No database authorization is needed, since all data manipulation is done through the `memcached` interface. All we need to know is the port number the `memcached` daemon is listening to on the local system.
- We load sample values for a few arbitrary countries. (Area and population figures from Wikipedia.)
- To make the program use the `multicol` table, we call the `switch_table()` function that does a dummy `GET` or `SET` request using `@@` notation. The name in the request is `bbb`, which is the value we stored in `innodb_memcache.containers.name`. (In a real application, we would use a more descriptive name. This example just illustrates that you specify a table identifier, not the table name, with the `GET @@...` request.
- The utility functions to insert and query the data demonstrate how we might turn a Python data structure into pipe-separated values for sending to MySQL with `ADD` or `SET` requests, and unpack the pipe-separated values returned by `GET` requests. This extra processing is only required when mapping the single `memcached` value to multiple MySQL table columns.

```
import sys, os
import memcache

def connect_to_memcached():
    memc = memcache.Client(['127.0.0.1:11211'], debug=0);
    print "Connected to memcached."
    return memc

def banner(message):
    print
    print "=" * len(message)
    print message
    print "=" * len(message)

country_data = [
  ("Canada", "34820000", "9984670", "R"),
  ("USA", "314242000", "9826675", "R"),
  ("Ireland", "6399152", "84421", "L"),
  ("UK", "62262000", "243610", "L"),
  ("Mexico", "113910608", "1972550", "R"),
  ("Denmark", "5543453", "43094", "R"),
  ("Norway", "5002942", "385252", "R"),
  ("UAE", "8264070", "83600", "R"),
  ("India", "1210193422", "3287263", "L"),
  ("China", "1347350000", "9640821", "R"),
```

```

]

def switch_table(memc,table):
    key = "@@" + table
    print "Switching default table to '" + table + "' by issuing GET for '" + key + "'."
    result = memc.get(key)

def insert_country_data(memc):
    banner("Inserting initial data via memcached interface")
    for item in country_data:
        country = item[0]
        population = item[1]
        area = item[2]
        drive_side = item[3]

        key = country
        value = "|".join([population,area,drive_side])
        print "Key = " + key
        print "Value = " + value

        if memc.add(key,value):
            print "Added new key, value pair."
        else:
            print "Updating value for existing key."
            memc.set(key,value)

def query_country_data(memc):
    banner("Retrieving data for all keys (country names)")
    for item in country_data:
        key = item[0]
        result = memc.get(key)
        print "Here is the result retrieved from the database for key " + key + ":"
        print result
        (m_population, m_area, m_drive_side) = result.split("|")
        print "Unpacked population value: " + m_population
        print "Unpacked area value      : " + m_area
        print "Unpacked drive side value: " + m_drive_side

if __name__ == '__main__':

    memc = connect_to_memcached()
    switch_table(memc,"bbb")
    insert_country_data(memc)
    query_country_data(memc)

    sys.exit(0)

```

Here are some SQL queries to illustrate the state of the MySQL data after the script is run, and show how you could access the same data directly through SQL, or from an application written in any language using the appropriate [MySQL Connector or API](#).

The table descriptor 'bbb' is in place, allowing us to switch to the `multicol` table by issuing a `memcached` request `GET @bbb`:

```
mysql: use innodb_memcache;
Database changed
```

```
mysql: select * from containers;
```

name	db_schema	db_table	key_columns	value_columns	flags	cas_column
aaa	test	demo_test	c1	c2	c3	c4
bbb	test	multicol	country	population,area_sq_km,drive_side	c3	c4

```
2 rows in set (0.01 sec)
```

After running the script, the data is in the `multicol` table, available for traditional MySQL [queries](#) or [DML](#) statements:

```
mysql: use test;
Database changed

mysql: select * from multicol;
+-----+-----+-----+-----+-----+-----+
| country | population | area_sq_km | drive_side | c3 | c4 | c5 |
+-----+-----+-----+-----+-----+-----+
| Canada | 34820000 | 9984670 | R | 0 | 11 | 0 |
| China | 1347350000 | 9640821 | R | 0 | 20 | 0 |
| Denmark | 5543453 | 43094 | R | 0 | 16 | 0 |
| India | 1210193422 | 3287263 | L | 0 | 19 | 0 |
| Ireland | 6399152 | 84421 | L | 0 | 13 | 0 |
| Mexico | 113910608 | 1972550 | R | 0 | 15 | 0 |
| Norway | 5002942 | 385252 | R | 0 | 17 | 0 |
| UAE | 8264070 | 83600 | R | 0 | 18 | 0 |
| UK | 62262000 | 243610 | L | 0 | 14 | 0 |
| USA | 314242000 | 9826675 | R | 0 | 12 | 0 |
+-----+-----+-----+-----+-----+-----+
10 rows in set (0.00 sec)

mysql: desc multicol;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| country | varchar(128) | NO | PRI | | |
| population | varchar(10) | YES | | NULL | |
| area_sq_km | varchar(9) | YES | | NULL | |
| drive_side | varchar(1) | YES | | NULL | |
| c3 | int(11) | YES | | NULL | |
| c4 | bigint(20) unsigned | YES | | NULL | |
| c5 | int(11) | YES | | NULL | |
+-----+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)
```

Allow sufficient size to hold all necessary digits, decimal points, sign characters, leading zeros, and so on when defining the length for columns that will be treated as numbers. Too-long values in a string column such as a `VARCHAR` are truncated by removing some characters, which might produce a nonsensical numeric value.

We can produce reports through SQL queries, doing calculations and tests across any columns, not just the `country` key column. (Because these examples use data from only a few countries, the numbers are for illustration purposes only.) Here, we find the average population of countries where people drive on the right, and the average size of countries whose names start with “U”:

```
mysql: select avg(population) from multicol where drive_side = 'R';
+-----+
| avg(population) |
+-----+
| 261304724.7142857 |
+-----+
1 row in set (0.00 sec)

mysql: select sum(area_sq_km) from multicol where country like 'U%';
+-----+
| sum(area_sq_km) |
+-----+
| 10153885 |
+-----+
1 row in set (0.00 sec)
```

Because the `population` and `area_sq_km` columns store character data rather than strongly typed numeric data, functions such as `avg()` and `sum()` work by converting each value to a number first. This approach *does not work* for operators such as `<` or `>`: for example, when comparing character-based values, `9 > 1000`, which is not you expect from a clause such as `ORDER BY population DESC`. For the most accurate type treatment, perform queries against views that cast numeric columns to the appropriate types. This technique lets you issue very simple `SELECT *` queries from your database applications, while ensuring that all casting, filtering, and ordering is correct. Here, we make a view that can be queried to find the top 3 countries in descending order of population, with the results

always reflecting the latest data from the `multicol` table, and with the population and area figures always treated as numbers:

```
mysql: create view populous_countries as
  select
    country,
    cast(population as unsigned integer) population,
    cast(area_sq_km as unsigned integer) area_sq_km,
    drive_side from multicol
  order by cast(population as unsigned integer) desc
  limit 3;
Query OK, 0 rows affected (0.01 sec)
```

```
mysql: select * from populous_countries;
+-----+-----+-----+-----+
| country | population | area_sq_km | drive_side |
+-----+-----+-----+-----+
| China   | 1347350000 | 9640821    | R          |
| India   | 1210193422 | 3287263    | L          |
| USA     | 314242000  | 9826675    | R          |
+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

```
mysql: desc populous_countries;
+-----+-----+-----+-----+-----+-----+
| Field      | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| country    | varchar(128)        | NO   |     |          |       |
| population | bigint(10) unsigned | YES  |     | NULL    |       |
| area_sq_km | int(9) unsigned     | YES  |     | NULL    |       |
| drive_side | varchar(1)          | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
4 rows in set (0.02 sec)
```

### 14.17.5.2 Adapting an Existing memcached Application for the Integrated memcached Daemon

Consider these aspects of MySQL and InnoDB tables when adapting an existing memcached application to use the MySQL integration:

- If you have key values longer than a few bytes, you might find it more efficient to use a numeric auto-increment column for the **primary key** in the InnoDB table, and create a unique **secondary index** on the column holding the memcached key values. This is because InnoDB performs best for large-scale insertions if the primary key values are added in sorted order (as they are with auto-increment values), and the primary key values are duplicated in each secondary index, which can take up unnecessary space when the primary key is a long string value.
- If you store several different classes of information in memcached, you might set up a separate InnoDB table for each kind of data. Define additional table identifiers in the `innodb_memcache.containers` table, and use the notation `@@table_id.key` to store or retrieve items from different tables. Physically dividing the items lets you tune the characteristics of each table for best space utilization, performance, and reliability. For example, you might enable **compression** for a table that holds blog posts, but not for one that holds thumbnail images. You might back up one table more frequently than another because it holds critical data. You might create additional **secondary indexes** on tables that are frequently used to generate reports through SQL.
- Preferably, set up a stable set of table definitions for use with the memcached interface and leave them in place permanently. Changes to the `containers` table take effect the next time that table is queried. The entries in that table are processed at startup, and are consulted whenever an unrecognized table ID is requested by the @@ notation. Thus, new entries are visible as soon as you try to use the associated table ID, but changes to existing entries require a server restart before they take effect.
- When you use the default caching policy `innodb_only`, your calls to `add()`, `set()`, `incr()`, and so on can succeed but still trigger debugging messages such as `while expecting 'STORED'`,

got unexpected response 'NOT\_STORED'. This is because in the `innodb_only` configuration, new and updated values are sent directly to the `InnoDB` table without being saved in the memory cache.

### 14.17.5.3 Tuning Performance of the InnoDB memcached Plugin

Because using `InnoDB` in combination with `memcached` involves writing all data to disk, whether immediately or sometime later, understand that raw performance is expected to be somewhat lower than using `memcached` by itself. Focus your tuning goals for the `InnoDB memcached` plugin on achieving higher performance than equivalent SQL operations.

Benchmarks suggest that both queries and `DML` operations (inserts, updates, and deletes) are faster going through the `memcached` interface than with traditional SQL. `DML` operations typically see a larger speedup. Thus, the types of applications you might adapt to use the `memcached` interface first are those that are write-intensive. You might also use MySQL as a data store for types of write-intensive applications that formerly used some fast, lightweight mechanism where reliability was not a priority.

### Adapting SQL Queries

The types of queries that are most suited to the simple `GET` request style are those with a single clause, or a set of `AND` conditions, in the `WHERE` clause:

```
SQL:
select col from tbl where key = 'key_value';

memcached:
GET key_value

SQL:
select col from tbl where col1 = val1 and col2 = val2 and col3 = val3;

memcached:
# Since you must always know these 3 values to look up the key,
# combine them into a unique string and use that as the key
# for all ADD, SET, and GET operations.
key_value = val1 + ":" + val2 + ":" + val3
GET key_value

SQL:
select 'key exists!' from tbl
  where exists (select col1 from tbl where key = 'key_value') limit 1;

memcached:
# Test for existence of key by asking for its value and checking if the call succeeds,
# ignoring the value itself. For existence checking, you typically only store a very
# short value such as "1".
GET key_value
```

### Taking Advantage of System Memory

For best performance, deploy the `InnoDB memcached` plugin on machines that are configured like typical database servers: in particular, with the majority of system RAM devoted to the `InnoDB buffer pool` through the `innodb_buffer_pool_size` configuration option. For systems with multi-gigabyte buffer pools, consider raising the value of the `innodb_buffer_pool_instances` configuration option for maximum throughput when most operations involve data already cached in memory.

### Reducing Redundant I/O

`InnoDB` has a number of settings that let you choose the balance between high reliability in case of a crash, and the amount of I/O overhead during high write workloads. For example, consider setting the configuration options `innodb_doublewrite=0` and `innodb_flush_log_at_trx_commit=2`. Measure the performance with different settings for the `innodb_flush_method` option. If the `binary log` is not turned on for the server, use the setting `innodb_support_xa=0`.

**Note**

`innodb_support_xa` is deprecated and will be removed in a future release. As of MySQL 5.7.10, InnoDB support for two-phase commit in XA transactions is always enabled and disabling `innodb_support_xa` is no longer permitted.

For other ways to reduce or tune I/O for table operations, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

## Reducing Transactional Overhead

The default value of 1 for the configuration options `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` is intended for maximum reliability of results and safety of stored or updated data.

Depending on the type of application, you might increase one or both of these settings to reduce the overhead of frequent `commit` operations. On a busy system, you might increase `daemon_memcached_r_batch_size`, knowing that changes to the data made through SQL might not become visible to `memcached` immediately (that is, until  $N$  more `get` operations were processed). When processing data where every write operation must be reliably stored, you would leave `daemon_memcached_w_batch_size` set to 1. You might increase it when processing large numbers of updates intended to only be used for statistical analysis, where it is not critical if the last  $N$  updates are lost in case of a crash.

For example, imagine a system that monitors traffic crossing a busy bridge, recording approximately 100,000 vehicles each day. If the application simply counts different types of vehicles to analyze traffic patterns, it might change `daemon_memcached_w_batch_size` from 1 to 100, reducing the I/O overhead for commit operations by 99%. In case of an unexpected outage, only a maximum of 100 records could be lost, which might be an acceptable margin of error. If instead the application was doing automated toll collection for each car, it would keep `daemon_memcached_w_batch_size` set to 1 to ensure that every toll record was immediately saved to disk.

Because of the way InnoDB organizes the `memcached` key values on disk, if you have a large number of keys to create, it can be faster to sort all the data items by the key value in your application and `add` them in sorted order, rather than creating them in arbitrary order.

The `memslap` command, which is part of the regular `memcached` distribution but not included with the MySQL server, can be useful for benchmarking different configurations. It can also be used to generate sample key/value pairs that you can use in your own benchmarking. See [libmemcached Command-Line Utilities](#) for details.

### 14.17.5.4 Controlling Transactional Behavior of the InnoDB memcached Plugin

Unlike with the traditional `memcached`, with the InnoDB + `memcached` combination you can control how “durable” are the data values produced through calls to `add`, `set`, `incr`, and so on. Because MySQL places a high priority on durability and consistency of data, by default all data written through the `memcached` interface is always stored to disk, and calls to `get` always return the most recent value from disk. Although this default setting does not give the highest possible raw performance, it is still very fast compared to the traditional SQL interface for InnoDB tables.

As you gain experience with this feature, you can make the decision to relax the durability settings for non-critical classes of data, at the risk of possibly losing some updated values in case of an outage, or returning data that is slightly out-of-date.

## Frequency of Commits

One tradeoff between durability and raw performance is how frequently new and changed data is `committed`. If the data is critical, you want it to be committed immediately so that it is safe in case of any crash or outage. If the data is less critical, such as counters that would be reset after a crash, or debugging or logging data where you could afford to lose a few seconds worth, you might prefer the higher raw throughput that comes with less frequent commits.

When a `memcached` operation causes an insert, update, or delete in the underlying InnoDB table, that change might be committed to the underlying table instantly (if `daemon_memcached_w_batch_size=1`) or some time later (if that configuration option value is greater than 1). In either case, the change cannot be rolled back. If you increase the value of `daemon_memcached_w_batch_size=1` to avoid high I/O overhead during busy times, commits could become very infrequent when the workload decreases. As a safety measure, a background thread automatically commits changes made through the `memcached` API at regular intervals. The interval is controlled by the `innodb_api_bk_commit_interval` configuration option, and by default is 5 seconds.

When a `memcached` operation causes an insert or update in the underlying InnoDB table, the changed data is immediately visible to other `memcached` requests because the new value remains in the memory cache, even if it is not committed yet on the MySQL side.

## Transaction Isolation

When a `memcached` operation such as `get` or `incr` causes a query or DML operation in the underlying InnoDB table, you can control whether it sees the very latest data written to the table, only data that has been committed, or other variations of transaction `isolation level`. You control this feature through the `innodb_api_trx_level` configuration option. The numeric values specified with this option correspond to the familiar isolation level names such as `REPEATABLE READ`. See the description of the `innodb_api_trx_level` option for the full list.

The stricter the isolation level, the more certain you can be that the data you retrieve will not be rolled back or changed suddenly so that a subsequent query sees a different value. But that strictness comes with greater `locking` overhead that can cause waits. For a NoSQL-style application that does not use long-running transactions, you can typically stay with the default isolation level or switch to a less strict one.

## Disabling Row Locks for memcached DML Operations

The `innodb_api_disable_rowlock` option can be used to disable row locks when InnoDB `memcached` performs DML operations. By default, `innodb_api_disable_rowlock` is set to `OFF` which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is set to `ON`, `memcached` requests a table lock instead of row locks.

The `innodb_api_disable_rowlock` option is not dynamic. It must be specified at startup on the `mysqld` command line or entered in the MySQL configuration file.

## Allowing or Disallowing DDL

By default, you can perform `DDL` operations such as `ALTER TABLE` on the tables being used by the InnoDB `memcached` plugin. To avoid potential slowdowns when these tables are being used for high-throughput applications, you can disable DDL operations on these tables by turning on the `innodb_api_enable_mdl` configuration option at startup. This option is less appropriate when you are accessing the same underlying tables through both the `memcached` interface and SQL, because it blocks `CREATE INDEX` statements on the tables, which could be important for configuring the system to run reporting queries.

## Data Stored on Disk, in Memory, or Both

Table `innodb_memcache.cache_policies` specifies whether to store data written through the `memcached` on disk (`innodb_only`, the default); to store the data in memory only, as in the traditional `memcached` (`cache-only`); or both (`caching`).

With the `caching` setting, if `memcached` cannot find a key in memory, it searches for the value in an InnoDB table. Values returned from `get` calls under the `caching` setting could be out-of-date, if they were updated on disk in the InnoDB table but not yet expired from the memory cache.

The caching policy can be set independently for `get`, `set` (including `incr` and `decr`), `delete`, and `flush` operations. For example:

- You might allow `get` and `set` operations to query or update a table and the `memcached` memory cache at the same time (through the `caching` setting), while making `delete`, `flush`, or both operate only on the in-memory copy (through the `cache_only` setting). That way, deleting or flushing an item just expires it from the cache, and the latest value is returned from the `InnoDB` table the next time the item is requested.

```
mysql> desc innodb_memcache.cache_policies;
+-----+-----+-----+-----+-----+-----+
| Field          | Type                               | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| policy_name    | varchar(40)                        | NO   |     | NULL    |      |
| get_policy     | enum('innodb_only','cache_only','caching','disabled') | NO   |     | NULL    |      |
| set_policy     | enum('innodb_only','cache_only','caching','disabled') | NO   |     | NULL    |      |
| delete_policy  | enum('innodb_only','cache_only','caching','disabled') | NO   |     | NULL    |      |
| flush_policy   | enum('innodb_only','cache_only','caching','disabled') | NO   |     | NULL    |      |
+-----+-----+-----+-----+-----+-----+

mysql> select * from innodb_memcache.cache_policies;
+-----+-----+-----+-----+-----+
| policy_name | get_policy | set_policy | delete_policy | flush_policy |
+-----+-----+-----+-----+-----+
| cache_policy | innodb_only | innodb_only | innodb_only | innodb_only |
+-----+-----+-----+-----+-----+

mysql> update innodb_memcache.cache_policies set set_policy = 'caching'
-> where policy_name = 'cache_policy';
```

The `cache_policies` values are only read at startup, and are tightly integrated with the operation of the `memcached` plugin. After changing any of the values in this table, uninstall the plugin and reinstall it:

```
mysql> uninstall plugin daemon_memcached;
Query OK, 0 rows affected (2.00 sec)
mysql> install plugin daemon_memcached soname "libmemcached.so";
Query OK, 0 rows affected (0.00 sec)
```

### 14.17.5.5 Adapting DML Statements to memcached Operations

Benchmarks suggest that the `InnoDB memcached` plugin speeds up **DML** operations (inserts, updates, and deletes) more than it speeds up queries. You might focus your initial development efforts on write-intensive applications that are I/O-bound, and look for opportunities to use MySQL for new kinds of write-intensive applications.

- ```
INSERT INTO t1 (key,val) VALUES (some_key,some_value);
SELECT val FROM t1 WHERE key = some_key;
UPDATE t1 SET val = new_value WHERE key = some_key;
UPDATE t1 SET val = val + x WHERE key = some_key;
DELETE FROM t1 WHERE key = some_key;
```

Single-row DML statements are the most straightforward kinds of statements to turn into `memcached` operations: `INSERT` becomes `add`, `UPDATE` becomes `set`, `incr` or `decr`, and `DELETE` becomes `delete`. When issued through the `memcached` interface, these operations are guaranteed to affect only 1 row because `key` is unique within the table.

In the preceding SQL examples, `t1` refers to the table currently being used by the `InnoDB memcached` plugin based on the configuration settings in the `innodb_memcache.containers` table, `key` refers to the column listed under `key_columns`, and `val` refers to the column listed under `value_columns`.

```
TRUNCATE TABLE t1;
DELETE FROM t1;
```

Corresponds to the `flush_all` operation, when `t1` is configured as the table for `memcached` operations as in the previous step. Removes all the rows in the table.

### 14.17.5.6 Performing DML and DDL Statements on the Underlying InnoDB Table

You can access the InnoDB table (by default, `test.demo_test`) through the standard SQL interfaces. However, there are some restrictions:

- When query a table through SQL that is also being accessed through the `memcached` interface, remember that `memcached` operations can be configured to be committed periodically rather than after every write operation. This behavior is controlled by the `daemon_memcached_w_batch_size` option. If this option is set to a value greater than 1, use `READ UNCOMMITTED` queries to find the just-inserted rows:

```
mysql> set session TRANSACTION ISOLATION LEVEL read uncommitted;
Query OK, 0 rows affected (0.00 sec)

mysql> select * from demo_test;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| cx   | cy   | c1   | cz   | c2   | ca   | CB   | c3   | cu   | c4   | C5   |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| NULL | NULL | a11  | NULL | 123456789 | NULL | NULL | 10  | NULL | 3   | NULL |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

- When modifying a table using SQL that is also accessed through the `memcached` interface, you can configure `memcached` operations to start a new transaction periodically rather than for every read operation. This behavior is controlled by the `daemon_memcached_r_batch_size` option. If this option is set to a value greater than 1, changes made to the table using SQL are not immediately visible to `memcached` operations.
- The InnoDB table is locked IS (shared intention) or IX (exclusive intentional) for all operations in a transaction. If you increase `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` substantially from their default value of 1, the table is most likely intentionally locked between each operation, preventing you from running `DDL` statements on the table.

### 14.17.6 Using the InnoDB memcached Plugin with Replication

Because the InnoDB `memcached` daemon plugin supports the MySQL `binary log`, any updates made on a `master server` through the `memcached` interface can be replicated for backup, balancing intensive read workloads, and high availability. All `memcached` commands are supported for binary logging.

You do not need to set up the InnoDB `memcached` plugin on the `slave servers`. In this configuration, the primary advantage is increased write throughput on the master. The speed of the replication mechanism is not affected.

The following sections show how to use the binary log capability, to use the InnoDB `memcached` plugin along with MySQL replication. It assumes you have already done the basic setup described in [Section 14.17.3, “Getting Started with InnoDB Memcached Plugin”](#).

#### Enable InnoDB Memcached Binary Log with `innodb_api_enable_binlog`:

- To use the InnoDB `memcached` plugin with the MySQL `binary log`, enable the `innodb_api_enable_binlog` configuration option on the `master server`. This option can only be set at server boot time. You must also enable the MySQL binary log on the master server with the `--`

`log-bin` option. You can add these options to your server configuration file such as `my.cnf`, or on the `mysqld` command line.

```
mysqld ... --log-bin --innodb_api_enable_binlog=1
```

- Then configure your master and slave server, as described in [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#).
- Use `mysqldump` to create a master data snapshot, and sync it to the slave server.

```
master shell: mysqldump --all-databases --lock-all-tables > dbdump.db
slave shell: mysql < dbdump.db
```

- On the master server, issue `show master status` to obtain the Master Binary Log Coordinates:

```
mysql> show master status;
```

- On the slave server, use a `change master to` statement to set up a slave server with the above coordinates:

```
mysql> CHANGE MASTER TO
  MASTER_HOST='localhost',
  MASTER_USER='root',
  MASTER_PASSWORD='',
  MASTER_PORT = 13000,
  MASTER_LOG_FILE='0.000001',
  MASTER_LOG_POS=114;
```

- Then start the slave:

```
mysql> start slave;
```

If the error log prints output similar to the following, the slave is ready for replication:

```
2013-09-24T13:04:38.639684Z 49 [Note] Slave I/O thread: connected to
master 'root@localhost:13000', replication started in log '0.000001'
at position 114
```

## Test with the memcached telnet Interface

To test the server with the above replication setup, we use the `memcached` telnet interface, and also query the master and slave servers using SQL to verify the results.

In our configuration setup SQL, one example table `demo_test` is created in the `test` database for use by `memcached`. We will use this default table for the demonstrations:

- Use `set` to insert a record, key `test1`, value `t1`, and flag `10`:

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 2
t1
STORED
```

In the master server, you can see that the row is inserted. `c1` maps to the key, `c2` maps to the value, `c3` is the flag, `c4` is the `cas` value, and `c5` is the expiration.

```
mysql> select * from test.demo_test;
```

| c1    | c2 | c3 | c4 | c5 |
|-------|----|----|----|----|
| test1 | t1 | 10 | 2  | 0  |

```
1 row in set (0.00 sec)
```

In the slave server, you will see the same record is inserted by replication:

```
mysql> select * from test.demo_test;
```

| c1    | c2 | c3 | c4 | c5 |
|-------|----|----|----|----|
| test1 | t1 | 10 | 2  | 0  |

```
1 row in set (0.00 sec)
```

- Use `set` command to update the key `test1` to a new value `new`:

```
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 3
new
STORED
```

From the slave server, the update is replicated (notice the `cas` value also updated):

```
mysql> select * from test.demo_test;
```

| c1    | c2  | c3 | c4 | c5 |
|-------|-----|----|----|----|
| test1 | new | 10 | 3  | 0  |

```
1 row in set (0.00 sec)
```

- Delete the record with a `delete` command:

```
Connected to 127.0.0.1.
Escape character is '^]'.
delete test1
DELETED
```

When the delete is replicated to the slave, the record on the slave is also deleted:

```
mysql> select * from test.demo_test;
Empty set (0.00 sec)
```

- Truncate the table with the `flush_all` command.

First, insert two records by telnetting to the master server:

```
Connected to 127.0.0.1.
Escape character is '^]'
set test2 10 0 5
again
STORED
set test3 10 0 6
again1
STORED
```

In the slave server, confirm these two records are replicated:

```
mysql> select * from test.demo_test;
```

| c1    | c2     | c3 | c4 | c5 |
|-------|--------|----|----|----|
| test2 | again  | 10 | 5  | 0  |
| test3 | again1 | 10 | 6  | 0  |

```
2 rows in set (0.00 sec)
```

Call `flush_all` in the telnet interface to truncate the table:

```
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

Then check that the truncation operation is replicated on the slave server:

```
mysql> select * from test.demo_test;
Empty set (0.00 sec)
```

All `memcached` commands are supported in terms of replication.

## Notes for the InnoDB Memcached Binlog

Binlog Format:

- Most `memcached` operations are mapped to `DML` statements (analogous to insert, delete, update). Since there is no actual SQL statement being processed by the MySQL server, all `memcached` commands (except for `flush_all`) use Row-Based Replication (RBR) logging. This is independent of any server `binlog_format` setting.
- The `memcached flush_all` command is mapped to the `TRUNCATE TABLE` command. Since `DDL` commands can only use statement-based logging, this `flush_all` command is replicated by sending a `TRUNCATE TABLE` statement.

Transactions:

- The concept of [transactions](#) has not typically been part of [memcached](#) applications. We use `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` to control the read and write transaction batch size for performance considerations. These settings do not affect replication: each SQL operation on the underlying table is replicated right after successful completion.
- The default value of `daemon_memcached_w_batch_size` is 1, so each [memcached](#) write operation is committed immediately. This default setting incurs a certain amount of performance overhead, to avoid any inconsistency in the data visible on the master and slave servers. The replicated records will always be available immediately on the slave server. If you set `daemon_memcached_w_batch_size` greater than 1, records inserted or updated through the [memcached](#) interface are not immediately visible on the master server; to view these records on the master server before they are committed, issue `set transaction isolation level read uncommitted`.

## 14.17.7 Internals of the InnoDB memcached Plugin

### InnoDB API for the InnoDB memcached Plugin

The [InnoDB memcached](#) engine accesses [InnoDB](#) through [InnoDB](#) APIs. Most of the APIs are directly adopted from embedded [InnoDB](#). [InnoDB](#) API functions are passed to [InnoDB memcached](#) as “callback functions”. [InnoDB](#) API functions access the [InnoDB](#) table directly, and are mostly DML operations except for the `TRUNCATE TABLE` operation.

All [memcached](#) commands, listed below, are implemented through the [InnoDB memcached](#) API. The following table outlines how each [memcached](#) command is mapped to a DML operation.

**Table 14.13 memcached Commands and Associated DML Operation**

| memcached Command      | DML Operation                                                                          |
|------------------------|----------------------------------------------------------------------------------------|
| <code>get</code>       | a read/fetch command                                                                   |
| <code>set</code>       | a search followed by an insertion or update (depending on whether or not a key exists) |
| <code>add</code>       | a search followed by an insertion or update                                            |
| <code>replace</code>   | a search followed by an update                                                         |
| <code>append</code>    | a search followed by an update (appends data to the result before update)              |
| <code>prepend</code>   | a search followed by an update (prepends data to the result before update)             |
| <code>incr</code>      | a search followed by an update                                                         |
| <code>decr</code>      | a search followed by an update                                                         |
| <code>delete</code>    | a search followed by a deletion                                                        |
| <code>flush_all</code> | truncate table                                                                         |

### Underlying Tables Used by the InnoDB memcached Plugin

This section describes the underlying tables used by the [InnoDB memcached](#) plugin.

The `innodb_memcached_config.sql` configuration script installs three tables required by the [InnoDB memcached](#) plugin. The tables are created in a dedicated `innodb_memcache` database:

```
mysql> USE innodb_memcache;
Database changed
mysql> SHOW TABLES;
+-----+
| Tables_in_innodb_memcache |
```

```

+-----+
| cache_policies |
| config_options |
| containers     |
+-----+
3 rows in set (0.01 sec)

```

## containers Table

The `containers` table is the most important of the three tables. Entries in this table are “containers” for InnoDB tables that are used to store memcached values. The containers map the columns of the InnoDB table to the values outlined in the table below. This mapping is necessary for memcached to work with InnoDB tables.

The `containers` table has a default entry for the `test.demo_test` table. To use the InnoDB memcached plugin with your own InnoDB table, you must add an entry for your table to the `containers` table.

**Table 14.14 containers Columns**

| Column                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>          | The name given to the container.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>db_schema</code>     | The name of the database in which the InnoDB table resides. This is a required value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>db_table</code>      | The name of the InnoDB table that stores memcached values. This is a required value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>key_columns</code>   | The column in the InnoDB table that contains lookup key values for memcached operations. This is a required value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>value_columns</code> | The columns (one or more) in the InnoDB table that store memcached data. Multiple columns can be specified using the separator character that is specified in the <code>innodb_memcached.config_options</code> table. By default, the separator is a pipe character (“ ”). To specify multiple columns, separate them with the defined separator character. For example: <code>col1 col2 col3</code> . This is a required value.                                                                                                                                                                                                                                                                                                    |
| <code>flags</code>         | Specifies the columns in the InnoDB table that are used as flags (a user-defined numeric value that is stored and retrieved along with the main value) for memcached. A flag value can be used as a column specifier for some operations (such as <code>incr</code> , <code>prepend</code> ) if memcached value is mapped to multiple columns, so that an operation is performed on a specified column. For example, if you have mapped a value to 3 columns, and only want the increment operation performed on one of these columns, you can use <code>flags</code> to specify which column will be used for these operations. If you do not use the <code>flags</code> column, set its value to 0 to indicate that it is unused. |
| <code>cas_column</code>    | The column in the InnoDB table that stores compare-and-swap (cas) values. The <code>cas_column</code> value and <code>expire_time_column</code> value are related to the way memcached hashes requests to different servers and caches data in                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Column                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | memory. Because the <a href="#">InnoDB memcached</a> plugin is tightly integrated with a single <a href="#">memcached</a> daemon, and the in-memory caching mechanism is handled by MySQL and the <a href="#">buffer pool</a> , these columns are rarely needed in this type of deployment. If you do not use these columns, set their value to 0 to indicate that the columns are unused.                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>expire_time_column</code>     | The column in the <a href="#">InnoDB</a> table that stores expiration values. The <code>cas_column</code> value and <code>expire_time_column</code> value are related to the way <a href="#">memcached</a> hashes requests to different servers and caches data in memory. Because the <a href="#">InnoDB memcached</a> plugin is tightly integrated with a single <a href="#">memcached</a> daemon, and the in-memory caching mechanism is handled by MySQL and the <a href="#">buffer pool</a> , these columns are rarely needed in this type of deployment. If you do not use these columns, set their value to 0 to indicate that the columns are unused. As of MySQL 5.7.8, maximum expire time is defined as <code>INT_MAX32</code> or 2147483647 seconds (approximately 68 years). |
| <code>unique_idx_name_on_key</code> | The name of the index on the key column. It must be a unique index. It can be the <a href="#">primary key</a> or a <a href="#">secondary index</a> . Preferably, make the key column the primary key of the <a href="#">InnoDB</a> table. Doing so saves a lookup step over using a secondary index for this column. You cannot make a <a href="#">covering index</a> for <a href="#">memcached</a> lookups; <a href="#">InnoDB</a> returns an error if you try to define a composite secondary index over both the key and value columns.                                                                                                                                                                                                                                                |

## containers Table Column Constraints

- You must supply a value for `db_schema`, `db_name`, `key_columns`, `value_columns` and `unique_idx_name_on_key`. Otherwise, the setup will fail. Specify 0 for `flags`, `cas_column`, and `expire_time_column` if they are unused. Failing to do so could cause your setup to fail.
- `key_columns`: The maximum limit for a [memcached](#) key is 250 characters, which is enforced by [memcached](#). If a mapped key longer than the maximum limit is used, the operation will fail. The mapped key must be a non-Null [CHAR](#) or [VARCHAR](#) type.
- `value_columns`: Must be mapped to a [CHAR](#), [VARCHAR](#), or [BLOB](#) column. There is no length restriction and the value can be NULL.
- `cas_column`: The `cas` value is a 64 bit integer. It must be mapped to a [BIGINT](#) of at least 8 bytes. If you do not use this column, set its value to 0 to indicate that it is unused.
- `expiration_time_column`: Must mapped to an [INTEGER](#) of at least 4 bytes. Expiration time is defined as a 32-bit integer for Unix time (the number of seconds since January 1, 1970, as a 32-bit value), or the number of seconds starting from the current time. For the latter, the number of seconds may not exceed 60\*60\*24\*30 (the number of seconds in 30 days). If the number sent by a client is larger, the server will consider it to be a real Unix time value rather than an offset from the current time. If you do not use this column, set its value to 0 to indicate that it is unused.
- `flags`: Must be mapped to an [INTEGER](#) of at least 32-bits and can be NULL. If you do not use this column, set its value to 0 to indicate that it is unused.

A pre-check is performed at plugin load time to enforce column constraints. If any mismatches are found, the plugin will not load.

## cache\_policies Table

The `cache_policies` table defines a cache policy for your InnoDB memcached setup. You can specify individual policies for `get`, `set`, `delete`, and `flush` operations within a single cache policy. The default setting for all operations is `innodb_only`.

- `innodb_only`: Use InnoDB as the data store of memcached.
- `cache-only`: Use the traditional memcached engine as the data store.
- `caching`: Use both InnoDB and the traditional memcached engine as data stores. In this case, if memcached cannot find a key in memory, it searches for the value in an InnoDB table.
- `disable`: Disable caching.

**Table 14.15** `cache_policies` Columns

| Column                     | Description                                                                                                                                                                                                       |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>policy_name</code>   | Name of the cache policy. The default cache policy name is <code>cache_policy</code> .                                                                                                                            |
| <code>get_policy</code>    | The cache policy for get operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .    |
| <code>set_policy</code>    | The cache policy for set operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .    |
| <code>delete_policy</code> | The cache policy for delete operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> . |
| <code>flush_policy</code>  | The cache policy for flush operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .  |

## config\_options Table

The `config_options` table stores memcached-related settings that can be changed at runtime, using SQL. Supported configuration options are `separator` and `table_map_delimiter`:

**Table 14.16** `config_options` Columns

| Column            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Name</code> | Name of the memcached-related configuration option. The following configuration options are supported through the <code>config_options</code> table: <ul style="list-style-type: none"> <li>• <code>separator</code>: Used to separate values of a long string into separate values when there are multiple <code>value_columns</code> defined. By default, the <code>separator</code> is a <code> </code> character. For example, if you defined <code>col1</code>, <code>col2</code> as value columns, and you define <code> </code> as the separator, you can issue the following command in memcached to insert values into <code>col1</code> and <code>col2</code> respectively: <pre>set keyx 10 0 19</pre> </li> </ul> |

| Column | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | <p><code>valuecolx valuecoly</code></p> <p><code>valuecol1x</code> is stored in <code>col1</code> and <code>valuecoly</code> is stored in <code>col2</code>.</p> <ul style="list-style-type: none"> <li><code>table_map_delimiter</code>: The character separating the schema name and the table name when you use the @@ notation in a key name to access a key in a specific table. For example, <code>@@t1.some_key</code> and <code>@@t2.some_key</code> have the same key value, but are stored in different tables.</li> </ul> |
| Value  | The value assigned to the <code>memcached</code> -related configuration option.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Multiple-column Mapping

- During plugin initialization, when `InnoDB memcached` is configured with information defined in the `containers` table, each mapped column that is parsed from `value_columns` is verified against the mapped table. If multiple columns are mapped, there is a check to ensure that each column exists and is the right type.
- At run-time, for `memcached` insert operations, if there are more delimiters in the value than the number of mapped columns, only the number of mapped values are taken. For example, if there are 6 mapped columns and 7 delimited values are provided, only the first 6 delimited values are taken. The 7th delimited value is ignored.
- If there are fewer delimited values than mapped columns, unfilled columns are set to NULL. If an unfilled column cannot be NULL, the insert will fail.
- If a table has more columns than mapped values, the extra columns do not affect output results.

## Example Tables

The `innodb_memcached_config.sql` configuration script creates a table `demo_test` in the `test` database as an example. It also allows the `InnoDB memcached` plugin to work immediately, without creating any additional tables.

The entries in the `container` table define which column is used for what purpose as described above:

```
mysql> select * from innodb_memcache.containers;
+-----+-----+-----+-----+-----+-----+-----+-----+
| name | db_schema | db_table | key_columns | value_columns | flags | cas_column | expire_time_column | ur
+-----+-----+-----+-----+-----+-----+-----+-----+
| aaa  | test     | demo_test | c1          | c2           | c3    | c4        | c5                 | PR
+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> desc test.demo_test;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
c1	varchar(32)	NO	PRI		
c2	varchar(1024)	YES		NULL	
c3	int(11)	YES		NULL	
c4	bigint(20) unsigned	YES		NULL	
c5	int(11)	YES		NULL	
+-----+-----+-----+-----+-----+-----+
5 rows in set (0.01 sec)
```

When no table ID is requested through the @@ notation in the key name:

- If a row has a `name` value of `default`, the corresponding table is used by the `memcached` plugin. Thus, when you make your first entry in `innodb_memcache.containers` to move beyond the `demo_test` table, use a `name` value of `default`.
- If there is no `innodb_memcache.containers.name` value of `default`, the row with the first `name` value in alphabetical order is used.

## 14.17.8 Troubleshooting the InnoDB memcached Plugin

The following list shows some potential issues you might encounter using the `InnoDB memcached` plugin, and solutions or workarounds where available:

- If you see this error in your MySQL error log, the server might fail to start:

```
failed to set rlimit for open files. Try running as root or requesting
smaller maxconns value.
```

The error message is actually from the `memcached` daemon. One solution is to raise the OS limit for the number of open files. The command varies depending on the operating system. For example, here are the commands to check and increase the limit on several operating systems:

```
# Linux
$ ulimit -n
1024
ulimit -n 4096
$ ulimit -n
4096

# OS X Lion (10.6)
$ ulimit -n
256
ulimit -n 4096
$ ulimit -n
4096
```

The other solution is to reduce the number of concurrent connections available for the `memcached` daemon, using the `-c` option which defaults to 1024. Encode that `memcached` option using the MySQL option `daemon_memcached_option` inside the MySQL configuration file:

```
[mysqld]
...
loose-daemon_memcached_option='-c 64'
```

- To troubleshoot problems where the `memcached` daemon is unable to store data in or retrieve data from the `InnoDB` table, specify the `memcached` option `-vvv` through the MySQL configuration option `daemon_memcached_option`. Examine the MySQL error log for debug output related to `memcached` operations.
- If the column specified to hold the `memcached` item values is the wrong data type, such as a numeric type instead of a string type, attempts to store key/value pairs will fail with no specific error code or message.
- If the `daemon_memcached` plugin causes any issues with starting the MySQL server, disable it during troubleshooting by adding this line under the `[mysqld]` group in your MySQL configuration file:

```
daemon_memcached=OFF
```

For example, if you run the `install plugin` command before running the `innodb_memcached_config.sql` configuration script to set up the necessary database and tables, the server might crash and be unable to start. Or, if you set up an incorrect entry in the `innodb_memcached.containers` table, the server might be unable to start.

To permanently turn off the `memcached` plugin for a MySQL instance, issue the following command:

```
mysql> uninstall plugin daemon_memcached;
```

- If you run more than one instance of MySQL on the same machine, with the `memcached` daemon plugin enabled in each, make sure to specify a unique `memcached` port for each one using the `daemon_memcached_option` configuration option.
- You might find that a SQL statement cannot find an expected table, or there is no data in the table, but `memcached` API calls still work and retrieve the expected data. This can happen if you do not set up the entry in the `innodb_memcached.containers` table, or do not switch to that table by issuing a `GET` or `SET` request with the key `@@table_id`, or make a change to an existing entry in `innodb_memcached.containers` without restarting the MySQL server afterward. The free-form storage mechanism is flexible enough that your requests to store or retrieve a multi-column value like `col1|col2|col3` will usually still work, even if the daemon is using the `test.demo_test` table which stores all the data within a single column.
- When defining your own InnoDB table for use with InnoDB `memcached`, and columns in your table are defined as NOT NULL, ensure that values are supplied for the NOT NULL columns when inserting a descriptor for the InnoDB table into the `memcached` containers table (`innodb_memcached.containers`). If your descriptor `INSERT` statement contains fewer delimited values than there are mapped columns, unfilled columns are set to NULL. Attempting to insert a NULL value into a NOT NULL column causes the `INSERT` to fail, which may only become evident after you reinitialize the InnoDB `memcached` plugin to apply changes to the containers table.
- If `cas_column` and `expire_time_column` of the `innodb_memcached.containers` table are set to NULL, the following error will be returned when attempting to load the `memcached` plugin:

```
InnoDB_Memcached: column 6 in the entry for config table 'containers' in
database 'innodb_memcached' has an invalid NULL value.
```

The `memcached` plugin rejects usage of NULL in the `cas_column` and `expire_time_column` columns. Set the value of these columns to 0 if the columns are unused.

- As the length of the `memcached` key and values increase, you encounter size and length limits at different points:
  - When the key exceeds 250 bytes in size, `memcached` operations return an error. This is currently a fixed limit within `memcached`.
  - You might encounter InnoDB-related limits when the value exceeds 768 bytes in size, or 3072 bytes in size, or the InnoDB row size limit which depends on `innodb_page_size` setting. These limits primarily apply if you intend to create an index on the value column to run report-generating queries on that column from SQL. See [Section 14.5.7, “Limits on InnoDB Tables”](#) for details.
  - The maximum size for the combination of the key and the value is 1 MB.
- If you share configuration files across MySQL servers with different versions, using the latest configuration options for the `memcached` plugin could cause startup errors for older MySQL versions. To avoid compatibility problems, use the `loose` forms of these option names, for example `loose-daemon_memcached_option='-c 64'` instead of `daemon_memcached_option='-c 64'`.

- There is no restriction or check in place to validate character set settings. `memcached` stores and retrieves keys and values in bytes and is therefore not character set sensitive. However, you must ensure that the `memcached` client and the MySQL table use the same character set.

## 14.18 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting InnoDB problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see [Section 5.2.2, “The Error Log”](#)).
- If the failure is related to a [deadlock](#), run with the `innodb_print_all_deadlocks` option enabled so that details about each InnoDB deadlock are printed to the MySQL server error log.
- Issues relating to the InnoDB data dictionary include failed `CREATE TABLE` statements (orphaned table files), inability to open `.InnoDB` files, and `system cannot find the path specified` errors. For information about these sorts of problems and errors, see [Section 14.18.3, “Troubleshooting InnoDB Data Dictionary Operations”](#).
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.
- Enable the InnoDB Monitors to obtain information about a problem (see [Section 14.14, “InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of InnoDB. If the problem is with locks, enable the Lock Monitor. If the problem is in creation of tables or other data dictionary operations, enable the Table Monitor to print the contents of the InnoDB internal data dictionary. To see tablespace information enable the Tablespace Monitor.

InnoDB temporarily enables standard InnoDB Monitor output under the following conditions:

- A long semaphore wait
- InnoDB cannot find free blocks in the buffer pool
- Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

### 14.18.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for InnoDB I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

#### Initialization Problems

If something goes wrong when InnoDB attempts to initialize its tablespace or its log files, delete all files created by InnoDB: all `ibdata` files and all `ib_logfile` files. If you already created some InnoDB tables, also delete the corresponding `.frm` files for these tables, and any `.ibd` files if you are using multiple tablespaces, from the MySQL database directories. Then try the InnoDB database creation again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

#### Runtime Problems

If InnoDB prints an operating system error during a file operation, usually the problem has one of the following solutions:

- Make sure the [InnoDB](#) data file directory and the [InnoDB](#) log directory exist.
- Make sure `mysqld` has access rights to create files in those directories.
- Make sure `mysqld` can read the proper `my.cnf` or `my.ini` option file, so that it starts with the options that you specified.
- Make sure the disk is not full and you are not exceeding any disk quota.
- Make sure that the names you specify for subdirectories and data files do not clash.
- Doublecheck the syntax of the `innodb_data_home_dir` and `innodb_data_file_path` values. In particular, any `MAX` value in the `innodb_data_file_path` option is a hard limit, and exceeding that limit causes a fatal error.

## 14.18.2 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with `SELECT ... INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Serious corruption might cause `SELECT * FROM tbl_name` statements or [InnoDB](#) background operations to crash or assert, or even cause [InnoDB](#) roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the [InnoDB](#) storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 1
```

### Warning

Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start [InnoDB](#) and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on separate physical copy of your database. When forcing [InnoDB](#) recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into [B-trees](#) and other database structures.

As a safety measure, [InnoDB](#) prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. As of MySQL 5.7.3, an `innodb_force_recovery` setting of 4 or greater places [InnoDB](#) in read-only mode.

- 1 (`SRV_FORCE_IGNORE_CORRUPT`)

Lets the server run even if it detects a corrupt [page](#). Tries to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- 2 (`SRV_FORCE_NO_BACKGROUND`)

Prevents the [master thread](#) and any [purge threads](#) from running. If a crash would occur during the [purge](#) operation, this recovery value prevents it.

- 3 ([SRV\\_FORCE\\_NO\\_TRX\\_UNDO](#))

Does not run transaction [rollbacks](#) after [crash recovery](#).

- 4 ([SRV\\_FORCE\\_NO\\_IBUF\\_MERGE](#))

Prevents [insert buffer](#) merge operations. If they would cause a crash, does not do them. Does not calculate table [statistics](#). This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes. As of MySQL 5.7.3, sets [InnoDB](#) to read-only.

- 5 ([SRV\\_FORCE\\_NO\\_UNDO\\_LOG\\_SCAN](#))

Does not look at [undo logs](#) when starting the database: [InnoDB](#) treats even incomplete transactions as committed. This value can permanently corrupt data files. As of MySQL 5.7.3, sets [InnoDB](#) to read-only.

- 6 ([SRV\\_FORCE\\_NO\\_LOG\\_REDO](#))

Does not do the [redo log](#) roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures. As of MySQL 5.7.3, sets [InnoDB](#) to read-only.

You can [SELECT](#) from tables to dump them. With an [innodb\\_force\\_recovery](#) value of 3 or less you can [DROP](#) or [CREATE](#) tables. As of MySQL 5.7.9, [DROP TABLE](#) is also supported with an [innodb\\_force\\_recovery](#) value greater than 3.

If you know that a given table is causing a crash on rollback, you can drop it. If you encounter a runaway rollback caused by a failing mass import or [ALTER TABLE](#), you can kill the [mysqld](#) process and set [innodb\\_force\\_recovery](#) to 3 to bring the database up without the rollback, and then [DROP](#) the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an [ORDER BY primary\\_key DESC](#) clause might be able to dump the portion of the table after the corrupted part.

If a high [innodb\\_force\\_recovery](#) value is required to start [InnoDB](#), there may be corrupted data structures that could cause complex queries (queries containing [WHERE](#), [ORDER BY](#), or other clauses) to fail. In this case, you may only be able to run basic [SELECT \\* FROM t](#) queries.

### 14.18.3 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored both in the [.frm](#) files, and in the [InnoDB data dictionary](#). If you move [.frm](#) files around, or if the server crashes in the middle of a data dictionary operation, these sources of information can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting [InnoDB](#), see [Section 14.18.2, “Forcing InnoDB Recovery”](#) for information about manual recovery.

#### Problem with CREATE TABLE

A symptom of an out-of-sync data dictionary is that a [CREATE TABLE](#) statement fails. If this occurs, look in the server's error log. If the log says that the table already exists inside the [InnoDB](#) internal data dictionary, you have an orphaned table inside the [InnoDB](#) tablespace files that has no corresponding [.frm](#) file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
```

```
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphaned table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this problem, start the `mysql` client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

## Problem Opening Table

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open a `.InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.InnoDB'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphaned `.frm` file without a corresponding table inside `InnoDB`. You can drop the orphaned `.frm` file by deleting it manually.

## Orphaned Intermediate Tables

If MySQL crashes in the middle of an `ALTER TABLE` operation, you may be left with an orphaned intermediate table. Intermediate table names begin with “#sql-”. In your data directory you will see an `#sql-*.ibd` file and possibly an accompanying `#sql-*.frm` file. The intermediate table is also listed in `Table Monitor` output and referenced in `InnoDB INFORMATION_SCHEMA` tables.

Removing an orphaned intermediate table requires a table format file (a `.frm` file) that matches the table schema defined in the `#sql-*.ibd` file (it must have the same columns and indexes). Depending on when the crash occurred during the `ALTER TABLE` operation, the orphaned `#sql-*.ibd` file could have a pre-`ALTER` or post-`ALTER` schema definition, and the data in the accompanying `#sql-*.frm` file (if present) may or may not match.

To remove the orphaned intermediate table, perform the following steps:

1. Determine if the `#sql-*.ibd` file has a pre-`ALTER` or post-`ALTER` schema definition. You can view the columns and indexes of the intermediate table by querying `InnoDB INFORMATION_SCHEMA` tables. `INNODB_SYS_TABLES` provides the `TABLE_ID` for the intermediate table, which you can use to retrieve column and index information from `INNODB_SYS_COLUMNS`, and `INNODB_SYS_INDEXES`.
2. Once you have determined if the `#sql-*.ibd` file has a pre-`ALTER` or post-`ALTER` schema definition, create a matching `#sql-*.frm` file in a different database directory. For example, if an intermediate table has a post-`ALTER` schema definition, create an `.frm` file that matches the altered schema definition:

```
mysql> CREATE TABLE tmp LIKE employees.salaries; ALTER TABLE tmp DROP COLUMN to_date;
Query OK, 0 rows affected (0.02 sec)

Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

- Copy the `.frm` file to the database directory where the orphaned table is located and rename it to match the name of the `#sql-*.ibd` file

```
shell> cp tmp.frm employees/#sql-ib87.frm
```

- Drop the intermediate table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-ib87`;
Query OK, 0 rows affected (0.01 sec)
```

The `#mysql50#` prefix tells MySQL to ignore `file name safe encoding` introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as “#”.

- If there is a leftover `#sql-*.frm` file, drop it. MySQL reports an “unknown table” error, which can be ignored.

```
mysql> DROP TABLE `#mysql50##sql-36ab_2`;
ERROR 1051 (42S02): Unknown table 'employees.#mysql50##sql-36ab_2'
```

## Restoring Orphaned File-Per-Table ibd Files

This procedure describes how to restore orphaned `file_per_table .ibd` files to another MySQL instance. You might use this procedure if the system tablespace is lost or unrecoverable and you want to restore `.ibd` file backups on a new MySQL instance.

The procedure is not supported for `general tablespace .ibd` files.

The procedure assumes that you only have `.ibd` file backups, you are recovering to the same version of MySQL that initially created the orphaned `.ibd` files, and that `.ibd` file backups are clean. See [Section 14.5.2, “Moving or Copying InnoDB Tables to Another Machine”](#) for information about creating clean backups.

Tablespace copying limitations outlined in [Section 14.4.6, “Copying File-Per-Table Tablespaces to Another Server”](#) are applicable to this procedure.

- On the new MySQL instance, recreate the table in a database of the same name.

```
mysql> CREATE DATABASE sakila;

mysql> USE sakila;

mysql> CREATE TABLE actor (
->   actor_id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
->   first_name VARCHAR(45) NOT NULL,
->   last_name VARCHAR(45) NOT NULL,
->   last_update TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
->   PRIMARY KEY (actor_id),
->   KEY idx_actor_last_name (last_name)
-> )ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

- Discard the tablespace of the newly created table.

```
mysql> ALTER TABLE sakila.actor DISCARD TABLESPACE;
```

- Copy the orphaned `.ibd` file from your backup directory to the new database directory.

```
shell> cp /backup_directory/actor.ibd path/to/mysql-5.7/data/sakila/
```

- Ensure that the `.ibd` file has the necessary file permissions.
- Import the orphaned `.ibd` file. A warning is issued indicating that InnoDB will attempt to import the file without schema verification.

```
mysql> ALTER TABLE sakila.actor IMPORT TABLESPACE; SHOW WARNINGS;
```

```
Query OK, 0 rows affected, 1 warning (0.15 sec)

Warning | 1810 | InnoDB: IO Read error: (2, No such file or directory)
Error opening './sakila/actor.cfg', will attempt to import
without schema verification
```

- Query the table to verify that the `.ibd` file was successfully restored.

```
mysql> SELECT COUNT(*) FROM sakila.actor;
+-----+
| count(*) |
+-----+
|      200 |
+-----+
```

## 14.18.4 InnoDB Error Handling

The following items describe how `InnoDB` performs error handling. `InnoDB` sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in a `tablespace`, a MySQL `Table is full` error occurs and `InnoDB` rolls back the SQL statement.
- A transaction `deadlock` causes `InnoDB` to `roll back` the entire `transaction`. Retry the whole transaction when this happens.

A lock wait timeout causes `InnoDB` to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option.) Retry the statement if using the current behavior, or the entire transaction if using `--innodb_rollback_on_timeout`.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.
- A `row too long error` rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the `InnoDB` storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL statement, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

## 14.18.5 InnoDB Error Codes

The following is a nonexhaustive list of common `InnoDB`-specific errors that you may encounter, with information about why each occurs and how to resolve the problem.

- 1005 (`ER_CANT_CREATE_TABLE`)

Cannot create table. If the error message refers to error 150, table creation failed because a [foreign key constraint](#) was not correctly formed. If the error message refers to error -1, table creation probably failed because the table includes a column name that matched the name of an internal InnoDB table.

- 1016 (ER\_CANT\_OPEN\_FILE)

Cannot find the InnoDB table from the InnoDB data files, although the .frm file for the table exists. See [Section 14.18.3, “Troubleshooting InnoDB Data Dictionary Operations”](#).

- 1114 (ER\_RECORD\_FILE\_FULL)

InnoDB has run out of free space in the tablespace. Reconfigure the tablespace to add a new data file.

- 1205 (ER\_LOCK\_WAIT\_TIMEOUT)

Lock wait timeout expired. The statement that waited too long was [rolled back](#) (not the entire [transaction](#)). You can increase the value of the `innodb_lock_wait_timeout` configuration option if SQL statements should wait longer for other transactions to complete, or decrease it if too many long-running transactions are causing [locking](#) problems and reducing [concurrency](#) on a busy system.

- 1206 (ER\_LOCK\_TABLE\_FULL)

The total number of locks exceeds the amount of memory InnoDB devotes to managing locks. To avoid this error, increase the value of `innodb_buffer_pool_size`. Within an individual application, a workaround may be to break a large operation into smaller pieces. For example, if the error occurs for a large `INSERT`, perform several smaller `INSERT` operations.

- 1213 (ER\_LOCK\_DEADLOCK)

The [transaction](#) encountered a [deadlock](#) and was automatically [rolled back](#) so that your application could take corrective action. To recover from this error, run all the operations in this transaction again. A deadlock occurs when requests for locks arrive in inconsistent order between transactions. The transaction that was rolled back released all its locks, and the other transaction can now get all the locks it requested. Thus when you re-run the transaction that was rolled back, it might have to wait for other transactions to complete, but typically the deadlock does not recur. If you encounter frequent deadlocks, make the sequence of locking operations (`LOCK TABLES`, `SELECT ... FOR UPDATE`, and so on) consistent between the different transactions or applications that experience the issue. See [Section 14.2.2.10, “How to Cope with Deadlocks”](#) for details.

- 1216 (ER\_NO\_REFERENCED\_ROW)

You are trying to add a row but there is no parent row, and a [foreign key constraint](#) fails. Add the parent row first.

- 1217 (ER\_ROW\_IS\_REFERENCED)

You are trying to delete a parent row that has children, and a [foreign key constraint](#) fails. Delete the children first.

- ERROR 1553 (HY000): Cannot drop index 'fooIdx': needed in a foreign key constraint

This error message is reported when you attempt to drop the last index that can enforce a particular referential constraint.

For optimal performance with DML statements, InnoDB requires an index to exist on [foreign key](#) columns, so that `UPDATE` and `DELETE` operations on a [parent table](#) can easily check whether corresponding rows exist in the [child table](#). MySQL creates or drops such indexes automatically when needed, as a side-effect of `CREATE TABLE`, `CREATE INDEX`, and `ALTER TABLE` statements.

When you drop an index, [InnoDB](#) checks whether the index is not used for checking a foreign key constraint. It is still OK to drop the index if there is another index that can be used to enforce the same constraint. [InnoDB](#) prevents you from dropping the last index that can enforce a particular referential constraint.

---

Storage engines are MySQL components that handle the SQL operations for different table types. [InnoDB](#) is the default and most general-purpose storage engine, and Oracle recommends using it for tables except for specialized use cases. (The [CREATE TABLE](#) statement in MySQL 5.7 creates [InnoDB](#) tables by default.)

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the [SHOW ENGINES](#) statement. The value in the [Support](#) column indicates whether an engine can be used. A value of [YES](#), [NO](#), or [DEFAULT](#) indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
  XA: NO
  Savepoints: NO
***** 2. row *****
  Engine: InnoDB
  Support: DEFAULT
  Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
  XA: YES
```

```

Savepoints: YES
***** 3. row *****
  Engine: MRG_MYISAM
  Support: YES
  Comment: Collection of identical MyISAM tables
Transactions: NO
  XA: NO
  Savepoints: NO
***** 4. row *****
  Engine: BLACKHOLE
  Support: YES
  Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
  XA: NO
  Savepoints: NO
***** 5. row *****
  Engine: MyISAM
  Support: YES
  Comment: MyISAM storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
...

```

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default [InnoDB](#) storage engine or the [NDB](#) storage engine which are covered in [Chapter 14, The InnoDB Storage Engine](#), and [MySQL Cluster NDB 7.3](#) and [MySQL Cluster NDB 7.4](#). For advanced users, this chapter also contains a description of the pluggable storage engine architecture (see [Section 15.11, “Overview of MySQL Storage Engine Architecture”](#)).

For information about storage engine support offered in commercial MySQL Server binaries, see [MySQL Enterprise Server 5.7](#), on the MySQL Web site. The storage engines available might depend on which edition of Enterprise Server you are using.

For answers to commonly asked questions about MySQL storage engines, see [Section A.2, “MySQL 5.7 FAQ: Storage Engines”](#).

## MySQL 5.7 Supported Storage Engines

- [InnoDB](#): The default storage engine in MySQL 5.7. [InnoDB](#) is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. [InnoDB](#) row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. [InnoDB](#) stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, [InnoDB](#) also supports [FOREIGN KEY](#) referential-integrity constraints. For more information about [InnoDB](#), see [Chapter 14, The InnoDB Storage Engine](#).
- [MyISAM](#): These tables have a small footprint. [Table-level locking](#) limits the performance in read/write workloads, so it is often used in read-only or read-mostly workloads in Web and data warehousing configurations.
- [Memory](#): Stores all data in RAM, for fast access in environments that require quick lookups of non-critical data. This engine was formerly known as the [HEAP](#) engine. Its use cases are decreasing; [InnoDB](#) with its buffer pool memory area provides a general-purpose and durable way to keep most or all data in memory, and [NDBCLUSTER](#) provides fast key-value lookups for huge distributed data sets.
- [CSV](#): Its tables are really text files with comma-separated values. CSV tables let you import or dump data in CSV format, to exchange data with scripts and applications that read and write that same format. Because CSV tables are not indexed, you typically keep the data in [InnoDB](#) tables during normal operation, and only use CSV tables during the import or export stage.
- [Archive](#): These compact, unindexed tables are intended for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.

- **Blackhole:** The Blackhole storage engine accepts but does not store data, similar to the Unix `/dev/null` device. Queries always return an empty set. These tables can be used in replication configurations where DML statements are sent to slave servers, but the master server does not keep its own copy of the data.
- **Merge:** Enables a MySQL DBA or developer to logically group a series of identical **MyISAM** tables and reference them as one object. Good for VLDB environments such as data warehousing.
- **Federated:** Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- **Example:** This engine serves as an example in the MySQL source code that illustrates how to begin writing new storage engines. It is primarily of interest to developers. The storage engine is a “stub” that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them.

You are not restricted to using the same storage engine for an entire server or schema. You can specify the storage engine for any table. For example, an application might use mostly **InnoDB** tables, with one **CSV** table for exporting data to a spreadsheet and a few **MEMORY** tables for temporary workspaces.

### Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. The following table provides an overview of some storage engines provided with MySQL:

**Table 15.1 Storage Engines Feature Summary**

| Feature                      | MyISAM | Memory | InnoDB           | Archive | NDB   |
|------------------------------|--------|--------|------------------|---------|-------|
| Storage limits               | 256TB  | RAM    | 64TB             | None    | 384EB |
| Transactions                 | No     | No     | Yes              | No      | Yes   |
| Locking granularity          | Table  | Table  | Row              | Row     | Row   |
| MVCC                         | No     | No     | Yes              | No      | No    |
| Geospatial data type support | Yes    | No     | Yes              | Yes     | Yes   |
| Geospatial indexing support  | Yes    | No     | Yes <sup>a</sup> | No      | No    |
| B-tree indexes               | Yes    | Yes    | Yes              | No      | No    |
| T-tree indexes               | No     | No     | No               | No      | Yes   |
| Hash indexes                 | No     | Yes    | No <sup>b</sup>  | No      | Yes   |
| Full-text search indexes     | Yes    | No     | Yes <sup>c</sup> | No      | No    |
| Clustered indexes            | No     | No     | Yes              | No      | No    |
| Data caches                  | No     | N/A    | Yes              | No      | Yes   |

| Feature                                      | MyISAM           | Memory | InnoDB           | Archive | NDB |
|----------------------------------------------|------------------|--------|------------------|---------|-----|
| Index caches                                 | Yes              | N/A    | Yes              | No      | Yes |
| Compressed data                              | Yes <sup>d</sup> | No     | Yes <sup>e</sup> | Yes     | No  |
| Encrypted data <sup>f</sup>                  | Yes              | Yes    | Yes              | Yes     | Yes |
| Cluster database support                     | No               | No     | No               | No      | Yes |
| Replication support <sup>g</sup>             | Yes              | Yes    | Yes              | Yes     | Yes |
| Foreign key support                          | No               | No     | Yes              | No      | No  |
| Backup / point-in-time recovery <sup>h</sup> | Yes              | Yes    | Yes              | Yes     | Yes |
| Query cache support                          | Yes              | Yes    | Yes              | Yes     | Yes |
| Update statistics for data dictionary        | Yes              | Yes    | Yes              | Yes     | Yes |

<sup>a</sup>InnoDB support for geospatial indexing is available in MySQL 5.7.5 and higher.

<sup>b</sup>InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

<sup>c</sup>InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and higher.

<sup>d</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>e</sup>Compressed InnoDB tables require the InnoDB Barracuda file format.

<sup>f</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>g</sup>Implemented in the server, rather than in the storage engine.

<sup>h</sup>Implemented in the server, rather than in the storage engine.

## 15.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```
-- ENGINE=INNODB not needed unless you have set a different
-- default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

When you omit the `ENGINE` option, the default storage engine is used. The default engine is `InnoDB` in MySQL 5.7. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

The storage engine for [TEMPORARY](#) tables created with [CREATE TEMPORARY TABLE](#) can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime.

When MySQL is installed on Windows using the MySQL Configuration Wizard, the [InnoDB](#) or [MyISAM](#) storage engine can be selected as the default. See [The Database Usage Dialog](#).

To convert a table from one storage engine to another, use an [ALTER TABLE](#) statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See [Section 13.1.14, “CREATE TABLE Syntax”](#), and [Section 13.1.6, “ALTER TABLE Syntax”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your master server uses [InnoDB](#) tables for maximum safety, but the slave servers use other storage engines for speed at the expense of durability or concurrency.

By default, a warning is generated whenever [CREATE TABLE](#) or [ALTER TABLE](#) cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See [Section 5.1.7, “Server SQL Modes”](#).

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

## 15.2 The MyISAM Storage Engine

[MyISAM](#) is based on the older (and no longer available) [ISAM](#) storage engine but has many useful extensions.

**Table 15.2 [MyISAM](#) Storage Engine Features**

|                                                    |       |                                        |                  |                                              |       |
|----------------------------------------------------|-------|----------------------------------------|------------------|----------------------------------------------|-------|
| <b>Storage limits</b>                              | 256TB | <b>Transactions</b>                    | No               | <b>Locking granularity</b>                   | Table |
| <b>MVCC</b>                                        | No    | <b>Geospatial data type support</b>    | Yes              | <b>Geospatial indexing support</b>           | Yes   |
| <b>B-tree indexes</b>                              | Yes   | <b>T-tree indexes</b>                  | No               | <b>Hash indexes</b>                          | No    |
| <b>Full-text search indexes</b>                    | Yes   | <b>Clustered indexes</b>               | No               | <b>Data caches</b>                           | No    |
| <b>Index caches</b>                                | Yes   | <b>Compressed data</b>                 | Yes <sup>a</sup> | <b>Encrypted data<sup>b</sup></b>            | Yes   |
| <b>Cluster database support</b>                    | No    | <b>Replication support<sup>c</sup></b> | Yes              | <b>Foreign key support</b>                   | No    |
| <b>Backup / point-in-time recovery<sup>d</sup></b> | Yes   | <b>Query cache support</b>             | Yes              | <b>Update statistics for data dictionary</b> | Yes   |

<sup>a</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>b</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

<sup>d</sup>Implemented in the server, rather than in the storage engine.

Each [MyISAM](#) table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format. The data file has an `.MYD` ([MYData](#)) extension. The index file has an `.MYI` ([MYIndex](#)) extension.

To specify explicitly that you want a [MyISAM](#) table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 5.7, it is normally necessary to use `ENGINE` to specify the [MyISAM](#) storage engine because [InnoDB](#) is the default engine.

You can check or repair [MyISAM](#) tables with the `mysqlcheck` client or `myisamchk` utility. You can also compress [MyISAM](#) tables with `myisampack` to take up much less space. See [Section 4.5.3](#), “[mysqlcheck — A Table Maintenance Program](#)”, [Section 4.6.3](#), “[myisamchk — MyISAM Table-Maintenance Utility](#)”, and [Section 4.6.5](#), “[myisampack — Generate Compressed, Read-Only MyISAM Tables](#)”.

[MyISAM](#) tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.
- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of  $(2^{32})^2$  (1.844E+19) rows in a [MyISAM](#) table.
- The maximum number of indexes per [MyISAM](#) table is 64.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an `AUTO_INCREMENT` column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one `AUTO_INCREMENT` column per table is supported. [MyISAM](#) automatically updates this column for `INSERT` and `UPDATE` operations. This makes `AUTO_INCREMENT` columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an `AUTO_INCREMENT` column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The `AUTO_INCREMENT` value can be reset with `ALTER TABLE` or `myisamchk`.
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- [MyISAM](#) supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. A

free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 8.11.3, “Concurrent Inserts”](#).

- You can put the data file and index file in different directories on different physical devices to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See [Section 13.1.14, “CREATE TABLE Syntax”](#).
- `BLOB` and `TEXT` columns can be indexed.
- `NULL` values are permitted in indexed columns. This takes 0 to 1 bytes per key.
- Each character column can have a different character set. See [Section 10.1, “Character Set Support”](#).
- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover-options` option, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.
- Tables with `VARCHAR` columns may have fixed or dynamic row length.
- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.
- Arbitrary length `UNIQUE` constraints.

## Additional Resources

- A forum dedicated to the `MyISAM` storage engine is available at <http://forums.mysql.com/list.php?21>.

### 15.2.1 MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see [Section 5.1.3, “Server Command Options”](#).

**Table 15.3 MyISAM Option/Variable Reference**

| Name                                           | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|------------------------------------------------|----------|-------------|------------|------------|-----------|---------|
| <a href="#">bulk_insert_buffer</a>             | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">concurrent_insert</a>              | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">delay-key-write</a>                | Yes      | Yes         |            |            | Global    | Yes     |
| - Variable:<br><a href="#">delay_key_write</a> |          |             | Yes        |            | Global    | Yes     |
| <a href="#">have_rtree_keys</a>                |          |             | Yes        |            | Global    | No      |
| <a href="#">key_buffer_size</a>                | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">log-isam</a>                       | Yes      | Yes         |            |            |           |         |
| <a href="#">myisam-block-size</a>              | Yes      | Yes         |            |            |           |         |

| Name                                                  | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|-------------------------------------------------------|----------|-------------|------------|------------|-----------|---------|
| <a href="#">myisam_data_pointer_size</a>              | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">myisam_max_sort_file_size</a>             | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">myisam_mmap_size</a>                      | Yes      | Yes         | Yes        |            | Global    | No      |
| <a href="#">myisam-recover-options</a>                | Yes      | Yes         |            |            |           |         |
| - Variable:<br><a href="#">myisam_recover_options</a> |          |             |            |            |           |         |
| <a href="#">myisam_recover_options</a>                |          |             | Yes        |            | Global    | No      |
| <a href="#">myisam_repair_threads</a>                 | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">myisam_sort_buffer_size</a>               | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">myisam_stats_method</a>                   | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">myisam_use_mmap</a>                       | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">skip-concurrent-insert</a>                | Yes      | Yes         |            |            |           |         |
| - Variable:<br><a href="#">concurrent_insert</a>      |          |             |            |            |           |         |
| <a href="#">tmp_table_size</a>                        | Yes      | Yes         | Yes        |            | Both      | Yes     |

- `--myisam-recover-options=mode`

Set the mode for automatic recovery of crashed [MyISAM](#) tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any [MyISAM](#) table.

**Note**

If you do this, you should not access [MyISAM](#) tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of [MyISAM](#) tables. For additional information, see [Section 5.1.4, "Server System Variables"](#).

- `bulk_insert_buffer_size`

The size of the tree cache used in bulk insert optimization.

**Note**

This is a limit *per thread*!

- `myisam_max_sort_file_size`

The maximum size of the temporary file that MySQL is permitted to use while re-creating a [MyISAM](#) index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_sort_buffer_size`

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover-options` option. In this case, when the server opens a `MyISAM` table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover-options` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

## 15.2.2 Space Needed for Keys

`MyISAM` tables use B-tree indexes. You can roughly calculate the size for the index file as  $(key\_length+4)/0.67$ , summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In `MyISAM` tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

## 15.2.3 MyISAM Table Storage Formats

`MyISAM` supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#)).

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See [Section 13.1.14, “CREATE TABLE Syntax”](#), for information about `ROW_FORMAT`.

You can decompress (unpack) compressed MyISAM tables using `myisamchk --unpack`; see Section 4.6.3, “`myisamchk` — MyISAM Table-Maintenance Utility”, for more information.

### 15.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. MyISAM table indexes can always be reconstructed based on the data rows.

#### Note

Fixed-length row format is only available for tables without `BLOB` or `TEXT` columns. Creating a table with these columns with an explicit `ROW_FORMAT` clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- `CHAR` and `VARCHAR` columns are space-padded to the specified column width, although the column type is not altered. `BINARY` and `VARBINARY` columns are padded with `0x00` bytes to the column width.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.
- Usually require more disk space than dynamic-format tables.

### 15.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a MyISAM table contains any variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain `NULL` values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of

zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.

- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```
3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

### 15.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `mysampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

#### Note

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For

example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

## 15.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

### 15.2.4.1 Corrupted MyISAM Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or `MyISAM` code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a `MyISAM` table using the `CHECK TABLE` statement, and repair a corrupted `MyISAM` table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), [Section 13.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 24.5, “Debugging and Porting MySQL”](#).

### 15.2.4.2 Problems from Tables Not Being Closed Properly

Each `MyISAM` index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 5.3, “Running Multiple MySQL Instances on One Machine”](#), for additional discussion.

## 15.3 The MEMORY Storage Engine

The `MEMORY` storage engine (formerly known as `HEAP`) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

**Table 15.4** `MEMORY` Storage Engine Features

|                                                    |     |                                        |     |                                              |       |
|----------------------------------------------------|-----|----------------------------------------|-----|----------------------------------------------|-------|
| <b>Storage limits</b>                              | RAM | <b>Transactions</b>                    | No  | <b>Locking granularity</b>                   | Table |
| <b>MVCC</b>                                        | No  | <b>Geospatial data type support</b>    | No  | <b>Geospatial indexing support</b>           | No    |
| <b>B-tree indexes</b>                              | Yes | <b>T-tree indexes</b>                  | No  | <b>Hash indexes</b>                          | Yes   |
| <b>Full-text search indexes</b>                    | No  | <b>Clustered indexes</b>               | No  | <b>Data caches</b>                           | N/A   |
| <b>Index caches</b>                                | N/A | <b>Compressed data</b>                 | No  | <b>Encrypted data<sup>a</sup></b>            | Yes   |
| <b>Cluster database support</b>                    | No  | <b>Replication support<sup>b</sup></b> | Yes | <b>Foreign key support</b>                   | No    |
| <b>Backup / point-in-time recovery<sup>c</sup></b> | Yes | <b>Query cache support</b>             | Yes | <b>Update statistics for data dictionary</b> | Yes   |

<sup>a</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>b</sup>Implemented in the server, rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

**When to Use `MEMORY` or MySQL Cluster.** Developers looking to deploy applications that use the `MEMORY` storage engine for important, highly available, or frequently updated data should consider

whether MySQL Cluster is a better choice. A typical use case for the `MEMORY` engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in `MEMORY` tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
- A read-only or read-mostly data access pattern (limited updates).

MySQL Cluster offers the same features as the `MEMORY` engine with higher performance levels, and provides additional features not available with `MEMORY`:

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.
- Support for variable-length data types (including `BLOB` and `TEXT`) not supported by `MEMORY`.

For a white paper with more detailed comparison of the `MEMORY` storage engine and MySQL Cluster, see [Scaling Web Services with MySQL Cluster: An Alternative to the MySQL Memory Storage Engine](#). This white paper includes a performance study of the two technologies and a step-by-step guide describing how existing `MEMORY` users can migrate to MySQL Cluster.

## Performance Characteristics

`MEMORY` performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for `MEMORY` tables, they are not necessarily faster than `InnoDB` tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of `MEMORY` tables from multiple sessions.

Depending on the kinds of queries performed on a `MEMORY` table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

## Physical Characteristics of `MEMORY` Tables

The `MEMORY` storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of `.frm`.

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.

- **MEMORY** tables use a fixed-length row-storage format. Variable-length types such as **VARCHAR** are stored using a fixed length.
- **MEMORY** tables cannot contain **BLOB** or **TEXT** columns.
- **MEMORY** includes support for **AUTO\_INCREMENT** columns.
- Non-**TEMPORARY MEMORY** tables are shared among all clients, just like any other non-**TEMPORARY** table.

## DDL Operations for MEMORY Tables

To create a **MEMORY** table, specify the clause **ENGINE=MEMORY** on the **CREATE TABLE** statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, **MEMORY** tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in **MEMORY** tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a **MEMORY** table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
->     SELECT ip,SUM(downloads) AS down
->     FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of **MEMORY** tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for **MEMORY** tables, change the value of this variable. The value in effect for **CREATE TABLE**, or a subsequent **ALTER TABLE** or **TRUNCATE TABLE**, is the value used for the life of the table. A server restart also sets the maximum size of existing **MEMORY** tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

## Indexes

The **MEMORY** storage engine supports both **HASH** and **BTREE** indexes. You can specify one or the other for a given index by adding a **USING** clause as shown here:

```
CREATE TABLE lookup
  (id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

**MEMORY** tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a **MEMORY** table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a **BTREE** index to avoid this problem.

`MEMORY` tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain `NULL` values.

## User-Created and Temporary Tables

`MEMORY` table contents are stored in memory, which is a property that `MEMORY` tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that `MEMORY` tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).
- User-created `MEMORY` tables are never converted to disk tables.

## Loading Data

To populate a `MEMORY` table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 5.1.3, “Server Command Options”](#), and [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

## MEMORY Tables and Replication

A server's `MEMORY` tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave `MEMORY` tables, when a `MEMORY` table is used on a master for the first time since it was started, a `DELETE` statement is written to the master's binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master's restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the `--init-file` option to populate the `MEMORY` table on the master at startup.

## Managing Memory Use

The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a `MEMORY` table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a `MEMORY` table when you no longer require its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

## Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

## 15.4 The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
-> ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+-----+-----+
| i    | c          |
+-----+-----+
| 1    | record one |
| 2    | record two |
+-----+-----+
2 rows in set (0.00 sec)
```

Creating a `CSV` table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

## 15.4.1 Repairing and Checking CSV Tables

The CSV storage engines supports the `CHECK` and `REPAIR` statements to verify and if possible repair a damaged CSV table.

When running the `CHECK` statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | error    | Corrupt  |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | warning  | Table is marked as crashed |
| test.csvtest | check | status   | OK       |
+-----+-----+-----+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use `REPAIR`, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+-----+-----+-----+
| Table      | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | repair | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

### Warning

During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

## 15.4.2 CSV Limitations

The `CSV` storage engine does not support indexing.

Partitioning is not supported for tables using the `CSV` storage engine.

All tables that you create using the `CSV` storage engine must have the `NOT NULL` attribute on all columns. However, for backward compatibility, you can continue to use tables with nullable columns that were created in previous MySQL releases. (Bug #32050)

## 15.5 The ARCHIVE Storage Engine

The `ARCHIVE` storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

**Table 15.5** `ARCHIVE` Storage Engine Features

|                                                    |      |                                        |     |                                              |     |
|----------------------------------------------------|------|----------------------------------------|-----|----------------------------------------------|-----|
| <b>Storage limits</b>                              | None | <b>Transactions</b>                    | No  | <b>Locking granularity</b>                   | Row |
| <b>MVCC</b>                                        | No   | <b>Geospatial data type support</b>    | Yes | <b>Geospatial indexing support</b>           | No  |
| <b>B-tree indexes</b>                              | No   | <b>T-tree indexes</b>                  | No  | <b>Hash indexes</b>                          | No  |
| <b>Full-text search indexes</b>                    | No   | <b>Clustered indexes</b>               | No  | <b>Data caches</b>                           | No  |
| <b>Index caches</b>                                | No   | <b>Compressed data</b>                 | Yes | <b>Encrypted data<sup>a</sup></b>            | Yes |
| <b>Cluster database support</b>                    | No   | <b>Replication support<sup>b</sup></b> | Yes | <b>Foreign key support</b>                   | No  |
| <b>Backup / point-in-time recovery<sup>c</sup></b> | Yes  | <b>Query cache support</b>             | Yes | <b>Update statistics for data dictionary</b> | Yes |

<sup>a</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>b</sup>Implemented in the server, rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

The `ARCHIVE` storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the `ARCHIVE` engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the `ARCHIVE` storage engine is available with the `SHOW ENGINES` statement.

When you create an `ARCHIVE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT` and `SELECT`, but not `DELETE`, `REPLACE`, or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see [Section 11.5.1, “Spatial Data Types”](#)). The `ARCHIVE` engine uses row-level locking.

The `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

`ARCHIVE` does not support inserting a value into an `AUTO_INCREMENT` column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

The `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading.

**Storage:** Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur.
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval:** On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#), [Section 13.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 13.7.5.36, “SHOW TABLE STATUS Syntax”](#).

## Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

## 15.6 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the `BLACKHOLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the `BLACKHOLE` engine, look in the `sql` directory of a MySQL source distribution.

When you create a `BLACKHOLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The `BLACKHOLE` storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the `BLACKHOLE` storage engine is available with the `SHOW ENGINES` statement.

Inserts into a [BLACKHOLE](#) table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

### Note

When using the row based format for the binary log, updates and deletes are skipped, and neither logged nor applied. For this reason, you should use `STATEMENT` for the binary logging format, and not `ROW` or `MIXED`.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is [BLACKHOLE](#), depicted as follows:

The master writes to its binary log. The “dummy” `mysql` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysql` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for [BLACKHOLE](#) tables work as expected. However, because the [BLACKHOLE](#) table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the [BLACKHOLE](#) storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using [BLACKHOLE](#) with and without binary logging enabled.
- [BLACKHOLE](#) is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The [BLACKHOLE](#) engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

### Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.
2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

### Column Filtering

When using row-based replication, (`binlog_format=ROW`), a slave where the last columns are missing from a table is supported, as described in the section [Section 17.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#).

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how master table filtering is achieved - by using the `BLACKHOLE` engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the master is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,
                 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

## 15.7 The MERGE Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

An alternative to a [MERGE](#) table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the [MyISAM](#) storage engine. For more information, see [Chapter 18, Partitioning](#).

When you create a [MERGE](#) table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the underlying [MyISAM](#) tables that should be used as one. The tables do not have to be in the same database as the [MERGE](#) table.

You can use [SELECT](#), [DELETE](#), [UPDATE](#), and [INSERT](#) on [MERGE](#) tables. You must have [SELECT](#), [DELETE](#), and [UPDATE](#) privileges on the [MyISAM](#) tables that you map to a [MERGE](#) table.

### Note

The use of [MERGE](#) tables entails the following security issue: If a user has access to [MyISAM](#) table `t`, that user can create a [MERGE](#) table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of [DROP TABLE](#) with a [MERGE](#) table drops only the [MERGE](#) specification. The underlying tables are not affected.

To create a [MERGE](#) table, you must specify a `UNION=(list-of-tables)` option that indicates which [MyISAM](#) tables to use. You can optionally specify an `INSERT_METHOD` option to control how inserts into the [MERGE](#) table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no `INSERT_METHOD` option or if you specify it with a value of `NO`, inserts into the [MERGE](#) table are not permitted and attempts to do so result in an error.

The following example shows how to create a [MERGE](#) table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column `a` is indexed as a [PRIMARY KEY](#) in the underlying [MyISAM](#) tables, but not in the [MERGE](#) table. There it is indexed but not as a [PRIMARY KEY](#) because a [MERGE](#) table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a [UNIQUE](#) index in the underlying tables should be indexed in the [MERGE](#) table but not as a [UNIQUE](#) index.)

After creating the [MERGE](#) table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+----+-----+
| a | message |
+----+-----+
1	Testing
2	table
3	t1
1	Testing
2	table
3	t2
+----+-----+
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- `DROP` the `MERGE` table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new `MERGE` tables with `CREATE TABLE ... LIKE`.

The underlying table definitions and indexes must conform closely to the definition of the `MERGE` table. Conformance is checked when a table that is part of a `MERGE` table is opened, not when the `MERGE` table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a `MERGE` may cause a failure when the `MERGE` table is accessed. The conformance checks applied to each table are:

- The underlying table and the `MERGE` table must have the same number of columns.
- The column order in the underlying table and the `MERGE` table must match.
- Additionally, the specification for each corresponding column in the parent `MERGE` table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the `MERGE` table must be equal.
  - The column length in the underlying table and the `MERGE` table must be equal.
  - The column of the underlying table and the `MERGE` table can be `NULL`.
- The underlying table must have at least as many indexes as the `MERGE` table. The underlying table may have more indexes than the `MERGE` table, but cannot have fewer.

**Note**

A known issue exists where indexes on the same columns must be in identical order, in both the `MERGE` table and the underlying `MyISAM` table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the `MERGE` table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the `MERGE` table must be the same.
- For each index part:
  - Index part lengths must be equal.
  - Index part types must be equal.
  - Index part languages must be equal.
  - Check whether index parts can be `NULL`.

If a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

## Additional Resources

- A forum dedicated to the `MERGE` storage engine is available at <http://forums.mysql.com/list.php?93>.

## 15.7.1 MERGE Table Advantages and Disadvantages

**MERGE** tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a **MERGE** table to use them as one.
- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A **MERGE** table structured this way could be much faster than using a single large table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a **MERGE** table for others. You can even have many different **MERGE** tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a **MERGE** table than to repair a single large table.
- Instantly map many tables as one. A **MERGE** table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, **MERGE** table collections are very fast to create or remap. (You must still specify the index definitions when you create a **MERGE** table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you can instead create a **MERGE** table from them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each **MyISAM** table is bound by this limit, but a collection of **MyISAM** tables is not.
- You can create an alias or synonym for a **MyISAM** table by defining a **MERGE** table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy( )` calls for each read).

The disadvantages of **MERGE** tables are:

- You can use only identical **MyISAM** tables for a **MERGE** table.
- Some **MyISAM** features are unavailable in **MERGE** tables. For example, you cannot create **FULLTEXT** indexes on **MERGE** tables. (You can create **FULLTEXT** indexes on the underlying **MyISAM** tables, but you cannot search the **MERGE** table with a full-text search.)
- If the **MERGE** table is nontemporary, all underlying **MyISAM** tables must be nontemporary. If the **MERGE** table is temporary, the **MyISAM** tables can be any mix of temporary and nontemporary.
- **MERGE** tables use more file descriptors than **MyISAM** tables. If 10 clients are using a **MERGE** table that maps to 10 tables, the server uses  $(10 \times 10) + 10$  file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Index reads are slower. When you read an index, the **MERGE** storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the **MERGE** storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes **MERGE** indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see [Section 13.8.2, “EXPLAIN Syntax”](#).

## 15.7.2 MERGE Table Problems

The following are known problems with **MERGE** tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child **MyISAM** tables.

From versions 5.1.23, MERGE children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the MyISAM tables corrupted them.

- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.
- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.
- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.
- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
  - If `REPLACE` detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the `MERGE` table will report table corruption. If this occurs after one of the named operations on the underlying `MyISAM` tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.
- The definition of the `MyISAM` tables and the `MERGE` table are checked when the tables are accessed (for example, as part of a `SELECT` or `INSERT` statement). The checks ensure that the definitions of the tables and the parent `MERGE` table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.
- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE`

to add a nonunique index on the `MERGE` table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.

- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the `MyISAM` storage engine. Confirm that all of these tables are `MyISAM`.
- The maximum number of rows in a `MERGE` table is  $2^{64}$  (~1.844E+19; the same as for a `MyISAM` table). It is not possible to merge multiple `MyISAM` tables into a single `MERGE` table that would have more than this number of rows.
- Use of underlying `MyISAM` tables of differing row formats with a parent `MERGE` table is currently known to fail. See Bug #32364.
- You cannot change the union list of a nontemporary `MERGE` table when `LOCK TABLES` is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary `MERGE` table.

- You cannot create a `MERGE` table with `CREATE ... SELECT`, neither as a temporary `MERGE` table, nor as a nontemporary `MERGE` table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: `tbl_name` is not `BASE TABLE`.

- In some cases, differing `PACK_KEYS` table option values among the `MERGE` and underlying tables cause unexpected results if the underlying tables contain `CHAR` or `BINARY` columns. As a workaround, use `ALTER TABLE` to ensure that all involved tables have the same `PACK_KEYS` value. (Bug #50646)

## 15.8 The FEDERATED Storage Engine

The `FEDERATED` storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local `FEDERATED` table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the `FEDERATED` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_FEDERATED_STORAGE_ENGINE` option.

The `FEDERATED` storage engine is not enabled by default in the running server; to enable `FEDERATED`, you must start the MySQL server binary using the `--federated` option.

To examine the source for the `FEDERATED` engine, look in the `storage/federated` directory of a MySQL source distribution.

### 15.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as `MyISAM`, `CSV` or `InnoDB`), the table consists of the table definition and the associated data. When you create a `FEDERATED` table, the table definition is the same, but the physical storage of the data is handled on a remote server.

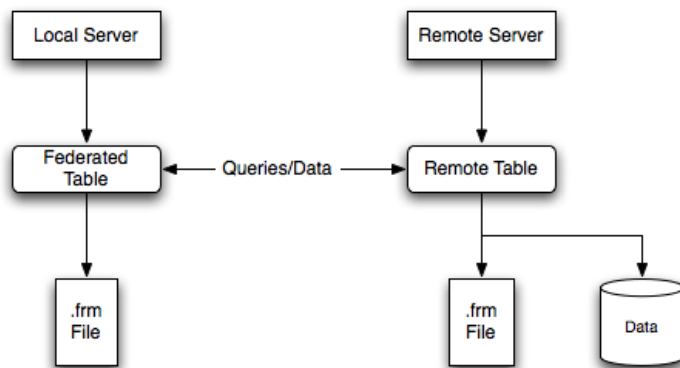

A `FEDERATED` table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the `.frm` file) and the associated table. The table type of the remote table may be any type supported by the remote `mysqld` server, including `MyISAM` or `InnoDB`.
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the `.frm` file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a `FEDERATED` table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a `FEDERATED` table setup is shown in [Figure 15.1, “FEDERATED Table Structure”](#).

**Figure 15.1 FEDERATED Table Structure**

When a client issues an SQL statement that refers to a `FEDERATED` table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the `FEDERATED` table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).
4. If the statement produces a result set, each column is converted to internal storage engine format that the `FEDERATED` engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

## 15.8.2 How to Create FEDERATED Tables

To create a `FEDERATED` table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.

2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;
```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the [CONNECTION](#), or you can use an existing connection that you have previously created using the [CREATE SERVER](#) statement.

#### Important

When you create the local table it *must* have an identical field definition to the remote table.

#### Note

You can improve the performance of a [FEDERATED](#) table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the [WHERE](#) clause and will be sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

### 15.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the [CONNECTION](#) string after the engine type in a [CREATE TABLE](#) statement. For example:

```
CREATE TABLE federated_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

#### Note

[CONNECTION](#) replaces the [COMMENT](#) used in some previous versions of MySQL.

The [CONNECTION](#) string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- *scheme*: A recognized connection protocol. Only `mysql` is supported as the *scheme* value at this point.
- *user\_name*: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- *password*: (Optional) The corresponding password for *user\_name*.
- *host\_name*: The host name or IP address of the remote server.
- *port\_num*: (Optional) The port number for the remote server. The default is 3306.
- *db\_name*: The name of the database holding the remote table.
- *tbl\_name*: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'  
CONNECTION='mysql://username@hostname/database/tablename'  
CONNECTION='mysql://username:password@hostname/database/tablename'
```

### 15.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of `FEDERATED` tables on the same server, or if you want to simplify the process of creating `FEDERATED` tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER  
server_name  
FOREIGN DATA WRAPPER wrapper_name  
OPTIONS (option [, option] ...)
```

The *server\_name* is used in the connection string when creating a new `FEDERATED` table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink  
FOREIGN DATA WRAPPER mysql  
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a `FEDERATED` table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (  
  id      INT(20) NOT NULL AUTO_INCREMENT,  
  name    VARCHAR(32) NOT NULL DEFAULT '',  
  other   INT(20) NOT NULL DEFAULT '0',  
  PRIMARY KEY (id),
```

```

INDEX name (name),
INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='fedlink/test_table';

```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see [Section 13.1.13, “CREATE SERVER Syntax”](#).

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```

scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name

```

| Description       | CONNECTION string | CREATE SERVER option      | mysql.servers column  |
|-------------------|-------------------|---------------------------|-----------------------|
| Connection scheme | <i>scheme</i>     | <code>wrapper_name</code> | <code>Wrapper</code>  |
| Remote user       | <i>user_name</i>  | <code>USER</code>         | <code>Username</code> |
| Remote password   | <i>password</i>   | <code>PASSWORD</code>     | <code>Password</code> |
| Remote host       | <i>host_name</i>  | <code>HOST</code>         | <code>Host</code>     |
| Remote port       | <i>port_num</i>   | <code>PORT</code>         | <code>Port</code>     |
| Remote database   | <i>db_name</i>    | <code>DATABASE</code>     | <code>Db</code>       |

### 15.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.
- A `FEDERATED` table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a **FEDERATED** table since the index definition from an equivalent **MyISAM** or other table may not be supported. For example, creating a **FEDERATED** table with an index prefix on **VARCHAR**, **TEXT** or **BLOB** columns will fail. The following definition in **MyISAM** is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the **FEDERATED** engine, and the equivalent statement will fail:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses **SELECT**, **INSERT**, **UPDATE**, and **DELETE**, but not **HANDLER**.
- The **FEDERATED** storage engine supports **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE TABLE**, and indexes. It does not support **ALTER TABLE**, or any Data Definition Language statements that directly affect the structure of the table, other than **DROP TABLE**. The current implementation does not use prepared statements.
- **FEDERATED** accepts **INSERT ... ON DUPLICATE KEY UPDATE** statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Performance on a **FEDERATED** table when performing bulk inserts (for example, on a **INSERT INTO ... SELECT ...** statement) is slower than with other table types because each selected row is treated as an individual **INSERT** statement on the **FEDERATED** table.
- Transactions are not supported.
- **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
  - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
  - Bulk-insert handling does not occur for **INSERT ... ON DUPLICATE KEY UPDATE**.
- There is no way for the **FEDERATED** engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a **CONNECTION** string, you cannot use an '@' character in the password. You can get round this limitation by using the **CREATE SERVER** statement to create a server connection.
- The **insert\_id** and **timestamp** options are not propagated to the data provider.
- Any **DROP TABLE** statement issued against a **FEDERATED** table drops only the local table, not the remote table.
- **FEDERATED** tables do not work with the query cache.
- User-defined partitioning is not supported for **FEDERATED** tables.

## 15.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the **FEDERATED** storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at <http://forums.mysql.com/list.php?105>.

## 15.9 The EXAMPLE Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
      have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

## 15.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [MySQL Internals: Writing a Custom Storage Engine](#).

## 15.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high

availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

### 15.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

#### Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
mysql> INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

#### Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
mysql> UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

### 15.11.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency*: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.

- *Transaction Support*: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity*: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage*: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support*: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.
- *Memory Caches*: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL's high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids*: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features*: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

Data is the currency of today's web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no “one size fits all” approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. **Availability** refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. **Scalability** refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.
- The type of application being deployed.
- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: [Chapter 17, Replication](#).
- MySQL Fabric. Learn more: [MySQL Fabric](#).
- MySQL Cluster. Learn more: [MySQL Cluster NDB 7.3](#) and [MySQL Cluster NDB 7.4](#).
- Oracle Clusterware Agent for MySQL. [Learn more about Oracle Clusterware](#).
- MySQL with Solaris Cluster. [Learn more about Solaris Cluster](#).

Further options are available using third-party solutions.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.
- Clustered & Virtualized Systems.
- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

**Figure 16.1 Tradeoffs: Cost and Complexity versus Availability**

The following table compares the HA and Scalability capabilities of the various MySQL solutions:

**Table 16.1 Feature Comparison of MySQL HA Solutions**

| Requirement                      | MySQL Replication                                                                                                                                                           | MySQL Cluster                                                                                                                                                              |

| Scale On-Line (add nodes, repartition, etc.) | No                                   | Yes                        |

## 16.1 Using MySQL within an Amazon EC2 Instance

The Amazon Elastic Compute Cloud (EC2) service provides virtual servers that you can build and deploy to run a variety of different applications and services, including MySQL. The EC2 service is based around the Xen framework, supporting x86, Linux based, platforms with individual instances of a virtual machine referred to as an Amazon Machine Image (AMI). You have complete (root) access to the AMI instance that you create, enabling you to configure and install your AMI in any way you choose.

To use EC2, you create an AMI based on the configuration and applications that you intend to use, and upload the AMI to the Amazon Simple Storage Service (S3). From the S3 resource, you can deploy one or more copies of the AMI to run as an instance within the EC2 environment. The EC2 environment provides management and control of the instance and contextual information about the instance while it is running.

Because you can create and control the AMI, the configuration, and the applications, you can deploy and create any environment you choose. This includes a basic MySQL server in addition to more extensive replication, HA and scalability scenarios that enable you to take advantage of the EC2 environment, and the ability to deploy additional instances as the demand for your MySQL services and applications grow.

To aid the deployment and distribution of work, three different Amazon EC2 instances are available, small (identified as `m1.small`), large (`m1.large`) and extra large (`m1.xlarge`). The different types provide different levels of computing power measured in EC2 computer units (ECU). A summary of the different instance configurations is shown in the following table.

| EC2 Attribute   | Small  | Large  | Extra Large |
|-----------------|--------|--------|-------------|
| Platform        | 32-bit | 64-bit | 64-bit      |
| CPU cores       | 1      | 2      | 4           |
| ECUs            | 1      | 4      | 8           |
| RAM             | 1.7GB  | 7.5GB  | 15GB        |
| Storage         | 150GB  | 840GB  | 1680GB      |
| I/O Performance | Medium | High   | High        |

The typical model for deploying and using MySQL within the EC2 environment is to create a basic AMI that you can use to hold your database data and application. Once the basic environment for

your database and application has been created you can then choose to deploy the AMI to a suitable instance. Here the flexibility of having an AMI that can be re-deployed from the small to the large or extra large EC2 instance makes it easy to upgrade the hardware environment without rebuilding your application or database stack.

To get started with MySQL on EC2, including information on how to set up and install MySQL within an EC2 installation and how to port and migrate your data to the running instance, see [Section 16.1.1, “Setting Up MySQL on an EC2 AMI”](#).

For tips and advice on how to create a scalable EC2 environment using MySQL, including guides on setting up replication, see [Section 16.1.3, “Deploying a MySQL Database Using EC2”](#).

## 16.1.1 Setting Up MySQL on an EC2 AMI

There are many different ways of setting up an EC2 AMI with MySQL, including using any of the pre-configured AMIs supplied by Amazon.

The default *Getting Started* AMI provided by Amazon uses Fedora Core 4, and you can install MySQL by using `yum`:

```
shell> yum install mysql
```

This installs both the MySQL server and the Perl DBD::mysql driver for the Perl DBI API.

Alternatively, you can use one of the AMIs that include MySQL within the standard installation.

Finally, you can also install a standard version of MySQL downloaded from the MySQL Web site. The installation process and instructions are identical to any other installation of MySQL on Linux. See [Chapter 2, \*Installing and Upgrading MySQL\*](#).

The standard configuration for MySQL places the data files in the default location, `/var/lib/mysql`. The default data directory on an EC2 instance is `/mnt` (although on the large and extra large instance you can alter this configuration). You must edit `/etc/my.cnf` to set the `datadir` option to point to the larger storage area.

### Important

The first time you use the main storage location within an EC2 instance it needs to be initialized. The initialization process starts automatically the first time you write to the device. You can start using the device right away, but the write performance of the new device is significantly lower on the initial writes until the initialization process has finished.

To avoid this problem when setting up a new instance, you should start the initialization process before populating your MySQL database. One way to do this is to use `dd` to write to the file system:

```
root-shell> dd if=/dev/zero of=initialize bs=1024M count=50
```

The preceding creates a 50GB on the file system and starts the initialization process. Delete the file once the process has finished.

The initialization process can be time-consuming. On the small instance, initialization takes between two and three hours. For the large and extra large drives, the initialization can be 10 or 20 hours, respectively.

In addition to configuring the correct storage location for your MySQL data files, also consider setting the following other settings in your instance before you save the instance configuration for deployment:

- Set the MySQL server ID, so that when you use it for replication, the ID information is set correctly.
- Enabling binary logging, so that replication can be initialized without starting and stopping the server.
- Set the caching and memory parameters for your storage engines. There are no limitations or restrictions on what storage engines you use in your EC2 environment. Choose a configuration, possibly using one of the standard configurations provided with MySQL appropriate for the instance on which you expect to deploy. The large and extra large instances have RAM that can be dedicated to caching. Be aware that if you choose to install [memcached](#) on the servers as part of your application stack you must ensure there is enough memory for both MySQL and [memcached](#).

Once you have configured your AMI with MySQL and the rest of your application stack, save the AMI so that you can deploy and reuse the instance.

Once you have your application stack configured in an AMI, populating your MySQL database with data should be performed by creating a dump of your database using [mysqldump](#), transferring the dump to the EC2 instance, and then reloading the information into the EC2 instance database.

Before using your instance with your application in a production situation, be aware of the limitations of the EC2 instance environment. See [Section 16.1.2, “EC2 Instance Limitations”](#). To begin using your MySQL AMI, consult the notes on deployment. See [Section 16.1.3, “Deploying a MySQL Database Using EC2”](#).

## 16.1.2 EC2 Instance Limitations

Be aware of the following limitations of the EC2 instances before deploying your applications. Although these shouldn't affect your ability to deploy within the Amazon EC2 environment, they may alter the way you setup and configure your environment to support your application.

- Data stored within instances is not persistent. If you create an instance and populate the instance with data, then the data only remains in place while the machine is running, and does not survive a reboot. If you shut down the instance, any data it contained is lost.

To ensure that you do not lose information, take regular backups using [mysqldump](#). If the data being stored is critical, consider using replication to keep a “live” backup of your data in the event of a failure. When creating a backup, write the data to the Amazon S3 service to avoid the transfer charges applied when copying data offsite.

- EC2 instances are not persistent. If the hardware on which an instance is running fails, the instance is shut down. This can lead to loss of data or service.

However, if you use EBS, you can attach an EBS storage volume to an EC2 instance, and that EBS volume is persistent. Like a disk, an EBS volume can fail, but it is possible to create point-in-time snapshots of the volume. Snapshots are persisted to Amazon S3 and can be used to restore data in the event of volume failure.

- To replicate your EC2 instances to a non-EC2 environment, be aware of the transfer costs to and from the EC2 service. Data transfer between different EC2 instances is free, so using replication within the EC2 environment does not incur additional charges.
- Certain HA features are either not directly supported, or have limiting factors or problems that could reduce their utility. For example, using DRBD or MySQL Cluster might not work. The default storage configuration is also not redundant. You can use software-based RAID to improve redundancy, but this implies a further performance hit.

## 16.1.3 Deploying a MySQL Database Using EC2

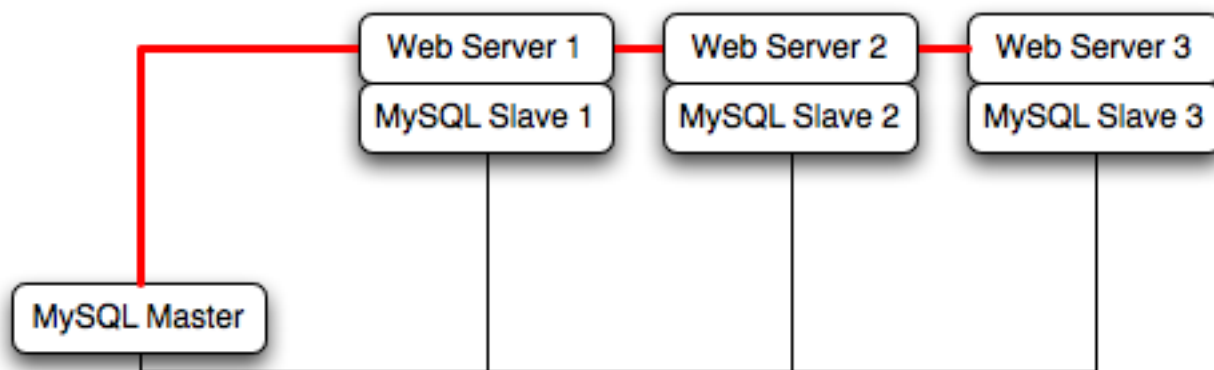

Because you cannot guarantee the uptime and availability of your EC2 instances, when deploying MySQL within the EC2 environment, use an approach that enables you to easily distribute work among

your EC2 instances. There are a number of ways of doing this. Using sharding techniques, where you split the application across multiple servers dedicating specific blocks of your dataset and users to different servers is an effective way of doing this. As a general rule, it is easier to create more EC2 instances to support more users than to upgrade the instance to a larger machine.

The EC2 architecture works best when you treat the EC2 instances as temporary, cache-based solutions, rather than as a long-term, high availability solution. In addition to using multiple machines, take advantage of other services, such as [memcached](#) to provide additional caching for your application to help reduce the load on the MySQL server so that it can concentrate on writes. On the large and extra large instances within EC2, the RAM available can provide a large memory cache for data.

Most types of scale-out topology that you would use with your own hardware can be used and applied within the EC2 environment. However, use the limitations and advice already given to ensure that any potential failures do not lose you any data. Also, because the relative power of each EC2 instance is so low, be prepared to alter your application to use sharding and add further EC2 instances to improve the performance of your application.

For example, take the typical scale-out environment shown following, where a single master replicates to one or more slaves (three in this example), with a web server running on each replication slave.

You can reproduce this structure completely within the EC2 environment, using an EC2 instance for the master, and one instance for each of the web and MySQL slave servers.

**Note**

Within the EC2 environment, internal (private) IP addresses used by the EC2 instances are constant. Always use these internal addresses and names when communicating between instances. Only use public IP addresses when communicating with the outside world - for example, when publicizing your application.

To ensure reliability of your database, add at least one replication slave dedicated to providing an active backup and storage to the Amazon S3 facility. You can see an example of this in the following topology.

**Using [memcached](#)** within your EC2 instances should provide better performance. The large and extra large instances have a significant amount of RAM. To use [memcached](#) in your application, when loading information from the database, first check whether the item exists in the cache. If the data you are looking for exists in the cache, use it. If not, reload the data from the database and populate the cache.

**Sharding** divides up data in your entire database by allocating individual machines or machine groups to provide a unique set of data according to an appropriate group. For example, you might put all users with a surname ending in the letters A-D onto a single server. When a user connects to the application and their surname is known, queries can be redirected to the appropriate MySQL server.

When using sharding with EC2, separate the web server and MySQL server into separate EC2 instances, and then apply the sharding decision logic into your application. Once you know which MySQL server you should be using for accessing the data you then distribute queries to the appropriate server. You can see a sample of this in the following illustration.

### Warning

With sharding and EC2, be careful that the potential for failure of an instance does not affect your application. If the EC2 instance that provides the MySQL server for a particular shard fails, then all of the data on that shard becomes unavailable.

## 16.2 Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, such as [Chapter 17, Replication](#).

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at `/scratchpool`:

| Filesystem      | size | used | avail | capacity | Mounted on        |
|-----------------|------|------|-------|----------|-------------------|
| /dev/dsk/c0d0s0 | 4.6G | 3.7G | 886M  | 82%      | /                 |
| /devices        | 0K   | 0K   | 0K    | 0%       | /devices          |
| ctfs            | 0K   | 0K   | 0K    | 0%       | /system/contract  |
| proc            | 0K   | 0K   | 0K    | 0%       | /proc             |
| mnttab          | 0K   | 0K   | 0K    | 0%       | /etc/mnttab       |
| swap            | 1.4G | 892K | 1.4G  | 1%       | /etc/svc/volatile |
| objfs           | 0K   | 0K   | 0K    | 0%       | /system/object    |

```

/usr/lib/libc/libc_hwcap1.so.1
4.6G 3.7G 886M 82% /lib/libc.so.1
fd 0K 0K 0K 0% /dev/fd
swap 1.4G 40K 1.4G 1% /tmp
swap 1.4G 28K 1.4G 1% /var/run
/dev/dsk/c0d0s7 26G 913M 25G 4% /export/home
scratchpool 16G 24K 16G 1% /scratchpool

```

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```

total 17
drwxr-xr-x 31 root bin 50 Jul 21 07:32 DTT/
drwxr-xr-x 4 root bin 5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root sys 16 Nov 5 09:56 SUNWspro/
drwxrwxrwx 19 1000 1000 40 Nov 6 19:16 emacs-22.1/

```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```

root-shell> zfs list -t snapshot
NAME          USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1  0    -    24.5K  -
scratchpool@snap2  0    -    24.5K  -

```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

## 16.2.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to `slavepool`. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x  6 root    root      7 Nov  8 09:13 ./
drwxr-xr-x 29 root    root     34 Nov  9 07:06 ../
drwxr-xr-x 31 root    bin     50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root    bin     5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root    sys    16 Nov  5 09:56 SUNWspro/
drwxrwxrwx 19 1000   1000   40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

## 16.2.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send/zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals.

### 16.2.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

```
root-shell> zfs set readonly=off slavepool
```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

```
InnoDB: The log sequence number in ibdata files does not match
InnoDB: the log sequence number in the ib_logfiles!
081109 15:59:59 InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
081109 16:00:03 InnoDB: Started; log sequence number 0 1142807951
081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
```

Use `InnoDB` tables and a regular synchronization schedule to reduce the risk for significant data loss. On `MyISAM` tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

## 16.3 Using MySQL with `memcached`

`memcached` is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the `memcached` command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see [Section 16.3.2, “Using memcached”](#)

Benefits of using memcached include:

- Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.
- Because the “value” portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.
- If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any memcached server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by memcached. If the information is not in memcached, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see [Figure 16.2, “memcached Architecture Overview”](#).

**Figure 16.2 memcached Architecture Overview**

In the example structure, any of the clients can contact one of the memcached servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the memcached servers. The selection of the memcached server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same memcached server is selected as the source for the data. Using this method, the cached data is spread among all of the memcached servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional memcached server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a memcached server fails, the data can always be recovered from the MySQL database.

### 16.3.1 Installing memcached

You can build and install memcached from the source code directly, or you can use an existing operating system package or installation.

#### Installing memcached from a Binary Distribution

To install `memcached` on a Red Hat, or Fedora host, use `yum`:

```
root-shell> yum install memcached
```

**Note**

On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
root-shell> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
root-shell> emerge install memcached
```

**Building `memcached` from Source**

On other Unix-based platforms, including Solaris, AIX, HP-UX and OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface. For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from [libevent web page](#).

You can obtain the source for `memcached` from [memcached Web site](#).

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

```
shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
```

2. Change to the `memcached-1.2.5` directory:

```
shell> cd memcached-1.2.5
```

3. Run `configure`

```
shell> ./configure
```

Some additional options you might specify to the `configure`:

- `--prefix`

To specify a different installation directory, use the `--prefix` option:

```
shell> ./configure --prefix=/opt
```

The default is to use the `/usr/local` directory.

- `--with-libevent`

If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

To enable multi-threading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see [Section 16.3.2.7, “memcached Thread Support”](#).

- `--enable-dtrace`

`memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see [Section 16.3.2.5, “Using memcached and DTrace”](#).

4. Run `make` to build `memcached`:

```
shell> make
```

5. Run `make install` to install `memcached`:

```
shell> make install
```

## 16.3.2 Using memcached

To start using `memcached`, start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

### Note

You do not need to be a privileged user (`root`) to run `memcached` except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

`memcached` supports the following options:

- `-u user`

If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

```
shell> memcached -u memcache
```

- `-m memory`

Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

### Warning

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
shell> vmstat
kthr      memory          page        disk        faults        cpu
r  b  w    swap free  re  mf  pi  po  fr  de  sr  sl  s2  --  --  in  sy  cs  us  sy  id
0  0  0  5170504 3450392 2   7   2  0  0  0  4  0  0  0  0  296  54 199  0  0 100
```

For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

### Note

On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- `-l interface`

Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

```
shell> memcached -l 192.168.0.110
```

Support for IPv6 address support was added in `memcached` 1.2.5.

- `-p port`

Specify the TCP port to use for connections. Default is 18080.

```
shell> memcached -p 18080
```

- `-U port`

Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

```
shell> memcached -U 18080
```

- `-s socket`

Specify a Unix socket to listen on.

If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local Unix socket using the `-s` option:

```
shell> memcached -s /tmp/memcached
```

Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

```
shell> memcached -c 2048
```

Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

Specify the number of threads to use when processing incoming requests.

By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

```
shell> memcached -t 8
```

- `-d`

Run `memcached` as a daemon (background) process:

```
shell> memcached -d
```

- `-r`

Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- `-k`

Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

**Note**

There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- `-v`

Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-vvv`

Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- `-h`

Print the help message and exit.

- `-i`

Print the `memcached` and `libevent` license.

- `-I mem`

Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

```
shell> memcached -I 32m
```

The maximum object size you can specify is 128MB, the default remains at 1MB.

This option was added in 1.4.2.

- `-b`

Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- `-P pidfile`

Save the process ID of the `memcached` instance into `file`.

- `-f`

Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see [Section 16.3.2.8, “memcached Logs”](#).

- `-n bytes`

The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- `-C`

Disable the use of compare and swap (CAS) operations.

This option was added in `memcached` 1.3.x.

- `-D char`

Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see [Section 16.3.4, “Getting memcached Statistics”](#)). The default is the colon (:). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

This option was added in `memcached` 1.3.x.

- `-R num`

Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

This option was added in `memcached` 1.4.0.

### 16.3.2.1 `memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying `memcached` within your system, keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.
- There is no security built into the `memcached` protocol. At a minimum, make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the `memcached` servers that is being stored is any sensitive, then encrypt the information before storing it in `memcached`.
- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must be capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.
- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.
- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.

- Try to use at least two `memcached` instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many `memcached` nodes as possible. When adding and removing `memcached` instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see [Section 16.3.2.4, “memcached Hashing/Distribution Types”](#).

### 16.3.2.2 Using Namespaces

The `memcached` cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

#### Note

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

### 16.3.2.3 Data Expiry

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key/value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see [Section 16.3.4, “Getting memcached Statistics”](#).

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

### 16.3.2.4 memcached Hashing/Distribution Types

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within `memcache` clients uses a simple modulus calculation on the value against the number of configured `memcached` servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 ( $7009 \% 3 = 1$ ), and store or retrieve the key and value with that server.

#### Note

This selection and hashing process is handled automatically by the `memcached` client you are using; you need only provide the list of `memcached` servers to use.

You can see a graphical representation of this below in [Figure 16.3, “memcached Hash Selection”](#).

**Figure 16.3** memcached Hash Selection

The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.
- Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).

- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.
- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.
- Using client-side hashing simplifies the distribution of data over each memcached server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your memcached and leading to potential differences in the information.

#### Note

One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

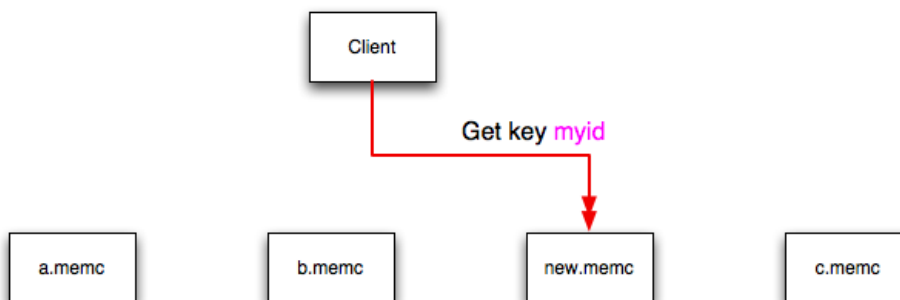

The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the memcached servers, and the servers must be available. If you try to perform an operation on a key when:

- A new memcached instance has been added to the list of available instances
- A memcached instance has been removed from the list of available instances
- The order of the memcached instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new memcached instance is added into the list of servers, as `new.memc` is in the example below, then a GET operation using the same key, `myid`, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server `c.memc` where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another memcached instance.

**Figure 16.4** memcached Hash Selection with New memcached instance

This means that servers `c.memc` and `new.memc` both contain the information for key `myid`, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new

---

server changes the distribution of keys, and this in turn requires rebuilding the cached data on the `memcached` instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured `memcached` instances as each instance is identified as being available. For example, removing a `memcached` instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

### 16.3.2.5 Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, build from source and use the `--enable-dtrace` option. For more information, see [Section 16.3.1, "Installing `memcached`"](#).

The probes supported by `memcached` are:

- `conn-allocate(connid)`

Fired when a connection object is allocated from the connection pool.

- `connid`: The connection ID.
- `conn-release(connid)`

Fired when a connection object is released back to the connection pool.

Arguments:

- `connid`: The connection ID.
- `conn-create(ptr)`

Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

Arguments:

- `ptr`: A pointer to the connection. object
- `conn-destroy(ptr)`

Fired when a connection object is being destroyed.

Arguments:

- `ptr`: A pointer to the connection object.
- `conn-dispatch(connid, threadid)`

Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

Arguments:

- `connid`: The connection ID.
- `threadid`: The thread ID.
- `slabs-allocate(size, slabclass, slabsize, ptr)`

Allocate memory from the slab allocator.

Arguments:

- `size`: The requested size.
- `slabclass`: The allocation is fulfilled in this class.
- `slabsize`: The size of each item in this class.
- `ptr`: A pointer to allocated memory.
- `slabs-allocate-failed(size, slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `size`: The requested size.
- `slabclass`: The class that failed to fulfill the request.
- `slabs-slabclass-allocate(slabclass)`

Fired when a slab class needs more space.

Arguments:

- `slabclass`: The class that needs more memory.

- `slabs-slabclass-allocate-failed(slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `slabclass`: The class that failed to grab more memory.

- `slabs-free(size, slabclass, ptr)`

Release memory.

Arguments:

- `size`: The amount of memory to release, in bytes.
- `slabclass`: The class the memory belongs to.
- `ptr`: A pointer to the memory to release.

- `assoc-find(key, depth)`

Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.

Arguments:

- `key`: The key searched for.
- `depth`: The depth in the list of hash table.

- `assoc-insert(key, nokeys)`

Fired when a new item has been inserted.

Arguments:

- `key`: The key just inserted.
- `nokeys`: The total number of keys currently being stored, including the key for which insert was called.

- `assoc-delete(key, nokeys)`

Fired when a new item has been removed.

Arguments:

- `key`: The key just deleted.
- `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.

- `item-link(key, size)`

Fired when an item is being linked in the cache.

Arguments:

- `key`: The items key.

- `size`: The size of the data.

- `item-unlink(key, size)`

Fired when an item is being deleted.

Arguments:

- `key`: The items key.
- `size`: The size of the data.

- `item-remove(key, size)`

Fired when the refcount for an item is reduced.

Arguments:

- `key`: The item's key.
- `size`: The size of the data.

- `item-update(key, size)`

Fired when the "last referenced" time is updated.

Arguments:

- `key`: The item's key.
- `size`: The size of the data.

- `item-replace(oldkey, oldsize, newkey, newsize)`

Fired when an item is being replaced with another item.

Arguments:

- `oldkey`: The key of the item to replace.
- `oldsize`: The size of the old item.
- `newkey`: The key of the new item.
- `newsize`: The size of the new item.

- `process-command-start(connid, request, size)`

Fired when the processing of a command starts.

Arguments:

- `connid`: The connection ID.
- `request`: The incoming request.
- `size`: The size of the request.

- `process-command-end(connid, response, size)`

Fired when the processing of a command is done.

Arguments:

- `connid`: The connection ID.
  - `response`: The response to send back to the client.
  - `size`: The size of the response.
- `command-get(connid, key, size)`  
Fired for a `get` command.  
Arguments:
    - `connid`: The connection ID.
    - `key`: The requested key.
    - `size`: The size of the key's data (or -1 if not found).
  - `command-gets(connid, key, size, casid)`  
Fired for a `gets` command.  
Arguments:
    - `connid`: The connection ID.
    - `key`: The requested key.
    - `size`: The size of the key's data (or -1 if not found).
    - `casid`: The casid for the item.
  - `command-add(connid, key, size)`  
Fired for a `add` command.  
Arguments:
    - `connid`: The connection ID.
    - `key`: The requested key.
    - `size`: The new size of the key's data (or -1 if not found).
  - `command-set(connid, key, size)`  
Fired for a `set` command.  
Arguments:
    - `connid`: The connection ID.
    - `key`: The requested key.
    - `size`: The new size of the key's data (or -1 if not found).
  - `command-replace(connid, key, size)`  
Fired for a `replace` command.  
Arguments:
    - `connid`: The connection ID.

- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-prepend(connid, key, size)`

Fired for a `prepend` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-append(connid, key, size)`

Fired for a `append` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-cas(connid, key, size, casid)`

Fired for a `cas` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `casid`: The cas ID requested.

- `command-incr(connid, key, val)`

Fired for `incr` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `val`: The new value.

- `command-decr(connid, key, val)`

Fired for `decr` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.

- `val`: The new value.
- `command-delete(connid, key, exptime)`

Fired for a `delete` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `exptime`: The expiry time.

### 16.3.2.6 Memory Allocation within memcached

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

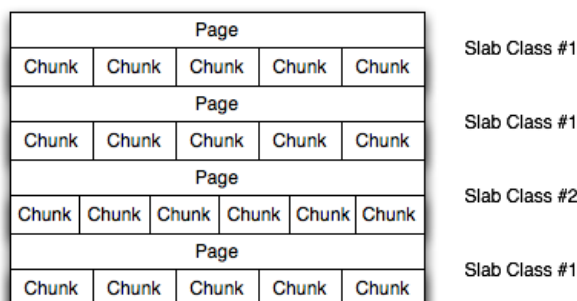

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see [Figure 16.5, “Memory Allocation in memcached”](#).

**Figure 16.5** Memory Allocation in `memcached`

The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages

allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for  $104 \times 1.25$ , or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see [Section 16.3.4.2, “memcached Slabs Statistics”](#).

If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

### 16.3.2.7 `memcached` Thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
- Each thread uses its own instance of the `libevent` to help improve performance.
- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.
- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

### 16.3.2.8 `memcached` Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by `memcached` includes details of the operations being performed.

Without the verbose options, `memcached` normally produces no output during normal operating.

- **Output when using `-v`**

The lowest verbosity level shows you:

- Errors and warnings
- Transient errors

- Protocol and socket errors, including exhausting available connections
- Each registered client connection, including the socket descriptor number and the protocol used.

For example:

```
32: Client using the ascii protocol
33: Client using the ascii protocol
```

The socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

Examples of the error messages output at this level include:

```
<%d send buffer was %d, now %d
Can't listen for events on fd %d
Can't read from libevent pipe
Catastrophic: event fd doesn't match conn fd!
Couldn't build response
Couldn't realloc input buffer
Couldn't update event
Failed to build UDP headers
Failed to read, and not due to blocking
Too many open connections
Unexpected state %d
```

- **Output when using `-vv`**

When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operations and details.

During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```
shell> memcached -vv
slab class 1: chunk size      80 per slab 13107
slab class 2: chunk size     104 per slab 10082
slab class 3: chunk size     136 per slab  7710
slab class 4: chunk size     176 per slab  5957
slab class 5: chunk size     224 per slab  4681
slab class 6: chunk size     280 per slab  3744
slab class 7: chunk size     352 per slab  2978
slab class 8: chunk size     440 per slab  2383
slab class 9: chunk size     552 per slab  1899
slab class 10: chunk size    696 per slab  1506
slab class 11: chunk size    872 per slab  1202
slab class 12: chunk size   1096 per slab   956
slab class 13: chunk size   1376 per slab   762
slab class 14: chunk size   1720 per slab   609
slab class 15: chunk size   2152 per slab   487
slab class 16: chunk size   2696 per slab   388
slab class 17: chunk size   3376 per slab   310
slab class 18: chunk size   4224 per slab   248
slab class 19: chunk size   5280 per slab   198
slab class 20: chunk size   6600 per slab   158
slab class 21: chunk size   8256 per slab  127
slab class 22: chunk size  10320 per slab  101
slab class 23: chunk size  12904 per slab   81
slab class 24: chunk size  16136 per slab   64
slab class 25: chunk size  20176 per slab   51
slab class 26: chunk size  25224 per slab   41
slab class 27: chunk size  31536 per slab   33
```

```

slab class 28: chunk size 39424 perslab 26
slab class 29: chunk size 49280 perslab 21
slab class 30: chunk size 61600 perslab 17
slab class 31: chunk size 77000 perslab 13
slab class 32: chunk size 96256 perslab 10
slab class 33: chunk size 120320 perslab 8
slab class 34: chunk size 150400 perslab 6
slab class 35: chunk size 188000 perslab 5
slab class 36: chunk size 235000 perslab 4
slab class 37: chunk size 293752 perslab 3
slab class 38: chunk size 367192 perslab 2
slab class 39: chunk size 458992 perslab 2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)

```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```

shell> memcached -f 4 -m 1g -vv
slab class 1: chunk size 80 perslab 13107
slab class 2: chunk size 320 perslab 3276
slab class 3: chunk size 1280 perslab 819
slab class 4: chunk size 5120 perslab 204
slab class 5: chunk size 20480 perslab 51
slab class 6: chunk size 81920 perslab 12
slab class 7: chunk size 327680 perslab 3
...

```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```

32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key

```

```
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key1 1 36

>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the `memcached` server and > for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if `memcached` is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```
<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in `memcached` are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using `memcached`. Therefore, use in production or deployment environments is not recommended.

### 16.3.3 Developing a `memcached` Application

A number of language interfaces let applications store and retrieve information with `memcached` servers. You can write `memcached` applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

### 16.3.3.1 Basic `memcached` Operations

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- `get(key)`: Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns `NULL`, `nil`, `undefined`, or the closest equivalent in the corresponding language, if the specified key does not exist.
- `set(key, value [, expiry])`: Sets the item associated with a key in the cache to the specified value. This either updates an existing item if the key already exists, or adds a new key/value pair if the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days ( $30 \times 24 \times 60 \times 60$ ), or an absolute time (epoch) if larger than this value.
- `add(key, value [, expiry])`: Adds the key and associated value to the cache, if the specified key does not already exist.
- `replace(key, value [, expiry])`: Replaces the item associated with the specified `key`, only if the key already exists. The new value is given by the `value` parameter.
- `delete(key [, time])`: Deletes the `key` and its associated item from the cache. If you supply a `time`, then adding another item with the specified `key` is blocked for the specified period.
- `incr(key, value)`: Increments the item associated with the `key` by the specified `value`.
- `decr(key, value)`: Decrements the item associated with the `key` by the specified `value`.
- `flush_all`: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use `memcached` to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

### 16.3.3.2 Using `memcached` as a MySQL Caching Layer

When using `memcached` to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the `InnoDB buffer pool` and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

#### Caution

Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a `memcached`

instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use IPTables or similar techniques to restrict access to the memcached ports to a select set of hosts.

You can introduce memcached to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

The general sequence for using memcached in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see [Figure 16.6, “Typical memcached Application Flowchart”](#).

**Figure 16.6 Typical memcached Application Flowchart**

### Adapting Database Best Practices to memcached Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a primary key. Because of the uniqueness requirements for memcached keys, make sure your database schema makes appropriate use of primary keys and unique constraints.

If you combine multiple column values into a single memcached item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to memcached lookups are those with a single WHERE clause, using an = or IN operator. For complicated WHERE clauses, or those using operators such as <, >, BETWEEN, or LIKE, memcached does not provide a simple or efficient way to scan through or filter the keys

or associated values, so typically you perform those operations as SQL queries on the underlying database.

### 16.3.3.3 Using `libmemcached` with C and C++

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides functions and operational systems not always exposed in interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run `configure`, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get`, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main `memcached_st` structure, or separately populate a list of servers, and then add this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to `localhost` is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key= "keystring";
    char *value= "keyvalue";

    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);

    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Key stored successfully\n");
    else
        fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));
}
```

```
return 0;
}
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
Added server successfully
Key stored successfully
```

## `libmemcached` Base Functions

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

## `libmemcached` Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```
memcached_return
memcached_server_add (memcached_st *ptr,
                    char *hostname,
                    unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```
memcached_return
```

```
memcached_server_add_unix_socket (memcached_st *ptr,
                                char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *
memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return
memcached_server_push (memcached_st *ptr,
                      memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *
memcached_server_list_append (memcached_server_st *ptr,
                              char *hostname,
                              unsigned int port,
                              memcached_return *error);
```

Adds a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

## libmemcached Set Functions

The set-related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (`add`, `replace`, `prepend`, `append`). For example, the function definition for `memcached_set()` is:

```
memcached_return
memcached_set (memcached_st *ptr,
              const char *key,
```

```

size_t key_length,
const char *value,
size_t value_length,
time_t expiration,
uint32_t flags);
    
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see [Controlling libmemcached Behaviors](#).

This table outlines the remainder of the set-related `libmemcached` functions and the equivalent core functions supported by the `memcached` protocol.

| libmemcached Function                                                                                                               | Equivalent Core Function                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code>                                           | Generic <code>set()</code> operation.                                                                                                               |
| <code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code>                                           | Generic <code>add()</code> function.                                                                                                                |
| <code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code>                                       | Generic <code>replace()</code> .                                                                                                                    |
| <code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code>                                       | Prepends the specified <code>value</code> before the current value of the specified <code>key</code> .                                              |
| <code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code>                                        | Appends the specified <code>value</code> after the current value of the specified <code>key</code> .                                                |
| <code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code>                                      | Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.                        |
| <code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>     | Similar to the generic <code>set()</code> , but has the option of an additional master key that can be used to identify an individual server.       |
| <code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>     | Similar to the generic <code>add()</code> , but has the option of an additional master key that can be used to identify an individual server.       |
| <code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code> | Similar to the generic <code>replace()</code> , but has the option of an additional master key that can be used to identify an individual server.   |
| <code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code> | Similar to the <code>memcached_prepend()</code> , but has the option of an additional master key that can be used to identify an individual server. |
| <code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>  | Similar to the <code>memcached_append()</code> , but has the option of an additional master key that can be used to identify an individual server.  |
| <code>memcached_cas_by_key(memc, master_key, master_key_length, key,</code>                                                         | Similar to the <code>memcached_cas()</code> , but has the option of an additional master key that can be used to identify an individual server.     |

| libmemcached Function                                            | Equivalent Core Function |
|------------------------------------------------------------------|--------------------------|
| <code>key_length, value, value_length, expiration, flags)</code> |                          |

The `by_key` methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
memcached_set_by_key(memcached_st *ptr,
                    const char *master_key,
                    size_t master_key_length,
                    const char *key,
                    size_t key_length,
                    const char *value,
                    size_t value_length,
                    time_t expiration,
                    uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

### libmemcached Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```
char *memcached_get (memcached_st *ptr,
                   const char *key, size_t key_length,
                   size_t *value_length,
                   uint32_t *flags,
                   memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```
memcached_return
memcached_mget (memcached_st *ptr,
               char **keys, size_t *key_length,
               unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                     const char *key, size_t *key_length,
                     size_t *value_length,
                     uint32_t *flags,
                     memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```

#include <stdio.h>
#include <sstring.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie"};
    size_t key_length[3];
    char *values[] = {"red", "blue", "green"};
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;

    char return_key[MEMCACHED_MAX_KEY];
    size_t return_key_length;
    char *return_value;
    size_t return_value_length;

    memc = memcached_create(NULL);

    servers = memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc = memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    for(x = 0; x < 3; x++)
    {
        key_length[x] = strlen(keys[x]);
        value_length[x] = strlen(values[x]);

        rc = memcached_set(memc, keys[x], key_length[x], values[x],
                           value_length[x], (time_t)0, (uint32_t)0);
        if (rc == MEMCACHED_SUCCESS)
            fprintf(stderr, "Key %s stored successfully\n", keys[x]);
        else
            fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));
    }

    rc = memcached_mget(memc, keys, key_length, 3);

    if (rc == MEMCACHED_SUCCESS)
    {
        while ((return_value = memcached_fetch(memc, return_key, &return_key_length,
   &return_value_length, &flags, &rc)) != NULL)
        {
            if (rc == MEMCACHED_SUCCESS)
            {
                fprintf(stderr, "Key %s returned %s\n", return_key, return_value);
            }
        }
    }

    return 0;
}

```

Running the above application produces the following output:

```

shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red

```

```
Key dewey returned blue
Key louie returned green
```

## Controlling `libmemcached` Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```
memcached_return
memcached_behavior_set (memcached_st *ptr,
                        memcached_behavior flag,
                        uint64_t data);
```

To get the current behavior setting:

```
uint64_t
memcached_behavior_get (memcached_st *ptr,
                        memcached_behavior flag);
```

The following table describes `libmemcached` behavior flags.

| Behavior                                        | Description                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>MEMCACHED_BEHAVIOR_NO_BLOCK</code>        | Caused <code>libmemcached</code> to use asynchronous I/O.                                                                                                                                                                                                                                                                                                                   |
| <code>MEMCACHED_BEHAVIOR_TCP_NODELAY</code>     | Turns on no-delay for network sockets.                                                                                                                                                                                                                                                                                                                                      |
| <code>MEMCACHED_BEHAVIOR_HASH</code>            | Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include <code>MEMCACHED_HASH_DEFAULT</code> , <code>MEMCACHED_HASH_MD5</code> , <code>MEMCACHED_HASH_CRC</code> , <code>MEMCACHED_HASH_FNV1_64</code> , <code>MEMCACHED_HASH_FNV1A_64</code> , <code>MEMCACHED_HASH_FNV1_32</code> , and <code>MEMCACHED_HASH_FNV1A_32</code> . |
| <code>MEMCACHED_BEHAVIOR_DISTRIBUTION</code>    | Changes the method of selecting the server used to store a given value. The default method is <code>MEMCACHED_DISTRIBUTION_MODULA</code> . You can enable consistent hashing by setting <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> . <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> is an alias for the value <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> .   |
| <code>MEMCACHED_BEHAVIOR_CACHE_LOOKUPS</code>   | Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.                                                                                                                                                                                                                            |
| <code>MEMCACHED_BEHAVIOR_SUPPORT_CAS</code>     | Support CAS operations. By default, this is disabled because it imposes a performance penalty.                                                                                                                                                                                                                                                                              |
| <code>MEMCACHED_BEHAVIOR_KETAMA</code>          | Sets the default distribution to <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> and the hash to <code>MEMCACHED_HASH_MD5</code> .                                                                                                                                                                                                                                    |
| <code>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</code>    | Modify the timeout value used by <code>poll()</code> . Supply a signed <code>int</code> pointer for the timeout value.                                                                                                                                                                                                                                                      |
| <code>MEMCACHED_BEHAVIOR_BUFFER_REQUESTS</code> | Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.                                                                                                                                                                                                                                                   |
| <code>MEMCACHED_BEHAVIOR_VERIFY_KEY</code>      | Forces <code>libmemcached</code> to verify that a specified key is valid.                                                                                                                                                                                                                                                                                                   |

| Behavior                                        | Description                                                                                                                                                                                                    |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>MEMCACHED_BEHAVIOR_SORT_HOSTS</code>      | If set, hosts added to the list of configured hosts for a <code>memcached_st</code> structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled. |
| <code>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</code> | In nonblocking mode this changes the value of the timeout during socket connection.                                                                                                                            |

### `libmemcached` Command-Line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command-line utilities that can be useful when working with and debugging `memcached` applications.

All of the command-line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat`: Display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- `memcp`: Copy the contents of a file into the cache, using the file name as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- `memrm`: Remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- `memslap`: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
Took 13.571 seconds to read data
```

- `memflush`: Flush (empty) the contents of the `memcached` cache.

```
shell> memflush --servers=localhost
```

#### 16.3.3.4 Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. Install the module using your operating system's package management system, or using `CPAN`:

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through the `Cache::Memcached` module, first create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection.

The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
};
```

**Note**

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.
- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.
- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.
- `readonly` or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured, you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

| Cache::Memcached Function    | Equivalent Generic Method                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>get()</code>           | Generic <code>get()</code> .                                                                                     |
| <code>get_multi(keys)</code> | Gets multiple <code>keys</code> from memcache using just one query. Returns a hash reference of key/value pairs. |
| <code>set()</code>           | Generic <code>set()</code> .                                                                                     |
| <code>add()</code>           | Generic <code>add()</code> .                                                                                     |
| <code>replace()</code>       | Generic <code>replace()</code> .                                                                                 |
| <code>delete()</code>        | Generic <code>delete()</code> .                                                                                  |
| <code>incr()</code>          | Generic <code>incr()</code> .                                                                                    |

| Cache::Memcached Function | Equivalent Generic Method     |
|---------------------------|-------------------------------|
| <code>decr()</code>       | Generic <code>decr()</code> . |

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server

my $cache = new Cache::Memcached {
    'servers' => [
        'localhost:11211',
    ],
};

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores

my $filename = shift or die "Must specify the film name\n";
my $filmkey = $filename;
$filmkey =~ s/ /_/;

# Load the data from the cache

my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database

if (!defined($filmdata))
{
    $filmdata = load_filmdata($filename);

    if (defined($filmdata))
    {
        # Set the data into the cache, using the key

        if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
        }
    }
    else
    {
        die "Couldn't find $filename\n";
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filename) = @_;

    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";

    $dbh = DBI->connect($dsn, 'sakila', 'password');

    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
```

```

  $dbh->quote($filmlname));

    if (!defined($filmlname))
    {
        return (undef);
    }

    $filmlbase->{stars} =
    $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
        'from film_actor left join (actor) ' .
        'on (film_actor.actor_id = actor.actor_id) ' .
        ' where film_id=%s',
    $dbh->quote($filmlbase->{film_id})));

    return($filmlbase);
}

```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to `memcached`. When calling it for a film does not exist, you get this result:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached

```

When accessing a film that has already been added to the cache:

```

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached

```

### 16.3.3.5 Using MySQL and `memcached` with Python

The Python `memcache` module interfaces to `memcached` servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from [Python Memcached](#).

To install, download the package and then run the Python installer:

```

python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43

```

Once installed, the `memcache` module provides a class-based interface to your `memcached` servers. When you store Python data structures as `memcached` items, they are automatically serialized (turned into string values) using the Python `cPickle` or `pickle` modules.

To create a new `memcache` interface, import the `memcache` module and create a new instance of the `memcache.Client` class. For example, if the `memcached` daemon is running on localhost using the default port:

```

import memcache
memc = memcache.Client(['127.0.0.1:11211'])

```

The first argument is an array of strings containing the server and port number for each `memcached` instance to use. To enable debugging, set the optional `debug` parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is `crc32`. To change the function used, set the value of `memcache.serverHashFunction` to the alternate function to use. For example:

```
from zlib import Adler32
memcache.serverHashFunction = Adler32
```

Once you have defined the servers to use within the `memcache` instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

| Python <code>memcache</code> Function                      | Equivalent Generic Function                                                                                      |
|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>get()</code>                                         | Generic <code>get()</code> .                                                                                     |
| <code>get_multi(keys)</code>                               | Gets multiple values from the supplied array of <code>keys</code> . Returns a hash reference of key/value pairs. |
| <code>set()</code>                                         | Generic <code>set()</code> .                                                                                     |
| <code>set_multi(dict [, expiry [, key_prefix]])</code>     | Sets multiple key/value pairs from the supplied <code>dict</code> .                                              |
| <code>add()</code>                                         | Generic <code>add()</code> .                                                                                     |
| <code>replace()</code>                                     | Generic <code>replace()</code> .                                                                                 |
| <code>prepend(key, value [, expiry])</code>                | Prepends the supplied <code>value</code> to the value of the existing <code>key</code> .                         |
| <code>append(key, value [, expiry])</code>                 | Appends the supplied <code>value</code> to the value of the existing <code>key</code> .                          |
| <code>delete()</code>                                      | Generic <code>delete()</code> .                                                                                  |
| <code>delete_multi(keys [, expiry [, key_prefix]] )</code> | Deletes all the keys from the hash matching each string in the array <code>keys</code> .                         |
| <code>incr()</code>                                        | Generic <code>incr()</code> .                                                                                    |
| <code>decr()</code>                                        | Generic <code>decr()</code> .                                                                                    |

**Note**

Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```
memc.get_multi(['a', 'b'], key_prefix='users:')
```

The function retrieves the keys `users:a` and `users:b` from the servers.

Here is an example showing the storage and retrieval of information to a `memcache` instance, loading the raw data from MySQL:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                            user = "sakila",
                            passwd = "password",
                            db = "sakila")
except MySQLdb.Error, e:
```

```

    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
    
```

When executed for the first time, the data is loaded from the MySQL database and stored to the `memcached` server.

```

shell> python memc_python.py
Updated memcached with MySQL data
    
```

Because the data is automatically serialized using `cPickle/pickle`, when you load the data back from `memcached`, you can use the object directly. In the example above, the information stored to `memcached` is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from `memcached` and dumped:

```

shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
    
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

### 16.3.3.6 Using MySQL and `memcached` with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP `memcache` extensions, build PHP using the `--enable-memcache` option to `configure` when building from source.

If you are installing on a Red Hat-based server, you can install the `php-pecl-memcache` RPM:

```

root-shell> yum --install php-pecl-memcache
    
```

On Debian-based distributions, use the `php-memcache` package.

To set global runtime configuration options, specify the configuration option values within your `php.ini` file. The following table provides the name, default value, and a description for each global runtime configuration option.

| Configuration option                        | Default | Description                                                                                        |
|---------------------------------------------|---------|----------------------------------------------------------------------------------------------------|
| <code>memcache.allow_failover</code>        | 1       | Specifies whether another server in the list should be queried if the first server selected fails. |
| <code>memcache.max_failover_attempts</code> | 20      | Specifies the number of servers to try before returning a failure.                                 |

| Configuration option                | Default  | Description                                                                                                                                                                                                                                                                                                       |
|-------------------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>memcache.chunk_size</code>    | 8192     | Defines the size of network chunks used to exchange data with the <code>memcached</code> server.                                                                                                                                                                                                                  |
| <code>memcache.default_port</code>  | 11211    | Defines the default port to use when communicating with the <code>memcached</code> servers.                                                                                                                                                                                                                       |
| <code>memcache.hash_strategy</code> | standard | Specifies which hash strategy to use. Set to <code>consistent</code> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <code>standard</code> , an older (modula) strategy is used that potentially uses different servers for storage. |
| <code>memcache.hash_function</code> | crc32    | Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm.                                                                                                                                                |

To create a connection to a `memcached` server, create a new `Memcache` object and then specify the connection options. For example:

```
<?php
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the `memcache` object using `addServer()`:

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                        [, int $weight [, int $timeout [, int $retry_interval
                        [, bool $status [, callback $failure_callback
                        ]]]]] ] )
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```
<?php
$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to `memcached` instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by `memcached`, as shown in this table:

| PECL <code>memcache</code> Function | Generic Function                 |
|-------------------------------------|----------------------------------|
| <code>get()</code>                  | Generic <code>get()</code> .     |
| <code>set()</code>                  | Generic <code>set()</code> .     |
| <code>add()</code>                  | Generic <code>add()</code> .     |
| <code>replace()</code>              | Generic <code>replace()</code> . |
| <code>delete()</code>               | Generic <code>delete()</code> .  |
| <code>increment()</code>            | Generic <code>incr()</code> .    |
| <code>decrement()</code>            | Generic <code>decr()</code> .    |

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```
<?php
$memc = new Memcache;
$memc->addServer('localhost', '11211');

if(empty($_POST['film'])) {
?>
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
  <head>
    <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
    <title>Simple Memcache Lookup</title>
  </head>
  <body>
    <form method="post">
      <p><b>Film</b>: <input type="text" size="20" name="film"></p>
      <input type="submit">
    </form>
  </body>
</html>
<?php
} else {

    echo "Loading data...\n";

    $film = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);

    if ($mfilms) {

        printf("<p>Film data for %s loaded from memcache</p>", $mfilms['title']);

        foreach (array_keys($mfilms) as $key) {
            printf("<p><b>%s</b>: %s</p>", $key, $mfilms[$key]);
        }

    } else {

        $mysqli = mysqli('localhost', 'sakila', 'password', 'sakila');

        if (mysqli_connect_error()) {
            printf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }

        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));

        $result = $mysqli->query($sql);
```

```

    if (!$result) {
        sprintf("Database error: (%d) %s", $mysqli->errno, $mysqli->error);
        exit;
    }

    $row = $result->fetch_assoc();

    $memc->set($row['title'], $row);

    printf("<p>Loaded (%s) from MySQL</p>", htmlspecialchars($row['title'], ENT_QUOTES, 'UTF-8'));
}
?>
</body>
</html>

```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

### 16.3.3.7 Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The `Ruby-MemCache` client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from <http://www.deveiate.org/projects/RMemCache>.

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the `Ruby-MemCache` gem:

```

shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn] y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...

```

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```

require 'memcache'
memc = MemCache::new '192.168.0.100:11211'

```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```

require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'

```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```
memc += ["192.168.0.101:11211"]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table:

| Ruby <code>MemCache</code> Method | Equivalent <code>memcached</code> API Functions                                                                  |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>get()</code>                | Generic <code>get()</code> .                                                                                     |
| <code>get_hash(keys)</code>       | Get the values of multiple <code>keys</code> , returning the information as a hash of the keys and their values. |
| <code>set()</code>                | Generic <code>set()</code> .                                                                                     |
| <code>set_many(pairs)</code>      | Set the values of the keys and values in the hash <code>pairs</code> .                                           |
| <code>add()</code>                | Generic <code>add()</code> .                                                                                     |
| <code>replace()</code>            | Generic <code>replace()</code> .                                                                                 |
| <code>delete()</code>             | Generic <code>delete()</code> .                                                                                  |
| <code>incr()</code>               | Generic <code>incr()</code> .                                                                                    |
| <code>decr()</code>               | Generic <code>decr()</code> .                                                                                    |

### 16.3.3.8 Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from <https://github.com/gwhalin/Memcached-Java-Client/downloads>. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SocketIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally, you can configure the `memcached` interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SocketIOPool` settings:

```
public class MyClass {
    protected static MemCachedClient mcc = new MemCachedClient();

    static {
        String[] servers =
            {
                "localhost:11211",
            };
    }
}
```

```
Integer[] weights = { 1 };

SockIOPool pool = SockIOPool.getInstance();

pool.setServers( servers );
pool.setWeights( weights );
```

In the above sample, the list of servers is configured by creating an array of the `memcached` instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your `memcached` instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use `pool.setHashingAlg()`:

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modular hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `libmemcached`.

The following table outlines the Java `com.danga.MemCached` methods and the equivalent generic methods in the `memcached` interface specification.

| Java <code>com.danga.MemCached</code> Method | Equivalent Generic Method                                                                                                                                                                             |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>get()</code>                           | Generic <code>get()</code> .                                                                                                                                                                          |
| <code>getMulti(keys)</code>                  | Get the values of multiple <code>keys</code> , returning the information as Hash map using <code>java.lang.String</code> for the keys and <code>java.lang.Object</code> for the corresponding values. |
| <code>set()</code>                           | Generic <code>set()</code> .                                                                                                                                                                          |
| <code>add()</code>                           | Generic <code>add()</code> .                                                                                                                                                                          |
| <code>replace()</code>                       | Generic <code>replace()</code> .                                                                                                                                                                      |
| <code>delete()</code>                        | Generic <code>delete()</code> .                                                                                                                                                                       |
| <code>incr()</code>                          | Generic <code>incr()</code> .                                                                                                                                                                         |
| <code>decr()</code>                          | Generic <code>decr()</code> .                                                                                                                                                                         |

### 16.3.3.9 Using the `memcached` TCP Text Protocol

Communicating with a `memcached` server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.

When communicating with `memcached`, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted) should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands:** `set`, `add`, `replace`, `append`, `prepend`, `cas`

Storage commands to the server take the form:

```
command key [flags] [exptime] length [noreply]
```

Or when using compare and swap (`cas`):

```
cas key [flags] [exptime] length [casunique] [noreply]
```

Where:

- `command`: The command name.
  - `set`: Store value against key
  - `add`: Store this value against key if the key does not already exist
  - `replace`: Store this value against key if the key already exists
  - `append`: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `prepend`: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `cas`: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
- `key`: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
- `flags`: The flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.
- `exptime`: The expiry time, or zero for no expiry.
- `length`: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.

- `casunique`: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.
- `noreply`: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n
```

The return value from the server is one line, specifying the status or error information. For more information, see [Table 16.3, “memcached Protocol Responses”](#).

- **Retrieval commands:** `get`, `gets`

Retrieval commands take the form:

```
get key1 [key2 ... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- `key`: The key name.
- `flags`: The value of the flag integer supplied to the `memcached` server when the value was stored.
- `bytes`: The size (excluding the terminating `\r\n` character sequence) of the stored value.
- `casunique`: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\n
VALUE xyzkey 0 6\r\n
abcdef\r\n
```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands:** `delete`

Deletion commands take the form:

```
delete key [time] [noreply]
```

Where:

- `key`: The key name.
- `time`: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

If not supplied, the value is assumed to be zero (delete immediately).

- `noreply`: Tells the server not to reply to the command.

Responses to the command are either `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement:** `incr`, `decr`

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- `key`: The key name.
- `value`: An integer to be used as the increment or decrement value.
- `noreply`: Tells the server not to reply to the command.

The response is:

- `NOT_FOUND`: The specified key could not be located.
- `value`: The new value associated with the specified key.

Values are assumed to be unsigned. For `decr` operations, the value is never decremented below 0. For `incr` operations, the value wraps around the 64-bit maximum.

- **Statistics commands:** `stats`

The `stats` command provides detailed statistical information about the current status of the `memcached` instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- `name`: The optional name of the statistics to return. If not specified, the general statistics are returned.
- `value`: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, `END`.

For more information, see [Section 16.3.4, “Getting `memcached` Statistics”](#).

For reference, a list of the different commands supported and their formats is provided below.

**Table 16.2 memcached Command Reference**

| Command | Command Formats                                                                        |
|---------|----------------------------------------------------------------------------------------|
| set     | set key flags exptime length, set key flags exptime length noreply                     |
| add     | add key flags exptime length, add key flags exptime length noreply                     |
| replace | replace key flags exptime length, replace key flags exptime length noreply             |
| append  | append key length, append key length noreply                                           |
| prepend | prepend key length, prepend key length noreply                                         |
| cas     | cas key flags exptime length casunique, cas key flags exptime length casunique noreply |
| get     | get key1 [key2 ... keyn]                                                               |
| gets    |                                                                                        |
| delete  | delete key, delete key noreply, delete key expiry, delete key expiry noreply           |
| incr    | incr key, incr key noreply, incr key value, incr key value noreply                     |
| decr    | decr key, decr key noreply, decr key value, decr key value noreply                     |
| stat    | stat, stat name, stat name value                                                       |

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by `\r\n`:

**Table 16.3 memcached Protocol Responses**

| String                      | Description                                                                                                                                                                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STORED                      | Value has successfully been stored.                                                                                                                                                                                                     |
| NOT_STORED                  | The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as <code>add</code> and <code>replace</code> ), or where the item has already been set to be deleted. |
| EXISTS                      | When using a <code>cas</code> command, the item you are trying to store already exists and has been modified since you last checked it.                                                                                                 |
| NOT_FOUND                   | The item you are trying to store, update or delete does not exist or has already been deleted.                                                                                                                                          |
| ERROR                       | You submitted a nonexistent command name.                                                                                                                                                                                               |
| CLIENT_ERROR<br>errorstring | There was an error in the input line, the detail is contained in <code>errorstring</code> .                                                                                                                                             |
| SERVER_ERROR<br>errorstring | There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.                                                                  |
| VALUE key flags<br>length   | The requested key has been found, and the stored <code>key</code> , <code>flags</code> and data block are returned, of the specified <code>length</code> .                                                                              |
| DELETED                     | The requested key was deleted from the server.                                                                                                                                                                                          |
| STAT name value             | A line of statistics data.                                                                                                                                                                                                              |

| String           | Description                     |
|------------------|---------------------------------|
| <code>END</code> | The end of the statistics data. |

### 16.3.4 Getting `memcached` Statistics

The `memcached` system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the [Section 16.3.4.2, “memcached Slabs Statistics”](#) and [Section 16.3.4.1, “memcached General Statistics”](#) information. For more information, see [Section 16.3.4.6, “Using memcached-tool”](#).

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
```

```
$memc->set_servers(\@ARGV);  
  
print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {  
  'hosts' => {  
    'localhost:11211' => {  
      'misc' => {  
        'bytes' => '2421',  
        'curr_connections' => '3',  
        'connection_structures' => '56',  
        'pointer_size' => '32',  
        'time' => '1211440166',  
        'total_items' => '410956',  
        'cmd_set' => '588167',  
        'bytes_written' => '35715151',  
        'evictions' => '0',  
        'curr_items' => '31',  
        'pid' => '23599',  
        'limit_maxbytes' => '67108864',  
        'uptime' => '1254',  
        'rusage_user' => '9.857805',  
        'cmd_get' => '838451',  
        'rusage_system' => '34.096988',  
        'version' => '1.2.5',  
        'get_hits' => '581511',  
        'bytes_read' => '46665716',  
        'threads' => '1',  
        'total_connections' => '3104',  
        'get_misses' => '256940'  
      },  
      'sizes' => {  
        '128' => '16',  
        '64' => '15'  
      }  
    }  
  },  
  'self' => {},  
  'total' => {  
    'cmd_get' => 838451,  
    'bytes' => 2421,  
    'get_hits' => 581511,  
    'connection_structures' => 56,  
    'bytes_read' => 46665716,  
    'total_items' => 410956,  
    'total_connections' => 3104,  
    'cmd_set' => 588167,  
    'bytes_written' => 35715151,  
    'curr_items' => 31,  
    'get_misses' => 256940  
  }  
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see [Section 16.3.4.1, “memcached General Statistics”](#).
- Slab statistics (`slabs`), see [Section 16.3.4.2, “memcached Slabs Statistics”](#).
- Item statistics (`items`), see [Section 16.3.4.3, “memcached Item Statistics”](#).
- Size statistics (`sizes`), see [Section 16.3.4.4, “memcached Size Statistics”](#).
- Detailed status (`detail`), see [Section 16.3.4.5, “memcached Detail Statistics”](#).

### 16.3.4.1 `memcached` General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u`: 32-bit unsigned integer
- `64u`: 64-bit unsigned integer
- `32u:32u`: Two 32-bit unsigned integers separated by a colon
- `String`: Character string

| Statistic                          | Data type            | Description                                                          | Version |
|------------------------------------|----------------------|----------------------------------------------------------------------|---------|
| <code>pid</code>                   | <code>32u</code>     | Process ID of the <code>memcached</code> instance.                   |         |
| <code>uptime</code>                | <code>32u</code>     | Uptime (in seconds) for this <code>memcached</code> instance.        |         |
| <code>time</code>                  | <code>32u</code>     | Current time (as epoch).                                             |         |
| <code>version</code>               | string               | Version string of this instance.                                     |         |
| <code>pointer_size</code>          | string               | Size of pointers for this host specified in bits (32 or 64).         |         |
| <code>rusage_user</code>           | <code>32u:32u</code> | Total user time for this instance (seconds:microseconds).            |         |
| <code>rusage_system</code>         | <code>32u:32u</code> | Total system time for this instance (seconds:microseconds).          |         |
| <code>curr_items</code>            | <code>32u</code>     | Current number of items stored by this instance.                     |         |
| <code>total_items</code>           | <code>32u</code>     | Total number of items stored during the life of this instance.       |         |
| <code>bytes</code>                 | <code>64u</code>     | Current number of bytes used by this server to store items.          |         |
| <code>curr_connections</code>      | <code>32u</code>     | Current number of open connections.                                  |         |
| <code>total_connections</code>     | <code>32u</code>     | Total number of connections opened since the server started running. |         |
| <code>connection_structures</code> | <code>32u</code>     | Number of connection structures allocated by the server.             |         |
| <code>cmd_get</code>               | <code>64u</code>     | Total number of retrieval requests ( <code>get</code> operations).   |         |
| <code>cmd_set</code>               | <code>64u</code>     | Total number of storage requests ( <code>set</code> operations).     |         |
| <code>get_hits</code>              | <code>64u</code>     | Number of keys that have been requested and found present.           |         |
| <code>get_misses</code>            | <code>64u</code>     | Number of items that have been requested and not found.              |         |
| <code>delete_hits</code>           | <code>64u</code>     | Number of keys that have been deleted and found present.             | 1.3.x   |
| <code>delete_misses</code>         | <code>64u</code>     | Number of items that have been delete and not found.                 | 1.3.x   |
| <code>incr_hits</code>             | <code>64u</code>     | Number of keys that have been incremented and found present.         | 1.3.x   |
| <code>incr_misses</code>           | <code>64u</code>     | Number of items that have been incremented and not found.            | 1.3.x   |
| <code>decr_hits</code>             | <code>64u</code>     | Number of keys that have been decremented and found present.         | 1.3.x   |

| Statistic                   | Data type | Description                                                                                                               | Version |
|-----------------------------|-----------|---------------------------------------------------------------------------------------------------------------------------|---------|
| <code>decr_misses</code>    | 64u       | Number of items that have been decremented and not found.                                                                 | 1.3.x   |
| <code>cas_hits</code>       | 64u       | Number of keys that have been compared and swapped and found present.                                                     | 1.3.x   |
| <code>cas_misses</code>     | 64u       | Number of items that have been compared and swapped and not found.                                                        | 1.3.x   |
| <code>cas_badvalue</code>   | 64u       | Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value. | 1.3.x   |
| <code>evictions</code>      | 64u       | Number of valid items removed from cache to free memory for new items.                                                    |         |
| <code>bytes_read</code>     | 64u       | Total number of bytes read by this server from network.                                                                   |         |
| <code>bytes_written</code>  | 64u       | Total number of bytes sent by this server to network.                                                                     |         |
| <code>limit_maxbytes</code> | 32u       | Number of bytes this server is permitted to use for storage.                                                              |         |
| <code>threads</code>        | 32u       | Number of worker threads requested.                                                                                       |         |
| <code>conn_yields</code>    | 64u       | Number of yields for connections (related to the <code>-R</code> option).                                                 | 1.4.0   |

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

### 16.3.4.2 memcached Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
```

```
STAT total_malloced 67083616
END
```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

| Statistic                    | Description                                                             | Version |
|------------------------------|-------------------------------------------------------------------------|---------|
| <code>chunk_size</code>      | Space allocated to each chunk within this slab class.                   |         |
| <code>chunks_per_page</code> | Number of chunks within a single page for this slab class.              |         |
| <code>total_pages</code>     | Number of pages allocated to this slab class.                           |         |
| <code>total_chunks</code>    | Number of chunks allocated to the slab class.                           |         |
| <code>used_chunks</code>     | Number of chunks allocated to an item..                                 |         |
| <code>free_chunks</code>     | Number of chunks not yet allocated to items.                            |         |
| <code>free_chunks_end</code> | Number of free chunks at the end of the last allocated page.            |         |
| <code>get_hits</code>        | Number of get hits to this chunk                                        | 1.3.x   |
| <code>cmd_set</code>         | Number of set commands on this chunk                                    | 1.3.x   |
| <code>delete_hits</code>     | Number of delete hits to this chunk                                     | 1.3.x   |
| <code>incr_hits</code>       | Number of increment hits to this chunk                                  | 1.3.x   |
| <code>decr_hits</code>       | Number of decrement hits to this chunk                                  | 1.3.x   |
| <code>cas_hits</code>        | Number of CAS hits to this chunk                                        | 1.3.x   |
| <code>cas_badval</code>      | Number of CAS hits on this chunk where the existing value did not match | 1.3.x   |
| <code>mem_requested</code>   | The true amount of memory of memory requested within this chunk         | 1.4.1   |

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

| Statistic                   | Description                                     | Version |
|-----------------------------|-------------------------------------------------|---------|
| <code>active_slabs</code>   | Total number of slab classes allocated.         |         |
| <code>total_malloced</code> | Total amount of memory allocated to slab pages. |         |

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

### 16.3.4.3 memcached Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

| Statistic                    | Description                                                                                                                                                |       |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| <code>number</code>          | The number of items currently stored in this slab class.                                                                                                   |       |
| <code>age</code>             | The age of the oldest item within the slab class, in seconds.                                                                                              |       |
| <code>evicted</code>         | The number of items evicted to make way for new entries.                                                                                                   |       |
| <code>evicted_time</code>    | The time of the last evicted entry                                                                                                                         |       |
| <code>evicted_nonzero</code> | The time of the last evicted non-zero entry                                                                                                                | 1.4.0 |
| <code>outofmemory</code>     | The number of items for this slab class that have triggered an out of memory error (only value when the <code>-M</code> command line option is in effect). |       |
| <code>tailrepairs</code>     | Number of times the entries for a particular ID need repairing                                                                                             |       |

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions than others.

#### 16.3.4.4 memcached Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
```

```
480 30
512 54
544 39
576 10065
```

### Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

### 16.3.4.5 `memcached` Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the `get`, `set`, and `del` operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the `memcached` server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your `memcached` clients are using a large number of keys that do not exist in the server by comparing the `hit` and `get` or `del` counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

### 16.3.4.6 Using memcached-tool

The `memcached-tool`, located within the `scripts` directory within the `memcached` source directory. The tool provides convenient access to some reports and statistics from any `memcached` instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
```

| #  | Item_Size | Max_age | Pages | Count | Full? | Evicted | Evict_Time | OOM |
|----|-----------|---------|-------|-------|-------|---------|------------|-----|
| 1  | 80B       | 93s     | 1     | 20    | no    | 0       | 0          | 0   |
| 2  | 104B      | 93s     | 1     | 16    | no    | 0       | 0          | 0   |
| 3  | 136B      | 1335s   | 1     | 28    | no    | 0       | 0          | 0   |
| 4  | 176B      | 1335s   | 1     | 24    | no    | 0       | 0          | 0   |
| 5  | 224B      | 1335s   | 1     | 32    | no    | 0       | 0          | 0   |
| 6  | 280B      | 1335s   | 1     | 34    | no    | 0       | 0          | 0   |
| 7  | 352B      | 1335s   | 1     | 36    | no    | 0       | 0          | 0   |
| 8  | 440B      | 1335s   | 1     | 46    | no    | 0       | 0          | 0   |
| 9  | 552B      | 1335s   | 1     | 58    | no    | 0       | 0          | 0   |
| 10 | 696B      | 1335s   | 1     | 66    | no    | 0       | 0          | 0   |
| 11 | 872B      | 1335s   | 1     | 89    | no    | 0       | 0          | 0   |
| 12 | 1.1K      | 1335s   | 1     | 112   | no    | 0       | 0          | 0   |
| 13 | 1.3K      | 1335s   | 1     | 145   | no    | 0       | 0          | 0   |
| 14 | 1.7K      | 1335s   | 1     | 123   | no    | 0       | 0          | 0   |
| 15 | 2.1K      | 1335s   | 1     | 198   | no    | 0       | 0          | 0   |

| 29 | 48.1K     | 1336s   | 1     | 21    | yes   | 1287    | 1          | 0   |
| 30 | 60.2K     | 1336s   | 1     | 17    | yes   | 1093    | 169        | 0   |
| 31 | 75.2K     | 1337s   | 1     | 13    | yes   | 713     | 168        | 0   |
| 32 | 94.0K     | 1337s   | 1     | 10    | yes   | 278     | 168        | 0   |
| 33 | 117.5K    | 1336s   | 1     | 3     | no    | 0       | 0          | 0   |

This output is the same if you specify the `command` as `display`:

```
shell> memcached-tool localhost:11211 display
```

| #   | Item_Size | Max_age | Pages | Count | Full? | Evicted | Evict_Time | OOM |
|-----|-----------|---------|-------|-------|-------|---------|------------|-----|
| 1   | 80B       | 93s     | 1     | 20    | no    | 0       | 0          | 0   |
| 2   | 104B      | 93s     | 1     | 16    | no    | 0       | 0          | 0   |
| ... |           |         |       |       |       |         |            |     |

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- `#`: The slab number
- `Item_Size`: The size of the slab
- `Max_age`: The age of the oldest item in the slab
- `Pages`: The number of pages allocated to the slab

- **Count**: The number of items in this slab
- **Full?**: Whether the slab is fully populated
- **Evicted**: The number of objects evicted from this slab
- **Evict\_Time**: The time (in seconds) since the last eviction
- **OOM**: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211  Field      Value

| 16.3.5.14 | What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of <code>memcached</code> configuration changes? And would you recommend keeping the configuration very simple to start? ..... | 2394 |

#### 16.3.5.0 Can memcached be run on a Windows environment?

No. Currently `memcached` is available only on the Unix/Linux platform. There is an unofficial port available, see <http://www.codeplex.com/memcachedproviders>.

#### 16.3.5.1 What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In `memcached` 1.4.2 and later, you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile `memcached`. You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In `memcached` 1.4.2 and higher, you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. `memcached` is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

#### 16.3.5.2 Is it true memcached will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. `memcached` plays no role in database writes, it is a method of caching data already read from the database in RAM.

#### 16.3.5.3 Are there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with `memcached`, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

#### 16.3.5.4 How is an event such as a crash of one of the memcached servers handled by the memcached client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see [Section 16.3.2.4, "memcached Hashing/Distribution Types"](#).

**16.3.5.0** What is a recommended hardware configuration for a memcached server?

memcached has a very low processing overhead. All that is required is spare physical RAM capacity. A memcached server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with memcached.

To build and deploy a dedicated memcached server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

**16.3.5.1** Is memcached more effective for video and audio as opposed to textual read/writes?

memcached works equally well for all kinds of data. To memcached, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in memcached is 1MB, but can be configured to be larger by using the `-I` option in memcached 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using memcached with audio and video content, you will probably want to increase the maximum object size. Also remember that memcached is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

**16.3.5.2** Can memcached work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# memcached library. For more information, see <https://sourceforge.net/projects/memcacheddotnet/>.

**16.3.5.3** How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a memcached instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

**16.3.5.4** How is the data handled when the memcached server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the memcached information). If you are using multiple memcached servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the memcached server that corresponds to the key you are trying to load.

**16.3.5.5** How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and memcached unless your application (or, if you are using the MySQL UDFs for memcached, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of memcached, the information is only stored on one of the memcached instances anyway. The client uses the key value to determine which memcached instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

**16.3.5.6** Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

**16.3.5.7** Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of [memcached](#) on a single server, and in your client configuration you choose the list of servers you want to use.

**16.3.5.** What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of [memcached](#) configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a [memcached](#) instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into [memcached](#). Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from [memcached](#). If the data cannot be loaded from [memcached](#), default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using [memcached](#) as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with [memcached](#). Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the [memcached](#) servers, and there is no complex configuration; just add more servers to the list and let the client API and the [memcached](#) servers make the decisions.

Replication enables data from one MySQL database server (the master) to be copied to one or more MySQL database servers (the slaves). Replication is asynchronous by default; slaves do not need to be connected permanently to receive updates from the master. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
- Long-distance data distribution - you can use replication to create a local copy of data for a remote site to use, without permanent access to the master.

For information on how to use replication in such scenarios, see [Section 17.3, “Replication Solutions”](#).

MySQL 5.7 supports different methods of replication. The traditional method is based on replicating events from the master's binary log, and requires the log files and positions in them to be synchronized between master and slave. The newer method based on *global transaction identifiers* (GTIDs) is transactional and therefore does not require working with log files or positions within these files, which greatly simplifies many common replication tasks. Replication using GTIDs guarantees consistency between master and slave as long as all transactions committed on the master have also been applied on the slave. For more information about GTIDs and GTID-based replication in MySQL, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#). For information on using binary log file position based replication, see [Section 17.1, “Configuring Replication”](#).

Replication in MySQL supports different types of synchronization. The original type of synchronization is one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. In MySQL 5.7, semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the master blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction; see [Section 17.3.8, “Semisynchronous Replication”](#). MySQL 5.7 also supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time; see [Section 17.3.9, “Delayed Replication”](#). For scenarios where *synchronous* replication is required, use MySQL Cluster (see [MySQL Cluster NDB 7.3](#) and [MySQL Cluster NDB 7.4](#)).

There are a number of solutions available for setting up replication between servers, and the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You can also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see [Section 17.2.1, “Replication Formats”](#).

Replication is controlled through a number of different options and variables. For more information, see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 17.3, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and potential problems and their resolution, see [Section 17.4, “Replication Notes and Tips”](#). For answers to some questions often asked by those who are new to MySQL Replication, see [Section A.13, “MySQL 5.7 FAQ: Replication”](#).

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replicated, see [Section 17.2, “Replication Implementation”](#).

## 17.1 Configuring Replication

This section describes how to configure the different types of replication available in MySQL and includes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication using binary log file positions, [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#), deals with the configuration of the servers and provides methods for copying data between the master and slaves.
- For a guide to setting up two or more servers for replication using GTID transactions, [Section 17.1.3, “Replication with Global Transaction Identifiers”](#), deals with the configuration of the servers.

- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 17.2.1, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 17.1.7, “Common Replication Administration Tasks”](#).

### 17.1.1 Binary Log File Position Based Replication Configuration Overview

This section describes replication between MySQL servers based on the binary log file position method, where the MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed. Unless you specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

#### Important

You cannot configure the master to log only certain events.

Each slave keeps a record of the binary log coordinates: the file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave records the current position within the binary log, it is possible for slaves to be disconnected, reconnect and then resume processing.

The master and each slave must be configured with a unique ID (using the `server-id [2426]` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's master info repository, which can be either a file or a table (see [Section 17.2.4, “Replication Relay and Status Logs”](#)).

### 17.1.2 Setting Up Binary Log File Position Based Replication

This section describes how to set up a MySQL server to use binary log file position based replication. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See [Section 17.1.2.1, “Setting the Replication Master Configuration”](#).
- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See [Setting the Replication Slave Configuration](#).

- Optionally, create a separate user for your slaves to use during authentication with the master when reading the binary log for replication. See [Section 17.1.2.2, “Creating a User for Replication”](#).
- Before creating a data snapshot or starting the replication process, on the master you should record the current position in the binary log. You need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 17.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
- If you already have data on the master and want to use it to synchronize the slave, you need to create a data snapshot to copy the data to the slave. The storage engine you are using has an impact on how you create the snapshot. When you are using `MyISAM`, you must stop processing statements on the master to obtain a read-lock, then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information will not match, resulting in inconsistent or corrupted databases on the slaves. For more information on replicating a `MyISAM` master, see [Section 17.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#). If you are using `InnoDB`, you do not need a read-lock and a transaction that is long enough to transfer the data snapshot is sufficient. For more information, see [Section 14.16, “InnoDB and MySQL Replication”](#).
- Configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See [Setting the Master Configuration on the Slave](#).

**Note**

Certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege, it might not be possible to enable replication.

After configuring the basic options, select your scenario:

- To set up replication for a fresh installation of a master and slaves that contain no data, see [Setting Up Replication between a New Master and Slaves](#).
- To set up replication of a new master using the data from an existing MySQL server, see [Setting Up Replication with Existing Data](#).
- To add replication slaves to an existing replication environment, see [Section 17.1.2.6, “Adding Slaves to a Replication Environment”](#).

Before administering MySQL replication servers, read this entire chapter and try all statements mentioned in [Section 13.4.1, “SQL Statements for Controlling Master Servers”](#), and [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#). Also familiarize yourself with the replication startup options described in [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).

### 17.1.2.1 Setting the Replication Master Configuration

To configure a master to use binary log file position based replication, you must enable binary logging and establish a unique server ID. If this has not already been done, a server restart is required.

Binary logging *must* be enabled on the master because the binary log is the basis for replicating changes from the master to its slaves. If binary logging is not enabled on the master using the `log-bin` option, replication is not possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and  $(2^{32})-1$ . How you organize and select the numbers is your choice.

To configure the binary log and server ID options, shut down the MySQL server and edit the `my.cnf` or `my.ini` file. Within the `[mysqld]` section of the configuration file, add the `log-bin` and `server-id` options. If these options already exist, but are commented out, uncomment the options and alter them

according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

#### Note

The following options have an impact on this procedure:

- if you omit `server-id [2426]` (or set it explicitly to its default value of 0), the master refuses any connections from slaves.
- For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.
- Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, the slave can not communicate with the master and replication fails.

### 17.1.2.2 Creating a User for Replication

Each slave connects to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You can choose to create a different account for each slave, or connect to the master using the same account for each slave.

Although you do not have to create an account specifically for replication, you should be aware that the replication user name and password are stored in plain text in the master info repository file or table (see [Section 17.2.4.2, “Slave Status Logs”](#)). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%mydomain.com';
```

See [Section 13.7.1, “Account Management Statements”](#), for more information on statements for manipulation of user accounts.

### 17.1.2.3 Obtaining the Replication Master Binary Log Coordinates

To configure the slave to start the replication process at the correct point, you need the master's current coordinates within its binary log.

If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` are empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string ( `' '` ) and `4`.

If the master has been binary logging previously, use this procedure to obtain the master binary log coordinates:

### Warning

This procedure uses `FLUSH TABLES WITH READ LOCK`, which blocks `COMMIT` operations for `InnoDB` tables.

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

### Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.000003 | 73      | test        | manual,mysql     |
+-----+-----+-----+-----+
```

The `File` column shows the name of the log file and the `Position` column shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

The next step depends on whether you have existing data on the master. Choose one of the following options:

- If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place. This prevents any further changes being made, so that the data copied to the slave is in synchrony with the master. Proceed to [Section 17.1.2.4, "Choosing a Method for Data Snapshots"](#).
- If you are setting up a new master and slave replication group, you can exit the first session to release the read lock. See [Setting Up Replication between a New Master and Slaves](#) for how to proceed.

## 17.1.2.4 Choosing a Method for Data Snapshots

If the master database contains existing data it is necessary to copy this data to each slave. There are different ways to dump the data from the master database. The following sections describe possible options.

To select the appropriate method of dumping the database, choose between these options:

- Use the `mysqldump` tool to create a dump of all the databases you want to replicate. This is the recommended method, especially when using `InnoDB`.
- If your database is stored in binary portable files, you can copy the raw data files to a slave. This can be more efficient than using `mysqldump` and importing the file on each slave, because it skips the

overhead of updating indexes as the `INSERT` statements are replayed. With storage engines such as `InnoDB` this is not recommended.

## Creating a Data Snapshot Using `mysqldump`

To create a snapshot of the data in an existing master database, use the `mysqldump` tool. Once the data dump has been completed, import this data into the slave before starting the replication process.

The following example dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

### Note

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually. See [Section 17.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).

It is possible to exclude certain databases from the dump using the `mysqldump` tool. If you want to choose which databases to include in the dump, do not use `--all-databases`. Choose one of these options:

- Exclude all the tables in the database using `--ignore-table` option.
- Name only those databases which you want dumped using the `--databases` option.

For more information, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.

## Creating a Data Snapshot Using Raw Data Files

This section describes how to create a data snapshot using the raw files which make up the database. Employing this method with a table using a storage engine that has complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command could leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See [Section 25.2, “MySQL Enterprise Backup Overview”](#) for detailed information.

This method also does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

Assuming the above exceptions do not apply to your database, use the `cold backup` technique to obtain a reliable binary snapshot of `InnoDB` tables: do a `slow shutdown` of the MySQL Server, then copy the data files manually.

To create a raw data snapshot of `MyISAM` tables when your MySQL data files exist on a single file system, you can use standard file copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`. If you are replicating only certain databases, copy only those files that relate to those tables. For

InnoDB, all tables in all databases are stored in the [system tablespace](#) files, unless you have the `innodb_file_per_table` option enabled.

The following files are not required for replication:

- Files relating to the `mysql` database.
- The master info repository file, if used (see [Section 17.2.4, “Replication Relay and Status Logs”](#)).
- The master's binary log files.
- Any relay log files.

Depending on whether you are using InnoDB tables or not, choose one of the following:

If you are using InnoDB tables, and also to get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See [Section 17.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using InnoDB tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 17.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

### 17.1.2.5 Setting Up Replication Slaves

The following sections describe how to set up slaves. Before you proceed, ensure that you have:

- Configured the MySQL master with the necessary configuration properties. See [Section 17.1.2.1, “Setting the Replication Master Configuration”](#).

- Obtained the master status information. See [Section 17.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
- On the master, released the read lock:

```
mysql> UNLOCK TABLES;
```

## Setting the Replication Slave Configuration

Each replication slave *must* have a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, shut down the slave server and edit the `[mysqld]` section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` [\[2426\]](#) value that differs from that of the master and from any of the other slaves.

### Note

If you omit `server-id` [\[2426\]](#) (or set it explicitly to its default value of 0), the slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be set up. However, if you enable binary logging on the slave, you can use the slave's binary log for data backups and crash recovery, and also use the slave as part of a more complex replication topology. For example, where this slave then acts as a master to other slaves.

## Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, configure the slave with the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='replication_user_name',
->     MASTER_PASSWORD='replication_password',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

### Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

The next steps depend on whether you have existing data to import to the slave or not. See [Section 17.1.2.4, “Choosing a Method for Data Snapshots”](#) for more information. Choose one of the following:

- If you have a snapshot of a database to import, see [Setting Up Replication between a New Master and Slaves](#).
- If you do not have a snapshot of a database to import, see [Setting Up Replication between a New Master and Slaves](#).

## Setting Up Replication between a New Master and Slaves

When there is no snapshot of a previous database to import, configure the slave to start the replication from the new master.

To set up replication between a master and a new slave:

1. Start up the MySQL slave and connect to it.
2. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See [Setting the Master Configuration on the Slave](#).

Perform these slave setup steps on each slave.

This method can also be used if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data is automatically replicated to the slaves.

If you are setting up a new replication environment using the data from a different existing database server to create a new master, run the dump file generated from that server on the new master. The database updates are automatically propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

## Setting Up Replication with Existing Data

When setting up replication with existing data, transfer the snapshot from the master to the slave before starting replication. The process for importing data to the slave depends on how you created the snapshot of data on the master.

Choose one of the following:

If you used `mysqldump`:

1. Start the slave, using the `--skip-slave-start` option so that replication does not start.
2. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

1. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the slave server can access and modify them.

2. Start the slave, using the `--skip-slave-start` option so that replication does not start.
3. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the

login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see [Setting the Master Configuration on the Slave](#).

4. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave connects to the master and replicates any updates that have occurred on the master since the snapshot was taken.

If you have forgotten to set the `server-id` [2426] option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` [2426] option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

The slave uses information stored in its master info repository to keep track of how much of the master's binary log it has processed. The repository can be in the form of files or a table, as determined by the value set for `--master-info-repository`. When a slave runs with `--master-info-repository=FILE`, you can find in its data directory two files, named `master.info` and `relay-log.info`. If `--master-info-repository=TABLE` instead, this information is saved in the table `master_slave_info` in the `mysql` database. In either case, do *not* remove or edit the files or table unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave can use the values specified in the statement to update the status files automatically. See [Section 17.2.4, "Replication Relay and Status Logs"](#), for more information.

#### Note

The contents of the master info repository override some of the server options specified on the command line or in `my.cnf`. See [Section 17.1.6, "Replication and Binary Logging Options and Variables"](#), for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

### 17.1.2.6 Adding Slaves to a Replication Environment

You can add another slave to an existing replication configuration without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` [2426] value.

To duplicate an existing slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```

071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525'
(relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure

```

This situation can occur if the `--relay-log` option is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `--relay-log-index` option is not used. See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#), for more information about these options.

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`. If this is not possible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`. Alternatively, if you have already tried to start the new slave after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

- a. If you have not already done so, issue a `STOP SLAVE` on the new slave.
 

If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.
  - b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
  - c. Proceed with the remaining steps in this section.
3. Copy the master info and relay log info repositories (see [Section 17.2.4, “Replication Relay and Status Logs”](#)) from the existing slave to the new slave. These hold the current log coordinates for the master's binary log and the slave's relay log.
  4. Start the existing slave.
  5. On the new slave, edit the configuration and give the new slave a unique `server-id` [\[2426\]](#) not used by the master or any of the existing slaves.
  6. Start the new slave. The slave uses the information in its master info repository to start the replication process.

### 17.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using *global transaction identifiers* (GTIDs). When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any slaves; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new slave or failing over to a new master, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether masters and slaves are consistent; as long as all transactions committed on a master are also committed on a slave, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see [Section 17.2.1, “Replication Formats”](#)); however, for best results, we recommend that you use the row-based format.

This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in the MySQL Server (see [Section 17.1.3.1, “GTID Concepts”](#)).

- A general procedure for setting up and starting GTID-based replication (see [Section 17.1.3.2, “Setting Up Replication Using GTIDs”](#)).
- Suggested methods for provisioning new replication servers when using GTIDs (see [Section 17.1.3.3, “Using GTIDs for Failover and Scaleout”](#)).
- Restrictions and limitations that you should be aware of when using GTID-based replication (see [Section 17.1.3.4, “Restrictions on Replication with GTIDs”](#)).

For information about MySQL Server options and variables relating to GTID-based replication, see [Section 17.1.6.5, “Global Transaction ID Options and Variables”](#). See also [Section 12.17, “Functions Used with Global Transaction IDs”](#), which describes SQL functions supported by MySQL 5.7 for use with GTIDs.

### 17.1.3.1 GTID Concepts

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (master). This identifier is unique not only to the server on which it originated, but is unique across all servers in a given replication setup. There is a 1-to-1 mapping between all transactions and all GTIDs.

The following paragraphs provide a basic description of GTIDs. More advanced concepts are covered later in the following sections:

- [GTID Sets](#)
- [The `mysql.gtid\_executed` Table](#)
- [mysql.gtid\\_executed Table Compression](#)

A GTID is represented as a pair of coordinates, separated by a colon character (:), as shown here:

```
GTID = source_id:transaction_id
```

The *source\_id* identifies the originating server. Normally, the server's `server_uuid` [2426] is used for this purpose. The *transaction\_id* is a sequence number determined by the order in which the transaction was committed on this server; for example, the first transaction to be committed has 1 as its *transaction\_id*, and the tenth transaction to be committed on the same originating server is assigned a *transaction\_id* of 10. It is not possible for a transaction to have 0 as a sequence number in a GTID. For example, the twenty-third transaction to be committed originally on the server with the UUID `3E11FA47-71CA-11E1-9E33-C80AA9429562` has this GTID:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:23
```

This format is used to represent GTIDs in the output of statements such as `SHOW SLAVE STATUS` as well as in the binary log. They can also be seen when viewing the log file with `mysqlbinlog --base64-output=DECODE-ROWS` or in the output from `SHOW BINLOG EVENTS`.

As written in the output of statements such as `SHOW MASTER STATUS` or `SHOW SLAVE STATUS`, a sequence of GTIDs originating from the same server may be collapsed into a single expression, as shown here.

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
```

The example just shown represents the first through fifth transactions originating on the MySQL Server whose `server_uuid` [2426] is `3E11FA47-71CA-11E1-9E33-C80AA9429562`.

This format is also used to supply the argument required by the `START SLAVE` options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`.

## GTID Sets

A GTID set is a set of global transaction identifiers which is represented as shown here:

```

gtid_set:
  uuid_set [, uuid_set] ...
  | ''

uuid_set:
  uuid:interval[:interval]...

uuid:
  hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh

h:
  [0-9|A-F]

interval:
  n[-n]

  (n >= 1)

```

GTID sets are used in the MySQL Server in several ways. For example, the values stored by the `gtid_executed` and `gtid_purged` system variables are represented as GTID sets. In addition, the functions `GTID_SUBSET()` and `GTID_SUBTRACT()` require GTID sets as input. When GTID sets are returned from server variables, UUIDs are in alphabetical order and numeric intervals are merged and in ascending order.

GTIDs are always preserved between master and slave. This means that you can always determine the source for any transaction applied on any slave by examining its binary log. In addition, once a transaction with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the master can be applied no more than once on the slave, which helps to guarantee consistency.

When GTIDs are in use, the slave has no need for any nonlocal data, such as the name of a file on the master and a position within that file. All necessary information for synchronizing with the master is obtained directly from the replication data stream. GTIDs replace the file-offset pairs previously required to determine points for starting, stopping, or resuming the flow of data between master and slave. therefore, do not include `MASTER_LOG_FILE` or `MASTER_LOG_POS` options in the `CHANGE MASTER TO` statement used to direct a slave to replicate from a given master; instead it is necessary only to enable the `MASTER_AUTO_POSITION` option. For the exact steps needed to configure and start masters and slaves using GTID-based replication, see [Section 17.1.3.2, “Setting Up Replication Using GTIDs”](#).

The generation and life cycle of a GTID consist of the following steps:

1. A transaction is executed and committed on the master.

This transaction is assigned a GTID using the master's UUID and the smallest nonzero transaction sequence number not yet used on this server; the GTID is written to the master's binary log (immediately preceding the transaction itself in the log).

2. After the binary log data is transmitted to the slave and stored in the slave's relay log (using established mechanisms for this process—see [Section 17.2, “Replication Implementation”](#), for details), the slave reads the GTID and sets the value of its `gtid_next` system variable as this GTID. This tells the slave that the next transaction must be logged using this GTID.

It is important to note that the slave sets `gtid_next` in a session context.

3. The slave verifies that this GTID has not already been used to log a transaction in its own binary log. If this GTID has not been used, the slave then writes the GTID, applies the transaction, and writes the transaction to its binary log. By reading and checking the transaction's GTID first, before

processing the transaction itself, the slave guarantees not only that no previous transaction having this GTID has been applied on the slave, but also that no other session has already read this GTID but has not yet committed the associated transaction. In other words, multiple clients are not permitted to apply the same transaction concurrently.

4. Because `gtid_next` is not empty, the slave does not attempt to generate a GTID for this transaction but instead writes the GTID stored in this variable—that is, the GTID obtained from the master—immediately preceding the transaction in its binary log.

## The `mysql.gtid_executed` Table

Beginning with MySQL 5.7.5, GTIDs are stored in a table named `gtid_executed`, in the `mysql` database. A row in this table contains, for each GTID or set of GTIDs that it represents, the UUID of the originating server, and the starting and ending transaction IDs of the set; for a row referencing only a single GTID, these last two values are the same.

The `mysql.gtid_executed` table is created (if it does not already exist) when the MySQL Server is installed or upgraded, using a `CREATE TABLE` statement similar to that shown here:

```
CREATE TABLE gtid_executed (
  source_uuid CHAR(36) NOT NULL,
  interval_start BIGINT(20) NOT NULL,
  interval_end BIGINT(20) NOT NULL,
  PRIMARY KEY (source_uuid, interval_start)
)
```

### Warning

As with other MySQL system tables, do not attempt to create or modify this table yourself.

GTIDs are stored in the `mysql.gtid_executed` table only when `gtid_mode` is `ON` or `ON_PERMISSIVE`. GTIDs are stored in this table without regard to whether binary logging is enabled. However, the manner in which they are stored differs depending on whether `log_bin` is `ON` or `OFF`:

- If binary logging is disabled (`log_bin` is `OFF`), the server stores the GTID belonging to each transaction together with the transaction in the table.

In addition, when binary logging is disabled, this table is compressed periodically at a user-configurable rate; see [mysql.gtid\\_executed Table Compression](#), for more information.

- If binary logging is enabled (`log_bin` is `ON`), then in addition to storing the GTIDs in `mysql.gtid_executed`, whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log into the new binary log.

In the event of the server stopping unexpectedly, the set of GTIDs from the previous binary log is not saved in the `mysql.gtid_executed` table. In this case, these GTIDs are added to the table and to the set of GTIDs in the `gtid_executed` system variable during recovery.

The `mysql.gtid_executed` table is reset by `RESET MASTER`.

## mysql.gtid\_executed Table Compression

Over the course of time, the `mysql.gtid_executed` table can become filled with many rows referring to individual GTIDs that originate on the same server, and whose transaction IDs make up a sequence, similar to what is shown here:

```
mysql> SELECT * FROM mysql.gtid_executed;
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

| source_uuid                          | interval_start | interval_end |
|--------------------------------------|----------------|--------------|
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 37             | 37           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 38             | 38           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 39             | 39           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 40             | 40           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 41             | 41           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 42             | 42           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 43             | 43           |
| ...                                  |                |              |

Considerable space can be saved if this table is compressed periodically by replacing each such set of rows with a single row that spans the entire interval of transaction identifiers, like this:

| source_uuid                          | interval_start | interval_end |
|--------------------------------------|----------------|--------------|
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 37             | 43           |
| ...                                  |                |              |

When GTIDs are enabled, the server performs this type of compression on the `mysql.gtid_executed` table periodically. You can control the number of transactions that are allowed to elapse before the table is compressed, and thus the compression rate, by setting the `executed_gtids_compression_period` system variable. This variable's default value is 1000; this means that, by default, compression of the table is performed after each 1000 transactions. Setting `executed_gtid_compression_period` to 0 prevents the compression from being performed at all; however, you should be prepared for a potentially large increase in the amount of disk space that may be required by the `gtid_executed` table if you do this.

**Note**

When binary logging is enabled, the value of `executed_gtids_compression_period` is *not* used and the `mysql.gtid_executed` table is compressed on each binary log rotation.

Compression of the `mysql.gtid_executed` table is performed by a dedicated foreground thread that is created whenever GTIDs are enabled on the server. This thread is not listed in the output of `SHOW PROCESSLIST`, but it can be viewed as a row in the `threads` table, as shown here:

```
mysql> SELECT * FROM PERFORMANCE_SCHEMA.THREADS WHERE NAME LIKE '%gtid%\G
***** 1. row *****
      THREAD_ID: 21
        NAME: thread/sql/compress_gtid_table
         TYPE: FOREGROUND
PROCESSLIST_ID: 139635685943104
PROCESSLIST_USER: NULL
PROCESSLIST_HOST: NULL
PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: Daemon
PROCESSLIST_TIME: 611
PROCESSLIST_STATE: Suspending
PROCESSLIST_INFO: NULL
PARENT_THREAD_ID: 1
          ROLE: NULL
INSTRUMENTED: YES
```

This thread has the name `thread/sql/compress_gtid_table`, and normally sleeps until `executed_gtids_compression_period` transactions have been executed, then wakes up to perform compression of the `mysql.gtid_executed` table as described previously. It then sleeps until another `executed_gtids_compression_period` transactions have taken place, then wakes up to perform the compression again, repeating this loop indefinitely. Setting this value to 0 when binary logging is disabled means that the thread always sleeps and never wakes up.

### 17.1.3.2 Setting Up Replication Using GTIDs

This section describes a process for configuring and starting GTID-based replication in MySQL 5.7. This is a “cold start” procedure that assumes either that you are starting the replication master for the first time, or that it is possible to stop it; for information about provisioning replication slaves using GTIDs from a running master, see [Section 17.1.3.3, “Using GTIDs for Failover and Scaleout”](#). For information about changing GTID mode on servers online, see [Section 17.1.5, “Changing Replication Modes on Online Servers”](#).

The key steps in this startup process for the simplest possible GTID replication topology—consisting of one master and one slave—are as follows:

1. If replication is already running, synchronize both servers by making them read-only.
2. Stop both servers.
3. Restart both servers with GTIDs enabled and the correct options configured.

The `mysqld` options necessary to start the servers as described are discussed in the example that follows later in this section.

4. Instruct the slave to use the master as the replication data source and to use auto-positioning, and then start the slave.

The SQL statements needed to accomplish this step are described in the example that follows later in this section.

5. Enable read mode again on both servers, so that they can accept updates.

In the following example, two servers are already running as master and slave, using MySQL's binary log position-based replication protocol. If you are starting with new servers, see [Section 17.1.2.2, “Creating a User for Replication”](#) for information about adding a specific user for replication connections and [Section 17.1.2.1, “Setting the Replication Master Configuration”](#) for information about setting the server-id. The following examples show how to use startup options when running `mysqld`. Alternatively you can store startup options in an option file, see [Section 4.2.6, “Using Option Files”](#) for more information.

Most of the steps that follow require the use of the MySQL `root` account or another MySQL user account that has the `SUPER` privilege. `mysqladmin shutdown` requires either the `SUPER` privilege or the `SHUTDOWN` privilege.

**Step 1: Synchronize the servers.** Make the servers read-only. To do this, enable the `read_only` system variable by executing the following statement on both servers:

```
mysql> SET @@global.read_only = ON;
```

Then, allow the slave to catch up with the master. *It is extremely important that you make sure the slave has processed all updates before continuing.*

**Step 2: Stop both servers.** Stop each server using `mysqladmin` as shown here, where `username` is the user name for a MySQL user having sufficient privileges to shut down the server:

```
shell> mysqladmin -username -p shutdown
```

Then supply this user's password at the prompt.

**Step 3: Restart both servers with GTIDs enabled.** To enable GTID-based replication, each server must be started with GTID mode enabled, by setting the `--gtid-mode` option to `ON`, and with the `--enforce-gtid-consistency` option enabled to ensure that only statements which are safe for

GTID-based replication are logged. In addition, you should start the slave with the `--skip-slave-start` option before configuring the slave settings. For more information on GTID related options, see [Section 17.1.6.5, “Global Transaction ID Options and Variables”](#).

It is not mandatory to have binary logging enabled in order to use GTIDs due to the addition of the [The `mysql.gtid\_executed` Table](#) in MySQL 5.7.5. This means that you can have slave servers using GTIDs but without binary logging. Masters *must* always have binary logging enabled in order to be able to replicate. For example, to start a slave with GTIDs enabled but without binary logging, use at least these options:

```
shell> mysqld --gtid-mode=ON --enforce-gtid-consistency &
```

In MySQL 5.7.4 and earlier, binary logging is required to use GTIDs and both master and slave servers must be started with at least these options:

```
shell> mysqld --gtid-mode=ON --log-bin --enforce-gtid-consistency &
```

Depending on your configuration, supply additional options to `mysqld`.

**Step 4: Direct the slave to use the master.** Tell the slave to use the master as the replication data source, and to use GTID-based auto-positioning rather than file-based positioning. Execute a `CHANGE MASTER TO` statement on the slave, using the `MASTER_AUTO_POSITION` option to tell the slave that transactions will be identified by GTIDs.

You may also need to supply appropriate values for the master's host name and port number as well as the user name and password for a replication user account which can be used by the slave to connect to the master; if these have already been set prior to Step 1 and no further changes need to be made, the corresponding options can safely be omitted from the statement shown here.

```
mysql> CHANGE MASTER TO
>     MASTER_HOST = host,
>     MASTER_PORT = port,
>     MASTER_USER = user,
>     MASTER_PASSWORD = password,
>     MASTER_AUTO_POSITION = 1;
```

Neither the `MASTER_LOG_FILE` option nor the `MASTER_LOG_POS` option may be used with `MASTER_AUTO_POSITION` set equal to 1. Attempting to do so causes the `CHANGE MASTER TO` statement to fail with an error. (If you need to revert from GTID-based replication to replication based on files and positions, the slave uses the current values from the master info log to reconnect to the master. To change the values being used, set one or both of these options in a `CHANGE MASTER TO` statement.)

Assuming that the `CHANGE MASTER TO` statement has succeeded, you can then start the slave, like this:

```
mysql> START SLAVE;
```

**Step 5: Disable read-only mode.** Allow the master to begin accepting updates once again by running the following statement:

```
mysql> SET @@global.read_only = OFF;
```

GTID-based replication should now be running, and you can begin (or resume) activity on the master as before. [Section 17.1.3.3, “Using GTIDs for Failover and Scaleout”](#), discusses creation of new slaves when using GTIDs.

### 17.1.3.3 Using GTIDs for Failover and Scaleout

There are a number of techniques when using MySQL Replication with Global Transaction Identifiers (GTIDs) for provisioning a new slave which can then be used for scaleout, being promoted to master as necessary for failover. This section describes the following techniques:

- [Simple replication](#)
- [Copying data and transactions to the slave](#)
- [Injecting empty transactions](#)
- [Excluding transactions with `gtid\_purged`](#)
- [Restoring GTID mode slaves](#)

Global transaction identifiers were added to MySQL Replication for the purpose of simplifying in general management of the replication data flow and of failover activities in particular. Each identifier uniquely identifies a set of binary log events that together make up a transaction. GTIDs play a key role in applying changes to the database: the server automatically skips any transaction having an identifier which the server recognizes as one that it has processed before. This behavior is critical for automatic replication positioning and correct failover.

The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from the old server to the new one, and to preserve the relationship between the identifiers and the actual events. This is necessary for restoring a slave that is immediately available as a candidate to become a new master on failover or switchover.

**Simple replication.** The easiest way to reproduce all identifiers and transactions on a new server is to make the new server into the slave of a master that has the entire execution history, and enable global transaction identifiers on both servers. See [Section 17.1.3.2, “Setting Up Replication Using GTIDs”](#), for more information.

Once replication is started, the new server copies the entire binary log from the master and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the slave to read the binary log from the master; it can sometimes take a comparatively long time for the new slave to catch up with the master, so this method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the master by copying binary log files to the new server.

**Copying data and transactions to the slave.** Playing back the entire transaction history can be time-consuming, and represents a major bottleneck when setting up a new replication slave. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the master contains is imported to the slave. The binary log is played back, after which replication can be started, allowing the slave to become current with any remaining transactions.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transferred to the slave, as outlined here:

| Data Set                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Transaction History                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• Use the <code>mysql</code> client to import a dump file created with <code>mysqldump</code>. Use the <code>--master-data</code> option to include binary logging information and <code>--set-gtid-purged</code> to <code>AUTO</code> (the default) or <code>ON</code>, to include information about executed transactions. You should have <code>--gtid-mode=ON</code> while importing the dump on the slave.</li> </ul> | <p>If <code>gtid_mode</code> is not <code>ON</code>, restart the server with GTID mode enabled.</p> <ul style="list-style-type: none"> <li>• Import the binary log using <code>mysqlbinlog</code>, with the <code>--read-from-remote-server</code> and <code>--read-from-remote-master</code> options.</li> </ul> |

| Data Set                                                                                                                                                                  | Transaction History                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>Stop the slave, copy the contents of the master's data directory to the slave's data directory, then restart the slave.</li> </ul> | <ul style="list-style-type: none"> <li>Copy the master's binary log files to the slave. You can make copies from the slave using <code>mysqlbinlog --read-from-remote-server --raw</code>. These can be read in to the slave in either of the following ways: <ul style="list-style-type: none"> <li>Update the slave's <code>binlog.index</code> file to point to the copied log files. Then execute a <code>CHANGE MASTER TO</code> statement in the <code>mysql</code> client to point to the first log file, and <code>START SLAVE</code> to read them.</li> <li>Use <code>mysqlbinlog &gt; file</code> (without the <code>--raw</code> option) to export the binary log files to SQL files that can be processed by the <code>mysql</code> client.</li> </ul> </li> </ul> |

See also [Section 4.6.7.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).

This method has the advantage that a new server is available almost immediately; only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing master. This means that the slave's availability is not instantaneous—but only a relatively short amount of time should be required for the slave to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the master in real time. However, it may not always be feasible to move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new slave discussed in this section use other means to transfer information about transactions to the new slave.

**Injecting empty transactions.** The master's global `gtid_executed` variable contains the set of all transactions executed on the master. Rather than copy the binary logs when taking a snapshot to provision a new server, you can instead note the content of `gtid_executed` on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the master's `gtid_executed`, like this:

```
SET GTID_NEXT= 'aaa-bbb-ccc-ddd:N' ;

BEGIN;
COMMIT;

SET GTID_NEXT= 'AUTOMATIC' ;
```

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the slave's binary logs, as shown here, where `N` is the nonzero suffix of the current binary log file name:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'master-bin.00000N' ;
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to master. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a master as its binary log history converges with that of the replication stream (that is, as it catches up with the

master or masters). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

**Excluding transactions with `gtid_purged`.** The master's global `gtid_purged` variable contains the set of all transactions that have been purged from the master's binary log. As with the method discussed previously (see [Injecting empty transactions](#)), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the slave directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a master as its binary log history converges with that of the replication master or group.

**Restoring GTID mode slaves.** When restoring a slave in a GTID based replication setup that has encountered an error, injecting an empty transaction may not solve the problem because an event does not have a GTID.

Use `mysqlbinlog` to find the next transaction, which is probably the first transaction in the next log file after the event. Copy everything up to the `COMMIT` for that transaction, being sure to include the `SET @@SESSION.GTID_NEXT`. Even if you are not using row-based replication, you can still run binary log row events in the command line client.

Stop the slave and run the transaction you copied. The `mysqlbinlog` output sets the delimiter to `/*! */;`, so set it back:

```
mysql> DELIMITER ;
```

Restart replication from the correct position automatically:

```
mysql> SET GTID_NEXT=automatic;
mysql> RESET SLAVE;
mysql> START SLAVE;
```

### 17.1.3.4 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.

**Updates involving nontransactional storage engines.** When using GTIDs, updates to tables using nontransactional storage engines such as `MyISAM` cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as `InnoDB`.

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the master and the slave use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

**CREATE TABLE ... SELECT statements.** `CREATE TABLE ... SELECT` is not safe for statement-based replication. When using row-based replication, this statement is actually logged as two separate

events—one for the creation of the table, and another for the insertion of rows from the source table into the new table just created. When this statement is executed within a transaction, it is possible in some cases for these two events to receive the same transaction identifier, which means that the transaction containing the inserts is skipped by the slave. Therefore, `CREATE TABLE ... SELECT` is not supported when using GTID-based replication.

**Temporary tables.** `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements are not supported inside transactions when using GTIDs (that is, when the server was started with the `--enforce-gtid-consistency` option). It is possible to use these statements with GTIDs enabled, but only outside of any transaction, and only with `autocommit=1`.

**Preventing execution of unsupported statements.** To prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the `--enforce-gtid-consistency` option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

For information about other required startup options when enabling GTIDs, see [Section 17.1.3.2, “Setting Up Replication Using GTIDs”](#).

`sql_slave_skip_counter` is not supported when using GTIDs. If you need to skip transactions, use the value of the master's `gtid_executed` variable instead; see [Injecting empty transactions](#), for more information.

**GTID mode and mysqldump.** It is possible to import a dump made using `mysqldump` into a MySQL Server running with GTID mode enabled, provided that there are no GTIDs in the target server's binary log.

**GTID mode and mysql\_upgrade.** It is possible but is not recommended to use `mysql_upgrade` on a MySQL Server running with `--gtid-mode=ON`, since `mysql_upgrade` can make changes to system tables that use the `MyISAM` storage engine, which is nontransactional.

## 17.1.4 MySQL Multi-Source Replication

This section describes MySQL Multi-Source Replication, included in MySQL 5.7.6 and later. Multi-source replication enables you to replicate from multiple immediate masters in parallel. This section describes multi-source replication, and how to configure, monitor and troubleshoot it.

### 17.1.4.1 MySQL Multi-Source Replication Overview

MySQL Multi-Source Replication enables a replication slave to receive transactions from multiple sources simultaneously. Multi-source replication can be used to back up multiple servers to a single server, to merge table shards, and consolidate data from multiple servers to a single server. Multi-source replication does not implement any conflict detection or resolution when applying the transactions, and those tasks are left to the application if required. In a multi-source replication topology, a slave creates a replication channel for each master that it should receive transactions from. See [Section 17.2.3, “Replication Channels”](#). The following sections describe how to set up multi-source replication.

### 17.1.4.2 Multi-Source Replication Tutorials

This section provides tutorials on how to configure masters and slaves for multi-source replication, and how to start, stop and reset multi-source slaves.

## Configuring Multi-Source Replication

This section explains how to configure a multi-source replication topology, and provides details about configuring masters and slaves. Such a topology requires at least two masters and one slave configured.

Masters in a multi-source replication topology can be configured to use either global transaction identifier (GTID) based replication, or binary log position-based replication. See [Section 17.1.3.2, “Setting Up Replication Using GTIDs”](#) for how to configure a master using GTID based replication. See [Section 17.1.2.1, “Setting the Replication Master Configuration”](#) for how to configure a master using file position based replication.

Slaves in a multi-source replication topology require [TABLE](#) based repositories. Multi-source replication is not compatible with [FILE](#) based repositories. The type of repository being used by `mysqld` can be configured either at startup, or dynamically.

To configure the type of repository used by a replication slave at startup, start `mysqld` with the following options:

```
--master-info-repository=TABLE --relay-log-info-repository=TABLE
```

To modify an existing replication slave that is using a [FILE](#) repository to use [TABLE](#) repositories, convert the existing replication repositories dynamically by running the following commands:

```
STOP SLAVE;
SET GLOBAL master_info_repository = 'TABLE';
SET GLOBAL relay_log_info_repository = 'TABLE';
```

## Adding a GTID Based Master to a Multi-Source Replication Slave

This section assumes you have enabled GTID based transactions on the master using `gtid_mode=ON`, enabled a replication user, and ensured that the slave is using [TABLE](#) based replication repositories. Use the `CHANGE MASTER TO` statement to add a new master to a channel by using a `FOR CHANNEL channel` clause. For more information on replication channels, see [Section 17.2.3, “Replication Channels”](#)

For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='', \
MASTER_AUTO_POSITION = 1 FOR CHANNEL 'master-1';
```

Multi-source replication is compatible with auto-positioning. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#) for more information.

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

## Adding a Binary Log Based Master to a Multi-Source Replication Slave

This section assumes you have enabled binary logging on the master using `--log-bin`, enabled a replication user, noted the current binary log position, and ensured that the slave is using [TABLE](#) based replication repositories. You need to know the current `MASTER_LOG_FILE` and `MASTER_LOG_POSITION`. Use the `CHANGE MASTER TO` statement to add a new master to a channel by specifying a `FOR CHANNEL channel` clause. For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='' \
MASTER_LOG_FILE='master1-bin.000006', MASTER_LOG_POS=628 FOR CHANNEL 'master-1';
```

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

## Starting Multi-Source Replication Slaves

Once you have added all of the channels you want to use as replication masters, use a `START SLAVE thread_types` statement to start replication. When you have enabled multiple channels on a slave, you can choose to either start all channels, or select a specific channel to start.

- To start all currently configured replication channels:

```
START SLAVE thread_types;
```

- To start only a named channel, use a `FOR CHANNEL channel` clause:

```
START SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to start on the slave. See [Section 13.4.2.6, “START SLAVE Syntax”](#) for more information.

## Stopping Multi-Source Replication Slaves

The `STOP SLAVE` statement can be used to stop a multi-source replication slave. By default, if you use the `STOP SLAVE` statement on a multi-source replication slave all channels are stopped. Optionally, use the `FOR CHANNEL channel` clause to stop only a specific channel.

- To stop all currently configured replication channels:

```
STOP SLAVE thread_types;
```

- To stop only a named channel, use a `FOR CHANNEL channel` clause:

```
STOP SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to stop on the slave. See [Section 13.4.2.7, “STOP SLAVE Syntax”](#) for more information.

## Resetting Multi-Source Replication Slaves

The `RESET SLAVE` statement can be used to reset a multi-source replication slave. By default, if you use the `RESET SLAVE` statement on a multi-source replication slave all channels are reset. Optionally, use the `FOR CHANNEL channel` clause to reset only a specific channel.

- To reset all currently configured replication channels:

```
RESET SLAVE;
```

- To reset only a named channel, use a `FOR CHANNEL channel` clause:

```
RESET SLAVE FOR CHANNEL channel;
```

See [Section 13.4.2.4, “RESET SLAVE Syntax”](#) for more information.

### 17.1.4.3 Multi-Source Replication Monitoring

To monitor the status of replication channels the following options exist:

- Using the replication Performance Schema tables. The first column of these tables is `Channel_Name`. This enables you to write complex queries based on `Channel_Name` as a key. See [Section 21.9.10, “Performance Schema Replication Tables”](#).
- Using `SHOW SLAVE STATUS FOR CHANNEL channel_name`. By default, if the `FOR CHANNEL channel_name` clause is not used, this statement shows the slave status for all channels with

one row per channel. The identifier `channel_name` is added as a column in the result set. If a `FOR CHANNEL channel_name` clause is provided, the results show the status of only the named replication channel.

### Note

The `SHOW VARIABLES` statement does not work with multiple replication channels. The information that was available through these variables has been migrated to the replication performance tables. Using a `SHOW VARIABLES` statement in a topology with multiple channels shows the status of only the default channel.

## Monitoring Channels Using Performance Schema Tables

This section explains how to use the replication Performance Schema tables to monitor channels. You can choose to monitor all channels, or a subset of the existing channels.

To monitor the connection status of all channels:

```
mysql> SELECT * FROM replication_connection_status\G;
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
***** 2. row *****
CHANNEL_NAME: master2
GROUP_NAME:
SOURCE_UUID: 7475e474-a223-11e4-a978-0811960cc264
THREAD_ID: 26
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 7475e474-a223-11e4-a978-0811960cc264:4-6
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
2 rows in set (0.00 sec)
```

In the above output there are two channels enabled, and as shown by the `CHANNEL_NAME` field they are called `master1` and `master2`.

The addition of the `CHANNEL_NAME` field enables you to query the Performance Schema tables for a specific channel. To monitor the connection status of a named channel, use a `WHERE channel_name=channel` clause:

```
mysql> SELECT * FROM replication_connection_status WHERE channel_name='master1'\G
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
```

```
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
1 row in set (0.00 sec)
```

Similarly, the `WHERE channel_name=channel` clause can be used to monitor the other replication Performance Schema tables for a specific channel. For more information, see [Section 21.9.10, “Performance Schema Replication Tables”](#).

#### 17.1.4.4 Multi-Source Replication Error Messages

New error codes and messages have been added to MySQL 5.7.6 to provide information about errors encountered in a multi-source replication topology. These error codes and messages are only emitted when multi-source replication is enabled, and provide information related to the channel which generated the error. For example:

`Slave is already running` and `Slave is already stopped` have been replaced with `Replication thread(s) for channel channel_name are already running` and `Replication threads(s) for channel channel_name are already stopped` respectively.

The server log messages have also been changed to indicate which channel the log messages relate to. This makes debugging and tracing easier.

### 17.1.5 Changing Replication Modes on Online Servers

This section describes how to change the mode of replication being used without having to take the server offline. This is new functionality added in MySQL 5.7.6.

#### 17.1.5.1 Replication Mode Concepts

To be able to safely configure the replication mode of an online server it is important to understand some key concepts of replication. This section explains these concepts and is essential reading before attempting to modify the replication mode of an online server.

The modes of replication available in MySQL rely on different techniques for identifying transactions which are logged. The types of transactions used by replication are as follows:

- GTID transactions are identified by a global transaction identifier (GTID) in the form `UUID:NUMBER`. Every GTID transaction in a log is always preceded by a `Gtid_log_event`. GTID transactions can be addressed using either the GTID or using the file name and position.
- Anonymous transactions do not have a GTID assigned, and MySQL 5.7.6 and later ensures that every anonymous transaction in a log is preceded by an `Anonymous_gtid_log_event`. In previous versions, anonymous transactions were not preceded by any particular event. Anonymous transactions can only be addressed using file name and position.

When using GTIDs you can take advantage of auto-positioning and automatic fail-over, as well as use `WAIT_FOR_EXECUTED_GTID_SET()`, `session_track_gtids`, and monitor replicated transactions using Performance Schema tables. With GTIDs enabled you cannot use `sql_slave_skip_counter`, instead use empty transactions.

The changes introduced by MySQL 5.7.6 mean that transactions in a relay log that was received from a master running a previous version of MySQL may not be preceded by any particular event at all, but after being replayed and logged in the slave's binary log, they are preceded with an `Anonymous_gtid_log_event`.

The ability to configure the replication mode online means that the `gtid_mode` and `enforce_gtid_consistency` variables are now both dynamic and can be set by `SUPER` from a top-level statement. In previous versions, both of these variables could only be configured using

the appropriate option at server start, meaning that changes to the replication mode required a server restart. In all versions `gtid_mode` could be set to `ON` or `OFF`, which corresponded to whether GTIDs were used to identify transactions or not. When `gtid_mode=ON` it is not possible to replicate anonymous transactions, and when `gtid_mode=OFF` only anonymous transactions can be replicated. As of MySQL 5.7.6, the `gtid_mode` variable has two additional states, `OFF_PERMISSIVE` and `ON_PERMISSIVE`. When `gtid_mode=OFF_PERMISSIVE` then *new* transactions are anonymous while permitting replicated transactions to be either GTID or anonymous transactions. When `gtid_mode=ON_PERMISSIVE` then *new* transactions use GTIDs while permitting replicated transactions to be either GTID or anonymous transactions. This means it is possible to have a replication topology that has servers using both anonymous and GTID transactions. For example a master with `gtid_mode=ON` could be replicating to a slave with `gtid_mode=ON_PERMISSIVE`. The valid values for `gtid_mode` are as follows and in this order:

- `OFF`
- `OFF_PERMISSIVE`
- `ON_PERMISSIVE`
- `ON`

It is important to note that the state of `gtid_mode` can only be changed by one step at a time based on the above order. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`. This is to ensure that the process of changing from anonymous transactions to GTID transactions online is correctly handled by the server. When you switch between `gtid_mode=ON` and `gtid_mode=OFF`, the GTID state (in other words the value of `gtid_executed`) is persistent. This ensures that the GTID set that has been applied by the server is always retained, regardless of changes between types of `gtid_mode`.

As part of the changes introduced by MySQL 5.7.6, the fields related to GTIDs have been modified so that they display the correct information regardless of the currently selected `gtid_mode`. This means that fields which display GTID sets, such as `gtid_executed`, `gtid_purged`, `RECEIVED_TRANSACTION_SET` in the `replication_connection_status` Performance Schema table, and the GTID related results of `SHOW SLAVE STATUS`, now return the empty string when there are no GTIDs present. Fields that display a single GTID, such as `CURRENT_TRANSACTION` in the `replication_applier_status_by_worker` Performance Schema table, now display `ANONYMOUS` when GTID transactions are not being used.

Replication from a master using `gtid_mode=ON` provides the ability to use auto-positioning, configured using the `CHANGE MASTER TO MASTER_AUTO_POSITION = 1;` statement. The replication topology being used impacts on whether it is possible to enable auto-positioning or not, as this feature relies on GTIDs and is not compatible with anonymous transactions. An error is generated if auto-positioning is enabled and an anonymous transaction is encountered. It is strongly recommended to ensure there are no anonymous transactions remaining in the topology before enabling auto-positioning, see [Section 17.1.5.2, “Enabling GTID Transactions Online”](#). The valid combinations of `gtid_mode` and auto-positioning on master and slave are shown in the following table, where the master's `gtid_mode` is shown on the horizontal and the slave's `gtid_mode` is on the vertical:

**Table 17.1 Valid Combinations of Master and Slave `gtid_mode`**

| Master/Slave<br><code>gtid_mode</code> | <code>OFF</code> | <code>OFF_PERMISSIVE</code> | <code>ON_PERMISSIVE</code> | <code>ON</code> |
|----------------------------------------|------------------|-----------------------------|----------------------------|-----------------|
| <code>OFF</code>                       | Y                | Y                           | N                          | N               |
| <code>OFF_PERMISSIVE</code>            | Y                | Y                           | Y                          | Y*              |
| <code>ON_PERMISSIVE</code>             | Y                | Y                           | Y                          | Y*              |
| <code>ON</code>                        | N                | N                           | Y                          | Y*              |

In the above table, the entries are:

- **Y**: the `gtid_mode` of master and slave is compatible
- **N**: the `gtid_mode` of master and slave is not compatible
- **\***: auto-positioning can be used

The currently selected `gtid_mode` also impacts on the `gtid_next` variable. The following table shows the behavior of the server for the different values of `gtid_mode` and `gtid_next`.

**Table 17.2 Valid Combinations of `gtid_mode` and `gtid_next`**

| <code>gtid_next</code> | <b>AUTOMATIC</b>     | <b>AUTOMATIC</b>      | <b>ANONYMOUS</b> | <b>UUID:NUMBER</b> |
|------------------------|----------------------|-----------------------|------------------|--------------------|
|                        | <b>binary log on</b> | <b>binary log off</b> |                  |                    |
| <b>OFF</b>             | ANONYMOUS            | ANONYMOUS             | ANONYMOUS        | Error              |
| <b>OFF_PERMISSIVE</b>  | ANONYMOUS            | ANONYMOUS             | ANONYMOUS        | UUID:NUMBER        |
| <b>ON_PERMISSIVE</b>   | New GTID             | ANONYMOUS             | ANONYMOUS        | UUID:NUMBER        |
| <b>ON</b>              | New GTID             | ANONYMOUS             | Error            | UUID:NUMBER        |

In the above table, the entries are:

- **ANONYMOUS**: generate an anonymous transaction.
- **Error**: generate an error and fail to execute `SET GTID_NEXT`.
- **UUID:NUMBER**: generate a GTID with the specified `UUID:NUMBER`.
- **New GTID**: generate a GTID with an automatically generated number.

When the binary log is off and `gtid_next` is set to **AUTOMATIC**, then no GTID is generated. This is consistent with the behavior of previous versions.

### 17.1.5.2 Enabling GTID Transactions Online

This section describes how to enable GTID transactions, and optionally auto-positioning, on servers that are already online and using anonymous transactions. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when enabling GTID transactions that process is easier.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot enable GTID transactions online on any single server unless all servers which are in the topology are using this version.
- All servers have `gtid_mode` set to the default value **OFF**.

The following procedure can be paused at any time and later resumed where it was, or reversed by jumping to the corresponding step of [Section 17.1.5.3, “Disabling GTID Transactions Online”](#), the online procedure to disable GTIDs. This makes the procedure fault-tolerant because any unrelated issues that may appear in the middle of the procedure can be handled as usual, and then the procedure continued where it was left off.

**Note**

It is crucial that you complete every step before continuing to the next step.

To enable GTID transactions:

1. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = WARN;
```

Let the server run for a while with your normal workload and monitor the logs. If this step causes any warnings in the log, adjust your application so that it only uses GTID-compatible features and does not generate any warnings.

#### Important

This is the first important step. You must ensure that no warnings are being generated in the error logs before going to the next step.

2. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
```

3. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

It does not matter which server executes this statement first, but it is important that all servers complete this step before any server begins the next step.

4. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

It does not matter which server executes this statement first.

5. On each server, wait until the status variable `ONGOING_ANONYMOUS_TRANSACTION_COUNT` is zero. This can be checked using:

```
SHOW STATUS LIKE 'ONGOING_ANONYMOUS_TRANSACTION_COUNT';
```

#### Note

On a replication slave, it is theoretically possible that this shows zero and then non-zero again. This is not a problem, it suffices that it shows zero once.

6. Wait for all transactions generated up to step 5 to replicate to all servers. You can do this without stopping updates: the only important thing is that all anonymous transactions get replicated.

See [Section 17.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.

7. If you use binary logs for anything other than replication, for example point in time backup and restore, wait until you do not need the old binary logs having transactions without GTIDs.

For instance, after step 6 has completed, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 6 was completed. Also wait for any backup taken before step 6 to expire.

#### Important

This is the second important point. It is vital to understand that binary logs containing anonymous transactions, without GTIDs cannot be used after the next step. After this step, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

- On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON;
```

- On each server, add `gtid-mode=ON` to `my.cnf`.

You are now guaranteed that all transactions have a GTID (except transactions generated in step 5 or earlier, which have already been processed). To start using the GTID protocol so that you can later perform automatic fail-over, execute the following on each slave. Optionally, if you use multi-source replication, do this for each channel and include the `FOR CHANNEL channel` clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 1 [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

### 17.1.5.3 Disabling GTID Transactions Online

This section describes how to disable GTID transactions on servers that are already online. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when disabling GTIDs mode that process is easier.

The process is similar to enabling GTID transactions while the server is online, but reversing the steps. The only thing that differs is the point at which you wait for logged transactions to replicate.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot disable GTID transactions online on any single server unless *all* servers which are in the topology are using this version.
- All servers have `gtid_mode` set to `ON`.

- Execute the following on each slave, and if you using multi-source replication, do it for each channel and include the `FOR CHANNEL` channel clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 0, MASTER_LOG_FILE = file, \
MASTER_LOG_POS = position [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

- On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

- On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

- On each server, wait until the variable `@@GLOBAL.GTID_OWNED` is equal to the empty string. This can be checked using:

```
SELECT @@GLOBAL.GTID_OWNED;
```

On a replication slave, it is theoretically possible that this is empty and then nonempty again. This is not a problem, it suffices that it is empty once.

- Wait for all transactions that currently exist in any binary log to replicate to all slaves. See [Section 17.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.
- If you use binary logs for anything else than replication, for example to do point in time backup or restore: wait until you do not need the old binary logs having GTID transactions.

For instance, after step 5 has completed, you can execute `FLUSH LOGS` on the server where you are taking the backup. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 5 was completed. Also wait for any backup taken before step 5 to expire.

### Important

This is the one important point during this procedure. It is important to understand that logs containing GTID transactions cannot be used after the next step. Before proceeding you must be sure that GTID transactions do not exist anywhere in the topology.

7. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF;
```

8. On each server, set `gtid-mode=OFF` in `my.cnf`.

If you want to set `enforce_gtid_consistency=OFF`, you can do so now. Optionally add `enforce_gtid_consistency=OFF` to your configuration file.

If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

## 17.1.5.4 Verifying Replication of Anonymous Transactions

This section explains how to monitor a replication topology and verify that all anonymous transactions have been replicated. This is helpful when changing the replication mode online as you can verify that it is safe to change to GTID transactions.

There are several possible ways to wait for transactions to replicate:

The simplest method, which works regardless of your topology but relies on timing is as follows: if you are sure that the slave never lags more than N seconds, just wait for a bit more than N seconds. Or wait for a day, or whatever time period you consider safe for your deployment.

A safer method in the sense that it does not depend on timing: if you only have a master with one or more slaves, do the following:

1. On the master, execute:

```
SHOW MASTER STATUS;
```

Note down the values in the `File` and `Position` column.

2. On every slave, use the file and position information from the master to execute:

```
SELECT MASTER_POS_WAIT(file, position);
```

If you have a master and multiple levels of slaves, or in other words you have slaves of slaves, repeat step 2 on each level, starting from the master, then all the direct slaves, then all the slaves of slaves, and so on.

If you use a circular replication topology where multiple servers may have write clients, perform step 2 for each master-slave connection, until you have completed the full circle. Repeat the whole process so that you do the full circle *twice*.

For example, suppose you have three servers A, B, and C, replicating in a circle so that A -> B -> C -> A. The procedure is then:

- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.
- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.

## 17.1.6 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging and global transaction identifiers (GTIDs). A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `--server-id [2426]` option.

|                            |                            |                        |
|----------------------------|----------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--server-id=#</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                | <code>server_id</code> |
|                            | <b>Variable Scope</b>      | Global                 |
|                            | <b>Dynamic Variable</b>    | Yes                    |
| <b>Permitted Values</b>    | <b>Type</b>                | <code>integer</code>   |
|                            | <b>Default</b>             | 0                      |
|                            | <b>Min Value</b>           | 0                      |
|                            | <b>Max Value</b>           | 4294967295             |

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see [Section 17.1.6.2, “Replication Master Options and Variables”](#), and [Section 17.1.6.3, “Replication Slave Options and Variables”](#).

On the master and each slave, you *must* use the `--server-id [2426]` option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. For example, `server-id=3`.

In MySQL 5.7.2 and earlier, if you start a master server without using `--server-id [2426]` to set its ID, the default ID is 0. In this case, the master refuses connections from all slaves, slaves refuse to connect to the master, and the server sets the `server_id` system variable to 1. In MySQL 5.7.3 and later, the `--server-id` must be used if binary logging is enabled, and a value of 0 is not changed by the server. If you specify `--server-id [2426]` without an argument, the effect is the same as using 0. In either case, if the `server_id` is 0, binary logging takes place, but slaves cannot connect to the master, nor can any other servers connect to it as slaves. (Bug #11763963, Bug #56718)

For more information, see [Setting the Replication Slave Configuration](#).

`server_uuid [2426]`

In MySQL 5.7, the server generates a true UUID in addition to the `--server-id [2426]` supplied by the user. This is available as the global, read-only variable `server_uuid [2426]`.

**Note**

The presence of the `server_uuid` [2426] system variable in MySQL 5.7 does not change the requirement for setting a unique `--server-id` [2426] for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

|                         |                         |                                 |
|-------------------------|-------------------------|---------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>server_uuid</code> [2426] |
|                         | <b>Variable Scope</b>   | Global                          |
|                         | <b>Dynamic Variable</b> | No                              |
| <b>Permitted Values</b> | <b>Type</b>             | <code>string</code>             |

When starting, the MySQL server automatically obtains a UUID as follows:

1. Attempt to read and use the UUID written in the file `data_dir/auto.cnf` (where `data_dir` is the server's data directory).
2. If `data_dir/auto.cnf` is not found, generate a new UUID and save it to this file, creating the file if necessary.

The `auto.cnf` file has a format similar to that used for `my.cnf` or `my.ini` files. In MySQL 5.7, `auto.cnf` has only a single `[auto]` section containing a single `server_uuid` [2426] setting and value; the file's contents appear similar to what is shown here:

```
[auto]
server_uuid=8a94f357-aab4-11df-86ab-c80aa9429562
```

**Important**

The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

When using MySQL replication, masters and slaves know each other's UUIDs. The value of a slave's UUID can be seen in the output of `SHOW SLAVE HOSTS`. Once `START SLAVE` has been executed, the value of the master's UUID is available on the slave in the output of `SHOW SLAVE STATUS`.

**Note**

Issuing a `STOP SLAVE` or `RESET SLAVE` statement does *not* reset the master's UUID as used on the slave.

A server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see [Section 17.1.3, "Replication with Global Transaction Identifiers"](#).

When starting, the slave I/O thread generates an error and aborts if its master's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the slave I/O thread generates a warning if either of the following is true:

- No master having the expected `server_uuid` [2426] exists.
- The master's `server_uuid` [2426] has changed, although no `CHANGE MASTER TO` statement has ever been executed.

### 17.1.6.1 Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

**Table 17.3 Summary of Replication options and variables in MySQL 5.7**

| Option or Variable Name                                                         |                 |                 |
|---------------------------------------------------------------------------------|-----------------|-----------------|
| Command Line                                                                    | System Variable | Status Variable |
| Option File                                                                     | Scope           | Dynamic         |
| <b>Notes</b>                                                                    |                 |                 |
| <a href="#">abort-slave-event-count</a>                                         |                 |                 |
| Yes                                                                             | No              | No              |
| Yes                                                                             |                 | No              |

| DESCRIPTION: Option used by mysql-test for debugging and testing of replication |                 |                 |

Section 17.1.6.4, “Binary Logging Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.2.4, “The Binary Log”.

For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.4, “Server System Variables”.

For a table showing *all* command-line options, system and status variables used with `mysqld`, see Section 5.1.1, “Server Option and Variable Reference”.

## 17.1.6.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the `server-id` [2426] option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see Section 17.1.6.4, “Binary Logging Options and Variables”.

### System Variables Used on Replication Masters

The following system variables are used to control replication masters:

- `auto_increment_increment`

|                         |                         |                                       |
|-------------------------|-------------------------|---------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>auto_increment_increment</code> |
|                         | <b>Variable Scope</b>   | Global, Session                       |
|                         | <b>Dynamic Variable</b> | Yes                                   |
| <b>Permitted Values</b> | <b>Type</b>             | <code>integer</code>                  |
|                         | <b>Default</b>          | 1                                     |
|                         | <b>Min Value</b>        | 1                                     |
|                         | <b>Max Value</b>        | 65535                                 |

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of

`auto_increment_increment` or `auto_increment_offset` to a noninteger value produces an error, and the actual value of the variable remains unchanged.

### Note

`auto_increment_increment` is intended for use with MySQL Cluster, which is not currently supported in MySQL 5.7.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 1     |
| auto_increment_offset   | 1     |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 10    |
| auto_increment_offset   | 1     |
+-----+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
+-----+
4 rows in set (0.00 sec)
```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 10    |
| auto_increment_offset   | 5     |
+-----+-----+
```

```

2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
|  5 |
| 15 |
| 25 |
| 35 |
+-----+
4 rows in set (0.02 sec)
    
```

When the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

If either of these variables is changed, and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. The series is calculated like this:

$$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$$

where  $N$  is a positive integer value in the series [1, 2, 3, ...]. For example:

```

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset   | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|  1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|  1 |
| 11 |
| 21 |
| 31 |
| 35 |
| 45 |
| 55 |
+-----+
    
```

```
| 65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series  $5 + N \times 10$ , that is, [5, 15, 25, 35, 45, ...]. The highest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 17.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- `auto_increment_offset`

|                         |                         |                                    |
|-------------------------|-------------------------|------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>auto_increment_offset</code> |
|                         | <b>Variable Scope</b>   | Global, Session                    |
|                         | <b>Dynamic Variable</b> | Yes                                |
| <b>Permitted Values</b> | <b>Type</b>             | <code>integer</code>               |
|                         | <b>Default</b>          | 1                                  |
|                         | <b>Min Value</b>        | 1                                  |
|                         | <b>Max Value</b>        | 65535                              |

This variable has a default value of 1. For more information, see the description for `auto_increment_increment`.

#### Note

`auto_increment_offset` is intended for use with MySQL Cluster, which is not currently supported in MySQL 5.7.

### 17.1.6.3 Replication Slave Options and Variables

This section explains the server options and system variables that apply to slave replication servers and contains the following:

[Startup Options for Replication Slaves](#)

[Options for Logging Slave Status to Tables](#)

[Obsolete Replication Slave Options](#)

[System Variables Used on Replication Slaves](#)

Specify the options either on the [command line](#) or in an [option file](#). Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. Specify system variable values using `SET`.

**Server ID.** On the master and each slave, you must use the `server-id` [2426] option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

## Startup Options for Replication Slaves

This section explains startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--log-slave-updates`

|                            |                                  |                                |
|----------------------------|----------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--log-slave-updates</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                      | <code>log_slave_updates</code> |
|                            | <b>Variable Scope</b>            | Global                         |
|                            | <b>Dynamic Variable</b>          | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                      | boolean                        |
|                            | <b>Default</b>                   | OFF                            |

Normally, a slave does not write any updates that are received from a master server to its own binary log. This option causes the slave to write the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, `A` serves as the master for the slave `B`, and `B` serves as the master for the slave `C`. For this to work, `B` must be both a master *and* a slave. You must start both `A` and `B` with `--log-bin` to enable binary logging, and `B` with the `--log-slave-updates` option so that updates received from `A` are logged by `B` to its binary log.

- `--log-slow-slave-statements`

|                            |                                                  |         |
|----------------------------|--------------------------------------------------|---------|
| <b>Removed</b>             | 5.7.1                                            |         |
| <b>Command-Line Format</b> | <code>--log-slow-slave-statements</code> (5.7.0) |         |
| <b>Permitted Values</b>    | <b>Type</b>                                      | boolean |
|                            | <b>Default</b>                                   | OFF     |

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

This command-line option was removed in MySQL 5.7.1 and replaced by the `log_slow_slave_statements` system variable. The system variable can be set on the command line or in option files the same way as the option, so there is no need for any changes at server startup, but the system variable also makes it possible to examine or set the value at runtime.

- `--log-warnings[=level]`

|                   |       |
|-------------------|-------|
| <b>Deprecated</b> | 5.7.2 |
|-------------------|-------|

|                                                      |                                 |                           |
|------------------------------------------------------|---------------------------------|---------------------------|
| <b>Command-Line Format</b>                           | <code>--log-warnings[=#]</code> |                           |
| <b>System Variable</b>                               | <b>Name</b>                     | <code>log_warnings</code> |
|                                                      | <b>Variable Scope</b>           | Global                    |
|                                                      | <b>Dynamic Variable</b>         | Yes                       |
| <b>Permitted Values</b> (32-bit platforms, <= 5.7.1) | <b>Type</b>                     | <code>integer</code>      |
|                                                      | <b>Default</b>                  | 1                         |
|                                                      | <b>Min Value</b>                | 0                         |
|                                                      | <b>Max Value</b>                | 4294967295                |
| <b>Permitted Values</b> (32-bit platforms, >= 5.7.2) | <b>Type</b>                     | <code>integer</code>      |
|                                                      | <b>Default</b>                  | 2                         |
|                                                      | <b>Min Value</b>                | 0                         |
|                                                      | <b>Max Value</b>                | 4294967295                |
| <b>Permitted Values</b> (64-bit platforms, <= 5.7.1) | <b>Type</b>                     | <code>integer</code>      |
|                                                      | <b>Default</b>                  | 1                         |
|                                                      | <b>Min Value</b>                | 0                         |
|                                                      | <b>Max Value</b>                | 18446744073709551615      |
| <b>Permitted Values</b> (64-bit platforms, >= 5.7.2) | <b>Type</b>                     | <code>integer</code>      |
|                                                      | <b>Default</b>                  | 2                         |
|                                                      | <b>Min Value</b>                | 0                         |
|                                                      | <b>Max Value</b>                | 18446744073709551615      |

**Note**

As of MySQL 5.7.2, the `log_error_verbosity` system variable is preferred over, and should be used instead of, the `--log-warnings` option or `log_warnings` system variable. For more information, see the descriptions of `log_error_verbosity` and `log_warnings`. The `--log-warnings` command-line option and `log_warnings` system variable are deprecated and will be removed in a future MySQL release.

Causes the server to record more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network or connection failure, and provides information about how each slave thread started. This option is enabled (1) by default; to disable it, use `--log-warnings=0`. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

**Note**

The effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-info-file=file_name`

|                            |                                           |                          |
|----------------------------|-------------------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--master-info-file=file_name</code> |                          |
| <b>Permitted Values</b>    | <b>Type</b>                               | <code>file name</code>   |
|                            | <b>Default</b>                            | <code>master.info</code> |

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see [Section 17.2.4.2, “Slave Status Logs”](#).

- `--master-retry-count=count`

|                                            |                                     |                                   |
|--------------------------------------------|-------------------------------------|-----------------------------------|
| <b>Deprecated</b>                          | 5.6.1                               |                                   |
| <b>Command-Line Format</b>                 | <code>--master-retry-count=#</code> |                                   |
| <b>Permitted Values (32-bit platforms)</b> | <b>Type</b>                         | <code>integer</code>              |
|                                            | <b>Default</b>                      | <code>86400</code>                |
|                                            | <b>Min Value</b>                    | <code>0</code>                    |
|                                            | <b>Max Value</b>                    | <code>4294967295</code>           |
| <b>Permitted Values (64-bit platforms)</b> | <b>Type</b>                         | <code>integer</code>              |
|                                            | <b>Default</b>                      | <code>86400</code>                |
|                                            | <b>Min Value</b>                    | <code>0</code>                    |
|                                            | <b>Max Value</b>                    | <code>18446744073709551615</code> |

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

This option is deprecated and will be removed in a future MySQL release. Applications should be updated to use the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement instead.

- `--max-relay-log-size=size`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--max_relay_log_size=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>max_relay_log_size</code> |
|                            | <b>Variable Scope</b>               | Global                          |
|                            | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                         | <code>integer</code>            |
|                            | <b>Default</b>                      | <code>0</code>                  |
|                            | <b>Min Value</b>                    | <code>0</code>                  |
|                            | <b>Max Value</b>                    | <code>1073741824</code>         |

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see [Section 17.2.4.1, “The Slave Relay Log”](#).

- `--relay-log=file_name`

|                            |                                    |                        |
|----------------------------|------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--relay-log=file_name</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                        | <code>relay_log</code> |
|                            | <b>Variable Scope</b>              | Global                 |
|                            | <b>Dynamic Variable</b>            | No                     |
| <b>Permitted Values</b>    | <b>Type</b>                        | <code>file name</code> |

The base name for the relay log. For the default replication channel, the default base name for relay logs is `host_name-relay-bin`. For non-default replication channels, the default base name for relay logs is `host_name-channel-relay-bin`, where `channel` is the name of the replication channel recorded in this relay log. The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

When the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Previously, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.

You can obtain the relay log file name (and path) from the `relay_log_basename` system variable.

- `--relay-log-index=file_name`

|                            |                                          |                              |
|----------------------------|------------------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-index=file_name</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                              | <code>relay_log_index</code> |
|                            | <b>Variable Scope</b>                    | Global                       |

|                         |                         |           |
|-------------------------|-------------------------|-----------|
|                         | <b>Dynamic Variable</b> | No        |
| <b>Permitted Values</b> | <b>Type</b>             | file name |

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the server. For the default replication channel, the default name is `host_name-relay-bin.index`. For non-default replication channels, the default name is `host_name-channel-relay-bin.index`, where `channel` is the name of the replication channel recorded in this relay log index.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay logs. You can override this behavior by specifying a different relay log file base name using the `--relay-log` option.

- `--relay-log-info-file=file_name`

|                            |                                              |                |
|----------------------------|----------------------------------------------|----------------|
| <b>Command-Line Format</b> | <code>--relay-log-info-file=file_name</code> |                |
| <b>Permitted Values</b>    | <b>Type</b>                                  | file name      |
|                            | <b>Default</b>                               | relay-log.info |

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see [Section 17.2.4.2, “Slave Status Logs”](#).

- `--relay-log-purge={0|1}`

|                            |                                |                 |
|----------------------------|--------------------------------|-----------------|
| <b>Command-Line Format</b> | <code>--relay_log_purge</code> |                 |
| <b>System Variable</b>     | <b>Name</b>                    | relay_log_purge |
|                            | <b>Variable Scope</b>          | Global          |
|                            | <b>Dynamic Variable</b>        | Yes             |
| <b>Permitted Values</b>    | <b>Type</b>                    | boolean         |
|                            | <b>Default</b>                 | TRUE            |

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`. Disabling purging of relay logs when using the `--relay-log-recovery` option risks data consistency and is therefore not crash-safe.

- `--relay-log-recovery={0|1}`

|                            |                                   |         |
|----------------------------|-----------------------------------|---------|
| <b>Command-Line Format</b> | <code>--relay-log-recovery</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean |
|                            | <b>Default</b>                    | FALSE   |

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the

I/O thread to the SQL thread position. Reading of the relay log from the master then continues. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

To provide a crash-proof slave, this option must be enabled (set to 1), `--relay-log-info-repository` must be set to `TABLE`, and `relay-log-purge` must be enabled. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency, and is therefore not crash-safe. See [Crash-safe replication](#), for more information.

When using a multi-threaded slave (in other words `slave_parallel_workers` is greater than 0), inconsistencies such as gaps can occur in the sequence of transactions that have been executed from the relay log. Enabling the `--relay-log-recovery` option when there are inconsistencies causes an error and the option has no effect. The solution in this situation is to issue `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`, which brings the server to a more consistent state, then issue `RESET SLAVE` to remove the relay logs. See [Section 17.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `--relay-log-space-limit=size`

|                                            |                                        |                                    |
|--------------------------------------------|----------------------------------------|------------------------------------|
| <b>Command-Line Format</b>                 | <code>--relay_log_space_limit=#</code> |                                    |
| <b>System Variable</b>                     | <b>Name</b>                            | <code>relay_log_space_limit</code> |
|                                            | <b>Variable Scope</b>                  | Global                             |
|                                            | <b>Dynamic Variable</b>                | No                                 |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                            | <code>integer</code>               |
|                                            | <b>Default</b>                         | 0                                  |
|                                            | <b>Min Value</b>                       | 0                                  |
|                                            | <b>Max Value</b>                       | 4294967295                         |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                            | <code>integer</code>               |
|                                            | <b>Default</b>                         | 0                                  |
|                                            | <b>Min Value</b>                       | 0                                  |
|                                            | <b>Max Value</b>                       | 18446744073709551615               |

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

|                            |                                     |                     |
|----------------------------|-------------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--replicate-do-db=name</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                         | <code>string</code> |

Creates a replication filter using the name of a database. In MySQL 5.7.3 and later, such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_DO_DB`. The precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
```

```
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

**Note**

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

|                            |                                         |        |
|----------------------------|-----------------------------------------|--------|
| <b>Command-Line Format</b> | <code>--replicate-ignore-db=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                             | string |

Creates a replication filter using the name of a database. In MySQL 5.7.3 and later, such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_IGNORE_DB`. As with `--replicate-do-db`, the precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

**Statement-based replication.** Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

**Note**

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

|                            |                                        |                     |
|----------------------------|----------------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--replicate-do-table=name</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                            | <code>string</code> |

Creates a replication filter by telling the slave SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_DO_TABLE` statement.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name`

|                            |                                            |                     |
|----------------------------|--------------------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--replicate-ignore-table=name</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                                | <code>string</code> |

Creates a replication filter by telling the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_IGNORE_TABLE` statement.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

|                            |                                                           |                     |
|----------------------------|-----------------------------------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--replicate-rewrite-db=old_name-&gt;new_name</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                                               | <code>string</code> |

Tells the slave to create a replication filter that translates the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB` statement.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.
3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

If you use this option on the command line and the “>” character is special to your command interpreter, quote the option value. For example:

```
shell> mysql --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

|                            |                                         |         |
|----------------------------|-----------------------------------------|---------|
| <b>Command-Line Format</b> | <code>--replicate-same-server-id</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                             | boolean |
|                            | <b>Default</b>                          | FALSE   |

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

|                            |                                             |        |
|----------------------------|---------------------------------------------|--------|
| <b>Command-Line Format</b> | <code>--replicate-wild-do-table=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                                 | string |

Creates a replication filter by telling the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the “%” and “\_” wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE` statement.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `mylownAABCdb` database, you should escape the “`_`” and “`%`” characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

|                            |                                                 |                     |
|----------------------------|-------------------------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--replicate-wild-ignore-table=name</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                                     | <code>string</code> |

Creates a replication filter which keeps the slave thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_IGNORE_TABLE` statement.

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

|                            |                                      |                          |
|----------------------------|--------------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--report-host=host_name</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                          | <code>report_host</code> |
|                            | <b>Variable Scope</b>                | Global                   |
|                            | <b>Dynamic Variable</b>              | No                       |
| <b>Permitted Values</b>    | <b>Type</b>                          | <code>string</code>      |

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master.

**Note**

It is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

|                            |                                     |                              |
|----------------------------|-------------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--report-password=name</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                         | <code>report_password</code> |
|                            | <b>Variable Scope</b>               | Global                       |
|                            | <b>Dynamic Variable</b>             | No                           |
| <b>Permitted Values</b>    | <b>Type</b>                         | <code>string</code>          |

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num`

|                            |                              |                           |
|----------------------------|------------------------------|---------------------------|
| <b>Command-Line Format</b> | <code>--report-port=#</code> |                           |
| <b>System Variable</b>     | <b>Name</b>                  | <code>report_port</code>  |
|                            | <b>Variable Scope</b>        | Global                    |
|                            | <b>Dynamic Variable</b>      | No                        |
| <b>Permitted Values</b>    | <b>Type</b>                  | <code>integer</code>      |
|                            | <b>Default</b>               | <code>[slave_port]</code> |
|                            | <b>Min Value</b>             | 0                         |
|                            | <b>Max Value</b>             | 65535                     |

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

The default value for this option is the port number actually used by the slave (Bug #13333431). This is also the default value displayed by `SHOW SLAVE HOSTS`.

- `--report-user=user_name`

|                            |                                 |                          |
|----------------------------|---------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--report-user=name</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                     | <code>report_user</code> |
|                            | <b>Variable Scope</b>           | Global                   |

|                         |                         |        |
|-------------------------|-------------------------|--------|
|                         | <b>Dynamic Variable</b> | No     |
| <b>Permitted Values</b> | <b>Type</b>             | string |

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--show-slave-auth-info`

|                            |                                     |         |
|----------------------------|-------------------------------------|---------|
| <b>Command-Line Format</b> | <code>--show-slave-auth-info</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                         | boolean |
|                            | <b>Default</b>                      | FALSE   |

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--slave-checkpoint-group=#`

|                            |                                         |         |
|----------------------------|-----------------------------------------|---------|
| <b>Command-Line Format</b> | <code>--slave-checkpoint-group=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer |
|                            | <b>Default</b>                          | 512     |
|                            | <b>Min Value</b>                        | 32      |
|                            | <b>Max Value</b>                        | 524280  |
|                            | <b>Block Size</b>                       | 8       |

Sets the maximum number of transactions that can be processed by a multi-threaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multi-threading is not enabled.

This option works in combination with the `--slave-checkpoint-period` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception*: No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `--slave-checkpoint-period=#`

|                            |                                          |         |
|----------------------------|------------------------------------------|---------|
| <b>Command-Line Format</b> | <code>--slave-checkpoint-period=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer |
|                            | <b>Default</b>                           | 300     |
|                            | <b>Min Value</b>                         | 1       |
|                            | <b>Value</b>                             | 2461    |

|  |                  |    |
|--|------------------|----|
|  | <b>Max Value</b> | 4G |
|--|------------------|----|

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multi-threaded slave as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multi-threading is not enabled.

This option works in combination with the `--slave-checkpoint-group` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `--slave-parallel-workers`

|                            |                                         |                      |
|----------------------------|-----------------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--slave-parallel-workers=#</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                             | <code>integer</code> |
|                            | <b>Default</b>                          | 0                    |
|                            | <b>Min Value</b>                        | 0                    |
|                            | <b>Max Value</b>                        | 1024                 |

Sets the number of slave applier threads for executing replication transactions in parallel. When set to 0 (the default) parallel execution is disabled and the slave uses a single applier thread. Setting this variable to a number greater than 0 creates a multi-threaded slave with this number of applier threads. When the slave is multi-threaded and parallel execution is enabled, there is one coordinator thread and multiple applier threads. The way which transactions are distributed among threads is configured by `slave_parallel_type`. For more information see `slave-parallel-workers`.

- `--slave-pending-jobs-size-max=#`

|                            |                                              |                      |
|----------------------------|----------------------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--slave-pending-jobs-size-max=#</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                                  | <code>integer</code> |
|                            | <b>Default</b>                               | 16M                  |
|                            | <b>Min Value</b>                             | 1024                 |
|                            | <b>Max Value</b>                             | 18EB                 |
|                            | <b>Block Size</b>                            | 1024                 |

For multi-threaded slaves, this option sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this option has no effect on slaves for which multi-threading is not enabled.

The minimum possible value for this option is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

### Important

The value for this option must not be less than the master's value for `max_allowed_packet`; otherwise a slave worker queue may become full while there remain events coming from the master to be processed.

- `--skip-slave-start`

|                            |                                 |                      |
|----------------------------|---------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--skip-slave-start</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                     | <code>boolean</code> |
|                            | <b>Default</b>                  | <code>FALSE</code>   |

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

|                            |                                          |                                        |
|----------------------------|------------------------------------------|----------------------------------------|
| <b>Command-Line Format</b> | <code>--slave_compressed_protocol</code> |                                        |
| <b>System Variable</b>     | <b>Name</b>                              | <code>slave_compressed_protocol</code> |
|                            | <b>Variable Scope</b>                    | Global                                 |
|                            | <b>Dynamic Variable</b>                  | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                              | <code>boolean</code>                   |
|                            | <b>Default</b>                           | <code>OFF</code>                       |

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=dir_name`

|                            |                                           |                                |
|----------------------------|-------------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-load-tmpdir=dir_name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                               | <code>slave_load_tmpdir</code> |
|                            | <b>Variable Scope</b>                     | Global                         |
|                            | <b>Dynamic Variable</b>                   | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                               | <code>directory name</code>    |
|                            | <b>Default</b>                            | <code>/tmp</code>              |

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `slave-max-allowed-packet=bytes`

|                            |                                           |                         |
|----------------------------|-------------------------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--slave-max-allowed-packet=#</code> |                         |
| <b>Permitted Values</b>    | <b>Type</b>                               | <code>integer</code>    |
|                            | <b>Default</b>                            | <code>1073741824</code> |
|                            | <b>Min Value</b>                          | <code>1024</code>       |
|                            | <b>Max Value</b>                          | <code>1073741824</code> |

This option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. (Bug #12400221, Bug #60926)

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--slave-net-timeout=seconds`

|                                       |                                    |                                |
|---------------------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b>            | <code>--slave-net-timeout=#</code> |                                |
| <b>System Variable</b>                | <b>Name</b>                        | <code>slave_net_timeout</code> |
|                                       | <b>Variable Scope</b>              | Global                         |
|                                       | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b>               | <b>Type</b>                        | <code>integer</code>           |
|                                       | <b>Default</b>                     | <code>3600</code>              |
|                                       | <b>Min Value</b>                   | <code>1</code>                 |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                        | <code>integer</code>           |
|                                       | <b>Default</b>                     | <code>60</code>                |
|                                       | <b>Min Value</b>                   | <code>1</code>                 |

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. Prior to MySQL 5.7.7, the default was 3600 seconds (one hour). In MySQL 5.7.7 and later the default is 60 (one minute).

- `--slave-parallel-type=type`

|                            |                                         |                          |
|----------------------------|-----------------------------------------|--------------------------|
| <b>Introduced</b>          | 5.7.2                                   |                          |
| <b>Command-Line Format</b> | <code>--slave-parallel-type=type</code> |                          |
| <b>Permitted Values</b>    | <b>Type</b>                             | <code>enumeration</code> |
|                            | <b>Default</b>                          | <code>DATABASE</code>    |

|  |                     |               |
|--|---------------------|---------------|
|  | <b>Valid Values</b> | DATABASE      |
|  |                     | LOGICAL_CLOCK |

When using a multi-threaded slave (`slave_parallel_workers` is greater than 0), this option specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. The possible values are:

- **DATABASE**: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and concurrently on the master. Only recommended if there are no cross-database constraints, as such constraints may be violated on the slave.
- **LOGICAL\_CLOCK**: Transactions that are part of the same binary log group commit on a master are applied in parallel on a slave. There are no cross-database constraints, and data does not need to be partitioned into multiple databases.

Regardless of the value of this variable, there is no special configuration required on the master. When `slave_preserve_commit_order=1`, you can only use **LOGICAL\_CLOCK**. If your replication topology uses multiple levels of slaves, **LOGICAL\_CLOCK** may achieve less parallelization for each level the slave is away from the master.

- `slave-rows-search-algorithms=list`

|                            |                                                                         |                        |
|----------------------------|-------------------------------------------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--slave-rows-search-algorithms=list</code>                        |                        |
| <b>Permitted Values</b>    | <b>Type</b>                                                             | set                    |
|                            | <b>Default</b>                                                          | TABLE_SCAN, INDEX_SCAN |
|                            | <b>Valid Values</b>                                                     | TABLE_SCAN, INDEX_SCAN |
|                            |                                                                         | INDEX_SCAN, HASH_SCAN  |
|                            |                                                                         | TABLE_SCAN, HASH_SCAN  |
|                            | TABLE_SCAN, INDEX_SCAN, HASH_SCAN (equivalent to INDEX_SCAN, HASH_SCAN) |                        |

When preparing batches of rows for row-based logging and replication, this option controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, some other key, or no key at all. This option takes a comma-separated list of any 2 (or possibly 3) values from the list **INDEX\_SCAN**, **TABLE\_SCAN**, **HASH\_SCAN**. The list need not be quoted, but must contain no spaces, whether or not quotes are used. Possible combinations (lists) and their effects are shown in the following table:

| <b>Index used / option value</b> | <b>INDEX_SCAN, HASH_SCAN</b> | <b>INDEX_SCAN, TABLE_SCAN</b> | <b>TABLE_SCAN, HASH_SCAN</b> |
|----------------------------------|------------------------------|-------------------------------|------------------------------|
| <i>Primary key or unique key</i> | Index scan                   | Index scan                    | Hash scan over index         |
| <i>(Other) Key</i>               | Hash scan over index         | Index scan                    | Hash scan over index         |
| <i>No index</i>                  | Hash scan                    | Table scan                    | Hash scan                    |

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously). The default value is **TABLE\_SCAN, INDEX\_SCAN**, which means that all searches that can use indexes do use them, and searches without any indexes use table scans.

Specifying **INDEX\_SCAN, TABLE\_SCAN, HASH\_SCAN** has the same effect as specifying **INDEX\_SCAN, HASH\_SCAN**. To use hashing for any searches that does not use a primary or

unique key, set this option to `INDEX_SCAN, HASH_SCAN`. To force hashing for *all* searches, set it to `TABLE_SCAN, HASH_SCAN`.

**Note**

There is only a performance advantage for `INDEX_SCAN` and `HASH_SCAN` if the row events are big enough. The size of row events is configured using `--binlog-row-event-max-size`. For example, suppose a `DELETE` statement which deletes 25,000 rows generates large `Delete_row_event` events. In this case if `slave_rows_search_algorithms` is set to `INDEX_SCAN` or `HASH_SCAN` there is a performance improvement. However, if there are 25,000 `DELETE` statements and each is represented by a separate event then setting `slave_rows_search_algorithms` to `INDEX_SCAN` or `HASH_SCAN` provides no performance improvement while executing these separate events.

- `--slave-skip-errors=[err_code1,err_code2,...|all|ddl_exist_errors]`

|                            |                                       |                                |
|----------------------------|---------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-skip-errors=name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                           | <code>slave_skip_errors</code> |
|                            | <b>Variable Scope</b>                 | Global                         |
|                            | <b>Dynamic Variable</b>               | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                           | string                         |
|                            | <b>Default</b>                        | OFF                            |
|                            | <b>Valid Values</b>                   | OFF                            |
|                            |                                       | [list of error codes]<br>all   |
| <b>Permitted Values</b>    | <b>Type</b>                           | string                         |
|                            | <b>Default</b>                        | OFF                            |
|                            | <b>Valid Values</b>                   | OFF                            |
|                            |                                       | [list of error codes]<br>all   |
|                            |                                       | ddl_exist_errors               |
| <b>Permitted Values</b>    | <b>Type</b>                           | string                         |
|                            | <b>Default</b>                        | OFF                            |
|                            | <b>Valid Values</b>                   | OFF                            |
|                            |                                       | [list of error codes]<br>all   |
|                            |                                       | ddl_exist_errors               |

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This option causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. [Appendix B, Errors, Error Codes, and Common Problems](#), lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

MySQL 5.7 supports an additional shorthand value `ddl_exist_errors`, which is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

- `--slave-sql-verify-checksum={0|1}`

|                            |                                                |                                  |
|----------------------------|------------------------------------------------|----------------------------------|
| <b>Command-Line Format</b> | <code>--slave-sql-verify-checksum=value</code> |                                  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | <code>boolean</code>             |
|                            | <b>Default</b>                                 | <code>0</code>                   |
|                            | <b>Valid Values</b>                            | <code>0</code><br><code>1</code> |

When this option is enabled, the slave examines checksums read from the relay log, in the event of a mismatch, the slave stops with an error. Disabled by default.

The following options are used internally by the MySQL test suite for replication testing and debugging. They are not intended for use in a production setting.

- `--abort-slave-event-count`

|                            |                                          |                      |
|----------------------------|------------------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--abort-slave-event-count=#</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                              | <code>integer</code> |
|                            | <b>Default</b>                           | <code>0</code>       |
|                            | <b>Min Value</b>                         | <code>0</code>       |

When this option is set to some positive integer `value` other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, `value` log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

- `--disconnect-slave-event-count`

|                            |                                               |                      |
|----------------------------|-----------------------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--disconnect-slave-event-count=#</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                                   | <code>integer</code> |
|                            | <b>Default</b>                                | <code>0</code>       |

## Options for Logging Slave Status to Tables

MySQL 5.7 supports logging of replication slave status information to tables rather than files. Writing of the master info log and the relay log info log can be configured separately using the two server options listed here:

- `--master-info-repository={FILE|TABLE}`

|                            |                                                  |               |
|----------------------------|--------------------------------------------------|---------------|
| <b>Command-Line Format</b> | <code>--master-info-repository=FILE TABLE</code> |               |
| <b>Permitted Values</b>    | <b>Type</b>                                      | string        |
|                            | <b>Default</b>                                   | FILE          |
|                            | <b>Valid Values</b>                              | FILE<br>TABLE |

This option causes the server to write its master info log to a file or a table. The name of the file defaults to `master.info`; you can change the name of the file using the `--master-info-file` server option.

The default value for this option is `FILE`. If you use `TABLE`, the log is written to the `slave_master_info` table in the `mysql` database.

- `--relay-log-info-repository={FILE|TABLE}`

|                            |                                                     |               |
|----------------------------|-----------------------------------------------------|---------------|
| <b>Command-Line Format</b> | <code>--relay-log-info-repository=FILE TABLE</code> |               |
| <b>Permitted Values</b>    | <b>Type</b>                                         | string        |
|                            | <b>Default</b>                                      | FILE          |
|                            | <b>Valid Values</b>                                 | FILE<br>TABLE |

This option causes the server to log its relay log info to a file or a table. The name of the file defaults to `relay-log.info`; you can change the name of the file using the `--relay-log-info-file` server option.

The default value for this option is `FILE`. If you use `TABLE`, the log is written to the `slave_relay_log_info` table in the `mysql` database.

For replication to be crash-safe, this option must be set to `TABLE`; in addition, the `--relay-log-recovery` option must be enabled. See [Crash-safe replication](#), for more information.

The info log tables and their contents are considered local to a given MySQL Server. They are not replicated, and changes to them are not written to the binary log.

For more information, see [Section 17.2.4, “Replication Relay and Status Logs”](#).

## System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `slave_allow_batching`

|                            |                                     |                                   |
|----------------------------|-------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--slave-allow-batching</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                         | <code>slave_allow_batching</code> |
|                            | <b>Variable Scope</b>               | Global                            |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | off     |

Whether or not batched updates are enabled on replication slaves.

- `init_slave`

|                            |                                |                         |
|----------------------------|--------------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--init-slave=name</code> |                         |
| <b>System Variable</b>     | <b>Name</b>                    | <code>init_slave</code> |
|                            | <b>Variable Scope</b>          | Global                  |
|                            | <b>Dynamic Variable</b>        | Yes                     |
| <b>Permitted Values</b>    | <b>Type</b>                    | string                  |

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable. The setting of this variable takes effect for subsequent `START SLAVE` statements.

#### Note

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 13.4.2.6, “START SLAVE Syntax”](#), for more information.

- `log_slow_slave_statements`

|                         |                         |                                        |
|-------------------------|-------------------------|----------------------------------------|
| <b>Introduced</b>       | 5.7.1                   |                                        |
| <b>System Variable</b>  | <b>Name</b>             | <code>log_slow_slave_statements</code> |
|                         | <b>Variable Scope</b>   | Global                                 |
|                         | <b>Dynamic Variable</b> | Yes                                    |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                |
|                         | <b>Default</b>          | OFF                                    |

When the slow query log is enabled, this variable enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave. This variable was added in MySQL 5.7.1. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

- `master_info_repository`

|                            |                                                  |                                     |
|----------------------------|--------------------------------------------------|-------------------------------------|
| <b>Command-Line Format</b> | <code>--master-info-repository=FILE TABLE</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>master_info_repository</code> |
|                            | <b>Variable Scope</b>                            | Global                              |
|                            | <b>Dynamic Variable</b>                          | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                                      | string                              |

|  |                     |               |
|--|---------------------|---------------|
|  | <b>Default</b>      | FILE          |
|  | <b>Valid Values</b> | FILE<br>TABLE |

The setting of this variable determines whether the slave logs master status and connection information to a [FILE](#) (`master.info`), or to a [TABLE](#) (`mysql.slave_master_info`). You can only change the value of this variable when no replication threads are executing.

The setting of this variable also has a direct influence on the effect had by the setting of the [sync\\_master\\_info](#) system variable; see that variable's description for further information.

This variable must be set to [TABLE](#) before configuring multiple replication channels. If you are using multiple replication channels then you cannot set this variable back to [FILE](#).

- [relay\\_log](#)

|                            |                                    |                        |
|----------------------------|------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--relay-log=file_name</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                        | <code>relay_log</code> |
|                            | <b>Variable Scope</b>              | Global                 |
|                            | <b>Dynamic Variable</b>            | No                     |
| <b>Permitted Values</b>    | <b>Type</b>                        | file name              |

The base name of the relay log file, with no paths and no file extension. By default `relay-log`. The file name of individual files for the default replication channel is `relay-log.XXXXXX`, and for additional replication channels is `relay-log-channel.XXXXXX`.

- [relay\\_log\\_basename](#)

|                         |                         |                                                      |
|-------------------------|-------------------------|------------------------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>relay_log_basename</code>                      |
|                         | <b>Variable Scope</b>   | Global                                               |
|                         | <b>Dynamic Variable</b> | No                                                   |
| <b>Permitted Values</b> | <b>Type</b>             | file name                                            |
|                         | <b>Default</b>          | <code>datadir + '/' + hostname + '-relay-bin'</code> |

Holds the name and complete path to the relay log file.

- [relay\\_log\\_index](#)

|                            |                                |                                          |
|----------------------------|--------------------------------|------------------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-index</code> |                                          |
| <b>System Variable</b>     | <b>Name</b>                    | <code>relay_log_index</code>             |
|                            | <b>Variable Scope</b>          | Global                                   |
|                            | <b>Dynamic Variable</b>        | No                                       |
| <b>Permitted Values</b>    | <b>Type</b>                    | file name                                |
|                            | <b>Default</b>                 | <code>*host_name*-relay-bin.index</code> |

The name of the relay log index file for the default replication channel. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `relay_log_info_file`

|                            |                                              |                                  |
|----------------------------|----------------------------------------------|----------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-info-file=file_name</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>relay_log_info_file</code> |
|                            | <b>Variable Scope</b>                        | Global                           |
|                            | <b>Dynamic Variable</b>                      | No                               |
| <b>Permitted Values</b>    | <b>Type</b>                                  | file name                        |
|                            | <b>Default</b>                               | <code>relay-log.info</code>      |

The name of the file in which the slave records information about the relay logs, when `relay_log_info_repository=FILE`. If `relay_log_info_repository=TABLE`, it is the file name that would be used in case the repository was changed to `FILE`). The default name is `relay-log.info` in the data directory.

- `relay_log_info_repository`

|                         |                         |                                         |
|-------------------------|-------------------------|-----------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>relay_log_info_repository</code>  |
|                         | <b>Variable Scope</b>   | Global                                  |
|                         | <b>Dynamic Variable</b> | Yes                                     |
| <b>Permitted Values</b> | <b>Type</b>             | string                                  |
|                         | <b>Default</b>          | <code>FILE</code>                       |
|                         | <b>Valid Values</b>     | <code>FILE</code><br><code>TABLE</code> |

This variable determines whether the slave's position in the relay logs is written to a `FILE` (`relay-log.info`) or to a `TABLE` (`mysql.slave_relay_log_info`). You can only change the value of this variable when no replication threads are executing.

The setting of this variable also has a direct influence on the effect had by the setting of the `sync_relay_log_info` system variable; see that variable's description for further information.

This variable must be set to `TABLE` before configuring multiple replication channels. If you are using multiple replication channels then you cannot set this variable back to `FILE`.

- `relay_log_recovery`

|                            |                                   |                                 |
|----------------------------|-----------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-recovery</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                       | <code>relay_log_recovery</code> |
|                            | <b>Variable Scope</b>             | Global                          |
|                            | <b>Dynamic Variable</b>           | No                              |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean                         |
|                            | <b>Default</b>                    | <code>FALSE</code>              |

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. In MySQL 5.7, this global variable is read-only; its value can be changed by starting the slave with the `--relay-log-recovery` option, which should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed, and must be used in order to guarantee a crash-proof slave. The default value is 0 (disabled).

This variable also interacts with `relay-log-purge`, which controls purging of logs when they are no longer needed. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency, and is therefore not crash-safe.

When `relay_log_recovery` is enabled and the slave has stopped due to errors encountered while running in multi-threaded mode, you can use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to ensure that all gaps are processed before switching back to single-threaded mode or executing a `CHANGE MASTER TO` statement.

- `rpl_stop_slave_timeout`

|                            |                                               |                                     |
|----------------------------|-----------------------------------------------|-------------------------------------|
| <b>Introduced</b>          | 5.7.2                                         |                                     |
| <b>Command-Line Format</b> | <code>--rpl-stop-slave-timeout=seconds</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                                   | <code>rpl_stop_slave_timeout</code> |
|                            | <b>Variable Scope</b>                         | Global                              |
|                            | <b>Dynamic Variable</b>                       | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                                   | <code>integer</code>                |
|                            | <b>Default</b>                                | <code>31536000</code>               |
|                            | <b>Min Value</b>                              | <code>2</code>                      |
|                            | <b>Max Value</b>                              | <code>31536000</code>               |

In MySQL 5.7.2 and later, you can control the length of time (in seconds) that `STOP SLAVE` waits before timing out by setting this variable. This can be used to avoid deadlocks between `STOP SLAVE` and other slave SQL statements using different client connections to the slave. The maximum and default value of `rpl_stop_slave_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent `STOP SLAVE` statements. This variable affects only the client that issues a `STOP SLAVE` statement. When the timeout is reached, the issuing client stops waiting for the slave threads to stop, but the slave threads continue to try to stop.

- `slave_checkpoint_group`

|                            |                                         |                                       |
|----------------------------|-----------------------------------------|---------------------------------------|
| <b>Command-Line Format</b> | <code>--slave-checkpoint-group=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                             | <code>slave_checkpoint_group=#</code> |
|                            | <b>Variable Scope</b>                   | Global                                |
|                            | <b>Dynamic Variable</b>                 | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                             | <code>integer</code>                  |
|                            | <b>Default</b>                          | <code>512</code>                      |

|  |                   |        |
|--|-------------------|--------|
|  | <b>Min Value</b>  | 32     |
|  | <b>Max Value</b>  | 524280 |
|  | <b>Block Size</b> | 8      |

Sets the maximum number of transactions that can be processed by a multi-threaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

This variable works in combination with the `slave_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception*: No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `slave_checkpoint_period`

|                            |                                          |                                        |
|----------------------------|------------------------------------------|----------------------------------------|
| <b>Command-Line Format</b> | <code>--slave-checkpoint-period=#</code> |                                        |
| <b>System Variable</b>     | <b>Name</b>                              | <code>slave_checkpoint_period=#</code> |
|                            | <b>Variable Scope</b>                    | Global                                 |
|                            | <b>Dynamic Variable</b>                  | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer                                |
|                            | <b>Default</b>                           | 300                                    |
|                            | <b>Min Value</b>                         | 1                                      |
|                            | <b>Max Value</b>                         | 4G                                     |

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multi-threaded slave as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable takes effect for all replication channels immediately, including running channels.

This variable works in combination with the `slave_checkpoint_group` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `slave_compressed_protocol`

|                            |                                          |                                        |
|----------------------------|------------------------------------------|----------------------------------------|
| <b>Command-Line Format</b> | <code>--slave_compressed_protocol</code> |                                        |
| <b>System Variable</b>     | <b>Name</b>                              | <code>slave_compressed_protocol</code> |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | OFF     |

Whether to use compression of the slave/master protocol if both the slave and the master support it. Changes to this variable take effect on subsequent connection attempts; this includes after issuing a `START SLAVE` statement, as well as reconnections made by a running I/O thread (for example after issuing a `CHANGE MASTER TO MASTER_RETRY_COUNT` statement).

- `slave_exec_mode`

|                            |                                     |                              |
|----------------------------|-------------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--slave-exec-mode=mode</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                         | <code>slave_exec_mode</code> |
|                            | <b>Variable Scope</b>               | Global                       |
|                            | <b>Dynamic Variable</b>             | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                         | enumeration                  |
|                            | <b>Default</b>                      | STRICT (ALL)                 |
|                            | <b>Default</b>                      | IDEMPOTENT (NDB)             |
|                            | <b>Valid Values</b>                 | IDEMPOTENT<br>STRICT         |

Controls how a slave thread resolves conflicts and errors during replication. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors. This mode should be employed in multi-master replication, circular replication, and some other special replication scenarios. `STRICT` mode is the default, and is suitable for most other cases. Setting this variable takes effect for all replication channels immediately, including running channels.

- `slave_load_tmpdir`

|                            |                                           |                                |
|----------------------------|-------------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-load-tmpdir=dir_name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                               | <code>slave_load_tmpdir</code> |
|                            | <b>Variable Scope</b>                     | Global                         |
|                            | <b>Dynamic Variable</b>                   | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                               | directory name                 |
|                            | <b>Default</b>                            | /tmp                           |

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements. Setting this variable takes effect for all replication channels immediately, including running channels.

- `slave_max_allowed_packet`

|                        |                       |                                       |
|------------------------|-----------------------|---------------------------------------|
| <b>System Variable</b> | <b>Name</b>           | <code>slave_max_allowed_packet</code> |
|                        | <b>Variable Scope</b> | Global                                |

|                         |                         |                      |
|-------------------------|-------------------------|----------------------|
|                         | <b>Dynamic Variable</b> | Yes                  |
| <b>Permitted Values</b> | <b>Type</b>             | <code>integer</code> |
|                         | <b>Default</b>          | 1073741824           |
|                         | <b>Min Value</b>        | 1024                 |
|                         | <b>Max Value</b>        | 1073741824           |

This variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. Setting this variable takes effect for all replication channels immediately, including running channels.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- `slave_net_timeout`

|                                       |                                    |                                |
|---------------------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b>            | <code>--slave-net-timeout=#</code> |                                |
| <b>System Variable</b>                | <b>Name</b>                        | <code>slave_net_timeout</code> |
|                                       | <b>Variable Scope</b>              | Global                         |
|                                       | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b>               | <b>Type</b>                        | <code>integer</code>           |
|                                       | <b>Default</b>                     | 3600                           |
|                                       | <b>Min Value</b>                   | 1                              |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                        | <code>integer</code>           |
|                                       | <b>Default</b>                     | 60                             |
|                                       | <b>Min Value</b>                   | 1                              |

The number of seconds to wait for more data from a master/slave connection before aborting the read. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

- `slave_parallel_type=type`

|                            |                                         |                          |
|----------------------------|-----------------------------------------|--------------------------|
| <b>Introduced</b>          | 5.7.2                                   |                          |
| <b>Command-Line Format</b> | <code>--slave-parallel-type=type</code> |                          |
| <b>Permitted Values</b>    | <b>Type</b>                             | <code>enumeration</code> |
|                            | <b>Default</b>                          | DATABASE                 |
|                            | <b>Valid Values</b>                     | DATABASE                 |

|  |  |               |
|--|--|---------------|
|  |  | LOGICAL_CLOCK |
|--|--|---------------|

When using a multi-threaded slave (`slave_parallel_workers` is greater than 0), this variable specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. See `--slave-parallel-type` for more information.

- `slave_parallel_workers`

|                            |                                         |                                     |
|----------------------------|-----------------------------------------|-------------------------------------|
| <b>Command-Line Format</b> | <code>--slave-parallel-workers=#</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                             | <code>slave_parallel_workers</code> |
|                            | <b>Variable Scope</b>                   | Global                              |
|                            | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                             |
|                            | <b>Default</b>                          | 0                                   |
|                            | <b>Min Value</b>                        | 0                                   |
|                            | <b>Max Value</b>                        | 1024                                |

Sets the number of slave applier threads for executing replication transactions in parallel. When set to 0 (the default) parallel execution is disabled and the slave uses a single applier thread. Setting this variable to a number greater than 0 creates a multi-threaded slave with this number of applier threads. When the slave is multi-threaded and parallel execution is enabled, there is one coordinator thread and multiple applier threads. The way which transactions are distributed among threads is configured by `slave_parallel_type`. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

The transaction that the slave applies in parallel may commit out of order, unless `slave_preserve_commit_order=1`. Therefore, checking for the most recently executed transaction does not guarantee that all previous transactions from the master have been executed on the slave. This has implications for logging and recovery when using a multi-threaded slave. For information about how to interpret binary logging information when using multi-threading on the slave, see [Section 13.7.5.34, “SHOW SLAVE STATUS Syntax”](#). In addition, this means that `START SLAVE UNTIL` is not supported by a multi-threaded slave.

As of MySQL 5.7.5, retrying of transactions is supported when multi-threading is enabled on a slave. In previous versions, `slave_transaction_retries` was treated as equal to 0 when using multi-threaded slaves.

- `slave_pending_jobs_size_max`

|                         |                         |                                          |
|-------------------------|-------------------------|------------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>slave_pending_jobs_size_max</code> |
|                         | <b>Variable Scope</b>   | Global                                   |
|                         | <b>Dynamic Variable</b> | Yes                                      |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                  |
|                         | <b>Default</b>          | 16M                                      |
|                         | <b>Min Value</b>        | 1024                                     |

|  |                   |      |
|--|-------------------|------|
|  | <b>Max Value</b>  | 18EB |
|  | <b>Block Size</b> | 1024 |

For multi-threaded slaves, this variable sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

The minimum possible value for this variable is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

### Important

The value of this variable must not be less than the master's value for `max_allowed_packet`; otherwise a slave worker queue may become full while there remain events coming from the master to be processed.

- `slave_preserve_commit_order`

|                            |                                                  |                                          |
|----------------------------|--------------------------------------------------|------------------------------------------|
| <b>Introduced</b>          | 5.7.5                                            |                                          |
| <b>Command-Line Format</b> | <code>--slave-preserve-commit-order=value</code> |                                          |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>slave_preserve_commit_order</code> |

|                            | <b>Dynamic Variable</b>                          | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                      | boolean                                  |
|                            | <b>Default</b>                                   | 0                                        |
|                            | <b>Valid Values</b>                              | 0<br>1                                   |

For multi-threaded slaves, enabling this variable ensures that transactions are externalized on the slave in the same order as they appear in the slave's relay log. Setting this variable has no effect on slaves for which multi-threading is not enabled. All replication threads (for all replication channels if you are using multiple replication channels) must be stopped before changing this variable. `--log-bin` and `--log-slave-updates` must be enabled on the slave. In addition `--slave-parallel-type` must be set to `LOGICAL_CLOCK`.

Once a multi-threaded slave has been started, transactions can begin to execute in parallel. With `slave_preserve_commit_order` enabled, the executing thread waits until all previous transactions are committed before committing. While the slave thread is waiting for other workers to commit their transactions it reports its status as `Waiting for preceding transaction to commit`. (Prior to MySQL 5.7.8, this was shown as `Waiting for its turn to commit`.) Enabling this mode on a multi-threaded slave ensures that it never enters a state that the master was not in. This makes it well suited to using replication for read scale-out. See [Section 17.3.3, "Using Replication for Scale-Out"](#).

When using a multi-threaded slave, if `slave_preserve_commit_order` is not enabled, there is a chance of gaps in the sequence of transactions that have been executed from the slave's relay log. When this option is enabled, there is not this chance of gaps, but `Exec_master_log_pos` may be behind the position up to which has been executed. See [Section 17.4.1.34, "Replication and Transaction Inconsistencies"](#) for more information.

- `slave_rows_search_algorithms`

|                                                                                                    |                         |                                                |

|                                                                                                    | <b>Dynamic Variable</b> | Yes                                            |
| <b>Permitted Values</b>                                                                            | <b>Type</b>             | <code>set</code>                               |
|                                                                                                    | <b>Default</b>          | <code>TABLE_SCAN, INDEX_SCAN</code>            |
|                                                                                                    | <b>Valid Values</b>     | <code>TABLE_SCAN, INDEX_SCAN</code>            |
|                                                                                                    |                         | <code>INDEX_SCAN, HASH_SCAN</code>             |
|                                                                                                    |                         | <code>TABLE_SCAN, HASH_SCAN</code>             |
| <code>TABLE_SCAN, INDEX_SCAN, HASH_SCAN</code> (equivalent to <code>INDEX_SCAN, HASH_SCAN</code> ) |                         |                                                |

When preparing batches of rows for row-based logging and replication, this variable controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, using some other key, or using no key at all. Setting this variable takes effect for all replication channels immediately, including running channels.

> This variable takes a comma-separated list of at least 2 values from the list `INDEX_SCAN`, `TABLE_SCAN`, `HASH_SCAN`. The value expected as a string, so the value must be quoted. In addition, the value must not contain any spaces. Possible combinations (lists) and their effects are shown in the following table:

| <b>Index used / option value</b> | <code>INDEX_SCAN, HASH_SCAN</code>             | <code>INDEX_SCAN, TABLE_SCAN</code> | <code>TABLE_SCAN, HASH_SCAN</code> |
|----------------------------------|------------------------------------------------|-------------------------------------|------------------------------------|
|                                  | <code>INDEX_SCAN, TABLE_SCAN, HASH_SCAN</code> |                                     |                                    |
| <i>Primary key or unique key</i> | Index scan                                     | index scan                          | Index hash                         |
| <i>(Other) Key</i>               | Index hash                                     | Index scan                          | Index hash                         |
| <i>No index</i>                  | Table hash                                     | Table scan                          | Table hash                         |

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement, as shown here:

```
mysql> SET GLOBAL slave_rows_search_algorithms = "INDEX_SCAN, TABLE_SCAN";
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE '%algorithms%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_rows_search_algorithms | TABLE_SCAN, INDEX_SCAN |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET GLOBAL slave_rows_search_algorithms = "TABLE_SCAN, INDEX_SCAN";
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE '%algorithms%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| slave_rows_search_algorithms | TABLE_SCAN, INDEX_SCAN |
+-----+-----+
1 row in set (0.00 sec)
```

The default value is `TABLE_SCAN, INDEX_SCAN`, which means that all searches that can use indexes do use them, and searches without any indexes use table scans.

Specifying `INDEX_SCAN, TABLE_SCAN, HASH_SCAN` has the same effect as specifying `INDEX_SCAN, HASH_SCAN`. To use hashing for any searches that does not use a primary or unique key, set this variable to `INDEX_SCAN, HASH_SCAN`. To force hashing for *all* searches, set it to `TABLE_SCAN, HASH_SCAN`.

- `slave_skip_errors`

|                            |                                       |                                |
|----------------------------|---------------------------------------|--------------------------------|

|                            | <b>Default</b>                        | OFF                            |
|                            | <b>Valid Values</b>                   | OFF                            |
|                            |                                       | [list of error codes]<br>all   |
| <b>Permitted Values</b>    | <b>Type</b>                           | string                         |
|                            | <b>Default</b>                        | OFF                            |
|                            | <b>Valid Values</b>                   | OFF                            |
|                            |                                       | [list of error codes]<br>all   |
|                            |                                       | ddl_exist_errors               |
| <b>Permitted Values</b>    | <b>Type</b>                           | string                         |
|                            | <b>Default</b>                        | OFF                            |
|                            | <b>Valid Values</b>                   | OFF                            |
|                            |                                       | [list of error codes]<br>all   |
|                            |                                       | ddl_exist_errors               |

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This variable causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value. The setting of this variable takes effect immediately, even for running replication threads.

- `slave_sql_verify_checksum`

|                         |                         |                                        |
|-------------------------|-------------------------|----------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>slave_sql_verify_checksum</code> |
|                         | <b>Variable Scope</b>   | Global                                 |
|                         | <b>Dynamic Variable</b> | Yes                                    |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                |
|                         | <b>Default</b>          | 1                                      |

|  |                     |   |
|--|---------------------|---|
|  | <b>Valid Values</b> | 0 |
|  |                     | 1 |

Cause the slave SQL thread to verify data using the checksums read from the relay log. In the event of a mismatch, the slave stops with an error. Setting this variable takes effect for all replication channels immediately, including running channels.

**Note**

The slave I/O thread always reads checksums if possible when accepting events from over the network.

- [slave\\_transaction\\_retries](#)

|                                            |                                            |                                        |

If a replication slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because the transaction's execution time exceeded `InnoDB`'s `innodb_lock_wait_timeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default value is 10. Setting this variable takes effect for all replication channels immediately, including running channels.

As of MySQL 5.7.5, retrying of transactions is supported when multi-threading is enabled on a slave. In previous versions, `slave_transaction_retries` was treated as equal to 0 when using multi-threaded slaves.

Controls the type conversion mode in effect on the slave when using row-based replication. In MySQL 5.7.2 and later, its value is a comma-delimited set of zero or more elements from the list: [ALL\\_LOSSY](#), [ALL\\_NON\\_LOSSY](#), [ALL\\_SIGNED](#), [ALL\\_UNSIGNED](#). Set this variable to an empty string to disallow type conversions between the master and the slave. Setting this variable takes effect for all replication channels immediately, including running channels.

[ALL\\_SIGNED](#) and [ALL\\_UNSIGNED](#) were added in MySQL 5.7.2 (Bug#15831300). For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

- [sql\\_slave\\_skip\\_counter](#)

|-------------------------|-------------------------|----------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">sql_slave_skip_counter</a> |
|                         | <b>Variable Scope</b>   | Global                                 |
|                         | <b>Dynamic Variable</b> | Yes                                    |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                |

The number of events from the master that a slave server should skip. Setting the option has no immediate effect. The variable applies to the next `START SLAVE` statement; the next `START SLAVE` statement also changes the value back to 0. When this variable is set to a non-zero value and there are multiple replication channels configured, the `START SLAVE` statement can only be used with the `FOR CHANNEL channel` clause.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when `--gtid-mode=ON`. In MySQL 5.7.1 and later, trying to do so is specifically disallowed. (Bug #15833516) If you need to skip transactions when employing GTIDs, use [gtid\\_executed](#) from the master instead. See [Injecting empty transactions](#), for information about how to do this.

#### Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see [Section 13.4.2.5, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

The effects of this variable on a replication slave depend on whether the slave's `master_info_repository` is set to `FILE` or `TABLE`, as explained in the following paragraphs.

**master\_info\_repository = FILE.** If the value of `sync_master_info` is greater than 0, the slave synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. If it is 0, the MySQL server performs no synchronization of the `master.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

**master\_info\_repository = TABLE.** If the value of `sync_master_info` is greater than 0, the slave updates its master info repository table after every `sync_master_info` events. If it is 0, the table is never updated.

The default value for `sync_master_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

- `sync_relay_log`

|                                            |                                 |                             |

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatasync()`) after every `sync_relay_log` events are written to the relay log. Setting this variable takes effect for all replication channels immediately, including running channels.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of a crash you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

|                                            |                                      |                                  |
|--------------------------------------------|--------------------------------------|----------------------------------|
| <b>Command-Line Format</b>                 | <code>--sync-relay-log-info=#</code> |                                  |

The effects of this variable on the slave depend on the server's `relay_log_info_repository` setting (`FILE` or `TABLE`), and if this is `TABLE`, additionally on whether the storage engine used by the relay log info table is transactional (such as `InnoDB`) or not (`MyISAM`). The effects of these factors on the behavior of the server for `sync_relay_log_info` values of zero and greater than zero are shown in the following table:

| <code>sync_relay_log_info</code> | <code>relay_log_info_repository</code>                                                                                                                                 |                                                                             |                                              |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|----------------------------------------------|
|                                  | <code>FILE</code>                                                                                                                                                      | <code>TABLE</code>                                                          |                                              |

| $N > 0$                          | The slave synchronizes its <code>relay-log.info</code> file to disk (using <code>fdatasync()</code> ) after every $N$ transactions.                                    | The table is updated after each transaction. ( $N$ is effectively ignored.) | The table is updated after every $N$ events. |
| 0                                | The MySQL server performs no synchronization of the <code>relay-log.info</code> file to disk; instead, the server relies on the operating system to flush its contents |                                                                             | The table is never updated.                  |

|                                  |                                        |                      |                         |
|----------------------------------|----------------------------------------|----------------------|-------------------------|
| <code>sync_relay_log_info</code> | <code>relay_log_info_repository</code> |                      |                         |
|                                  | <b>FILE</b>                            | <b>TABLE</b>         |                         |
|                                  |                                        | <b>Transactional</b> | <b>Nontransactional</b> |
|                                  | periodically as with any other file.   |                      |                         |

The default value for `sync_relay_log_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

### 17.1.6.4 Binary Logging Options and Variables

[Startup Options Used with Binary Logging](#)

[System Variables Used with Binary Logging](#)

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 5.2.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 5.1.3, “Server Command Options”](#), and [Section 5.1.4, “Server System Variables”](#).

#### Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

|                                            |                                            |                      |  |
|--------------------------------------------|--------------------------------------------|----------------------|--|
| <b>Command-Line Format</b>                 | <code>--binlog-row-event-max-size=#</code> |                      |  |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                                | <code>integer</code> |  |
|                                            | <b>Default</b>                             | 8192                 |  |
|                                            | <b>Min Value</b>                           | 256                  |  |
|                                            | <b>Max Value</b>                           | 4294967295           |  |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                                | <code>integer</code> |  |
|                                            | <b>Default</b>                             | 8192                 |  |
|                                            | <b>Min Value</b>                           | 256                  |  |
|                                            | <b>Max Value</b>                           | 18446744073709551615 |  |

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 8192. See [Section 17.2.1, “Replication Formats”](#).

- `--log-bin[=base_name]`

|                            |                         |                      |
|----------------------------|-------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--log-bin</code>  |                      |
| <b>System Variable</b>     | <b>Name</b>             | <code>log_bin</code> |
|                            | <b>Variable Scope</b>   | Global               |
|                            | <b>Dynamic Variable</b> | No                   |

|                         |             |                        |
|-------------------------|-------------|------------------------|
| <b>Permitted Values</b> | <b>Type</b> | <code>file_name</code> |
|-------------------------|-------------|------------------------|

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See [Section 5.2.4, “The Binary Log”](#).

The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see [Section B.5.7, “Known Issues in MySQL”](#), for the reason). Otherwise, MySQL uses `host_name-bin` as the base name.

When the server reads an entry from the index file, it checks whether the entry contains a relative path, and if it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. (In older versions of MySQL, manual intervention was required whenever relocating the binary log or relay log files.) (Bug #11745230, Bug #12133)

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the base name. The binary log file name (with path) is available as the `log_bin_basename` system variable.

In MySQL 5.7.3 and later, if you specify this option without also specifying a `--server-id` [\[2426\]](#), the server is not allowed to start. (Bug #11763963, Bug #56739)

- `--log-bin-index[=file_name]`

|                            |                                        |                        |
|----------------------------|----------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--log-bin-index=file_name</code> |                        |
| <b>Permitted Values</b>    | <b>Type</b>                            | <code>file_name</code> |

The index file for binary log file names. See [Section 5.2.4, “The Binary Log”](#). If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- `--log-bin-trust-function-creators[={0|1}]`

|                            |                                                |                                              |
|----------------------------|------------------------------------------------|----------------------------------------------|
| <b>Command-Line Format</b> | <code>--log-bin-trust-function-creators</code> |                                              |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>log_bin_trust_function_creators</code> |
|                            | <b>Variable Scope</b>                          | Global                                       |
|                            | <b>Dynamic Variable</b>                        | Yes                                          |
| <b>Permitted Values</b>    | <b>Type</b>                                    | <code>boolean</code>                         |
|                            | <b>Default</b>                                 | <code>FALSE</code>                           |

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 19.7, “Binary Logging of Stored Programs”](#).

- `--log-bin-use-v1-row-events[={0|1}]`

|                            |                                                  |                                        |
|----------------------------|--------------------------------------------------|----------------------------------------|
| <b>Command-Line Format</b> | <code>--log-bin-use-v1-row-events[={0 1}]</code> |                                        |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>log_bin_use_v1_row_events</code> |
|                            | <b>Variable Scope</b>                            | Global                                 |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | No      |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | 0       |

MySQL 5.7 uses Version 2 binary log row events, which cannot be read by MySQL Server releases prior to MySQL 5.6.6. Setting this option to 1 causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves. Setting `--log-bin-use-v1-row-events` to 0 (the default) causes `mysqld` to use Version 2 binary log events.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

**Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 17.1.6.3, “Replication Slave Options and Variables”](#).

- `--binlog-do-db=db_name`

|                            |                                  |        |
|----------------------------|----------------------------------|--------|
| <b>Command-Line Format</b> | <code>--binlog-do-db=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                      | string |

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

|                            |                                      |                     |
|----------------------------|--------------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--binlog-ignore-db=name</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                          | <code>string</code> |

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Prior to MySQL 5.7.2, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when `SELECT DATABASE()` returned `NULL`). In MySQL 5.7.2 and later, when there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Checksum options.** MySQL 5.7 supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- `--binlog-checksum={NONE|CRC32}`

|                            |                                     |               |
|----------------------------|-------------------------------------|---------------|
| <b>Command-Line Format</b> | <code>--binlog-checksum=type</code> |               |
| <b>Permitted Values</b>    | <b>Type</b>                         | string        |
|                            | <b>Default</b>                      | CRC32         |
|                            | <b>Valid Values</b>                 | NONE<br>CRC32 |

Enabling this option causes the master to write checksums for events written to the binary log. Set to `NONE` to disable, or the name of the algorithm to be used for generating checksums; currently, only CRC32 checksums are supported, and CRC32 is the default.

- `--master-verify-checksum={0|1}`

|                            |                                            |                      |
|----------------------------|--------------------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--master-verify-checksum=name</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                                | <code>boolean</code> |
|                            | <b>Default</b>                             | <code>OFF</code>     |

Enabling this option causes the master to verify events from the binary log using checksums, and to stop with an error in the event of a mismatch. Disabled by default.

To control reading of checksums by the slave (from the relay) log, use the `--slave-sql-verify-checksum` option.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

|                            |                                         |                      |
|----------------------------|-----------------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--max-binlog-dump-events=#</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                             | <code>integer</code> |
|                            | <b>Default</b>                          | <code>0</code>       |

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

|                            |                                          |                      |
|----------------------------|------------------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--sporadic-binlog-dump-fail</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                              | <code>boolean</code> |
|                            | <b>Default</b>                           | <code>FALSE</code>   |

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--binlog-rows-query-log-events`

|                            |                                             |                      |
|----------------------------|---------------------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--binlog-rows-query-log-events</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                                 | <code>boolean</code> |
|                            | <b>Default</b>                              | <code>FALSE</code>   |

This option enables `binlog_rows_query_log_events`.

## System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section. For information about the `sql_log_bin` and `sql_log_off` variables, see [Section 5.1.4, “Server System Variables”](#).

- `binlog_cache_size`

|                                            |                                    |                                |
|--------------------------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b>                 | <code>--binlog_cache_size=#</code> |                                |
| <b>System Variable</b>                     | <b>Name</b>                        | <code>binlog_cache_size</code> |
|                                            | <b>Variable Scope</b>              | Global                         |
|                                            | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values (32-bit platforms)</b> | <b>Type</b>                        | <code>integer</code>           |
|                                            | <b>Default</b>                     | <code>32768</code>             |

|                                            |                  |                      |
|--------------------------------------------|------------------|----------------------|
|                                            | <b>Min Value</b> | 4096                 |
|                                            | <b>Max Value</b> | 4294967295           |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>      | integer              |
|                                            | <b>Default</b>   | 32768                |
|                                            | <b>Min Value</b> | 4096                 |
|                                            | <b>Max Value</b> | 18446744073709551615 |

The size of the cache to hold changes to the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.2.4, “The Binary Log”](#).

`binlog_cache_size` sets the size for the transaction cache only; the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- `binlog_checksum`

|                         |                         |                              |
|-------------------------|-------------------------|------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>binlog_checksum</code> |
|                         | <b>Variable Scope</b>   | Global                       |
|                         | <b>Dynamic Variable</b> | Yes                          |
| <b>Permitted Values</b> | <b>Type</b>             | string                       |
|                         | <b>Default</b>          | CRC32                        |
|                         | <b>Valid Values</b>     | NONE                         |
|                         |                         | CRC32                        |

When enabled, this variable causes the master to write a checksum for each event in the binary log. `binlog_checksum` supports the values `NONE` (disabled) and `CRC32`. The default is `CRC32`.

When `binlog_checksum` is disabled (value `NONE`), the server verifies that it is writing only complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

Changing the value of this variable causes the binary log to be rotated; checksums are always written to an entire binary log file, and never to only part of one.

Setting this variable on the master to a value unrecognized by the slave causes the slave to set its own `binlog_checksum` value to `NONE`, and to stop replication with an error. (Bug #13553750, Bug #61096) If backward compatibility with older slaves is a concern, you may want to set the value explicitly to `NONE`.

- `binlog_direct_non_transactional_updates`

|                            |                                                                |                                                      |
|----------------------------|----------------------------------------------------------------|------------------------------------------------------|
| <b>Command-Line Format</b> | <code>--binlog_direct_non_transactional_updates[=value]</code> |                                                      |
| <b>System Variable</b>     | <b>Name</b>                                                    | <code>binlog_direct_non_transactional_updates</code> |
|                            | <b>Variable Scope</b>                                          | Global, Session                                      |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | OFF     |

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

*`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.*

#### Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

In MySQL 5.7, this variable has no effect when the binary log format is `ROW` or `MIXED`. (Bug #51291)

- `binlog_error_action`

|                                       |                                            |                                                        |
|---------------------------------------|--------------------------------------------|--------------------------------------------------------|
| <b>Introduced</b>                     | 5.7.6                                      |                                                        |
| <b>Command-Line Format</b>            | <code>--binlog_error_action[=value]</code> |                                                        |
| <b>System Variable</b>                | <b>Name</b>                                | <code>binlog_error_action</code>                       |
|                                       | <b>Variable Scope</b>                      | Global, Session                                        |
|                                       | <b>Dynamic Variable</b>                    | Yes                                                    |
| <b>Permitted Values</b>               | <b>Type</b>                                | enumeration                                            |
|                                       | <b>Default</b>                             | <code>IGNORE_ERROR</code>                              |
|                                       | <b>Valid Values</b>                        | <code>IGNORE_ERROR</code><br><code>ABORT_SERVER</code> |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                                | enumeration                                            |
|                                       | <b>Default</b>                             | <code>ABORT_SERVER</code>                              |
|                                       | <b>Valid Values</b>                        | <code>IGNORE_ERROR</code><br><code>ABORT_SERVER</code> |

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the master's log to become inconsistent and replication slaves to lose synchronization.

In MySQL 5.7.7 and later, this variable defaults to `ABORT_SERVER`, which makes the server halt logging and shut down whenever it encounters such an error with the binary log. Upon server restart, all of the previously prepared and binary logged transactions are committed, while any transactions which were prepared but not binary logged due to the error are aborted.

When `binlog_error_action` is set to `IGNORE_ERROR`, if the server encounters such an error it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again. This provides backward compatibility with older versions of MySQL.

In previous releases this variable was named `binlogging_impossible_mode`.

- `binlog_format`

|                                       |                                     |                            |
|---------------------------------------|-------------------------------------|----------------------------|
| <b>Command-Line Format</b>            | <code>--binlog-format=format</code> |                            |
| <b>System Variable</b>                | <b>Name</b>                         | <code>binlog_format</code> |
|                                       | <b>Variable Scope</b>               | Global, Session            |
|                                       | <b>Dynamic Variable</b>             | Yes                        |
| <b>Permitted Values (&lt;= 5.7.6)</b> | <b>Type</b>                         | enumeration                |
|                                       | <b>Default</b>                      | <code>STATEMENT</code>     |
|                                       | <b>Valid Values</b>                 | <code>ROW</code>           |
|                                       |                                     | <code>STATEMENT</code>     |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                         | enumeration                |
|                                       | <b>Default</b>                      | <code>ROW</code>           |
|                                       | <b>Valid Values</b>                 | <code>ROW</code>           |
|                                       |                                     | <code>STATEMENT</code>     |
|                                       |                                     | <code>MIXED</code>         |

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See [Section 17.2.1, “Replication Formats”](#). `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

#### Note

While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's `binlog_format` setting; a given MySQL Server can change only its own logging format.

Prior to MySQL 5.7.7, the default format was `STATEMENT`. In MySQL 5.7.7 and later the default is `ROW`.

You must have the `SUPER` privilege to set either the global or session `binlog_format` value.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. See [Section 13.7.4, “SET Syntax”](#), for more information.

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the session is currently in row-based replication mode and has open temporary tables.
- From within a transaction.

Trying to switch the format in those cases results in an error.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `binlog_group_commit_sync_delay`

|                            |                                                 |                                             |
|----------------------------|-------------------------------------------------|---------------------------------------------|
| <b>Introduced</b>          | 5.7.5                                           |                                             |
| <b>Command-Line Format</b> | <code>--binlog-group-commit-sync-delay=#</code> |                                             |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>binlog_group_commit_sync_delay</code> |
|                            | <b>Variable Scope</b>                           | Global                                      |
|                            | <b>Dynamic Variable</b>                         | Yes                                         |
| <b>Permitted Values</b>    | <b>Type</b>                                     | <code>integer</code>                        |
|                            | <b>Default</b>                                  | 0                                           |
|                            | <b>Min Value</b>                                | 0                                           |
|                            | <b>Max Value</b>                                | 1000000                                     |

Controls how many microseconds the binary log commit waits before synchronizing the binary log file to disk. By default `binlog_group_commit_sync_delay` is set to 0, meaning that there is no delay. Setting `binlog_group_commit_sync_delay` to a microsecond delay enables more transactions to be synchronized together to disk at once, reducing the overall time to commit a group of transactions because the larger groups require fewer time units per group. With the correct tuning, this can increase slave performance without compromising the master's throughput.

- `binlog_group_commit_sync_no_delay_count`

|                            |                                                          |                                                      |
|----------------------------|----------------------------------------------------------|------------------------------------------------------|
| <b>Introduced</b>          | 5.7.5                                                    |                                                      |
| <b>Command-Line Format</b> | <code>--binlog-group-commit-sync-no-delay-count=#</code> |                                                      |
| <b>System Variable</b>     | <b>Name</b>                                              | <code>binlog_group_commit_sync_no_delay_count</code> |

|                         |                         |                      |
|-------------------------|-------------------------|----------------------|
|                         | <b>Variable Scope</b>   | Global               |
|                         | <b>Dynamic Variable</b> | Yes                  |
| <b>Permitted Values</b> | <b>Type</b>             | <code>integer</code> |
|                         | <b>Default</b>          | 0                    |
|                         | <b>Min Value</b>        | 0                    |
|                         | <b>Max Value</b>        | 1000000              |

The maximum number of transactions to wait for before aborting the current delay as specified by `binlog-group-commit-sync-delay`. If `binlog-group-commit-sync-delay` is set to 0, then this option has no effect.

- `binlogging_impossible_mode`

|                            |                                                   |                                         |
|----------------------------|---------------------------------------------------|-----------------------------------------|
| <b>Introduced</b>          | 5.7.5                                             |                                         |
| <b>Deprecated</b>          | 5.7.6                                             |                                         |
| <b>Command-Line Format</b> | <code>--binlogging_impossible_mode[=value]</code> |                                         |
| <b>System Variable</b>     | <b>Name</b>                                       | <code>binlogging_impossible_mode</code> |
|                            | <b>Variable Scope</b>                             | Global, Session                         |
|                            | <b>Dynamic Variable</b>                           | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                       | <code>enumeration</code>                |
|                            | <b>Default</b>                                    | <code>IGNORE_ERROR</code>               |
|                            | <b>Valid Values</b>                               | <code>IGNORE_ERROR</code>               |
|                            |                                                   | <code>ABORT_SERVER</code>               |

This option is deprecated and will be removed in a future MySQL release. Use the renamed `binlog_error_action` to control what happens when the server cannot write to the binary log.

- `binlog_max_flush_queue_time`

|                         |                         |                                          |
|-------------------------|-------------------------|------------------------------------------|
| <b>Deprecated</b>       | 5.7.9                   |                                          |
| <b>System Variable</b>  | <b>Name</b>             | <code>binlog_max_flush_queue_time</code> |
|                         | <b>Variable Scope</b>   | Global                                   |
|                         | <b>Dynamic Variable</b> | Yes                                      |
| <b>Permitted Values</b> | <b>Type</b>             | <code>integer</code>                     |
|                         | <b>Default</b>          | 0                                        |
|                         | <b>Min Value</b>        | 0                                        |
|                         | <b>Max Value</b>        | 100000                                   |

Formerly, this controlled the time in microseconds to continue reading transactions from the flush queue before proceeding with group commit. In MySQL 5.7, this variable no longer has any effect.

`binlog_max_flush_queue_time` is deprecated as of MySQL 5.7.9, and is marked for eventual removal in a future MySQL release.

- `binlog_order_commits`

|                         |                         |                                   |
|-------------------------|-------------------------|-----------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>binlog_order_commits</code> |
|                         | <b>Variable Scope</b>   | Global                            |
|                         | <b>Dynamic Variable</b> | Yes                               |
| <b>Permitted Values</b> | <b>Type</b>             | <code>boolean</code>              |
|                         | <b>Default</b>          | <code>ON</code>                   |

When this variable is enabled on a master (the default), transactions are externalized in the same order as they are written to the binary log. If disabled, transactions may be committed in parallel. In some cases, disabling this variable might produce a performance increment.

- `binlog_row_image`

|                            |                                                                                  |                                                                                      |
|----------------------------|----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| <b>Command-Line Format</b> | <code>--binlog-row-image=image_type</code>                                       |                                                                                      |
| <b>System Variable</b>     | <b>Name</b>                                                                      | <code>binlog_row_image=image_type</code>                                             |
|                            | <b>Variable Scope</b>                                                            | Global, Session                                                                      |
|                            | <b>Dynamic Variable</b>                                                          | Yes                                                                                  |
| <b>Permitted Values</b>    | <b>Type</b>                                                                      | <code>enumeration</code>                                                             |
|                            | <b>Default</b>                                                                   | <code>full</code>                                                                    |
|                            | <b>Valid Values</b>                                                              | <code>full</code> (Log all columns)                                                  |
|                            |                                                                                  | <code>minimal</code> (Log only changed columns, and columns needed to identify rows) |
|                            | <code>noblob</code> (Log all columns, except for unneeded BLOB and TEXT columns) |                                                                                      |

In MySQL row-based replication, each row change event contains two images, a “before” image whose columns are matched against when searching for the row to be updated, and an “after” image containing the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

**Note**

When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are `NOT NULL`, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any `NULL` columns, then all columns must be used in

the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

You can cause the server to log full or minimal rows using the `binlog_row_image` system variable. This variable actually takes one of three possible values, as shown in the following list:

- `full`: Log all columns in both the before image and the after image.
- `minimal`: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image that are actually changed.
- `noblob`: Log all columns (same as `full`), except for `BLOB` and `TEXT` columns that are not required to identify rows, or that have not changed.

The default value is `full`.

In MySQL 5.5 and earlier, full row images are always used for both before images and after images. If you need to replicate from a newer master to a slave running MySQL 5.5 or earlier, the master should always use this value.

When using `minimal` or `noblob`, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.
- The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables' primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the master and slave silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is `STATEMENT`. When `binlog_format` is `MIXED`, the setting for `binlog_row_image` is applied to changes that are logged using row-based format, but this setting no effect on changes logged as statements.

Setting `binlog_row_image` on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

- `binlog_rows_query_log_events`

|                         |                         |                                           |
|-------------------------|-------------------------|-------------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>binlog_rows_query_log_events</code> |
|                         | <b>Variable Scope</b>   | Global, Session                           |
|                         | <b>Dynamic Variable</b> | Yes                                       |
| <b>Permitted Values</b> | <b>Type</b>             | <code>boolean</code>                      |
|                         | <b>Default</b>          | <code>FALSE</code>                        |

The `binlog_rows_query_log_events` system variable affects row-based logging only. When enabled, it causes the MySQL Server to write informational log events such as row query log events into its binary log. This information can be used for debugging and related purposes; such as obtaining the original query issued on the master when it cannot be reconstructed from the row updates.

These events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup.

- `binlog_stmt_cache_size`

|                                            |                                         |                                     |
|--------------------------------------------|-----------------------------------------|-------------------------------------|
| <b>Command-Line Format</b>                 | <code>--binlog_stmt_cache_size=#</code> |                                     |
| <b>System Variable</b>                     | <b>Name</b>                             | <code>binlog_stmt_cache_size</code> |
|                                            | <b>Variable Scope</b>                   | Global                              |
|                                            | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                             | <code>integer</code>                |
|                                            | <b>Default</b>                          | <code>32768</code>                  |
|                                            | <b>Min Value</b>                        | <code>4096</code>                   |
|                                            | <b>Max Value</b>                        | <code>4294967295</code>             |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                             | <code>integer</code>                |
|                                            | <b>Default</b>                          | <code>32768</code>                  |
|                                            | <b>Min Value</b>                        | <code>4096</code>                   |
|                                            | <b>Max Value</b>                        | <code>18446744073709551615</code>   |

This variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. Separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.2.4, “The Binary Log”](#).

The `binlog_cache_size` system variable sets the size for the transaction cache.

- `log_bin`

|                        |                         |                      |
|------------------------|-------------------------|----------------------|
| <b>System Variable</b> | <b>Name</b>             | <code>log_bin</code> |
|                        | <b>Variable Scope</b>   | Global               |
|                        | <b>Dynamic Variable</b> | No                   |

Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is `ON`; otherwise it is `OFF`. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

See [Section 5.2.4, “The Binary Log”](#).

- `log_bin_basename`

|                        |                       |                               |
|------------------------|-----------------------|-------------------------------|
| <b>System Variable</b> | <b>Name</b>           | <code>log_bin_basename</code> |
|                        | <b>Variable Scope</b> | Global                        |

|                         |                         |                                   |
|-------------------------|-------------------------|-----------------------------------|
|                         | <b>Dynamic Variable</b> | No                                |
| <b>Permitted Values</b> | <b>Type</b>             | file name                         |
|                         | <b>Default</b>          | datadir + '/' + hostname + '-bin' |

Holds the name and complete path to the binary log file. Unlike the `log_bin` system variable, `log_bin_basename` reflects the name set with the `--log-bin` server option.

- `log_bin_index`

|                         |                         |                            |
|-------------------------|-------------------------|----------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>log_bin_index</code> |
|                         | <b>Variable Scope</b>   | Global                     |
|                         | <b>Dynamic Variable</b> | No                         |
| <b>Permitted Values</b> | <b>Type</b>             | file name                  |

The index file for binary log file names.

- `log_bin_use_v1_row_events`

|                            |                                                  |                                        |
|----------------------------|--------------------------------------------------|----------------------------------------|
| <b>Command-Line Format</b> | <code>--log-bin-use-v1-row-events[={0 1}]</code> |                                        |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>log_bin_use_v1_row_events</code> |
|                            | <b>Variable Scope</b>                            | Global                                 |
|                            | <b>Dynamic Variable</b>                          | No                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                      | boolean                                |
|                            | <b>Default</b>                                   | 0                                      |

Shows whether Version 2 binary logging is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

- `log_slave_updates`

|                            |                                  |                                |
|----------------------------|----------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--log-slave-updates</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                      | <code>log_slave_updates</code> |
|                            | <b>Variable Scope</b>            | Global                         |
|                            | <b>Dynamic Variable</b>          | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                      | boolean                        |
|                            | <b>Default</b>                   | FALSE                          |

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See [Section 17.1.6, "Replication and Binary Logging Options and Variables"](#).

- [master\\_verify\\_checksum](#)

|                         |                         |                                        |
|-------------------------|-------------------------|----------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">master_verify_checksum</a> |
|                         | <b>Variable Scope</b>   | Global                                 |
|                         | <b>Dynamic Variable</b> | Yes                                    |
| <b>Permitted Values</b> | <b>Type</b>             | <a href="#">boolean</a>                |
|                         | <b>Default</b>          | OFF                                    |

Enabling this variable causes the master to examine checksums when reading from the binary log. [master\\_verify\\_checksum](#) is disabled by default; in this case, the master uses the event length from the binary log to verify events, so that only complete events are read from the binary log.

- [max\\_binlog\\_cache\\_size](#)

|                            |                                           |                                       |
|----------------------------|-------------------------------------------|---------------------------------------|
| <b>Command-Line Format</b> | <a href="#">--max_binlog_cache_size=#</a> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <a href="#">max_binlog_cache_size</a> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | <a href="#">integer</a>               |
|                            | <b>Default</b>                            | <a href="#">18446744073709551615</a>  |
|                            | <b>Min Value</b>                          | <a href="#">4096</a>                  |
|                            | <b>Max Value</b>                          | <a href="#">18446744073709551615</a>  |

If a transaction requires more than this many bytes of memory, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error. The minimum value is 4096. The maximum possible value is 16EB (exabytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

[max\\_binlog\\_cache\\_size](#) sets the size for the transaction cache only; the upper limit for the statement cache is governed by the [max\\_binlog\\_stmt\\_cache\\_size](#) system variable.

In MySQL 5.7, the visibility to sessions of [max\\_binlog\\_cache\\_size](#) matches that of the [binlog\\_cache\\_size](#) system variable; in other words, changing its value effects only new sessions that are started after the value is changed.

- [max\\_binlog\\_size](#)

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <a href="#">--max_binlog_size=#</a> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <a href="#">max_binlog_size</a> |
|                            | <b>Variable Scope</b>               | Global                          |
|                            | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                         | <a href="#">integer</a>         |
|                            | <b>Default</b>                      | <a href="#">1073741824</a>      |

|  |                  |            |
|--|------------------|------------|
|  | <b>Min Value</b> | 4096       |
|  | <b>Max Value</b> | 1073741824 |

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_binlog_stmt_cache_size`

|                            |                                             |                                         |
|----------------------------|---------------------------------------------|-----------------------------------------|
| <b>Command-Line Format</b> | <code>--max_binlog_stmt_cache_size=#</code> |                                         |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>max_binlog_stmt_cache_size</code> |
|                            | <b>Variable Scope</b>                       | Global                                  |
|                            | <b>Dynamic Variable</b>                     | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                 | <code>integer</code>                    |
|                            | <b>Default</b>                              | 18446744073709547520                    |
|                            | <b>Min Value</b>                            | 4096                                    |
|                            | <b>Max Value</b>                            | 18446744073709547520                    |

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `sync_binlog`

|                                            |                              |                          |
|--------------------------------------------|------------------------------|--------------------------|
| <b>Command-Line Format</b>                 | <code>--sync-binlog=#</code> |                          |
| <b>System Variable</b>                     | <b>Name</b>                  | <code>sync_binlog</code> |
|                                            | <b>Variable Scope</b>        | Global                   |
|                                            | <b>Dynamic Variable</b>      | Yes                      |
| <b>Permitted Values (&gt;= 5.7.7)</b>      | <b>Type</b>                  | <code>integer</code>     |
|                                            | <b>Default</b>               | 1                        |
|                                            | <b>Min Value</b>             | 0                        |
|                                            | <b>Max Value</b>             | 4294967295               |
| <b>Permitted Values (32-bit platforms)</b> | <b>Type</b>                  | <code>integer</code>     |

|                                            |                  |            |
|--------------------------------------------|------------------|------------|
|                                            | <b>Default</b>   | 0          |
|                                            | <b>Min Value</b> | 0          |
|                                            | <b>Max Value</b> | 4294967295 |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>      | integer    |
|                                            | <b>Default</b>   | 0          |
|                                            | <b>Min Value</b> | 0          |
|                                            | <b>Max Value</b> | 4294967295 |

Controls the number of binary log commit groups to collect before synchronizing the binary log to disk. When `sync_binlog=0`, the binary log is never synchronized to disk, and when `sync_binlog` is set to a value greater than 0 this number of binary log commit groups is periodically synchronized to disk. When `sync_binlog=1`, all transactions are synchronized to the binary log before they are committed. Therefore, even in the event of an unexpected restart, any transactions that are missing from the binary log are only in prepared state. This causes the server's automatic recovery routine to rollback those transactions. This guarantees that no transaction is lost from the binary log, and is the safest option. However this can have a negative impact on performance because of an increased number of disk writes. Using a higher value improves performance, but with the increased risk of data loss.

When `sync_binlog=0` or `sync_binlog` is greater than 1, transactions are committed without having been synchronized to disk. Therefore, in the event of a power failure or operating system crash, it is possible that the server has committed some transactions that have not been synchronized to the binary log. Therefore it is impossible for the recovery routine to recover these transactions and they will be lost from the binary log.

Prior to MySQL 5.7.7, the default value of `sync_binlog` was 0, which configures no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from time to time as for any other file. MySQL 5.7.7 and later use a default value of 1, which is the safest choice, but as noted above can impact performance.

### 17.1.6.5 Global Transaction ID Options and Variables

[Startup Options Used with GTID Replication](#)

[System Variables Used with GTID Replication](#)

The MySQL Server options and system variables described in this section are used to monitor and control Global Transaction Identifiers (GTIDs).

For additional information, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

#### Startup Options Used with GTID Replication

The following server startup options are used with GTID-based replication:

- `--enforce-gtid-consistency`

|                                      |                                                 |                                       |
|--------------------------------------|-------------------------------------------------|---------------------------------------|
| <b>Command-Line Format</b>           | <code>--enforce-gtid-consistency[=value]</code> |                                       |
| <b>System Variable (&lt;= 5.7.5)</b> | <b>Name</b>                                     | <code>enforce_gtid_consistency</code> |
|                                      | <b>Variable Scope</b>                           | Global                                |
|                                      | <b>Dynamic Variable</b>                         | No                                    |

|                                       |                         |                                       |
|---------------------------------------|-------------------------|---------------------------------------|
| <b>System Variable (&gt;= 5.7.6)</b>  | <b>Name</b>             | <code>enforce_gtid_consistency</code> |
|                                       | <b>Variable Scope</b>   | Global                                |
|                                       | <b>Dynamic Variable</b> | Yes                                   |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>             | <code>boolean</code>                  |
|                                       | <b>Default</b>          | <code>false</code>                    |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>             | <code>enumeration</code>              |
|                                       | <b>Default</b>          | <code>OFF</code>                      |
|                                       | <b>Valid Values</b>     | <code>OFF</code>                      |
|                                       |                         | <code>ON</code>                       |
| <code>WARN</code>                     |                         |                                       |

When enabled, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this option to `ON` before enabling GTID based replication.

The values that `--enforce-gtid-consistency` can be configured to are:

- `OFF`: all transactions are allowed to violate GTID consistency.
- `ON`: no transaction is allowed to violate GTID consistency.
- `WARN`: all transactions are allowed to violate GTID consistency, but a warning is generated in this case. Added in MySQL 5.7.6.

Setting `--enforce-gtid-consistency` without a value is an alias for `--enforce-gtid-consistency=ON`. This impacts on the behavior of the variable, see `enforce_gtid_consistency`.

Only statements that can be logged using GTID safe statements can be logged when `enforce-gtid-consistency` is set to `ON`, so the operations listed here cannot be used with this option:

- `CREATE TABLE ... SELECT` statements
- `CREATE TEMPORARY TABLE` or `DROP TEMPORARY TABLE` statements inside transactions
- Transactions or statements that update both transactional and nontransactional tables. There is an exception that nontransactional DML is allowed in the same transaction or in the same statement as transactional DML, if all *nontransactional* tables are temporary.

For more information, see [Section 17.1.3.4, “Restrictions on Replication with GTIDs”](#).

- `--executed-gtids-compression-period`

|                            |                                                    |                         |
|----------------------------|----------------------------------------------------|-------------------------|
| <b>Introduced</b>          | 5.7.5                                              |                         |
| <b>Deprecated</b>          | 5.7.6                                              |                         |
| <b>Command-Line Format</b> | <code>--executed-gtids-compression-period=#</code> |                         |
| <b>Permitted Values</b>    | <b>Type</b>                                        | <code>integer</code>    |
|                            | <b>Default</b>                                     | <code>1000</code>       |
|                            | <b>Min Value</b>                                   | <code>0</code>          |
|                            | <b>Max Value</b>                                   | <code>4294967295</code> |

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- `--gtid-mode`

|                                       |                               |                             |
|---------------------------------------|-------------------------------|-----------------------------|
| <b>Command-Line Format</b>            | <code>--gtid-mode=MODE</code> |                             |
| <b>System Variable (&lt;= 5.7.5)</b>  | <b>Name</b>                   | <code>gtid_mode</code>      |
|                                       | <b>Variable Scope</b>         | Global                      |
|                                       | <b>Dynamic Variable</b>       | No                          |
| <b>System Variable (&gt;= 5.7.6)</b>  | <b>Name</b>                   | <code>gtid_mode</code>      |
|                                       | <b>Variable Scope</b>         | Global                      |
|                                       | <b>Dynamic Variable</b>       | Yes                         |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>                   | enumeration                 |
|                                       | <b>Default</b>                | OFF                         |
|                                       | <b>Valid Values</b>           | OFF                         |
|                                       |                               | <code>UPGRADE_STEP_1</code> |
|                                       |                               | <code>UPGRADE_STEP_2</code> |
| ON                                    |                               |                             |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>                   | enumeration                 |
|                                       | <b>Default</b>                | OFF                         |
|                                       | <b>Valid Values</b>           | OFF                         |
|                                       |                               | <code>OFF_PERMISSIVE</code> |
|                                       |                               | <code>ON_PERMISSIVE</code>  |
|                                       |                               | ON                          |

This option specifies whether global transaction identifiers (GTIDs) are used to identify transactions. Setting this option to `--gtid-mode=ON` requires that `enforce-gtid-consistency` be set to `ON`. Prior to MySQL 5.7.6 the `gtid_mode` variable which this option controls could only be set at server startup. In MySQL 5.7.6 and later the `gtid_mode` variable is dynamic and enables GTID based replication to be configured online. Before using this feature, see [Section 17.1.5, “Changing Replication Modes on Online Servers”](#).

Prior to MySQL 5.7.5, starting the server with `--gtid-mode=ON` required that the server also be started with the `--log-bin`, `--log-slave-updates`, options. In versions of MySQL 5.7.5 and later this is not a requirement. See [The `mysql.gtid\_executed` Table](#).

- `--gtid-executed-compression-period`

|                            |                                                   |         |
|----------------------------|---------------------------------------------------|---------|
| <b>Introduced</b>          | 5.7.6                                             |         |
| <b>Command-Line Format</b> | <code>--gtid-executed-compression-period=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                                       | integer |
|                            | <b>Default</b>                                    | 1000    |
|                            | <b>Min Value</b>                                  | 0       |

|  |                  |            |
|--|------------------|------------|
|  | <b>Max Value</b> | 4294967295 |
|--|------------------|------------|

Compress the `mysql.gtid_executed` table each time this many transactions have taken place. A setting of 0 means that this table is not compressed. No compression of the table occurs when binary logging is enabled, therefore the option has no effect unless `log_bin` is `OFF`.

See [mysql.gtid\\_executed Table Compression](#), for more information.

In MySQL version 5.7.5, this variable was added as `executed_gtids_compression_period` and in MySQL version 5.7.6 it was renamed to `gtid_executed_compression_period`.

## System Variables Used with GTID Replication

The following system variables are used with GTID-based replication:

- `binlog_gtid_simple_recovery`

|                                       |                                            |                                          |
|---------------------------------------|--------------------------------------------|------------------------------------------|
| <b>Introduced</b>                     | 5.7.6                                      |                                          |
| <b>Command-Line Format</b>            | <code>--binlog-gtid-simple-recovery</code> |                                          |
| <b>System Variable</b>                | <b>Name</b>                                | <code>binlog_gtid_simple_recovery</code> |
|                                       | <b>Variable Scope</b>                      | Global                                   |
|                                       | <b>Dynamic Variable</b>                    | No                                       |
| <b>Permitted Values</b>               | <b>Type</b>                                | boolean                                  |
|                                       | <b>Default</b>                             | FALSE                                    |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                                | boolean                                  |
|                                       | <b>Default</b>                             | TRUE                                     |

This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts. In MySQL version 5.7.5, this variable was added as `simplified_binlog_gtid_recovery` and in MySQL version 5.7.6 it was renamed to `binlog_gtid_simple_recovery`.

When `binlog_gtid_simple_recovery=FALSE`, the method of iterating the binary log files is:

- To initialize `gtid_executed`, binary log files are iterated from the newest file, stopping at the first binary log that has any `Previous_gtids_log_event`. All GTIDs from `Previous_gtids_log_event` and `Gtid_log_events` are read from this binary log file. This GTID set is stored internally and called `gtids_in_binlog`. The value of `gtid_executed` is computed as the union of this set and the GTIDs stored in the `mysql.gtid_executed` table.

This process could take a long time if you had a large number of binary log files without GTID events, for example created when `gtid_mode=OFF`.

- To initialize `gtid_purged`, binary log files are iterated from the oldest to the newest, stopping at the first binary log that contains either a `Previous_gtids_log_event` that is non-empty (that has at least one GTID) or that has at least one `Gtid_log_event`. From this binary log it reads `Previous_gtids_log_event`. This GTID set is subtracted from `gtids_in_binlog` and the result stored in the internal variable `gtids_in_binlog_not_purged`. The value of `gtid_purged` is initialized to the value of `gtid_executed`, minus `gtids_in_binlog_not_purged`.

When `binlog_gtid_simple_recovery=TRUE`, which is the default in MySQL 5.7.7 and later, the server iterates only the oldest and the newest binary log files and the values of

`gtid_purged` and `gtid_executed` are computed based only on `Previous_gtids_log_event` or `Gtid_log_event` found in these files. This ensures only two binary log files are iterated during server restart or when binary logs are being purged.

#### Note

If this option is enabled, `gtid_executed` and `gtid_purged` may be initialized incorrectly in the following situations:

- The newest binary log was generated by MySQL 5.7.5 or older, and `gtid_mode` was `ON` for some binary logs but `OFF` for the newest binary log.
- A `SET GTID_PURGED` statement was issued on a MySQL version prior to 5.7.7, and the binary log that was active at the time of the `SET GTID_PURGED` has not yet been purged.

If an incorrect GTID set is computed in either situation, it will remain incorrect even if the server is later restarted, regardless of the value of this option.

- `enforce_gtid_consistency`

|                                       |                                                 |                                       |
|---------------------------------------|-------------------------------------------------|---------------------------------------|
| <b>Command-Line Format</b>            | <code>--enforce-gtid-consistency[=value]</code> |                                       |
| <b>System Variable (&lt;= 5.7.5)</b>  | <b>Name</b>                                     | <code>enforce_gtid_consistency</code> |
|                                       | <b>Variable Scope</b>                           | Global                                |
|                                       | <b>Dynamic Variable</b>                         | No                                    |
| <b>System Variable (&gt;= 5.7.6)</b>  | <b>Name</b>                                     | <code>enforce_gtid_consistency</code> |
|                                       | <b>Variable Scope</b>                           | Global                                |
|                                       | <b>Dynamic Variable</b>                         | Yes                                   |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>                                     | <code>boolean</code>                  |
|                                       | <b>Default</b>                                  | <code>false</code>                    |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>                                     | <code>enumeration</code>              |
|                                       | <b>Default</b>                                  | <code>OFF</code>                      |
|                                       | <b>Valid Values</b>                             | <code>OFF</code>                      |
|                                       |                                                 | <code>ON</code>                       |
|                                       | <code>WARN</code>                               |                                       |

Depending on the value of this variable, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this variable to `ON` before enabling GTID based replication.

The values that `enforce_gtid_consistency` can be configured to are:

- `OFF`: all transactions are allowed to violate GTID consistency.
- `ON`: no transaction is allowed to violate GTID consistency.
- `WARN`: all transactions are allowed to violate GTID consistency, but a warning is generated in this case. Added in MySQL 5.7.6.

For more information on statements that can be logged using GTID based replication, see `--enforce-gtid-consistency`.

Prior to MySQL 5.7.6, the boolean `enforce-gtid-consistency` defaulted to `OFF`. To maintain compatibility with previous versions, in MySQL 5.7.6 the enumeration defaults to `OFF`, and setting `--enforce-gtid-consistency` without a value is interpreted as setting the value to `ON`. The variable also has multiple textual aliases for the values: `0=OFF=FALSE`, `1=ON=TRUE`, `2=WARN`. This differs from other enumeration types but maintains compatibility with the boolean type used in previous versions. These changes impact on what is returned by the variable. Using `SELECT @@ENFORCE_GTID_CONSISTENCY`, `SHOW VARIABLES LIKE 'ENFORCE_GTID_CONSISTENCY'`, and `SELECT * FROM INFORMATION_SCHEMA.VARIABLES WHERE 'VARIABLE_NAME' = 'ENFORCE_GTID_CONSISTENCY'`, all return the textual form, not the numeric form. This is an incompatible change, since `@@ENFORCE_GTID_CONSISTENCY` returns the numeric form for booleans but returns the textual form for `SHOW` and the Information Schema.

- `executed_gtids_compression_period`

|                                      |                         |                                                |
|--------------------------------------|-------------------------|------------------------------------------------|
| <b>Introduced</b>                    | 5.7.5                   |                                                |
| <b>Deprecated</b>                    | 5.7.6                   |                                                |
| <b>System Variable (&gt;= 5.7.5)</b> | <b>Name</b>             | <code>executed_gtids_compression_period</code> |
|                                      | <b>Variable Scope</b>   | Global                                         |
|                                      | <b>Dynamic Variable</b> | Yes                                            |
| <b>Permitted Values</b>              | <b>Type</b>             | <code>integer</code>                           |
|                                      | <b>Default</b>          | <code>1000</code>                              |
|                                      | <b>Min Value</b>        | <code>0</code>                                 |
|                                      | <b>Max Value</b>        | <code>4294967295</code>                        |

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- `gtid_executed`

|                                      |                         |                            |
|--------------------------------------|-------------------------|----------------------------|
| <b>System Variable</b>               | <b>Name</b>             | <code>gtid_executed</code> |
|                                      | <b>Variable Scope</b>   | Global, Session            |
|                                      | <b>Dynamic Variable</b> | No                         |
| <b>System Variable (&gt;= 5.7.7)</b> | <b>Name</b>             | <code>gtid_executed</code> |
|                                      | <b>Variable Scope</b>   | Global                     |
|                                      | <b>Dynamic Variable</b> | No                         |
| <b>Permitted Values</b>              | <b>Type</b>             | <code>string</code>        |

When used with global scope, this variable contains a representation of the set of all transactions executed on the server and GTIDs that have been set by a `SET gtid_purged` statement. This is the same as the value of the `Executed_Gtid_Set` column in the output of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, `@@global.gtid_executed` is initialized. See [binlog\\_gtid\\_simple\\_recovery](#) for more information on how binary logs are iterated to populate `gtid_executed`. GTIDs are then added to the set as transactions are executed, or if any `SET gtid_purged` statement is executed.

The set of transactions that can be found in the binary logs at any given time is equal to `GTID_SUBTRACT(@@global.gtid_executed, @@global.gtid_purged)`; that is, to all transactions in the binary log that have not yet been purged.

Issuing `RESET MASTER` causes the global value (but not the session value) of this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET MASTER`.

Prior to MySQL 5.7.7, this variable could also be used with session scope, where it contained a representation of the set of transactions that are written to the cache in the current session. The session scope was deprecated in MySQL 5.7.7.

- [gtid\\_executed\\_compression\\_period](#)

|                                      |                         |                                                  |

|                                      | <b>Max Value</b>        | 4294967295                                       |

Compress the `mysql.gtid_executed` table each time this many transactions have been processed. A setting of 0 means that this table is not compressed. Since no compression of the table occurs when using the binary log, setting the value of the variable has no effect unless binary logging is disabled.

See [mysql.gtid\\_executed Table Compression](#), for more information.

In MySQL version 5.7.5, this variable was added as `executed_gtids_compression_period` and in MySQL version 5.7.6 it was renamed to `gtid_executed_compression_period`.

- [gtid\\_mode](#)

|                                      |                         |                           |

|                                    | ON                  |                |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>         | enumeration    |
|                                    | <b>Default</b>      | OFF            |
|                                    | <b>Valid Values</b> | OFF            |
|                                    |                     | OFF_PERMISSIVE |
|                                    |                     | ON_PERMISSIVE  |
| ON                                 |                     |                |

Controls whether GTID based logging is enabled and what type of transactions the logs can contain. Prior to MySQL 5.7.6 this variable was read-only and was set using the `--gtid-mode` option only. MySQL 5.7.6 enables this variable to be set dynamically. You must have the `SUPER` privilege to set this variable. `enforce_gtid_consistency` must be true before you can set `gtid_mode=ON`. Before modifying this variable, see [Section 17.1.5, “Changing Replication Modes on Online Servers”](#).

Transactions logged in MySQL 5.7.6 and later can be either anonymous or use GTIDs. Anonymous transactions rely on binary log file and position to identify specific transactions. GTID transactions have a unique identifier that is used to refer to transactions. The `OFF_PERMISSIVE` and `ON_PERMISSIVE` modes added in MySQL 5.7.6 permit a mix of these transaction types in the topology. The different modes are now:

- `OFF`: Both new and replicated transactions must be anonymous.
- `OFF_PERMISSIVE`: New transactions are anonymous. Replicated transactions can be either anonymous or GTID transactions.
- `ON_PERMISSIVE`: New transactions are GTID transactions. Replicated transactions can be either anonymous or GTID transactions.
- `ON`: Both new and replicated transactions must be GTID transactions.

Changes from one value to another can only be one step at a time. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`.

In MySQL 5.7.6 and later, the values of `gtid_purged` and `gtid_executed` are persistent regardless of the value of `gtid_mode`. Therefore even after changing the value of `gtid_mode`, these variables contain the correct values. In MySQL 5.7.5 and earlier, the values of `gtid_purged` and `gtid_executed` are not persistent while `gtid_mode=OFF`. Therefore, after changing `gtid_mode` to `OFF`, once all binary logs containing GTIDs are purged, the values of these variables are lost.

- `gtid_next`

|                         |                         |                        |
|-------------------------|-------------------------|------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>gtid_next</code> |
|                         | <b>Variable Scope</b>   | Session                |
|                         | <b>Dynamic Variable</b> | Yes                    |
| <b>Permitted Values</b> | <b>Type</b>             | enumeration            |

|  |                     |                          |
|--|---------------------|--------------------------|
|  | <b>Default</b>      | <code>AUTOMATIC</code>   |
|  | <b>Valid Values</b> | <code>AUTOMATIC</code>   |
|  |                     | <code>ANONYMOUS</code>   |
|  |                     | <code>UUID:NUMBER</code> |

This variable is used to specify whether and how the next GTID is obtained. `gtid_next` can take any of the following values:

- `AUTOMATIC`: Use the next automatically-generated global transaction ID.
- `ANONYMOUS`: Transactions do not have global identifiers, and are identified by file and position only.
- A global transaction ID in `UUID:NUMBER` format.

Exactly which of the above options are valid depends on the setting of `gtid_mode`, see [Section 17.1.5.1, “Replication Mode Concepts”](#) for more information. Setting this variable has no effect if `gtid_mode` is `OFF`.

After this variable has been set to `UUID:NUMBER`, and a transaction has been committed or rolled back, an explicit `SET GTID_NEXT` statement must again be issued before any other statement.

In MySQL 5.7.5 and later, `DROP TABLE` or `DROP TEMPORARY TABLE` fails with an explicit error when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines. Prior to MySQL 5.7.5, when GTIDs were enabled but `gtid_next` was not `AUTOMATIC`, `DROP TABLE` did not work correctly when used with either of these combinations of tables. (Bug #17620053)

In MySQL 5.7.1, you cannot execute any of the statements `CHANGE MASTER TO`, `START SLAVE`, `STOP SLAVE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE SERVER`, `ALTER SERVER`, `DROP SERVER`, `CACHE INDEX`, `LOAD INDEX INTO CACHE`, `FLUSH`, or `RESET` when `gtid_next` is set to any value other than `AUTOMATIC`; in such cases, the statement fails with an error. Such statements are *not* disallowed in MySQL 5.7.2 and later. (Bug #16062608, Bug #16715809, Bug #69045) (Bug #16062608)

- `gtid_owned`

|                         |                         |                         |
|-------------------------|-------------------------|-------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>gtid_owned</code> |
|                         | <b>Variable Scope</b>   | Global, Session         |
|                         | <b>Dynamic Variable</b> | No                      |
| <b>Permitted Values</b> | <b>Type</b>             | <code>string</code>     |

This read-only variable holds a list whose contents depend on its scope. When used with session scope, the list holds all GTIDs that are owned by this client; when used with global scope, it holds a list of all GTIDs along with their owners.

- `gtid_purged`

|                        |                         |                          |
|------------------------|-------------------------|--------------------------|
| <b>System Variable</b> | <b>Name</b>             | <code>gtid_purged</code> |
|                        | <b>Variable Scope</b>   | Global                   |
|                        | <b>Dynamic Variable</b> | Yes                      |

|                         |             |                     |
|-------------------------|-------------|---------------------|
| <b>Permitted Values</b> | <b>Type</b> | <code>string</code> |
|-------------------------|-------------|---------------------|

The set of all transactions that have been purged from the binary log. This is a subset of the set of transactions in `gtid_executed`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, the global value of `gtid_purged` is initialized to a set of GTIDs. See [binlog\\_gtid\\_simple\\_recovery](#) for more information on how binary logs are iterated to populate `gtid_purged`. Issuing `RESET MASTER` causes the value of this variable to be reset to an empty string.

It is possible to update the value of this variable, but only when `gtid_executed` is the empty string, and therefore `gtid_purged` is the empty string. This can occur either when replication has not been started previously, or when replication was not previously using GTIDs. Prior to MySQL 5.7.6, this variable was settable only when `gtid_mode=ON`. In MySQL 5.7.6 and later, this variable is settable regardless of the value of `gtid_mode`.

If all existing binary logs were generated using MySQL 5.7.6 or later, after issuing a `SET gtid_purged` statement, `binlog_gtid_simple_recovery=TRUE` (the default setting in MySQL 5.7.7 and later) can safely be used. If binary logs from MySQL 5.7.7 or earlier exist, there is a chance that `gtid_purged` may be computed incorrectly. See [binlog\\_gtid\\_simple\\_recovery](#) for more information. If you are using MySQL 5.7.7 or earlier, after issuing a `SET gtid_purged` statement note down the current binary log file name, which can be checked using `SHOW MASTER STATUS`. If the server is restarted before this file has been purged, then you should use `binlog_gtid_simple_recovery=FALSE` to avoid `gtid_purged` or `gtid_executed` being computed incorrectly.

- [simplified\\_binlog\\_gtid\\_recovery](#)

|                            |                                                |                                              |

| <b>Command-Line Format</b> | <code>--simplified-binlog-gtid-recovery</code> |                                              |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>simplified_binlog_gtid_recovery</code> |
|                            | <b>Variable Scope</b>                          | Global                                       |
|                            | <b>Dynamic Variable</b>                        | No                                           |
| <b>Permitted Values</b>    | <b>Type</b>                                    | <code>boolean</code>                         |
|                            | <b>Default</b>                                 | <code>FALSE</code>                           |

This option is deprecated and will be removed in a future MySQL release. Use the renamed [binlog\\_gtid\\_simple\\_recovery](#) to control how MySQL iterates through binary log files after a crash.

## 17.1.7 Common Replication Administration Tasks

Once replication has been started it executes without requiring much regular administration. This section describes how to check the status of replication and how to pause a slave.

### 17.1.7.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: master1
      Master_User: root
      Master_Port: 3306
      Connect_Retry: 60
      Master_Log_File: mysql-bin.000004
      Read_Master_Log_Pos: 931
      Relay_Log_File: slavel-relay-bin.000056
      Relay_Log_Pos: 950
      Relay_Master_Log_File: mysql-bin.000004
      Slave_IO_Running: Yes
      Slave_SQL_Running: Yes
      Replicate_Do_DB:
      Replicate_Ignore_DB:
      Replicate_Do_Table:
      Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
      Replicate_Wild_Ignore_Table:
      Last_Errno: 0
      Last_Error:
      Skip_Counter: 0
      Exec_Master_Log_Pos: 931
      Relay_Log_Space: 1365
      Until_Condition: None
      Until_Log_File:
      Until_Log_Pos: 0
      Master_SSL_Allowed: No
      Master_SSL_CA_File:
      Master_SSL_CA_Path:
      Master_SSL_Cert:
      Master_SSL_Cipher:
      Master_SSL_Key:
      Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
      Last_IO_Errno: 0
      Last_IO_Error:
      Last_SQL_Errno: 0
      Last_SQL_Error:
      Replicate_Ignore_Server_Ids: 0
```

The key fields from the status report to examine are:

- **Slave\_IO\_State**: The current status of the slave. See [Section 8.14.5, “Replication Slave I/O Thread States”](#), and [Section 8.14.6, “Replication Slave SQL Thread States”](#), for more information.
- **Slave\_IO\_Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be **Yes** unless you have not yet started replication or have explicitly stopped it with **STOP SLAVE**.
- **Slave\_SQL\_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be **Yes**.
- **Last\_IO\_Error**, **Last\_SQL\_Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- **Seconds\_Behind\_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for **Seconds\_Behind\_Master** can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, **slave\_net\_timeout** has not yet elapsed.

It is also possible that transient values for **Seconds\_Behind\_Master** may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, **Seconds\_Behind\_Master** displays

0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (`Master_Log_File`, `Read_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
- (`Relay_Log_File`, `Relay_Log_Pos`): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```
mysql> SHOW PROCESSLIST \G;
***** 4. row *****
      Id: 10
     User: root
      Host: slave1:58371
        db: NULL
  Command: Binlog Dump
      Time: 777
     State: Has sent all binlog to slave; waiting for binlog to be updated
      Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
|          10 | slave1 | 3306 |          0         |          1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

### 17.1.7.2 Pausing Replication on the Slave

You can stop and start replication on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;  
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;  
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

## 17.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see [Section 17.2.2, “Replication Implementation Details”](#).

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See [Section 8.14, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See [Section 17.2.4, “Replication Relay and Status Logs”](#).

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see [Section 17.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

## 17.2.1 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- When using statement-based binary logging, the master writes SQL statements to the binary log. Replication of the master to the slave works by executing the SQL statements on the slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard MySQL statement-based binary logging format. Replication capabilities in MySQL version 5.1.4 and earlier used this format exclusively.
- When using row-based logging, the master writes *events* to the binary log that indicate how individual table rows are changed. Replication of the master to the slave works by copying the events representing the changes to the table rows to the slave. This is called *row-based replication* (often abbreviated as *RBR*).
- You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called *mixed-format logging*. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements, and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

Prior to MySQL 5.7.7, statement-based format was the default. In MySQL 5.7.7 and later, row-based format is the default.

When using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see [Section 13.7.4, “SET Syntax”](#).

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See [Section 5.2.4.2, “Setting The Binary Log Format”](#).

You must have the `SUPER` privilege to set either the global or session `binlog_format` value.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 19.7, “Binary Logging of Stored Programs”](#).

### 17.2.1.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- [Advantages of statement-based replication](#)
- [Disadvantages of statement-based replication](#)
- [Advantages of row-based replication](#)
- [Disadvantages of row-based replication](#)

### Advantages of statement-based replication

- Proven technology that has existed in MySQL since 3.23.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

### Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**  
Not all statements which modify data (such as `INSERT DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such Data Modification Language (DML) statements include the following:
  - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See [Section 17.4.1.12, “Replication of Invoked Features”](#), for more information.
  - `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See [Section 17.4.1.17, “Replication and LIMIT”](#).
  - Deterministic UDFs must be applied on the slaves.
- Statements using any of the following functions cannot be replicated properly using statement-based replication:
  - `LOAD_FILE()`
  - `UUID()`, `UUID_SHORT()`
  - `USER()`
  - `FOUND_ROWS()`
  - `SYSDATE()` (unless both the master and the slave are started with the `--sysdate-is-now` option)
  - `GET_LOCK()`
  - `IS_FREE_LOCK()`
  - `IS_USED_LOCK()`
  - `MASTER_POS_WAIT()`
  - `RAND()`
  - `RELEASE_LOCK()`

- `SLEEP()`
- `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `NOW()` and so forth.

For more information, see [Section 17.4.1.16, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For `InnoDB`: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 17.4.1.28, “Slave Errors During Replication”](#).
- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.
- Table definitions must be (nearly) identical on master and slave. See [Section 17.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#), for more information.

## Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

### Note

Statements that update the information in the `mysql` database—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - `INSERT ... SELECT`

- `INSERT` statements with `AUTO_INCREMENT`
- `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

### Disadvantages of row-based replication

- RBR can generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that making and restoring a backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use `binlog_row_image=minimal` to reduce the disadvantage considerably.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot see on the slave what statements were received from the master and executed. However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

Alternatively, use the `binlog_rows_query_log_events` variable, which if enabled adds a `Rows_query` event with the statement to `mysqlbinlog` output when the `-vv` option is used.

- For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

### 17.2.1.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and describes some best practices using it in replication.

For additional information, see [Section 17.2.1, “Replication Formats”](#), and [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

- **Row-based logging of temporary tables.** As noted in [Section 17.4.1.24, “Replication and Temporary Tables”](#), temporary tables are not replicated when using row-based format. When using mixed format logging, “safe” statements involving temporary tables are logged using statement-based format. For more information, see [Section 17.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

In MySQL 5.7, you can switch from statement-based to row-based binary logging mode even when temporary tables have been created. However, while using the row-based format, the MySQL server cannot determine the logging mode that was in effect when a given temporary table was created. For this reason, the server in such cases logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists for a given client session when that session ends. While this

means that it is possible that an unnecessary `DROP TEMPORARY TABLE` statement might be logged in some cases, the statement is harmless, and does not cause an error even if the table does not exist, due to the presence of the `IF EXISTS` option.

Nontransactional DML statements involving temporary tables are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. Depending on the engine used for the slave's copy of the table, this may or may not be effective.
- **Latency and binary log size.** RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see [Section 13.7.6.1, “BINLOG Syntax”](#)). This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see [Section 4.6.7.2, “mysqlbinlog Row Event Display”](#).
- **Binary log execution errors and `slave_exec_mode`.** If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see [Section 5.1.4, “Server System Variables”](#).

#### Note

`slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which `IDEMPOTENT` is the default value.

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.

The `NDBCLUSTER` storage engine is currently not supported in MySQL 5.7. See [MySQL Cluster NDB 7.3](#) and [MySQL Cluster NDB 7.4](#).

- **Lack of binary log checksums.** RBL does not use checksums, so network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption use SSL for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#), for general information about setting up MySQL with SSL.
- **Filtering based on server ID not supported.** In MySQL 5.7, you can filter based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with statement-based and row-based logging formats. Another method to filter out changes on some slaves is to use a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.

- **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Therefore, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact replication format has on how they operate, see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).
- **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format. Use of `STOP SLAVE` or `STOP SLAVE SQL_THREAD` prior to shutting down the slave MySQL server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.

### 17.2.1.3 Determination of Safe and Unsafe Statements in Binary Logging

The “safeness” of a statement in MySQL Replication, refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see [Nondeterministic functions not considered unsafe](#), later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see [Section 17.4.1.13, “Replication and Floating-Point Values”](#)).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.
- When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.
- When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. Formerly, if a large number of such statements were executed on the master, this could lead to excessively large error log files. To prevent this, MySQL 5.7 provides a warning suppression mechanism, which behaves as follows: Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note `The last warning was repeated N times in last S seconds` is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see [Section 17.2.1, “Replication Formats”](#).

#### Statements considered unsafe.

Statements with the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.** These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `PASSWORD()`, `RAND()`, `RELEASE_LOCK()`, `ROW_COUNT()`,

`SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

**Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LAST_INSERT_ID()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, and `UTC_TIMESTAMP()`.

For more information, see [Section 17.4.1.16, “Replication and System Functions”](#).

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. See [Section 17.4.1.38, “Replication and Variables”](#). For exceptions, see [Section 5.2.4.3, “Mixed Binary Logging Format”](#).
- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.
- **Fulltext plugin.** This plugin may behave differently on different MySQL servers; therefore, statements depending on it could have different results. For this reason, all statements relying on the fulltext plugin are treated as unsafe in MySQL 5.7.1 and later. (Bug #11756280, Bug #48183)
- **Trigger or stored program updates a table having an AUTO\_INCREMENT column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

For more information, see [Section 17.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- **INSERT ... ON DUPLICATE KEY UPDATE statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication. (Bug #11765650, Bug #58637)

- **Updates using LIMIT.** The order in which rows are retrieved is not specified, and is therefore considered unsafe. See [Section 17.4.1.17, “Replication and LIMIT”](#).
- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.
- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

For more information, see [Section 17.4.1.33, “Replication and Transactions”](#).

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.
- **LOAD DATA INFILE statements.** `LOAD DATA INFILE` is considered unsafe, it causes a warning in statement-based mode, and a switch to row-based format when using mixed-format logging. See [Section 17.4.1.18, “Replication and LOAD DATA INFILE”](#).

For additional information, see [Section 17.4.1, “Replication Features and Issues”](#).

## 17.2.2 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see [Section 8.14.4, "Replication Master Thread States"](#). For slave states, see [Section 8.14.5, "Replication Slave I/O Thread States"](#), and [Section 8.14.6, "Replication Slave SQL Thread States"](#).

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 2
  User: root
  Host: localhost:32931
  db: NULL
Command: Binlog Dump
  Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
        be updated
  Info: NULL
```

Here, thread 2 is a `Binlog Dump` replication thread that services a connected slave. The `State` information indicates that all outstanding updates have been sent to the slave and that the master is

waiting for more updates to occur. If you see no [Binlog Dump](#) threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 10
  User: system user
  Host:
  db: NULL
Command: Connect
  Time: 11
  State: Waiting for master to send event
  Info: NULL
***** 2. row *****
  Id: 11
  User: system user
  Host:
  db: NULL
Command: Connect
  Time: 11
  State: Has read all relay log; waiting for the slave I/O
        thread to update it
  Info: NULL
```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See [Section A.13, “MySQL 5.7 FAQ: Replication”](#). If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 5.1.4, “Server System Variables”](#).

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See [Section 17.1.7.1, “Checking Replication Status”](#).

## 17.2.3 Replication Channels

MySQL 5.7.6 introduces the concept of a replication channel, which represents the path of transactions flowing from a master to a slave. This section describes how channels can be used in a replication topology, and the impact they have on single-source replication.

To provide compatibility with previous versions, the MySQL server automatically creates on startup a default channel whose name is the empty string ("" ). This channel is always present; it cannot be created or destroyed by the user. If no other channels (having nonempty names) have been created, replication statements act on the default channel only, so that all replication statements from older slaves function as expected (see [Section 17.2.3.2, “Compatibility with Previous Replication Statements”](#)). Statements applying to replication channels as described in this section can be used only when there is at least one named channel.

A replication channel encompasses the path of transactions transmitted from a master to a slave. In multi-source replication a slave opens multiple channels, one per master, and each channel has its own relay log and applier (SQL) threads. Once transactions are received by a replication channel's receiver (I/O) thread, they are added to the channel's relay log file and passed through to an applier thread. This enables channels to function independently.

A replication channel is also associated with a host name and port. You can assign multiple channels to the same combination of host name and port; in MySQL 5.7, the maximum number of channels that can be added to one slave in a multi-source replication topology is 256. Each replication channel must

have a unique (nonempty) name (see [Section 17.2.3.4, “Replication Channel Naming Conventions”](#)). Channels can be configured independently.

### 17.2.3.1 Commands for Operations on a Single Channel

To enable existing MySQL replication statements to act on individual replication channels, MySQL 5.7.6 introduces the `FOR CHANNEL channel_name` option for use with the following replication statements in managing a replication channel independently of other channels:

- `CHANGE MASTER TO`
- `START SLAVE`
- `STOP SLAVE`
- `SHOW RELAYLOG EVENTS`
- `FLUSH RELAY LOGS`
- `SHOW SLAVE STATUS`
- `RESET SLAVE`

Similarly, an additional `channel_name` parameter is introduced for the following functions:

- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`

Beginning with MySQL 5.7.9, the following statements are disallowed for the `group_replication_recovery` channel.

- `START SLAVE`
- `STOP SLAVE`

### 17.2.3.2 Compatibility with Previous Replication Statements

When a replication slave has multiple channels and a `FOR CHANNEL channel_name` option is not specified, a valid statement generally acts on all available channels.

For example, the following statements behave as expected:

- `START SLAVE` starts replication threads for all channels. (In MySQL 5.7.9 and later, this does not include the `group_replication_recovery` channel.)
- `STOP SLAVE` stops replication threads for all the channels. (In MySQL 5.7.9 and later, this does not include the `group_replication_recovery` channel.)
- `SHOW SLAVE STATUS` reports the status for all channels.
- `FLUSH RELAY LOGS` flushes the relay logs for all channels.
- `RESET SLAVE` resets all channels.

#### Warning

Use `RESET SLAVE` with caution as this statement deletes all existing channels, purges their relay log files, and recreates only the default channel.

Some replication statements cannot operate on all channels. In this case, error 1964 `Multiple channels exist on the slave. Please provide channel name as an argument.` is generated. The following statements and functions generate this error when used in a multi-source replication topology and a `FOR CHANNEL channel_name` option is not used to specify which channel to act on:

- `SHOW RELAYLOG EVENTS`
- `CHANGE MASTER TO`
- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`
- `WAIT_FOR_EXECUTED_GTID_SET()`

Note that a default channel always exists in a single source replication topology, where statements and functions behave as in previous versions of MySQL.

### 17.2.3.3 Startup Options and Replication Channels

This section describes startup options which are impacted by the addition of replication channels.

The following startup options *must* be configured correctly to use multi-source replication.

- `--relay-log-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

- `--master-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

The following startup options now affect *all* channels in a replication topology.

- `--log-slave-updates`

All transactions received by the slave (even from multiple sources) are written in the binary log.

- `--relay-log-purge`

When set, each channel purges its own relay log automatically.

- `--slave_transaction_retries`

Applier threads of all channels retry transactions.

- `--skip-slave-start`

No replication threads start on any channels.

- `--slave-skip-errors`

Execution continues and errors are skipped for all channels.

The values set for the following startup options apply on each channel; since these are `mysqld` startup options, they are applied on every channel.

- `--max-relay-log-size=size`

Maximum size of the individual relay log file for each channel; after reaching this limit, the file is rotated.

- `--relay-log-space-limit=size`

Upper limit for the total size of all relay logs combined, for each individual channel. For  $N$  channels, the combined size of these logs is limited to `relay_log_space_limit * N`.

- `--slave-parallel-workers=value`

Number of slave parallel workers per channel.

- `--slave-checkpoint-group`

Waiting time by an I/O thread for each source.

- `--relay-log-index=filename`

Base name for each channel's relay log index file. See [Section 17.2.3.4, "Replication Channel Naming Conventions"](#).

- `--relay-log=filename`

Denotes the base name of each channel's relay log file. See [Section 17.2.3.4, "Replication Channel Naming Conventions"](#).

- `--slave_net-timeout=N`

This value is set per channel, so that each channel waits for *N* seconds to check for a broken connection.

- `--slave-skip-counter=N`

This value is set per channel, so that each channel skips *N* events from its master.

### 17.2.3.4 Replication Channel Naming Conventions

This section describes how naming conventions are impacted by replication channels.

Each replication channel has a unique name which is a string with a maximum length of 64 characters and is case insensitive. Because channel names are used in slave tables, the character set used for these is always UTF-8. Although you are generally free to use any name for channels, the following names are reserved:

- `group_replication_applier`
- `group_replication_recovery`

The name you choose for a replication channel also influences the file names used by a multi-source replication slave. The relay log files and index files for each channel are named `base_name-relay-bin-channel_name.0000x`, where `base_name` is generally a host name (if not specified using `--log-bin`) and `channel_name` is the name of the channel logged to this file.

## 17.2.4 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *master info log* contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.

This log can be written to the `mysql.slave_master_info` table instead of a file, by starting the slave with `--master-info-repository=TABLE`.

- The *relay log info log* holds status information about the execution point within the slave's relay log.

This log can be written to the `mysql.slave_relay_log_info` table instead of a file by starting the slave with `--relay-log-info-repository=TABLE`.

**Crash-safe replication.** In order for replication to be crash-safe when using tables for logging status and relay information, these tables must use a transactional storage engine, such as [InnoDB](#). In MySQL 5.7 these tables are created using [InnoDB](#).

Therefore, in order to guarantee crash safety on the slave, you must run the slave with `--relay-log-recovery` enabled, in addition to setting `--relay-log-info-repository` to `TABLE`.

In MySQL 5.7, a warning is given when `mysqld` is unable to initialize the replication logging tables, but the slave is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support slave logging tables to one in which they are supported.

In MySQL 5.7, execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing, while statements that perform only reads are permitted at any time.

### Important

Do not attempt to update or insert rows in the `slave_master_info` or `slave_relay_log_info` table manually. Doing so can cause undefined behavior, and is not supported.

#### 17.2.4.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#)).

By default, relay log file names have the form `host_name-relay-bin.nnnnnn` in the data directory, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#)).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see [Bug #2122](#)). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.

- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

### 17.2.4.2 Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. In MySQL 5.7, either or both of these logs can also be written to tables in the `mysql` database by starting the server with the appropriate option: use `--master-info-repository` to have the master info log written to the `mysql.slave_master_info` table, and use `--relay-log-info-repository` to have the relay log info log written to the `mysql.slave_relay_log_info` table. See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#). Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log file or table should be protected because it contains the password for connecting to the master. See [Section 6.1.2.3, “Passwords and Logging”](#).

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file, the columns in the `mysql.slave_master_info` table, and the columns displayed by `SHOW SLAVE STATUS`.

| Line in <code>master.info</code> File | <code>slave_master_info</code> Table Column | <code>SHOW SLAVE STATUS</code> Column | Description                                                                           |
|---------------------------------------|---------------------------------------------|---------------------------------------|---------------------------------------------------------------------------------------|
| 1                                     | <code>Number_of_lines</code>                | [None]                                | Number of lines in the file, or columns in the table                                  |
| 2                                     | <code>Master_log_name</code>                | <code>Master_Log_File</code>          | The name of the master binary log currently being read from the master                |
| 3                                     | <code>Master_log_pos</code>                 | <code>Read_Master_Log_Pos</code>      | The current position within the master binary log that have been read from the master |
| 4                                     | <code>Host</code>                           | <code>Master_Host</code>              | The host name of the master                                                           |

| Line in<br>master.info<br>File | slave_master_info<br>Table Column | SHOW SLAVE STATUS Column                  | Description                                                                               |
|--------------------------------|-----------------------------------|-------------------------------------------|-------------------------------------------------------------------------------------------|
| 5                              | User_name                         | Master_User                               | The user name used to connect to the master                                               |
| 6                              | User_password                     | Password (not shown by SHOW SLAVE STATUS) | The password used to connect to the master                                                |
| 7                              | Port                              | Master_Port                               | The network port used to connect to the master                                            |
| 8                              | Connect_retry                     | Connect_Retry                             | The period (in seconds) that the slave will wait before trying to reconnect to the master |
| 9                              | Enabled_ssl                       | Master_SSL_Allowed                        | Indicates whether the server supports SSL connections                                     |
| 10                             | Ssl_ca                            | Master_SSL_CA_File                        | The file used for the Certificate Authority (CA) certificate                              |
| 11                             | Ssl_capath                        | Master_SSL_CA_Path                        | The path to the Certificate Authority (CA) certificates                                   |
| 12                             | Ssl_cert                          | Master_SSL_Cert                           | The name of the SSL certificate file                                                      |
| 13                             | Ssl_cipher                        | Master_SSL_Cipher                         | The list of possible ciphers used in the handshake for the SSL connection                 |
| 14                             | Ssl_key                           | Master_SSL_Key                            | The name of the SSL key file                                                              |
| 15                             | Ssl_verify_server_cert            | Master_SSL_Verify_Server_Cert             | Whether to verify the server certificate                                                  |
| 16                             | Heartbeat                         | [None]                                    | Interval between replication heartbeats, in seconds                                       |
| 17                             | Bind                              | Master_Bind                               | Which of the slave's network                                                              |

| Line in <code>master.info</code> File | <code>slave_master_info</code> Table Column | <code>SHOW SLAVE STATUS</code> Column    | Description                                                                                                                                                         |
|---------------------------------------|---------------------------------------------|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       |                                             |                                          | interfaces should be used for connecting to the master                                                                                                              |
| 18                                    | <code>Ignored_server_ids</code>             | <code>Replicate_Ignore_Server_Ids</code> | The list of server IDs to be ignored. Note that for <code>Ignored_server_ids</code> the list of server IDs is preceded by the total number of server IDs to ignore. |
| 19                                    | <code>Uuid</code>                           | <code>Master_UUID</code>                 | The master's unique ID                                                                                                                                              |

| 24                                    | <code>Channel_name</code>                   | <code>Channel_name</code>                | The name of the replication channel                                                                                                                                 |

The slave SQL thread updates the relay log info log. In MySQL 5.7, the `relay-log.info` file includes a line count and a replication delay value. The following table shows the correspondence between the lines in the `relay-log.info` file, the columns in the `mysql.slave_relay_log_info` table, and the columns displayed by `SHOW SLAVE STATUS`.

| Line in <code>relay-log.info</code> | <code>slave_relay_log_info</code> Table Column | <code>SHOW SLAVE STATUS</code> Column | Description                                         |
|-------------------------------------|------------------------------------------------|---------------------------------------|-----------------------------------------------------|
| 1                                   | <code>Number_of_lines</code>                   | [None]                                | Number of lines in the file or columns in the table |

| Line in relay-log.info | slave_relay_log_info Table Column | SHOW SLAVE STATUS Column | Description                                                                                                         |
|------------------------|-----------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------|
| 2                      | Relay_log_name                    | Relay_Log_File           | The name of the current relay log file                                                                              |
| 3                      | Relay_log_pos                     | Relay_Log_Pos            | The current position within the relay log file; events up to this position have been executed on the slave database |
| 4                      | Master_log_name                   | Relay_Master_Log_File    | The name of the master binary log file from which the events in the relay log file were read                        |
| 5                      | Master_log_pos                    | Exec_Master_Log_Pos      | The equivalent position within the master's binary log file of events that have already been executed               |
| 6                      | Sql_delay                         | SQL_Delay                | The number of seconds that the slave must lag the master                                                            |
| 7                      | Number_of_workers                 | [None]                   | The number of slave worker threads for executing replication events (transactions) in parallel                      |
| 8                      | Id                                | [None]                   | ID used for internal purposes; currently this is always 1                                                           |
| 9                      | Channel_name                      | Channel_name             | The name of the replication channel                                                                                 |

In older versions of MySQL (prior to MySQL 5.6), the `relay-log.info` file does not include a line count or a delay value (and the `slave_relay_log_info` table is not available).

| Line | Status Column         | Description                                                                                                         |
|------|-----------------------|---------------------------------------------------------------------------------------------------------------------|
| 1    | Relay_Log_File        | The name of the current relay log file                                                                              |
| 2    | Relay_Log_Pos         | The current position within the relay log file; events up to this position have been executed on the slave database |
| 3    | Relay_Master_Log_File | The name of the master binary log file from which the events in the relay log file were read                        |

| Line | Status Column                    | Description                                                                                           |
|------|----------------------------------|-------------------------------------------------------------------------------------------------------|
| 4    | <code>Exec_Master_Log_Pos</code> | The equivalent position within the master's binary log file of events that have already been executed |

**Note**

If you downgrade a slave server to a version older than MySQL 5.6, the older server does not read the `relay-log.info` file correctly. To address this, modify the file in a text editor by deleting the initial line containing the number of lines.

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, you can use `SHOW SLAVE STATUS`, or query the `slave_master_info` and `slave_relay_log_info` tables if you are writing the status logs to tables.

When you back up the slave's data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

## 17.2.5 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 17.1.6, “Replication and Binary Logging Options and Variables”](#).) In MySQL 5.7.3 and later, the filters governed by these options can also be set dynamically using the `CHANGE REPLICATION FILTER` statement. The rules governing such filters are the same whether they are created on startup using `--replicate-*` options or while the slave server is running by `CHANGE REPLICATION FILTER`.

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#), for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see [Section 17.2.5.2, “Evaluation of Table-Level Replication Options”](#), for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), database-level options always take precedence over any `--replicate-wild-do-table` options. In other words, for such statements, `--replicate-wild-do-table` options are

checked if and only if there are no database-level options that apply. This is a change in behavior from previous versions of MySQL, where the statement `CREATE DATABASE dbx` was not replicated if the slave had been started with `--replicate-do-db=dbx --replicate-wild-do-table=db%.t1`. (Bug #46110)

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

#### Note

In MySQL 5.7, all replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the `lower_case_table_names` system variable.

This is a change from previous versions of MySQL. (Bug #51639)

### 17.2.5.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.

The steps involved are listed here:

1. Are there any `--replicate-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Execute the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 2.
2. Are there any `--replicate-ignore-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Ignore the statement and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 17.2.5.2, "Evaluation of Table-Level Replication Options"](#).

### Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
  - **Yes.** Continue to step 2.
  - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
  - **Yes.** Continue to step 3.
  - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Log the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
  - **Yes.** Ignore the statement and exit.
  - **No.** Log the statement and exit.

### Important

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

## 17.2.5.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.
- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see [Section 17.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits.

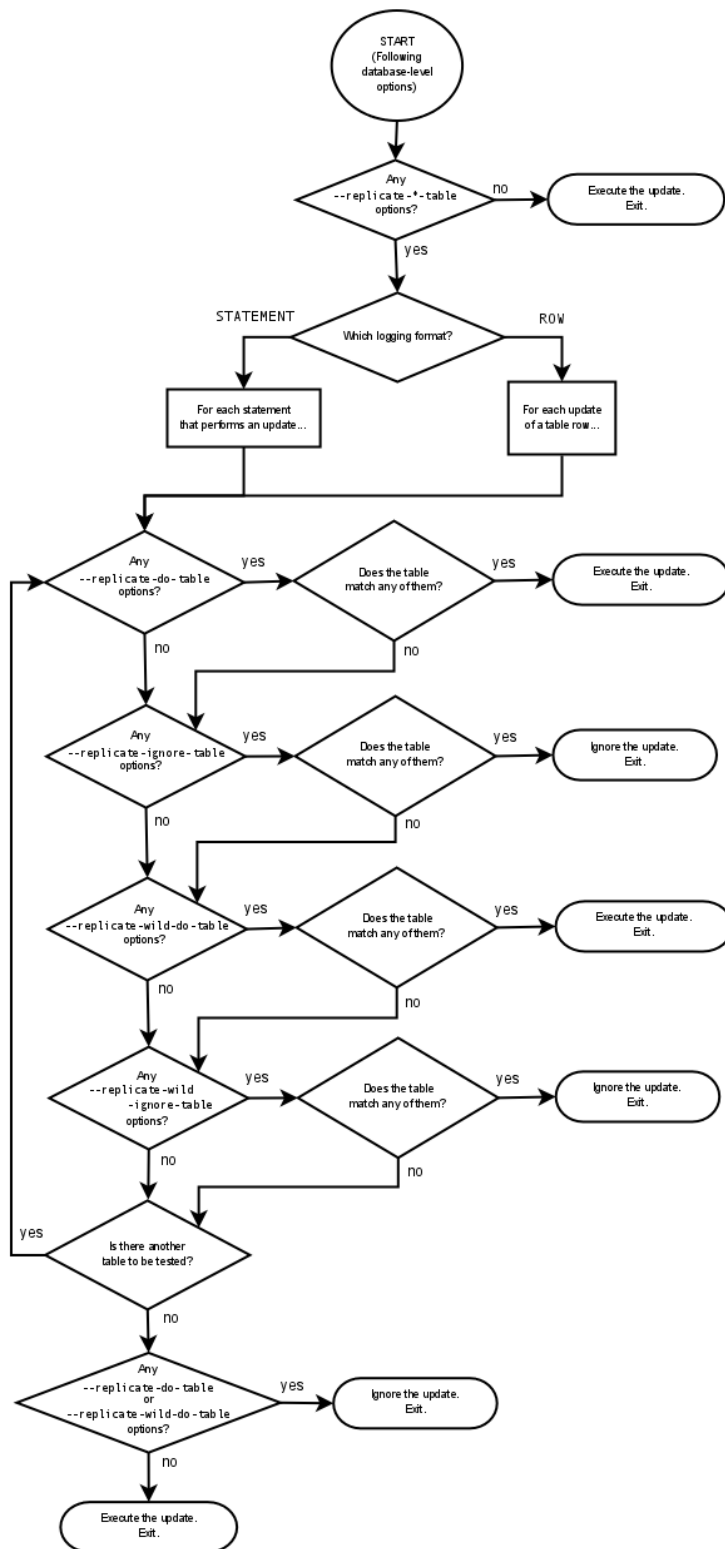

If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

**Note**

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.

The following steps describe this evaluation in more detail:

1. Are there any table options?
  - **Yes.** Continue to step 2.
  - **No.** Execute the event and exit.
2. Are there any `--replicate-do-table` options?

- **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-table` options?
- **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 4.
  - **No.** Continue to step 4.
4. Are there any `--replicate-wild-do-table` options?
- **Yes.** Does the table match any of them?
    - **Yes.** Execute the event and exit.
    - **No.** Continue to step 5.
  - **No.** Continue to step 5.
5. Are there any `--replicate-wild-ignore-table` options?
- **Yes.** Does the table match any of them?
    - **Yes.** Ignore the event and exit.
    - **No.** Continue to step 6.
  - **No.** Continue to step 6.
6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
- **Yes.** Ignore the event and exit.
  - **No.** Execute the event and exit.

### 17.2.5.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

| Condition (Types of Options)                                       | Outcome                                                                                                                                                    |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No <code>--replicate-*</code> options at all:                      | The slave executes all events that it receives from the master.                                                                                            |
| <code>--replicate-*-db</code> options, but no table options:       | The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions. |
| <code>--replicate-*-table</code> options, but no database options: | All events are accepted at the database-checking stage because there are no database conditions. The slave                                                 |

| Condition (Types of Options)                 | Outcome                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                              | executes or ignores events based solely on the table options.                                                                                                                                                                                                                                                                                              |
| A combination of database and table options: | The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example. |

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

## 17.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 17.3.1, "Using Replication for Backups"](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 17.3.2, "Using Replication with Different Master and Slave Storage Engines"](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 17.3.3, "Using Replication for Scale-Out"](#).

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See [Section 17.3.4, "Replicating Different Databases to Different Slaves"](#)

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving

your replication performance, including using a single secondary server as a replication master, see [Section 17.3.5, “Improving Replication Performance”](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 17.3.6, “Switching Masters During Failover”](#).

To secure your replication communication, you can use SSL to encrypt the communication channel. For step-by-step instructions, see [Section 17.3.7, “Setting Up Replication Using SSL”](#).

## 17.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 17.3.1.1, “Backing Up a Slave Using mysqldump”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 17.3.1.2, “Backing Up Raw Data from a Slave”](#).

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 17.3.1.3, “Backing Up a Master or Slave by Making It Read Only”](#).

### 17.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See [Section 17.1.7.1, "Checking Replication Status"](#). If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see [Section 17.3.4, "Replicating Different Databases to Different Slaves"](#).

### 17.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as [InnoDB](#). With [InnoDB](#), these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including [cp](#), [tar](#) or [WinZip](#). For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave's data, you should also back up the slave status files, the master info and relay log info repositories, and the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the [relay-log.info](#) file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use [CHANGE MASTER TO](#) with the [MASTER\\_LOG\\_FILE](#) and [MASTER\\_LOG\\_POS](#) options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating [LOAD DATA INFILE](#) statements, you should also back up any [SQL\\_LOAD-\\*](#) files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted [LOAD DATA INFILE](#) operations. The location of this directory is the value of the [--slave-load-tmpdir](#) option. If the server was not started with that option, the directory location is the value of the [tmpdir](#) system variable.

### 17.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

#### Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

#### Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
```

```
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

### Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

## 17.3.2 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 17.3.3, “Using Replication for Scale-Out”](#)), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-federated` option on your slave to disable the `FEDERATED` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This

requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `default_storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;  
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

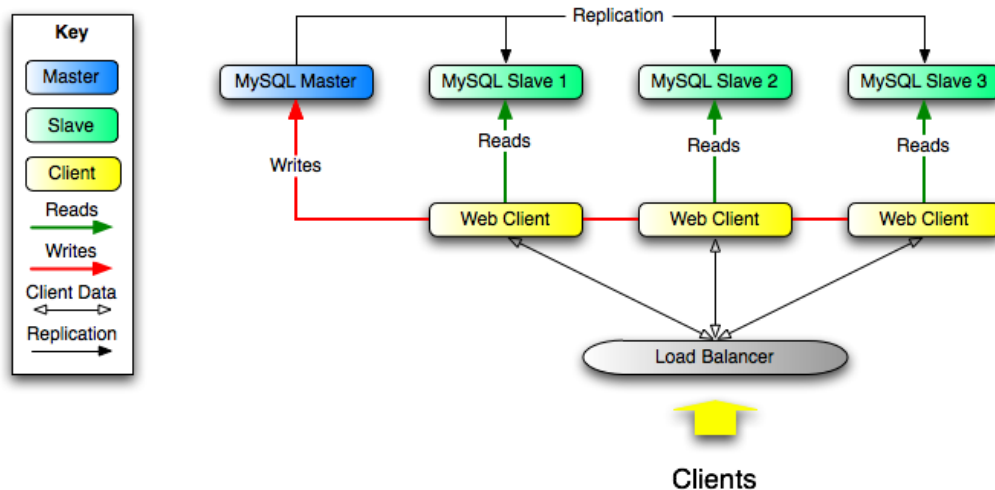

### 17.3.3 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 17.1, “Using Replication to Improve Performance During Scale-Out”](#).

**Figure 17.1 Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 17.3.4 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments

to help spread the load during data analysis. A sample of this layout is shown in [Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#).

**Figure 17.2 Using Replication to Replicate Databases to Separate Replication Slaves**

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

### Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#), you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

### Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

## 17.3.5 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 17.3, “Using an Additional Replication Host to Improve Performance”](#).

**Figure 17.3 Using an Additional Replication Host to Improve Performance**

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 17.3.4, “Replicating Different Databases to Different Slaves”](#).
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See [Section 17.3.2, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

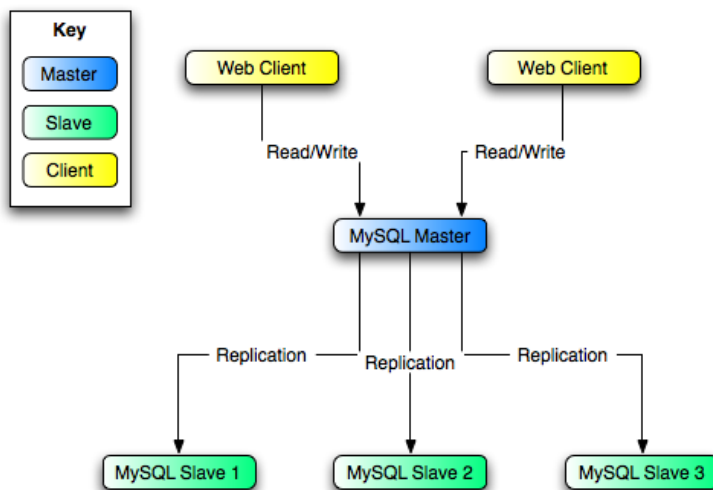

## 17.3.6 Switching Masters During Failover

When using replication with GTIDs (see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#)), you can provide failover between master and slaves in the event of a failure using `mysqlfailover`, which is provided by the MySQL Utilities; see [mysqlfailover — Automatic replication health monitoring and failover](#), for more information. If you're not using `mysqlfailover`, you must set up a master and one or more slaves; then, you need to write an application or script that monitors the master to check whether it is up, and instructs the slaves and applications to change to another master in case of failure. This section discusses some of the issues encountered when setting up failover in this fashion.

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in [Figure 17.4, “Redundancy Using Replication, Initial Structure”](#).

**Figure 17.4 Redundancy Using Replication, Initial Structure**

In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 17.3.3, “Using Replication for Scale-Out”](#).

Each `MySQL Slave` (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which writes the updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, it writes any updates that it receives from `Master` in its own binary log. This

means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

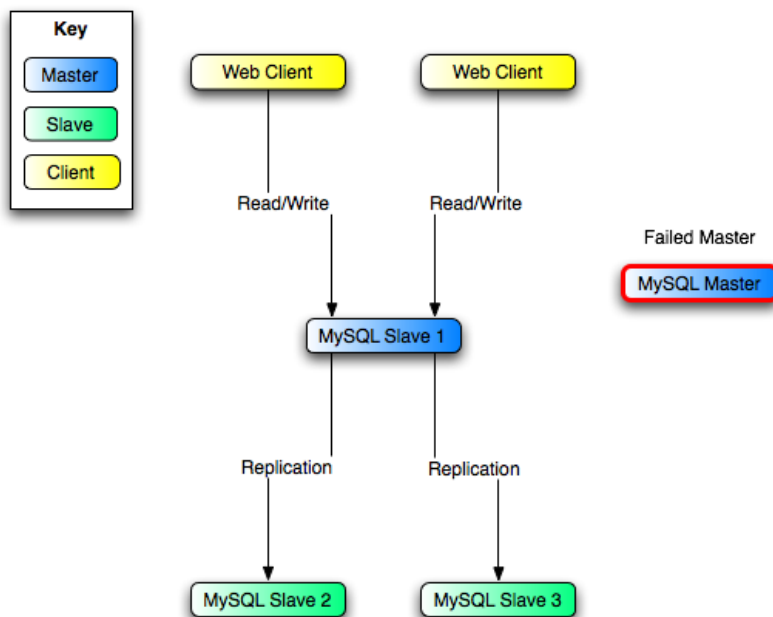

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in [Figure 17.5, “Redundancy Using Replication, After Master Failure”](#).

**Figure 17.5 Redundancy Using Replication, After Master Failure**

When `Master` becomes available again, you should make it a slave of `Slave 1`. To do this, issue on `Master` the same `CHANGE MASTER TO` statement as that issued on `Slave 2` and `Slave 3` previously. `Master` then becomes a slave of `Slave 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Master` a master again, use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. If you fail to do this, the slaves may pick up stale writes from the `Web Client` applications dating from before the point at which `Master` became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases

the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

### 17.3.7 Setting Up Replication Using SSL

To use SSL for encrypting the transfer of the binary log required during replication, both the master and the slave must support SSL network connections. If either host does not support SSL connections (because it has not been compiled or configured for SSL), replication through an SSL connection is not possible.

Setting up replication using an SSL connection is similar to setting up a server and client using SSL. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave.

For more information on setting up a server and client for SSL connectivity, see [Section 6.3.12.4, “Configuring MySQL to Use Secure Connections”](#).

To enable SSL on the master you must create or obtain suitable certificates, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the certificates may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, you have two options available for setting the SSL information. You can either add the slave certificates to the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify the SSL information using the `CHANGE MASTER TO` statement:

- To add the slave certificates using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to enable SSL connectivity:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
```

```
-> MASTER_SSL=1;
```

- To specify the SSL certificate options using the `CHANGE MASTER TO` statement, append the SSL options:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1,
-> MASTER_SSL_CA = 'ca_file_name',
-> MASTER_SSL_CAPATH = 'ca_directory_name',
-> MASTER_SSL_CERT = 'cert_file_name',
-> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that the SSL connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

If you want to enforce the use of SSL connections during replication, create a user and use the `REQUIRE SSL` option, then grant that user the `REPLICATION SLAVE` privilege. For example:

```
mysql> CREATE USER 'repl'@'%'.mydomain.com IDENTIFIED BY 'slavepass'
-> REQUIRE SSL;
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%'.mydomain.com;
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```
mysql> ALTER USER 'repl'@'%'.mydomain.com REQUIRE SSL;
```

## 17.3.8 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 5.7 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.
- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.

- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.
- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

As of MySQL 5.7.3, the number of slave acknowledgments the master must receive per transaction before proceeding is configurable using the `rpl_semi_sync_master_wait_for_slave_count` system variable. The default value is 1.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks for each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.
- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.
- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous master receives acknowledgment from the number of slaves configured by `rpl_semi_sync_master_wait_for_slave_count`, the transaction is on hold and not committed.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

The `rpl_semi_sync_master_wait_point` system variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- `AFTER_COMMIT`: The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With `AFTER_SYNC`, all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date.

- With `AFTER_COMMIT`, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

### 17.3.8.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
- System variables control plugin behavior. Some examples:

- `rpl_semi_sync_master_enabled`

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

- `rpl_semi_sync_master_timeout`

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

- `rpl_semi_sync_slave_enabled`

Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

All `rpl_semi_sync_xxx` system variables are described at [Section 5.1.4, “Server System Variables”](#).

- Status variables enable semisynchronous replication monitoring. Some examples:

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All `Rpl_semi_sync_xxx` status variables are described at [Section 5.1.6, “Server Status Variables”](#).

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

### 17.3.8.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

To use semisynchronous replication, the following requirements must be satisfied:

- MySQL 5.5 or higher must be installed.
- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working. For information on creating a master/slave relationship, see [Section 17.1.2, “Setting Up Binary Log File Position Based Replication”](#).
- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel.

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

The semisynchronous replication plugins are included with MySQL distributions.

Unpack the component distribution, which contains files for the master side and the slave side.

Install the component files in the plugin directory of the appropriate server. Install the `semisync_master*` files in the plugin directory of the master server. Install the `semisync_slave*` files in the plugin directory of each slave server. The location of the plugin directory is available as the value of the server's `plugin_dir` system variable.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous.

On the master:

---

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
mysql> INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

The preceding commands use a plugin file name suffix of `.so`. A different suffix might apply on your system. If you are not sure about the plugin file name, look for the plugins in the server's plugin directory.

If an attempt to install a plugin results in an error on Linux similar to that shown here, you will need to install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so' (errno: 22 libimf.so: cannot open
shared object file: No such file or directory)
```

You can obtain `libimf` from <http://dev.mysql.com/downloads/os-linux.html>.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
mysql> SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
mysql> SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```
mysql> SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value `N` is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
mysql> STOP SLAVE IO_THREAD; START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]
rpl_semi_sync_slave_enabled=1
```

### 17.3.8.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

## 17.3.9 Delayed Replication

MySQL 5.7 supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time. The default delay is 0 seconds. Use the `MASTER_DELAY` option for `CHANGE MASTER TO` to set the delay to `N` seconds:

```
CHANGE MASTER TO MASTER_DELAY = N;
```

An event received from the master is not executed until at least `N` seconds later than its execution on the master. The exceptions are that there is no delay for format description events or log file rotation events, which affect only the internal state of the SQL thread.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the master. A DBA can roll back a delayed slave to the time just before the disaster.

- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the slave. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging slave.
- To inspect what the database looked like long ago, without having to reload a backup. For example, if the delay is one week and the DBA needs to see what the database looked like before the last few days' worth of development, the delayed slave can be inspected.

`START SLAVE` and `STOP SLAVE` take effect immediately and ignore any delay. `RESET SLAVE` resets the delay to 0.

`SHOW SLAVE STATUS` has three fields that provide information about the delay:

- `SQL_Delay`: A nonnegative integer indicating the number of seconds that the slave must lag the master.
- `SQL_Remaining_Delay`: When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Slave_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the slave SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until MASTER_DELAY seconds after master executed event`.

## 17.4 Replication Notes and Tips

### 17.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.7 (or later), you cannot replicate to a slave that uses MySQL 5.6 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.7 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 19.7, "Binary Logging of Stored Programs"](#). For more information about row-based logging and row-based replication, see [Section 5.2.4.1, "Binary Logging Formats"](#), and [Section 17.2.1, "Replication Formats"](#).

For additional information specific to replication and [InnoDB](#), see [Section 14.16, “InnoDB and MySQL Replication”](#). For information relating to replication with MySQL Cluster, see [MySQL Cluster Replication](#).

### 17.4.1.1 Replication and AUTO\_INCREMENT

Statement-based replication of [AUTO\\_INCREMENT](#), [LAST\\_INSERT\\_ID\(\)](#), and [TIMESTAMP](#) values is done correctly, subject to the following exceptions:

- When using statement-based replication prior to MySQL 5.7.1, [AUTO\\_INCREMENT](#) columns in tables on the slave must match the same columns on the master; that is, [AUTO\\_INCREMENT](#) columns must be replicated to [AUTO\\_INCREMENT](#) columns.
- A statement invoking a trigger or function that causes an update to an [AUTO\\_INCREMENT](#) column is not replicated correctly using statement-based replication. In MySQL 5.7, such statements are marked as unsafe. (Bug #45677)
- An [INSERT](#) into a table that has a composite primary key that includes an [AUTO\\_INCREMENT](#) column that is not the first column of this composite key is not safe for statement-based logging or replication. In MySQL 5.7 and later, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the [InnoDB](#) storage engine, since an [InnoDB](#) table with an [AUTO\\_INCREMENT](#) column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an [AUTO\\_INCREMENT](#) column to a table with [ALTER TABLE](#) might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an [AUTO\\_INCREMENT](#) number. Assuming that you want to add an [AUTO\\_INCREMENT](#) column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an [AUTO\\_INCREMENT](#) column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

#### Important

To guarantee the same ordering on both master and slave, the [ORDER BY](#) clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of [CREATE TABLE ... LIKE](#): Foreign key definitions are ignored, as are the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) table options. If a table definition includes any of those characteristics, create `t2` using a [CREATE TABLE](#) statement that is identical to the one used to create `t1`, but with the addition of the [AUTO\\_INCREMENT](#) column.

Regardless of the method used to create and populate the copy having the [AUTO\\_INCREMENT](#) column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

### 17.4.1.2 Replication and BLACKHOLE Tables

The [BLACKHOLE](#) storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use.

Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. In MySQL 5.7.2 and later, a warning is logged whenever this occurs (Bug #13004581)

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

### 17.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

### 17.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format, which is not guaranteed to remain the same between MySQL release series. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

### 17.4.1.5 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 17.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated in MySQL 5.7, whether or not the event named in the statement already exists on the master.

See also Bug #45574.

### 17.4.1.6 Replication of CREATE TABLE ... SELECT Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

MySQL 5.7 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. Some older versions of MySQL permitted these statements to do so; this means that, when using statement-based replication between a MySQL 5.6 or later slave and a master running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the master fails on the slave, causing replication to stop. To prevent this from happening, you should use row-based replication, rewrite the offending statement before running it on the master, or upgrade the master to MySQL 5.7. (If you choose to upgrade the master, keep in mind that such a `CREATE TABLE ... SELECT` statement fails following the upgrade unless it is rewritten to remove any side effects on other tables.) This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events, rather than as the entire `CREATE TABLE ... SELECT`.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 13.3.3, “Statements That Cause an Implicit Commit”](#)).
- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL 5.7 ignores the statement completely; nothing is inserted or logged. The handling of such statements in this regard has changed considerably in previous MySQL releases; if you are replicating from a MySQL 5.5.6 or older master to a newer slave, see [Replication of CREATE ... IF NOT EXISTS Statements](#), for more information.

### 17.4.1.7 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 5.7, the statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

### 17.4.1.8 Replication of CURRENT\_USER()

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of the statements `CREATE FUNCTION`, `CREATE PROCEDURE`, `CREATE TRIGGER`, `CREATE EVENT`, `CREATE VIEW`, or `ALTER VIEW` when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the same user on both the master and the slave when the statement is replicated. `CURRENT_USER()` or `CURRENT_USER` is also expanded prior to being written to the binary log when used in `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE`, or `ALTER EVENT`.

### 17.4.1.9 Replication of DROP ... IF EXISTS Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

### 17.4.1.10 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

#### Note

Replication between tables which are partitioned differently from one another is not supported. See [Section 17.4.1.19, "Replication and Partitioning"](#).

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

#### Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

(This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
  c1 INT,
  c2 INT,
  c3 INT
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see [Section 11.7, “Data Type Default Values”](#)).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the master.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the slave.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

## Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

### Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, "If the statement run on the master would also execute successfully on the slave, it should also replicate successfully". In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Prior to MySQL 5.7.1, when using statement-based replication, `AUTO_INCREMENT` columns were required to be the same on both the master and the slave; otherwise, updates could be applied to the wrong table on the slave. (Bug #12669186)

**Row-based replication: attribute promotion and demotion.** Row-based replication in MySQL 5.7 supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a "fit" in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy conversion*.

**Type conversion modes (slave\_type\_conversions variable).** The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

| Mode                   | Effect                                                                                                                                                                                                                                                                                         |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ALL_LOSSY</code> | In this mode, type conversions that would mean loss of information are permitted.<br><br>This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this |

| Mode                                  | Effect                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       | mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.                                                                                                                                                                                                                                                                                                                                                         |
| <code>ALL_NON_LOSSY</code>            | This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.<br><br>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code> , then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code> , or <code>CHAR(25)</code> to <code>VARCHAR(20)</code> ) causes the slave to stop with an error. |
| <code>ALL_LOSSY, ALL_NON_LOSSY</code> | When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>ALL_SIGNED</code>               | Treat promoted integer types as signed values (the default behavior).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>ALL_UNSIGNED</code>             | Treat promoted integer types as unsigned values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>ALL_SIGNED, ALL_UNSIGNED</code> | Treat promoted integer types as signed if possible, otherwise as unsigned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| [empty]                               | When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.<br><br>This mode is the default.                                                                                                                                                                                                                                                                                                                                                                                                                            |

When an integer type is promoted, its signedness is not preserved. By default, the slave treats all such values as signed. Beginning with MySQL 5.7.2, you can control this behavior using `ALL_SIGNED`, `ALL_UNSIGNED`, or both. (Bug#15831300) `ALL_SIGNED` tells the slave to treat all promoted integer types as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the slave to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or `ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where  $D' \geq D$  and  $(M' - D') \geq (M - D)$  is non-lossy; for any case where  $M' < M$ ,  $D' < D$ , or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 12.21.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first  $N$  characters of the string on the slave, where  $N$  is the width of the target column.

### Important

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first  $N$  bytes of the string on the slave, where  $N$  is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT( $M$ )` column into a `BIT( $M'$ )` column, where  $M' > M$ , the most significant bits of the `BIT( $M'$ )` columns are cleared (set to zero) and the  $M$  bits of the `BIT( $M$ )` value are set as the least significant bits of the `BIT( $M'$ )` column.

When inserting a value from a source `BIT( $M$ )` column into a target `BIT( $M'$ )` column, where  $M' < M$ , the maximum possible value for the `BIT( $M'$ )` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

#### 17.4.1.11 Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 5.1.7, “Server SQL Modes”](#).

#### 17.4.1.12 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`

- `DROP EVENT`
- `CREATE PROCEDURE`
- `DROP PROCEDURE`
- `CREATE FUNCTION`
- `DROP FUNCTION`
- `CREATE TRIGGER`
- `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

#### Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See [Section 20.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#), and [Section 13.7.5.18, “SHOW EVENTS Syntax”](#), for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLED`, where *event\_name* is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID *master\_id*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

### 17.4.1.13 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 12.2, “Type Conversion in Expression Evaluation”](#), and [Section B.5.4.8, “Problems with Floating-Point Values”](#).

### 17.4.1.14 Replication and Fractional Seconds Support

MySQL 5.7 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 11.3.6, “Fractional Seconds in Time Values”](#).

There may be problems replicating from a master server that understands fractional seconds to an older slave (MySQL 5.6.3 and earlier) that does not:

- For `CREATE TABLE` statements containing columns that have an `fsp` (fractional seconds precision) value greater than 0, replication will fail due to parser errors.
- Statements that use temporal data types with an `fsp` value of 0 will work for with statement-based logging but not row-based logging. In the latter case, the data types have binary formats and type codes on the master that differ from those on the slave.
- Some expression results will differ on master and slave. Examples: On the master, the `timestamp` system variable returns a value that includes a microseconds fractional part; on the slave, it returns an integer. On the master, functions that return a result that includes the current time (such as `CURTIME()`, `SYSDATE()`, or `UTC_TIMESTAMP()`) interpret an argument as an `fsp` value and the return value includes a fractional seconds part of that many digits. On the slave, these functions permit an argument but ignore it.

### 17.4.1.15 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 13.7.6.3, “FLUSH Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 17.4.1.16 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See [Section 17.2.1, “Replication Formats”](#).)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also [Section 17.4.1.8, “Replication of CURRENT\\_USER\(\)”](#).) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both master and slave. See also [Section 17.4.1.32, “Replication and Time Zones”](#)

To explain the potential problems when replicating between servers which are in different time zones, suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
```

```
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also [Section 17.4.1.32, “Replication and Time Zones”](#).

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that

in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.7.3, the value of `LAST_INSERT_ID()` was not replicated correctly if any filtering options such as `--replicate-ignore-db` and `--replicate-do-table` were enabled on the slave. (Bug #17234370, BUG# 69861)

#### 17.4.1.17 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

#### 17.4.1.18 Replication and LOAD DATA INFILE

In MySQL 5.7, `LOAD DATA INFILE` is considered unsafe (see [Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#)). It causes a warning when using statement-based logging format, and is logged using row-based format when using mixed-format logging.

#### 17.4.1.19 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see [Section 17.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#)).

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

### 17.4.1.20 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

### 17.4.1.21 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 5.1.4, “Server System Variables”](#).

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see [Section 17.4.1.24, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. The default value of `sync_relay_log_info` is 0, which does not cause writes to be forced to disk; the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

### 17.4.1.22 Replication and max\_allowed\_packet

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

### 17.4.1.23 Replication and MEMORY Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see [Section 17.4.1.38, “Replication and Variables”](#)). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See [Section 15.3, “The MEMORY Storage Engine”](#), for more information about `MEMORY` tables.

#### 17.4.1.24 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when `binlog_format=ROW` because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the slave can be an issue, whenever `binlog_format` is `STATEMENT` or `MIXED`, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see [Row-based logging of temporary tables](#).

**Safe slave shutdown when using temporary tables.** Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.

3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

### 17.4.1.25 Replication of the mysql System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

### 17.4.1.26 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 17.4.1.17, “Replication and LIMIT”](#), for a detailed discussion of these.

### 17.4.1.27 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `virtual` on a 5.6 master that is replicating to a 5.7 or higher slave because `VIRTUAL` is a reserved word beginning in MySQL 5.7. Replication can fail in such cases with Error 1064 *You have an error in your SQL syntax... , even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 9.2, “Schema Object Names”](#).

### 17.4.1.28 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

### 17.4.1.29 Replication of Server-Side Help Tables

The server maintains tables in the `mysql` database that store information for the `HELP` statement (see [Section 13.8.3, “HELP Syntax”](#)). These tables can be loaded manually as described at [Section 5.1.10, “Server-Side Help”](#).

Help table content is derived from the MySQL Reference Manual. There are versions of the manual specific to each MySQL release series, so help content is specific to each series as well. Normally, you load a version of help content that matches the server version. This has implications for replication. For example, you would load MySQL 5.6 help content into a MySQL 5.6 master server, but not necessarily replicate that content to a MySQL 5.7 slave server for which 5.7 help content is more appropriate.

This section describes how to manage help table content upgrades when your servers participate in replication. Server versions are one factor in this task. Another is that help table structure may differ between the master and the slave.

Assume that help content is stored in a file named `fill_help_tables.sql`. In MySQL distributions, this file is located under the `share` or `share/mysql` directory, and the most recent version is always available for download from <http://dev.mysql.com/doc/index-other.html>.

To upgrade help tables, using the following procedure. Connection parameters are not shown for the `mysql` commands discussed here; in all cases, connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database.

1. Upgrade your servers by running `mysql_upgrade`, first on the slaves and then on the master. This is the usual principle of upgrading slaves first.
2. Decide whether you want to replicate help table content from the master to its slaves. If not, load the content on the master and each slave individually. Otherwise, check for and resolve any incompatibilities between help table structure on the master and its slaves, then load the content into the master and let it replicate to the slaves.

More detail about these two methods of loading help table content follows.

## Loading Help Table Content Without Replication to Slaves

To load help table content without replication, run this command on the master and each slave individually, using a `fill_help_tables.sql` file containing content appropriate to the server version (enter the command on one line):

```
mysql --init-command="SET sql_log_bin=0"
mysql < fill_help_tables.sql
```

Use the `--init-command` option on each server, including the slaves, in case a slave also acts as a master to other slaves in your replication topology. The `SET` statement suppresses binary logging. After the command has been run on each server to be upgraded, you are done.

### Note

As of MySQL 5.7.5, the `fill_help_tables.sql` file includes the `SET` statement to cause the file contents not to replicate. Thus, for 5.7. and up, the command is simpler:

```
mysql mysql < fill_help_tables.sql
```

## Loading Help Table Content With Replication to Slaves

### Note

As mentioned previously, `fill_help_tables.sql` in MySQL 5.7.5 and up includes a `SET` statement to suppress binary logging of the file contents. If you want to replicate help table contents for MySQL 5.7.5 or later, you must edit `fill_help_tables.sql` to remove the `SET` statement. This should rarely be desirable because help table contents are specific to the version of the server into which they are loaded, which may differ for master and slave.

If you do want to replicate help table content, check for help table incompatibilities between your master and its slaves. The `url` column in the `help_category` and `help_topic` tables was originally `CHAR(128)`, but is `TEXT` in newer MySQL versions to accommodate longer URLs. To check help table structure, use this statement:

```
SELECT TABLE_NAME, COLUMN_NAME, COLUMN_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'mysql'
AND COLUMN_NAME = 'url';
```

For tables with the old structure, the statement produces this result:

```
+-----+-----+-----+
| TABLE_NAME | COLUMN_NAME | COLUMN_TYPE |
+-----+-----+-----+
| help_category | url         | char(128)   |
| help_topic   | url         | char(128)   |
+-----+-----+-----+
```

For tables with the new structure, the statement produces this result:

```
+-----+-----+-----+
| TABLE_NAME | COLUMN_NAME | COLUMN_TYPE |
+-----+-----+-----+
| help_category | url         | text        |
| help_topic   | url         | text        |
+-----+-----+-----+
```

If the master and slave both have the old structure or both have the new structure, they are compatible and you can replicate help table content by executing this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

If the master and slave have incompatible help tables (one server has the old structure and the other has the new), you have a choice between not replicating help table content after all, or making the table structures compatible so that you can replicate the content.

- If you decide not to replicate the content after all, upgrade the master and slaves individually using `mysql` with the `--init-command` option, as described previously.
- If instead you decide to make the table structures compatible, upgrade the tables on the server that has the old structure. Suppose that your master server has the old table structure. Upgrade its tables to the new structure manually by executing these statements (binary logging is disabled here to prevent replication of the changes to the slaves, which already have the new structure):

```
SET sql_log_bin=0;
ALTER TABLE mysql.help_category ALTER COLUMN url TEXT;
ALTER TABLE mysql.help_topic ALTER COLUMN url TEXT;
```

Then run this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

### 17.4.1.30 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see [Section 5.1.7, “Server SQL Modes”](#). In particular, see [SQL Mode Changes in MySQL 5.7](#), which describes changes in MySQL 5.7 so that you can assess whether your applications will be affected.

### 17.4.1.31 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows:

If the slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDB TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the slave automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see [Section 5.1.6, “Server Status Variables”](#).

### 17.4.1.32 Replication and Time Zones

By default, master and slave servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both master and slave.

Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. Set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also [Section 17.4.1.16, “Replication and System Functions”](#).

### 17.4.1.33 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

#### **Transactional, nontransactional, and mixed statements.**

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. In MySQL 5.7, a statement that references both nontransactional and transactional tables and updates *any* of the tables involved, is considered a “mixed” statement. (In previous MySQL release series, a statement that changed both nontransactional and transactional tables was considered mixed.) Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a transactional table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_trans_update` is `OFF`

For more information, see [Section 17.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

#### **Note**

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before

the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

In MySQL 5.7, it is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases, an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

**Changing the binary logging format within transactions.** The `binlog_format` system variable is read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. In MySQL 5.7, this true is even for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

#### 17.4.1.34 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- *Half-applied transactions.* A transaction which updates non-transactional tables has applied some but not all of its changes.
- *Gaps.* A gap is a transaction that has not been (fully) applied, even though some later transaction has been applied. Gaps can only appear when using a multi-threaded slave. To avoid gaps occurring, set `slave_preserve_commit_order=1`, which requires `slave_parallel_type=LOGICAL_CLOCK`, and that `log-bin` and `log-slave-updates` are also enabled.
- *Gap-free low-watermark position.* Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have not been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N`. This can only happen on multi-threaded slaves. Enabling `slave_preserve_commit_order` does *not* prevent gap-free low-watermark positions.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and gap-free low-watermark position inconsistencies:

1. While slave threads are running, there may be gaps and half-applied transactions.
2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.

3. `KILL` of replication threads (the SQL thread when using a single-threaded slave, the coordinator thread when using a multi-threaded slave). This aborts ongoing transactions and may leave gaps and half-applied transactions.
4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multi-threaded slave, workers which have not received an error complete their queues, so it may take time to stop all threads.
5. `STOP SLAVE` when using a multi-threaded slave. After issuing `STOP SLAVE`, the slave waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or gap-free low-watermark positions, unless any of the cases above applies (in other words, before `STOP SLAVE` completes, either an error happens, or another thread issues `KILL`, or the server restarts. In these cases, `STOP SLAVE` returns successfully.)
6. If the last transaction in the relay log is only half-received and the multi-threaded slave coordinator has started to schedule the transaction to a worker, then `STOP SLAVE` waits up to 60 seconds for the transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.
7. `STOP SLAVE` when using a single-threaded slave. If the ongoing transaction only updates transactional tables, it is rolled back and `STOP SLAVE` stops immediately. If the ongoing transaction is mixed, `STOP SLAVE` waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global variable `rpl_stop_slave_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues `STOP SLAVE` return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The slave database is in a state that may never have existed on the master.
2. The field `Exec_master_log_pos` in `SHOW SLAVE STATUS` is only a "low-watermark". In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.
3. `CHANGE MASTER TO` statements for that channel fail with an error, unless the applier threads are running and the `CHANGE MASTER TO` statement only sets receiver options.
4. If `mysqld` is started with `--relay-log-recovery`, no recovery is done for that channel, and a warning is printed.
5. If `mysqldump` is used with `--dump-slave`, it does not record the existence of gaps; thus it prints `CHANGE MASTER TO` with `RELAY_LOG_POS` set to the low-watermark position in `Exec_master_log_pos`.

After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use `--dump-slave`).

If a replication channel has a gap-free low-watermark position, cases 2 to 5 above apply, but case 1 does not.

The gap-free low-watermark position information is persisted in binary format in the internal table `mysql.slave_worker_info`. `START SLAVE [SQL_THREAD]` always consults this information so that it applies only the correct transactions. This remains true even if `slave_parallel_workers` has been changed to 0 before `START SLAVE`, and even if `START SLAVE` is used with `UNTIL` clauses. `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` only applies as many transactions as needed in order to fill in the gaps. If `START SLAVE` is used with `UNTIL` clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

### Warning

`RESET SLAVE` removes the relay logs and resets the replication position. Thus issuing `RESET SLAVE` on a slave with gaps means the slave loses any information about the gaps, without correcting the gaps.

`slave-preserve-commit-order` ensures that there are no gaps. However, it is still possible that `Exec_master_log_pos` is just a gap-free low-watermark position in scenarios 1 to 4 above. That is, there may be transactions after `Exec_master_log_pos` which have been applied. Therefore the cases numbered 2 to 5 above (but not case 1) apply, even when `slave-preserve-commit-order` is enabled.

#### 17.4.1.35 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 5.7 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), but before MySQL 5.7.2 cannot have multiple triggers that have the same trigger event and action time. MySQL 5.7.2 lifts this limitation and multiple triggers are permitted. This change has replication implications for upgrades and downgrades.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

**Upgrades.** Suppose that you upgrade an old server that does not support multiple triggers to MySQL 5.7.2 or newer. If the new server is a replication master and has old slaves that do not support multiple triggers, an error occurs on those slaves if a trigger is created on the master for a table that already has a trigger with the same trigger event and action time. To avoid this problem, upgrade the slaves first, then upgrade the master.

**Downgrades.** If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions remain in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about `.TRG` files, see [Table Trigger Storage](#).
- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table's `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.
2. Drop all triggers for the table.
3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

### 17.4.1.36 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in [Section 13.1.29, “TRUNCATE TABLE Syntax”](#) governing such tables. (Bug #36763)

### 17.4.1.37 Replication and User Name Length

The maximum length of MySQL user names was increased from 16 characters to 32 characters in MySQL 5.7.8. Replication of user names longer than 16 characters to a slave that supports only shorter user names will fail. However, this should occur only when replicating from a newer master to an older slave, which is not a recommended configuration.

### 17.4.1.38 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`

- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 5.2.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` and `storage_engine` system variables are not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see [Section 17.4.1.23, “Replication and MEMORY Tables”](#).

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 17.2.1, “Replication Formats”](#).

In MySQL 5.7, the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`

- `collation_database`
- `collation_server`
- `sql_auto_is_null`

#### Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both master and slave, especially when you are running MySQL on platforms with case-sensitive file systems.

### 17.4.1.39 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. In MySQL 5.7.1 and later, trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

## 17.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.5 to a slave running MySQL 5.6, from a master running MySQL 5.6 to a slave running MySQL 5.7, and so on.

However, you may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, in MySQL 5.5, `CREATE TABLE ... SELECT` statements are permitted to change tables other than the one being created, but are no longer allowed to do so in MySQL 5.6 (see [Section 17.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#)).

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.7.1, MySQL 5.7.2, and MySQL 5.7.4 concurrently, although you could use any two of these releases together.

#### Important

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible.

This also has significant implications for upgrading replication servers; see [Section 17.4.3, “Upgrading a Replication Setup”](#), for more information.

- For more information about row-based replication, see [Section 17.2.1, “Replication Formats”](#).
- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see [Section 17.4.1, “Replication Features and Issues”](#).

### 17.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from older versions of MySQL to MySQL 5.7. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.7 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.7.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.7.x version, restart it, and restart replication. Relay logs created by the slave after the upgrade are in 5.7 format.

Changes affecting operations in strict SQL mode may result in replication failure on an updated slave. For example, as of MySQL 5.7.2, the server restricts insertion of a `DEFAULT` value of 0 for temporal data types in strict mode (`STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`). A resulting incompatibility for replication if you use statement-based logging (`binlog_format=STATEMENT`) is that if a slave is upgraded, a nonupgraded master will execute statements without error that may fail on the slave and replication will stop. To deal with this, stop all new statements on the master and wait until the slaves catch up. Then upgrade the slaves. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the master (`binlog_format=ROW`) and wait until all slaves have processed all binary logs produced up to the point of this change. Then upgrade the slaves.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.7.x release as the slaves, and restart it. If you had temporarily changed the master to row-based logging, change it back to statement-based logging. The 5.7 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.7 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.7 format. These too are recognized by the 5.7 slaves.

In other words, when upgrading to MySQL 5.7, the slaves must be MySQL 5.7 before you can upgrade the master to 5.7. Note that downgrading from 5.7 to older versions does not work so simply: You must ensure that any 5.7 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binlog. See [Section 17.2.1, “Replication Formats”](#).

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, will be detailed at [Section 2.11.1.1, “Changes Affecting Upgrades to MySQL 5.7”](#). It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.
2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.
3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.
4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.
5. Restart the slaves, this time without the `--skip-slave-start` option.

If you are upgrading an existing replication setup from a version of MySQL that does not support global transaction identifiers to a version that does, you should not enable GTIDs on either the master or the slave before making sure that the setup meets all the requirements for GTID-based replication. See [Section 17.1.3.2, “Setting Up Replication Using GTIDs”](#), which contains information about converting existing replication setups to use GTID-based replication.

## 17.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.
- Verify that the master and slave both were started with the `--server-id [2426]` option and that the ID value is unique on each server.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 17.2.2, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
  - Verify the privileges for the user being used for replication on the master.
  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
  - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.

- If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
- Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 17.4.1, “Replication Features and Issues”](#). If it is a bug, see [Section 17.4.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;  
mysql> START SLAVE;
```

The value of *N* should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also [Section 13.4.2.5, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 17.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*

2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary log files from the master
  - All binary log files from the slave
  - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
  - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
  - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.7, “How to Report Bugs or Problems”](#).

This chapter discusses MySQL's implementation of *user-defined partitioning*. You can determine whether your MySQL Server supports partitioning by checking the output of the `SHOW PLUGINS` statement, like this:

```
mysql> SHOW PLUGINS;
```

| Name             | Status        | Type                  | Library     | License    |
|------------------|---------------|-----------------------|-------------|------------|
| binlog           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| <b>partition</b> | <b>ACTIVE</b> | <b>STORAGE ENGINE</b> | <b>NULL</b> | <b>GPL</b> |
| ARCHIVE          | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| BLACKHOLE        | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| CSV              | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| FEDERATED        | DISABLED      | STORAGE ENGINE        | NULL        | GPL        |
| MEMORY           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| InnoDB           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| MRG_MYISAM       | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| MyISAM           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| ndbcluster       | DISABLED      | STORAGE ENGINE        | NULL        | GPL        |

```
11 rows in set (0.00 sec)
```

You can also check the `INFORMATION_SCHEMA.PLUGINS` table with a query similar to this one:

```
mysql> SELECT
->     PLUGIN_NAME as Name,
->     PLUGIN_VERSION as Version,
->     PLUGIN_STATUS as Status
-> FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_TYPE='STORAGE ENGINE';
```

```

+-----+-----+-----+
| Name          | Version | Status |
+-----+-----+-----+
binlog	1.0	ACTIVE
CSV	1.0	ACTIVE
MEMORY	1.0	ACTIVE
MRG_MYISAM	1.0	ACTIVE
MyISAM	1.0	ACTIVE
PERFORMANCE_SCHEMA	0.1	ACTIVE
BLACKHOLE	1.0	ACTIVE
ARCHIVE	3.0	ACTIVE
InnoDB	5.7	ACTIVE
partition	1.0	ACTIVE
+-----+-----+-----+
10 rows in set (0.00 sec)

```

In either case, if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output (shown in bold text in each of the examples just given), then your version of MySQL was not built with partitioning support.

MySQL 5.7 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in MySQL Enterprise Edition binaries, see [Chapter 25, MySQL Enterprise Edition](#).

To enable partitioning if you are compiling MySQL 5.7 from source, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information, see [Section 2.9, “Installing MySQL from Source”](#).

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option, in which case the value of `have_partitioning` is `DISABLED`. When partitioning support is disabled, you can see any existing partitioned tables and drop them (although doing this is not advised), but you cannot otherwise manipulate them or access their data.

See [Section 18.1, “Overview of Partitioning in MySQL”](#), for an introduction to partitioning and partitioning concepts.

MySQL supports several types of partitioning as well as subpartitioning; see [Section 18.2, “Partitioning Types”](#), and [Section 18.2.6, “Subpartitioning”](#).

[Section 18.3, “Partition Management”](#), covers methods of adding, removing, and altering partitions in existing partitioned tables.

[Section 18.3.4, “Maintenance of Partitions”](#), discusses table maintenance commands for use with partitioned tables.

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See [Section 20.14, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#), for more information; for some examples of queries against this table, see [Section 18.2.7, “How MySQL Partitioning Handles NULL”](#).

For known issues with partitioning in MySQL 5.7, see [Section 18.6, “Restrictions and Limitations on Partitioning”](#).

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.7 binaries are available from <http://dev.mysql.com/downloads/mysql/5.7.html>. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our GitHub repository. To enable partitioning, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see [Section 2.9, "Installing MySQL from Source"](#). If you have problems compiling a partitioning-enabled MySQL 5.7 build, check the [MySQL Partitioning Forum](#) and ask for assistance there if you do not find a solution to your problem already posted.

## 18.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.7.

For information on partitioning restrictions and feature limitations, see [Section 18.6, "Restrictions and Limitations on Partitioning"](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 8.12.4, "Using Symbolic Links"](#), for an explanation of how this is done).

*Partitioning* takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of `RANGE`, `LIST`, and `[LINEAR] HASH` partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer *intval* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.)

For `[LINEAR] KEY`, `RANGE COLUMNS`, and `LIST COLUMNS` partitioning, the partitioning expression consists of a list of one or more columns.

For `[LINEAR] KEY` partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see [Section 18.2, “Partitioning Types”](#), as well as [Section 13.1.14, “CREATE TABLE Syntax”](#), which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see [Section 18.6.3, “Partitioning Limitations Relating to Functions”](#).

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.7 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.7.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see [Chapter 18, Partitioning](#).

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.7, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use `MyISAM` for one partition and `InnoDB` for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the `MERGE`, `CSV`, or `FEDERATED` storage engines.

To employ a particular storage engine for a partitioned table, it is necessary only to use the `[STORAGE] ENGINE` option just as you would for a nonpartitioned table. However, you should keep in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the `InnoDB` storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) )
PARTITIONS 6;
```

Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.7 this has no effect.

### Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions of `MyISAM` tables on Windows. They are supported for individual partitions and subpartitions of `InnoDB` tables (as on all platforms).

All columns used in the table's partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```
CREATE TABLE tnp (
  id INT NOT NULL AUTO_INCREMENT,
  ref BIGINT NOT NULL,
  name VARCHAR(255),
  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table's primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See [Section 18.6.1, "Partitioning Keys, Primary Keys, and Unique Keys"](#), for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See [Section 18.3, "Partition Management"](#), for more information on these options.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see [Section 18.4, "Partition Pruning"](#).

In addition, MySQL 5.7 supports explicit partition selection for queries. For example, `SELECT * FROM t PARTITION (p0,p1) WHERE c < 5` selects only those rows in partitions `p0` and `p1` that match the `WHERE` condition. In this case, MySQL does not check any other partitions of table `t`; this can greatly speed up queries when you already know which partition or partitions you wish to examine. Partition selection is also supported for the data modification statements `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and `LOAD DATA`, `LOAD XML`. See the descriptions of these statements for more information and examples.

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;`. By "parallelized," we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as MySQL Partitioning development continues.

## 18.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.7. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See [Section 18.2.1, “RANGE Partitioning”](#). For information about an extension to this type, [RANGE COLUMNS](#), see [Section 18.2.3.1, “RANGE COLUMNS partitioning”](#).
- **LIST partitioning.** Similar to partitioning by [RANGE](#), except that the partition is selected based on columns matching one of a set of discrete values. See [Section 18.2.2, “LIST Partitioning”](#). For information about an extension to this type, [LIST COLUMNS](#), see [Section 18.2.3.2, “LIST COLUMNS partitioning”](#).
- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, [LINEAR HASH](#), is also available. See [Section 18.2.4, “HASH Partitioning”](#).
- **KEY partitioning.** This type of partitioning is similar to partitioning by [HASH](#), except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, [LINEAR KEY](#), is also available. See [Section 18.2.5, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.7. However, it is not difficult in MySQL to create partitioning schemes based on [DATE](#), [TIME](#), or [DATETIME](#) columns, or based on expressions making use of such columns.

When partitioning by [KEY](#) or [LINEAR KEY](#), you can use a [DATE](#), [TIME](#), or [DATETIME](#) column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

In MySQL 5.7, it is also possible to use a [DATE](#) or [DATETIME](#) column as the partitioning column using [RANGE COLUMNS](#) and [LIST COLUMNS](#) partitioning.

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or [NULL](#). If you wish to use date-based partitioning by [RANGE](#), [LIST](#), [HASH](#), or [LINEAR HASH](#), you can simply employ a function that operates on a [DATE](#), [TIME](#), or [DATETIME](#) column and returns such a value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
```

```
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- [Section 18.2.1, “RANGE Partitioning”](#)
- [Section 18.2.4, “HASH Partitioning”](#)
- [Section 18.2.4.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see the following sections:

- [Section 18.4, “Partition Pruning”](#)
- [Section 18.2.6, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the `TO_DAYS()`, `YEAR()`, and `TO_SECONDS()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See [Section 12.7, “Date and Time Functions”](#), for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user function employed must return an integer value greater than 0. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
-> PARTITION mypart VALUES IN (1,3,5),
-> PARTITION MyPart VALUES IN (2,4,6)
-> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 13.1.14, “CREATE TABLE Syntax”](#).

## 18.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
```

```

id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT NOT NULL,
store_id INT NOT NULL
);

```

**Note**

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see [Section 18.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#).

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21)
);

```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Michael', 'Widenius', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21<sup>st</sup> store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),

```

```

PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

**Note**

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see [Section 18.2.2, “LIST Partitioning”](#). Also see [Section 13.2.5, “INSERT Syntax”](#), for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 18.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
  PARTITION p0 VALUES LESS THAN (100),
  PARTITION p1 VALUES LESS THAN (1000),
  PARTITION p2 VALUES LESS THAN (10000)
);

```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN (<)` comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1996),
  PARTITION p2 VALUES LESS THAN (2001),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

It is also possible to partition a table by `RANGE`, based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
  report_id INT NOT NULL,
  report_status VARCHAR(20) NOT NULL,
  report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
  PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
  PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
  PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
  PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
  PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
  PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
  PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
  PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
  PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
  PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0`; to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 13.1.6, “ALTER TABLE Syntax”](#), and [Section 18.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990`;
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id`; MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 18.4, “Partition Pruning”](#), for more information about how this is accomplished.

A variant on this type of partitioning is `RANGE COLUMNS` partitioning. Partitioning by `RANGE COLUMNS` makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See [Section 18.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

**Partitioning schemes based on time intervals.** If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 5.7, you have two options:

1. Partition the table by `RANGE`, and for the partitioning expression, employ a function operating on a `DATE`, `TIME`, or `DATETIME` column and returning an integer value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
```

```

    joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

In MySQL 5.7, it is also possible to partition a table by [RANGE](#) based on the value of a [TIMESTAMP](#) column, using the [UNIX\\_TIMESTAMP\(\)](#) function, as shown in this example:

```

CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);

```

In MySQL 5.7, any other expressions involving [TIMESTAMP](#) values are not permitted. (See Bug #42849.)

#### Note

It is also possible in MySQL 5.7 to use [UNIX\\_TIMESTAMP\(timestamp\\_column\)](#) as a partitioning expression for tables that are partitioned by [LIST](#). However, it is usually not practical to do so.

- Partition the table by [RANGE COLUMNS](#), using a [DATE](#) or [DATETIME](#) column as the partitioning column. For example, the `members` table could be defined using the `joined` column directly, as shown here:

```

CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY RANGE COLUMNS(joined) (
    PARTITION p0 VALUES LESS THAN ('1960-01-01'),
    PARTITION p1 VALUES LESS THAN ('1970-01-01'),
    PARTITION p2 VALUES LESS THAN ('1980-01-01'),
    PARTITION p3 VALUES LESS THAN ('1990-01-01'),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

#### Note

The use of partitioning columns employing date or time types other than [DATE](#) or [DATETIME](#) is not supported with [RANGE COLUMNS](#).

## 18.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by [RANGE](#), each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where *expr* is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where *value\_list* is a comma-separated list of integers.

#### Note

In MySQL 5.7, it is possible to match against only a list of integers (and possibly `NULL`—see [Section 18.2.7, “How MySQL Partitioning Handles NULL”](#)) when partitioning by `LIST`.

However, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see [Section 13.1.14, “CREATE TABLE Syntax”](#).

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
);
```

(This is the same table used as a basis for the examples in [Section 18.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

| Region  | Store ID Numbers     |
|---------|----------------------|
| North   | 3, 5, 6, 9, 17       |
| East    | 1, 2, 10, 11, 19, 20 |
| West    | 4, 12, 13, 14, 18    |
| Central | 7, 8, 15, 16         |

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LIST(store_id) (
  PARTITION pNorth VALUES IN (3,5,6,9,17),
  PARTITION pEast VALUES IN (1,2,10,11,19,20),
```

```

PARTITION pWest VALUES IN (4,12,13,14,18),
PARTITION pCentral VALUES IN (7,8,15,16)
);

```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 5.7, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);` (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with [RANGE](#) partitioning, it is possible to combine [LIST](#) partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 18.2.6, “Subpartitioning”](#).

Unlike the case with [RANGE](#) partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```

mysql> CREATE TABLE h2 (
->   c1 INT,
->   c2 INT
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (1, 4, 7),
->   PARTITION p1 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3

```

When inserting multiple rows using a single `INSERT` statement the behavior depends on whether the table uses a transactional storage engine. For an `InnoDB` table, the statement is considered a single transaction, so the presence of any unmatched values causes the statement to fail completely, and no rows are inserted. For a table using a nontransactional storage engine such as `MyISAM`, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values are inserted, and no errors are reported:

```

mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5 Duplicates: 2 Warnings: 0

mysql> SELECT * FROM h2;
+-----+-----+
| c1    | c2    |
+-----+-----+
7	5
1	9
2	5
+-----+-----+
3 rows in set (0.00 sec)

```

MySQL 5.7 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, as well as to use multiple columns as partitioning keys. For more information, see [Section 18.2.3.2, “LIST COLUMNS partitioning”](#).

## 18.2.3 COLUMNS Partitioning

The next two sections discuss *COLUMNS partitioning*, which are variants on `RANGE` and `LIST` partitioning. `COLUMNS` partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both `RANGE COLUMNS` partitioning and `LIST COLUMNS` partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT (INTEGER)`, and `BIGINT`. (This is the same as with partitioning by `RANGE` and `LIST`.)

Other numeric data types (such as `DECIMAL` or `FLOAT`) are not supported as partitioning columns.

- `DATE` and `DATETIME`.

Columns using other data types relating to dates or times are not supported as partitioning columns.

- The following string types: `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY`.

`TEXT` and `BLOB` columns are not supported as partitioning columns.

The discussions of `RANGE COLUMNS` and `LIST COLUMNS` partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see [Section 18.2.1, “RANGE Partitioning”](#), and [Section 18.2.2, “LIST Partitioning”](#), respectively.

### 18.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

`RANGE COLUMNS` partitioning differs significantly from `RANGE` partitioning in the following ways:

- `RANGE COLUMNS` does not accept expressions, only names of columns.
- `RANGE COLUMNS` accepts a list of one or more columns.

`RANGE COLUMNS` partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in `RANGE COLUMNS` partitions is also based on comparisons between tuples; this is discussed further later in this section.

- `RANGE COLUMNS` partitioning columns are not restricted to integer columns; string, `DATE` and `DATETIME` columns can also be used as partitioning columns. (See [Section 18.2.3, “COLUMNS Partitioning”](#), for details.)

The basic syntax for creating a table partitioned by `RANGE COLUMNS` is shown here:

```
CREATE TABLE table_name
PARTITIONED BY RANGE COLUMNS(column_list) (
  PARTITION partition_name VALUES LESS THAN (value_list)[,
  PARTITION partition_name VALUES LESS THAN (value_list)[,
  ...]
```

```
)

column_list:
    column_name[, column_name][, ...]

value_list:
    value[, value][, ...]
```

**Note**

Not all `CREATE TABLE` options that can be used when creating partitioned tables are shown here. For complete information, see [Section 13.1.14, “CREATE TABLE Syntax”](#).

In the syntax just shown, `column_list` is a list of one or more columns (sometimes called a *partitioning column list*), and `value_list` is a list of values (that is, it is a *partition definition value list*). A `value_list` must be supplied for each partition definition, and each `value_list` must have the same number of values as the `column_list` has columns. Generally speaking, if you use `N` columns in the `COLUMNS` clause, then each `VALUES LESS THAN` clause must also be supplied with a list of `N` values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the `CREATE TABLE` statement. As with table partitioned by `RANGE`, you can use `MAXVALUE` to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a `CREATE TABLE` statement that helps to illustrate all of these points:

```
mysql> CREATE TABLE rcx (
->     a INT,
->     b INT,
->     c CHAR(3),
->     d INT
-> )
-> PARTITION BY RANGE COLUMNS(a,d,c) (
->     PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
->     PARTITION p1 VALUES LESS THAN (10,20,'mmmm'),
->     PARTITION p2 VALUES LESS THAN (15,30,'sss'),
->     PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
Query OK, 0 rows affected (0.15 sec)
```

Table `rcx` contains the columns `a`, `b`, `c`, `d`. The partitioning column list supplied to the `COLUMNS` clause uses 3 of these columns, in the order `a`, `d`, `c`. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form `(INT, INT, CHAR(3))`, which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the `COLUMNS` clause with the tuples used in the `VALUES LESS THAN` clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of `VALUES LESS THAN` as used with `RANGE COLUMNS` partitions differs somewhat from the case with simple `RANGE` partitions. In `RANGE` partitioning, a row generating an expression value that is equal to a limiting value in a `VALUES LESS THAN` is never placed in the corresponding partition; however, when using `RANGE COLUMNS` partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a `VALUES LESS THAN` value list to be placed in the corresponding partition.

Consider the `RANGE` partitioned table created by this statement:

```
CREATE TABLE r1 (
```

```

a INT,
b INT
)
PARTITION BY RANGE (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);

```

If we insert 3 rows into this table such that the column value for `a` is 5 for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the `INFORMATION_SCHEMA.PARTITIONS` table:

```

mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

```

```

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'r1';

```

| PARTITION_NAME | TABLE_ROWS |
|----------------|------------|
| p0             | 0          |
| p1             | 3          |

2 rows in set (0.00 sec)

Now consider a similar table `rc1` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```

CREATE TABLE rc1 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a, b) (
  PARTITION p0 VALUES LESS THAN (5, 12),
  PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);

```

If we insert exactly the same rows into `rc1` as we just inserted into `r1`, the distribution of the rows is quite different:

```

mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

```

```

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rc1';

```

| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
|--------------|----------------|------------|
| p            | p0             | 2          |
| p            | p1             | 1          |

2 rows in set (0.00 sec)

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition `p0` in table `rc1`, like this:

```

mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);

```

| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
|-----------------|-----------------|-----------------|
| 1               | 1               | 0               |

```
+-----+-----+
1 row in set (0.00 sec)
```

The 2 tuples (5,10) and (5,11) evaluate as less than (5,12), so they are stored in partition p0. Since 5 is not less than 5 and 12 is not less than 12, (5,12) is considered not less than (5,12), and is stored in partition p1.

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```

For more information about the use of row constructors in MySQL, see [Section 13.2.10.5, “Row Subqueries”](#).

For a table partitioned by `RANGE COLUMNS` using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by `RANGE`. The following `CREATE TABLE` statement creates a table partitioned by `RANGE COLUMNS` using 1 partitioning column:

```
CREATE TABLE rx (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert the rows (5,10), (5,11), and (5,12) into this table, we can see that their placement is the same as it is for the table `r` we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rx';
+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p             | p0             | 0           |
| p             | p1             | 3           |
+-----+-----+
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by `RANGE COLUMNS` where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc2 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);

CREATE TABLE rc3 (
  a INT,
```

## COLUMNS Partitioning

```
b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (10,35),
  PARTITION p4 VALUES LESS THAN (20,40),
  PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column `b` is 25 for partition `p0` and 20 for partition `p1`, and the limiting value of column `c` is 100 for partition `p1` and 50 for partition `p2`:

```
CREATE TABLE rc4 (
  a INT,
  b INT,
  c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) (
  PARTITION p0 VALUES LESS THAN (0,25,50),
  PARTITION p1 VALUES LESS THAN (10,20,100),
  PARTITION p2 VALUES LESS THAN (10,30,50)
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
);
```

When designing tables partitioned by `RANGE COLUMNS`, you can always test successive partition definitions by comparing the desired tuples using the `mysql` client, like this:

```
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```
mysql> CREATE TABLE rcf (
->   a INT,
->   b INT,
->   c INT
-> )
-> PARTITION BY RANGE COLUMNS(a,b,c) (
->   PARTITION p0 VALUES LESS THAN (0,25,50),
->   PARTITION p1 VALUES LESS THAN (20,20,100),
->   PARTITION p2 VALUES LESS THAN (10,30,50),
->   PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition `p2` because the tuple used to define it is not less than the tuple used to define partition `p3`, as shown here:

```
mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-----+-----+
| 1 | 0 |
+-----+-----+
1 row in set (0.00 sec)
```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See [Section 18.2.3, “COLUMNS Partitioning”](#), for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee's last name, like this:

```
CREATE TABLE employees_by_lname (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE COLUMNS (lname) (
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname) (
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

### Note

Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, `'and'` sorts before `'Andersen'`, but when using a collation that is case insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see [Section 10.1, “Character Set Support”](#).

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired) (
  PARTITION p0 VALUES LESS THAN ('1970-01-01'),
  PARTITION p1 VALUES LESS THAN ('1980-01-01'),
  PARTITION p2 VALUES LESS THAN ('1990-01-01'),
  PARTITION p3 VALUES LESS THAN ('2000-01-01'),
  PARTITION p4 VALUES LESS THAN ('2010-01-01'),
  PARTITION p5 VALUES LESS THAN (MAXVALUE)
);
```

See [Section 13.1.14, “CREATE TABLE Syntax”](#), for additional information about `PARTITION BY RANGE COLUMNS` syntax.

### 18.2.3.2 LIST COLUMNS partitioning

MySQL 5.7 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than integer types to be used as partitioning columns; you can use string types, `DATE`, and `DATETIME` columns. (For more information about permitted data types for `COLUMNS` partitioning columns, see [Section 18.2.3, “COLUMNS Partitioning”](#).)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

| Region | Cities                         |
|--------|--------------------------------|
| 1      | Oskarshamn, Högsby, Mönsterås  |
| 2      | Vimmerby, Hultsfred, Västervik |
| 3      | Nässjö, Eksjö, Vetlanda        |
| 4      | Uppvidinge, Alvesta, Växjö     |

With `LIST COLUMNS` partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```
CREATE TABLE customers_1 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(city) (
  PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
  PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
  PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
  PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjö')
);
```

As with partitioning by `RANGE COLUMNS`, you do not need to use expressions in the `COLUMNS()` clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with `COLUMNS()`.)

It is also possible to use `DATE` and `DATETIME` columns, as shown in the following example that uses the same name and columns as the `customers_1` table shown previously, but employs `LIST COLUMNS` partitioning based on the `renewal` column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```

CREATE TABLE customers_2 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) (
  PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03',
    '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),
  PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10',
    '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),
  PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17',
    '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),
  PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24',
    '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
);

```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ [RANGE](#) or [RANGE COLUMNS](#) partitioning instead. In this case, since the column we wish to use as the partitioning key is a [DATE](#) column, we use [RANGE COLUMNS](#) partitioning, as shown here:

```

CREATE TABLE customers_3 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY RANGE COLUMNS(renewal) (
  PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
  PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
  PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
  PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);

```

See [Section 18.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

In addition (as with [RANGE COLUMNS](#) partitioning), you can use multiple columns in the [COLUMNS\(\)](#) clause.

See [Section 13.1.14, “CREATE TABLE Syntax”](#), for additional information about [PARTITION BY LIST COLUMNS\(\)](#) syntax.

## 18.2.4 HASH Partitioning

Partitioning by [HASH](#) is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using [HASH](#) partitioning, it is necessary to append to the [CREATE TABLE](#) statement a [PARTITION BY HASH \(expr\)](#) clause, where *expr* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with [PARTITIONS num](#), where *num* is a positive integer representing the number of partitions into which the table is to be divided.

### Note

For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the

partitioning expression for this table must be part of every unique key, including the primary key. See [Section 18.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#), for more information.

The following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to 1.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for `expr`. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

`expr` must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in [Section 18.6, “Restrictions and Limitations on Partitioning”](#). You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce by

widely different changes in the value of the expression. For example, changing `int_col` from 5 to 6 produces a change of `-1` in the value of the expression, but changing the value of `int_col` from 6 to 7 produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation  $y=cx$  where  $c$  is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of `num` partitions to use based on the modulus of the result of the user function. In other words, for an expression `expr`, the partition in which the record is stored is partition number  $N$ , where  $N = \text{MOD}(\text{expr}, \text{num})$ . Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1
```

MySQL 5.7 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 18.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

#### Note

If a table to be partitioned has a `UNIQUE` key, then any columns supplied as arguments to the `HASH` user function or to the `KEY`'s `column_list` must be part of that key.

### 18.2.4.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(Suppose that *num* is 13. Then `LOG(2,13)` is 3.7004397181411. `CEILING(3.7004397181411)` is 4, and `V = POWER(2,4)`, which is 16.)

2. Set  $N = F(\textit{column\_list}) \& (V - 1)$ .

3. While  $N \geq \textit{num}$ :

- Set  $V = \text{CEIL}(V / 2)$
- Set  $N = N \& (V - 1)$

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3
(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6
(6 >= 6 is TRUE: additional step required)
N = 6 & CEILING(8 / 2)
  = 6 & 3
  = 2
(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

## 18.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. This internal hashing function is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.7:

```
CREATE TABLE k1 (
  id INT NOT NULL PRIMARY KEY,
  name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
  id INT NOT NULL,
  name VARCHAR(20),
  UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tm1 (
  s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see [Section 18.6, "Restrictions and Limitations on Partitioning"](#).

#### Important

For a key-partitioned table, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table.`

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
```

```

col1 INT NOT NULL,
col2 CHAR(5),
col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;

```

Using `LINEAR` has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 18.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

## 18.2.6 Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following `CREATE TABLE` statement:

```

CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
SUBPARTITIONS 2 (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);

```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into  $3 * 2 = 6$  partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.7, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

### Note

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see [Issues with subpartitions](#), for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```

CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
        SUBPARTITION s0,
        SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
        SUBPARTITION s2,
        SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s4,
        SUBPARTITION s5
    )
);

```

```
);
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s2,
    SUBPARTITION s3
  )
);
```

This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- Subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.7:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s2,
    SUBPARTITION s3
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s4,
    SUBPARTITION s5
  )
);
```

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0
      DATA DIRECTORY = '/disk0/data'
      INDEX DIRECTORY = '/disk0/idx',
    SUBPARTITION s1
      DATA DIRECTORY = '/disk1/data'
      INDEX DIRECTORY = '/disk1/idx'
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s2
```

## Subpartitioning

```
        DATA DIRECTORY = '/disk2/data'
        INDEX DIRECTORY = '/disk2/idx',
    SUBPARTITION s3
        DATA DIRECTORY = '/disk3/data'
        INDEX DIRECTORY = '/disk3/idx'
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s4
            DATA DIRECTORY = '/disk4/data'
            INDEX DIRECTORY = '/disk4/idx',
        SUBPARTITION s5
            DATA DIRECTORY = '/disk5/data'
            INDEX DIRECTORY = '/disk5/idx'
    )
);
```

In this case, a separate disk is used for the data and for the indexes of each `RANGE`. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE(YEAR(purchased))
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0a
                DATA DIRECTORY = '/disk0'
                INDEX DIRECTORY = '/disk1',
            SUBPARTITION s0b
                DATA DIRECTORY = '/disk2'
                INDEX DIRECTORY = '/disk3'
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s1a
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s1b
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s2a,
            SUBPARTITION s2b
        )
    );
```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
  - The data for subpartition `s0a` is stored on `/disk0`.
  - The indexes for subpartition `s0a` are stored on `/disk1`.
  - The data for subpartition `s0b` is stored on `/disk2`.
  - The indexes for subpartition `s0b` are stored on `/disk3`.
- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
  - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4`—the data in `/disk4/data`, and the indexes in `/disk4/idx`.
  - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5`—the data in `/disk5/data`, and the indexes in `/disk5/idx`.

- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See [Section 18.3, “Partition Management”](#), for an explanation of how this can be done.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are not permitted in partition definitions when the `NO_DIR_IN_CREATE` server SQL mode is in effect. In MySQL 5.7, these options are also not permitted when defining subpartitions (Bug #42954).

## 18.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL's partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

**Handling of `NULL` with `RANGE` partitioning.** If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. Consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
```

Query OK, 0 rows affected (0.09 sec)

```
mysql> CREATE TABLE t2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (-5),
->   PARTITION p1 VALUES LESS THAN (0),
->   PARTITION p2 VALUES LESS THAN (10),
->   PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
```

Query OK, 0 rows affected (0.09 sec)

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
->   FROM INFORMATION_SCHEMA.PARTITIONS
->   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_*';
```

| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------|----------------|------------|----------------|-------------|
| t1         | p0             | 0          | 0              | 0           |

```

t1	p1	0	0	0
t1	p2	0	0	0
t2	p0	0	0	0
t2	p1	0	0	0
t2	p2	0	0	0
t2	p3	0	0	0
+-----+-----+
7 rows in set (0.00 sec)

```

(For more information about this table, see [Section 20.14, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).) Now let us populate each of these tables with a single row containing a `NULL` in the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```

mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+-----+-----+
| id   | name  |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+-----+
| id   | name  |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1          | p0             | 1           | 20             | 20          |
| t1          | p1             | 0           | 0              | 0           |
| t1          | p2             | 0           | 0              | 0           |
| t2          | p0             | 1           | 20             | 20          |
| t2          | p1             | 0           | 0              | 0           |
| t2          | p2             | 0           | 0              | 0           |
| t2          | p3             | 0           | 0              | 0           |
+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)

```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the `SELECT` statements:

```

mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

```

```
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 13.1.6, “ALTER TABLE Syntax”](#).)

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (
  id INT,
  dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

**Handling of `NULL` with `LIST` partitioning.** A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
  ->   c1 INT,
  ->   c2 VARCHAR(20)
  -> )
  -> PARTITION BY LIST(c1) (
  ->   PARTITION p0 VALUES IN (0, 3, 6),
  ->   PARTITION p1 VALUES IN (1, 4, 7),
  ->   PARTITION p2 VALUES IN (2, 5, 8)
  -> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
  ->   c1 INT,
  ->   c2 VARCHAR(20)
  -> )
  -> PARTITION BY LIST(c1) (
  ->   PARTITION p0 VALUES IN (0, 3, 6),
  ->   PARTITION p1 VALUES IN (1, 4, 7),
  ->   PARTITION p2 VALUES IN (2, 5, 8),
  ->   PARTITION p3 VALUES IN (NULL)
  -> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
  ->   c1 INT,
  ->   c2 VARCHAR(20)
  -> )
  -> PARTITION BY LIST(c1) (
```

```
-> PARTITION p0 VALUES IN (0, 3, 6),
-> PARTITION p1 VALUES IN (1, 4, 7, NULL),
-> PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)
```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| ts2         | p0              | 0           | 0              | 0            |
| ts2         | p1              | 0           | 0              | 0            |
| ts2         | p2              | 0           | 0              | 0            |
| / ts2       | / p3            | / 1         | / 20           | / 20         |
| ts3         | p0              | 0           | 0              | 0            |
| / ts3       | / p1            | / 1         | / 20           | / 20         |
| ts3         | p2              | 0           | 0              | 0            |
+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

**Handling of NULL with HASH and KEY partitioning.** `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY HASH(c1)
-> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| th          | p0              | 0           | 0              | 0            |
+-----+-----+-----+-----+-----+
```

```
| th          | p1          |          0 |          0 |          0 |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

Note that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+-----+-----+
| c1   | c2     |
+-----+-----+
| NULL | mothra |
+-----+-----+
| 0    | gigan  |
+-----+-----+
2 rows in set (0.01 sec)
```

Recall that for any integer  $N$ , the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| th          | p0             | 2           | 20              | 20           |
| th          | p1             | 0           | 0               | 0            |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning.

## 18.3 Partition Management

MySQL 5.7 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 18.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 18.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 18.3.5, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 5.7 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 18.3.4, “Maintenance of Partitions”](#).

### Note

In MySQL 5.7, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE( YEAR(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (2000),
    PARTITION p3 VALUES LESS THAN (2005)
);
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. Use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See [Section 13.1.6, "ALTER TABLE Syntax"](#).

#### Important

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITIONS`).

In MySQL 5.7, it is possible to delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

### 18.3.1 Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 18.3.2, "Management of HASH and KEY Partitions"](#). Dropping a `RANGE` or `LIST` partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
->     PARTITION BY RANGE( YEAR(purchased) ) (
->         PARTITION p0 VALUES LESS THAN (1990),
->         PARTITION p1 VALUES LESS THAN (1995),
->         PARTITION p2 VALUES LESS THAN (2000),
->         PARTITION p3 VALUES LESS THAN (2005)
->     );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
->     (1, 'desk organiser', '2003-10-15'),
->     (2, 'CD player', '1993-11-05'),
```

```

-> (3, 'TV set', '1996-03-10'),
-> (4, 'bookcase', '1982-01-10'),
-> (5, 'exercise bike', '2004-05-09'),
-> (6, 'sofa', '1987-06-05'),
-> (7, 'popcorn maker', '2001-11-22'),
-> (8, 'aquarium', '1992-08-04'),
-> (9, 'study desk', '1984-09-16'),
-> (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)

```

You can see which items should have been inserted into partition `p2` as shown here:

```

mysql> SELECT * FROM tr
      -> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+-----+-----+-----+
| id   | name      | purchased |
+-----+-----+-----+
|    3 | TV set    | 1996-03-10 |
|   10 | lava lamp | 1998-12-25 |
+-----+-----+-----+
2 rows in set (0.00 sec)

```

To drop the partition named `p2`, execute the following command:

```

mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)

```

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```

mysql> SELECT * FROM tr WHERE purchased
      -> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)

```

Because of this, you must have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See [Section 13.1.29, “TRUNCATE TABLE Syntax”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 13.1.6, “ALTER TABLE Syntax”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```

mysql> SHOW CREATE TABLE tr\G
***** 1. row *****
      Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)

```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+-----+-----+-----+
| id  | name          | purchased |
+-----+-----+-----+
11	pencil holder	1995-07-12
1	desk organiser	2003-10-15
5	exercise bike	2004-05-09
7	popcorn maker	2001-11-22
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 18.2.2, “LIST Partitioning”](#), for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (
  id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970),
  PARTITION p1 VALUES LESS THAN (1980),
  PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990 to 1999 as shown here:

```
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```
mysql> ALTER TABLE members
> ADD PARTITION (
> PARTITION n VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```
ALTER TABLE members
  REORGANIZE PARTITION p0 INTO (
    PARTITION n0 VALUES LESS THAN (1960),
    PARTITION n1 VALUES LESS THAN (1970)
  );
```

Using `SHOW CREATE TABLE` you can see that the `ALTER TABLE` statement has had the desired effect:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
      Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1960) ENGINE = InnoDB,
PARTITION n1 VALUES LESS THAN (1970) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1980) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2000) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

See also [Section 13.1.6.1, “ALTER TABLE Partition Operations”](#).

You can also use `ALTER TABLE ... ADD PARTITION` to add new partitions to a table that is partitioned by `LIST`. Suppose a table `tt` is defined using the following `CREATE TABLE` statement:

```
CREATE TABLE tt (
  id INT,
  data INT
)
PARTITION BY LIST(data) (
  PARTITION p0 VALUES IN (5, 10, 15),
  PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

You *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value 12 have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes 12 in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and

rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
  PARTITION p5 VALUES LESS THAN (2010),
  PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
      Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
  PARTITION s0 VALUES LESS THAN (1960),
  PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
  PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, *tbl\_name* is the name of the partitioned table, and *partition\_list* is a comma-separated list of names of one or more existing partitions to be changed. *partition\_definitions* is a comma-separated list of new partition definitions, which follow the same rules as for the *partition\_definitions* list used in `CREATE TABLE` (see Section 13.1.14, “CREATE TABLE Syntax”). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` clauses used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by `RANGE`) or sets of values (when reorganizing tables partitioned by `LIST`).

- The combination of partitions in the *partition\_definitions* list should account for the same range or set of values overall as the combined partitions named in the *partition\_list*.

For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table's partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or vice versa. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`. For example:

```
ALTER TABLE members
PARTITION BY HASH( YEAR(dob) )
PARTITIONS 8;
```

## 18.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 18.3.1, “Management of RANGE and LIST Partitions”](#).

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
->   id INT,
->   fname VARCHAR(30),
->   lname VARCHAR(30),
->   signed DATE
-> )
-> PARTITION BY LINEAR KEY(signed)
-> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

### 18.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 5.7, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where *pt* is the partitioned table and *p* is the partition or subpartition of *pt* to be exchanged with unpartitioned table *nt*, provided that the following statements are true:

1. Table *nt* is not itself partitioned.
2. Table *nt* is not a temporary table.
3. The structures of tables *pt* and *nt* are otherwise identical.
4. Table *nt* contains no foreign key references, and no other table has any foreign keys that refer to *nt*.
5. There are no rows in *nt* that lie outside the boundaries of the partition definition for *p*. This condition does not apply if the `WITHOUT VALIDATION` option is used. The `[ {WITH|WITHOUT} VALIDATION ]` option was added in MySQL 5.7.5.

In addition to the `ALTER`, `INSERT`, and `CREATE` privileges usually required for `ALTER TABLE` statements, you must have the `DROP` privilege to perform `ALTER TABLE ... EXCHANGE PARTITION`.

You should also be aware of the following effects of `ALTER TABLE ... EXCHANGE PARTITION`:

- Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.
- Any `AUTO_INCREMENT` columns in the exchanged table are reset.
- The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

The syntax of the `ALTER TABLE ... EXCHANGE PARTITION` statement is shown here, where *pt* is the partitioned table, *p* is the partition or subpartition to be exchanged, and *nt* is the nonpartitioned table to be exchanged with *p*:

```
ALTER TABLE pt
  EXCHANGE PARTITION p
  WITH TABLE nt;
```

Optionally, you can append a `WITH VALIDATION` or `WITHOUT VALIDATION` clause. When `WITHOUT VALIDATION` is specified, the `ALTER TABLE ... EXCHANGE PARTITION` operation does not perform row-by-row validation when exchanging a partition a nonpartitioned table, allowing database administrators to assume responsibility for ensuring that rows are within the boundaries of the partition definition. `WITH VALIDATION` is the default behavior and need not be specified explicitly. The `[ {WITH|WITHOUT} VALIDATION ]` option was added in MySQL 5.7.5.

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE`

`PARTITION` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 5.7.

## Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table `e` has been created and populated using the following SQL statements:

```
CREATE TABLE e (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
)
PARTITION BY RANGE (id) (
  PARTITION p0 VALUES LESS THAN (50),
  PARTITION p1 VALUES LESS THAN (100),
  PARTITION p2 VALUES LESS THAN (150),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO e VALUES
(1669, "Jim", "Smith"),
(337, "Mary", "Jones"),
(16, "Frank", "White"),
(2005, "Linda", "Black");
```

Now we create a nonpartitioned copy of `e` named `e2`. This can be done using the `mysql` client as shown here:

```
mysql> CREATE TABLE e2 LIKE e;
Query OK, 0 rows affected (1.34 sec)

mysql> ALTER TABLE e2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.90 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can see which partitions in table `e` contain rows by querying the `INFORMATION_SCHEMA.PARTITIONS` table, like this:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
p0	1
p1	0
p2	0
p3	3
+-----+-----+
4 rows in set (0.00 sec)
```

### Note

For partitioned `InnoDB` tables, the row count given in the `TABLE_ROWS` column of the `INFORMATION_SCHEMA.PARTITIONS` table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition `p0` in table `e` with table `e2`, you can use the `ALTER TABLE` statement shown here:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the `INFORMATION_SCHEMA.PARTITIONS` table, as before. The table row that was previously found in partition `p0` is no longer present:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
->     FROM INFORMATION_SCHEMA.PARTITIONS
->     WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
p0	0
p1	0
p2	0
p3	3
+-----+-----+
4 rows in set (0.00 sec)
```

If you query table `e2`, you can see that the “missing” row can now be found there:

```
mysql> SELECT * FROM e2;
+-----+-----+-----+
| id | fname | lname |
+-----+-----+-----+
| 16 | Frank | White |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table `e`, making sure that this row is stored in partition `p0` by choosing an `id` column value that is less than 50, and verifying this afterwards by querying the `PARTITIONS` table:

```
mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
->     FROM INFORMATION_SCHEMA.PARTITIONS
->     WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
p0	1
p1	0
p2	0
p3	3
+-----+-----+
4 rows in set (0.00 sec)
```

Now we once again exchange partition `p0` with table `e2` using the same `ALTER TABLE` statement as previously:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

The output of the following queries shows that the table row that was stored in partition `p0` and the table row that was stored in table `e2`, prior to issuing the `ALTER TABLE` statement, have now switched places:

```
mysql> SELECT * FROM e;
+-----+-----+-----+
| id | fname | lname |
+-----+-----+-----+
| 16 | Frank | White |
+-----+-----+-----+
```

```

1669	Jim	Smith
337	Mary	Jones
2005	Linda	Black
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
->      FROM INFORMATION_SCHEMA.PARTITIONS
->      WHERE TABLE_NAME = 'e';
+-----+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
p0	1
p1	0
p2	0
p3	3
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> SELECT * FROM e2;
+-----+-----+-----+
| id | fname  | lname |
+-----+-----+-----+
| 41 | Michael | Green |
+-----+-----+-----+
1 row in set (0.00 sec)

```

## Nonmatching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the `ALTER TABLE ... EXCHANGE PARTITION` statement must meet the conditions required for them to be stored in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into `e2` that is outside the boundaries of the partition definition for partition `p0` of table `e`. For example, insert a row with an `id` column value that is too large; then, try to exchange the table with the partition again:

```

mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition

```

The `IGNORE` keyword is accepted, but has no effect when used with `EXCHANGE PARTITION`, as shown here:

```

mysql> ALTER IGNORE TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition

```

Only the `WITHOUT VALIDATION` option would permit this operation to succeed:

```

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.02 sec)

```

When a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using `REPAIR TABLE` or `ALTER TABLE ... REPAIR PARTITION`.

## Exchanging Partitions Without Row-By-Row Validation

To avoid time consuming validation when exchanging a partition with a table that has many rows, it is possible to skip the row-by-row validation step by appending `WITHOUT VALIDATION` to the `ALTER TABLE ... EXCHANGE PARTITION` statement.

The following example compares the difference between execution times when exchanging a partition with a nonpartitioned table, with and without validation. The partitioned table (table `e`) contains two

partitions of 1 million rows each. The rows in p0 of table e are removed and p0 is exchanged with a nonpartitioned table of 1 million rows. The `WITH VALIDATION` operation takes 0.74 seconds. By comparison, the `WITHOUT VALIDATION` operation takes 0.01 seconds.

```
# Create a partitioned table with 1 million rows in each partition

CREATE TABLE e (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
)
PARTITION BY RANGE (id) (
  PARTITION p0 VALUES LESS THAN (1000001),
  PARTITION p1 VALUES LESS THAN (2000001),
);

mysql> SELECT COUNT(*) FROM e;
+-----+
| COUNT(*) |
+-----+
| 2000000 |
+-----+
1 row in set (0.27 sec)

# View the rows in each partition

SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000     |
| p1              | 1000000     |
+-----+-----+
2 rows in set (0.00 sec)

# Create a nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e2 (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
);

mysql> SELECT COUNT(*) FROM e2;
+-----+
| COUNT(*) |
+-----+
| 1000000 |
+-----+
1 row in set (0.24 sec)

# Create another nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e3 (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
);

mysql> SELECT COUNT(*) FROM e3;
+-----+
| COUNT(*) |
+-----+
| 1000000 |
+-----+
1 row in set (0.25 sec)

# Drop the rows from p0 of table e

mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)
```

```
# Confirm that there are no rows in partition p0

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 0           |
| p1              | 1000000    |
+-----+-----+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e2 'WITH VALIDATION'

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITH VALIDATION;
Query OK, 0 rows affected (0.74 sec)

# Confirm that the partition was exchanged with table e2

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000    |
| p1              | 1000000    |
+-----+-----+
2 rows in set (0.00 sec)

# Once again, drop the rows from p0 of table e

mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

# Confirm that there are no rows in partition p0

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 0           |
| p1              | 1000000    |
+-----+-----+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e3 'WITHOUT VALIDATION'

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e3 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.01 sec)

# Confirm that the partition was exchanged with table e3

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000    |
| p1              | 1000000    |
+-----+-----+
2 rows in set (0.00 sec)
```

If a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using [REPAIR TABLE](#) or [ALTER TABLE ... REPAIR PARTITION](#).

### Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see [Section 18.2.6, “Subpartitioning”](#)) with a nonpartitioned table using an [ALTER TABLE ... EXCHANGE PARTITION](#) statement. In the following example, we first create a table `es` that is partitioned by [RANGE](#) and subpartitioned by [KEY](#),

populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:

```
mysql> CREATE TABLE es (
->   id INT NOT NULL,
->   fname VARCHAR(30),
->   lname VARCHAR(30)
-> )
-> PARTITION BY RANGE (id)
-> SUBPARTITION BY KEY (lname)
-> SUBPARTITIONS 2 (
->   PARTITION p0 VALUES LESS THAN (50),
->   PARTITION p1 VALUES LESS THAN (100),
->   PARTITION p2 VALUES LESS THAN (150),
->   PARTITION p3 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (2.76 sec)

mysql> INSERT INTO es VALUES
->   (1669, "Jim", "Smith"),
->   (337, "Mary", "Jones"),
->   (16, "Frank", "White"),
->   (2005, "Linda", "Black");
Query OK, 4 rows affected (0.04 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> CREATE TABLE es2 LIKE es;
Query OK, 0 rows affected (1.27 sec)

mysql> ALTER TABLE es2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.70 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
->   FROM INFORMATION_SCHEMA.PARTITIONS
->   WHERE TABLE_NAME = 'es';
+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
p0	p0sp0	1
p0	p0sp1	0
p1	p1sp0	0
p1	p1sp1	0
p2	p2sp0	0
p2	p2sp1	0
p3	p3sp0	3
p3	p3sp1	0
+-----+-----+-----+
8 rows in set (0.00 sec)
```

The following `ALTER TABLE` statement exchanges subpartition `p3sp0` table `es` with the nonpartitioned table `es2`:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;
Query OK, 0 rows affected (0.29 sec)
```

You can verify that the rows were exchanged by issuing the following queries:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
->   FROM INFORMATION_SCHEMA.PARTITIONS
->   WHERE TABLE_NAME = 'es';
+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
```

| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
|----------------|-------------------|------------|
| p0             | p0sp0             | 1          |
| p0             | p0sp1             | 0          |
| p1             | p1sp0             | 0          |
| p1             | p1sp1             | 0          |
| p2             | p2sp0             | 0          |
| p2             | p2sp1             | 0          |
| p3             | p3sp0             | 0          |
| p3             | p3sp1             | 0          |

8 rows in set (0.00 sec)

```
mysql> SELECT * FROM es2;
```

| id   | fname | lname |
|------|-------|-------|
| 1669 | Jim   | Smith |
| 337  | Mary  | Jones |
| 2005 | Linda | Black |

3 rows in set (0.00 sec)

If a table is subpartitioned, you can exchange only a subpartition of the table—not an entire partition—with an unpartitioned table, as shown here:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3 WITH TABLE es2;
ERROR 1704 (HY000): Subpartitioned table, use subpartition instead of partition
```

The comparison of table structures used by MySQL is very strict. The number, order, names, and types of columns and indexes of the partitioned table and the nonpartitioned table must match exactly. In addition, both tables must use the same storage engine:

```
mysql> CREATE TABLE es3 LIKE e;
Query OK, 0 rows affected (1.31 sec)
```

```
mysql> ALTER TABLE es3 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.53 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

```
mysql> SHOW CREATE TABLE es3\G
***** 1. row *****
Table: es3
Create Table: CREATE TABLE `es3` (
  `id` int(11) NOT NULL,
  `fname` varchar(30) DEFAULT NULL,
  `lname` varchar(30) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

```
mysql> ALTER TABLE es3 ENGINE = MyISAM;
Query OK, 0 rows affected (0.15 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es3;
ERROR 1497 (HY000): The mix of handlers in the partitions is not allowed in this version of MySQL
```

## 18.3.4 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.7.

Table maintenance of partitioned tables can be accomplished using the statements [CHECK TABLE](#), [OPTIMIZE TABLE](#), [ANALYZE TABLE](#), and [REPAIR TABLE](#), which are supported for partitioned tables.

You can use a number of extensions to [ALTER TABLE](#) for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having [VARCHAR](#), [BLOB](#), or [TEXT](#) columns), you can use [ALTER TABLE ... OPTIMIZE PARTITION](#) to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using [OPTIMIZE PARTITION](#) on a given partition is equivalent to running [CHECK PARTITION](#), [ANALYZE PARTITION](#), and [REPAIR PARTITION](#) on that partition.

Some MySQL storage engines, including [InnoDB](#), do not support per-partition optimization; in these cases, [ALTER TABLE ... OPTIMIZE PARTITION](#) analyzes and rebuilds the entire table, and causes an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use [ALTER TABLE ... REBUILD PARTITION](#) and [ALTER TABLE ... ANALYZE PARTITION](#) instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

Normally, [REPAIR PARTITION](#) fails when the partition contains duplicate key errors. In MySQL 5.7.2 and later, you can use [ALTER IGNORE TABLE](#) with this option, in which case all rows that cannot be moved due to the presence of duplicate keys are removed from the partition (Bug #16900947).

- **Checking partitions.** You can check partitions for errors in much the same way that you can use [CHECK TABLE](#) with nonpartitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you if the data or indexes in partition [p1](#) of table [t1](#) are corrupted. If this is the case, use [ALTER TABLE ... REPAIR PARTITION](#) to repair the partition.

Normally, [CHECK PARTITION](#) fails when the partition contains duplicate key errors. In MySQL 5.7.2 and later, you can use [ALTER IGNORE TABLE](#) with this option, in which case the statement returns the contents of each row in the partition where a duplicate key violation is found. Note that only the values for the columns in the partitioning expression for the table are reported. (Bug #16900947)

Each of the statements in the list just shown also supports the keyword [ALL](#) in place of the list of partition names. Using [ALL](#) causes the statement to act on all partitions in the table.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.

In MySQL 5.7, you can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

`ALTER TABLE ... TRUNCATE PARTITION ALL` truncates all partitions in the table.

Prior to MySQL 5.7.2, `ANALYZE`, `CHECK`, `OPTIMIZE`, `REBUILD`, `REPAIR`, and `TRUNCATE` operations were not permitted on subpartitions (Bug #14028340, Bug #65184).

### 18.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
      Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See [Section 13.7.5.36, “SHOW TABLE STATUS Syntax”](#), for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 20.14, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).

It is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` created and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
  PARTITION p0 VALUES LESS THAN (3),
  PARTITION p1 VALUES LESS THAN (7),
```

```

PARTITION p2 VALUES LESS THAN (9),
PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');

```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
  partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
          key: NULL
        key_len: NULL
         ref: NULL
         rows: 10
      Extra: Using filesort

```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
  partitions: p0,p1
         type: ALL
possible_keys: NULL
          key: NULL
        key_len: NULL
         ref: NULL
         rows: 10
      Extra: Using where

```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```

mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
  partitions: p0,p1
         type: range
possible_keys: PRIMARY
          key: PRIMARY
        key_len: 4
         ref: NULL

```

```
rows: 7
Extra: Using where
```

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.
- If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN PARTITIONS` output displays the total number of rows in the table.

See also [Section 13.8.2, “EXPLAIN Syntax”](#).

## 18.4 Partition Pruning

This section discusses an optimization known as *partition pruning*. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table `t1` defined by this statement:

```
CREATE TABLE t1 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
  PARTITION p0 VALUES LESS THAN (64),
  PARTITION p1 VALUES LESS THAN (128),
  PARTITION p2 VALUES LESS THAN (192),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a `SELECT` statement such as this one:

```
SELECT fname, lname, region_code, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

### Note

When pruning is performed on a partitioned `MyISAM` table, all partitions are opened, whether or not they are examined, due to the design of the `MyISAM` storage engine. This means that you must have a sufficient number of file descriptors available to cover all partitions of the table. See [MyISAM and partition file descriptor usage](#).

This limitation does not apply to partitioned tables using other MySQL storage engines such as `InnoDB`.

The optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- `partition_column = constant`

- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

MySQL can apply partition pruning to `SELECT`, `DELETE`, and `UPDATE` statements. `INSERT` statements currently cannot be pruned.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (126, 127, 128, 129)`. Then the optimizer can determine that the first two values in the list are found in partition `p1`, the remaining two values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

The optimizer can also perform pruning for `WHERE` conditions that involve comparisons of the preceding types on multiple columns for tables that use `RANGE COLUMNS` or `LIST COLUMNS` partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function. In addition, in MySQL 5.7, pruning can be applied for such tables when the partitioning expression uses the `TO_SECONDS()` function.

Suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION d0 VALUES LESS THAN (1970),
  PARTITION d1 VALUES LESS THAN (1975),
  PARTITION d2 VALUES LESS THAN (1980),
  PARTITION d3 VALUES LESS THAN (1985),
  PARTITION d4 VALUES LESS THAN (1990),
  PARTITION d5 VALUES LESS THAN (2000),
  PARTITION d6 VALUES LESS THAN (2005),
  PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following statements using `t2` can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';

UPDATE t2 SET region_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last statement, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.  
`YEAR('1984-06-21')` yields the value `1984`, which is found in partition `d3`.
2. Find the partition containing the high end of the range.

`YEAR('1999-06-21')` evaluates to 1999, which is found in partition `d5`.

3. Scan only these two partitions and any partitions that may lie between them.

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

### Important

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` condition of a statement against a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
  PARTITION r0 VALUES IN (1, 3),
  PARTITION r1 VALUES IN (2, 5, 8),
  PARTITION r2 VALUES IN (4, 9),
  PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a statement such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `[LINEAR] KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

A statement that compares a column value with a constant can be pruned:

```
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
```

```
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

### Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the `DELETE` cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

Prior to MySQL 5.7.1, partition pruning was disabled for all tables using a storage engine that provides automatic partitioning, such as the `NDB` storage engine used by MySQL Cluster (not currently supported in MySQL 5.7). (Bug #14672885) Beginning with MySQL 5.7.1, such tables can be pruned if they are explicitly partitioned. (Bug #14827952)

## 18.5 Partition Selection

MySQL 5.7 supports explicit selection of partitions and subpartitions that, when executing a statement, should be checked for rows matching a given `WHERE` condition. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.

SQL statements supporting explicit partition selection are listed here:

- `SELECT`
- `DELETE`
- `INSERT`
- `REPLACE`
- `UPDATE`
- `LOAD DATA`.
- `LOAD XML`.

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a `PARTITION` option. For all supported statements, this option uses the syntax shown here:

```
PARTITION (partition_names)

partition_names:
    partition_name, ...
```

This option always follows the name of the table to which the partition or partitions belong. *partition\_names* is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (`partition 'partition_name' doesn't exist`). Partitions and subpartitions named in *partition\_names* may be listed in any order, and may overlap.

When the `PARTITION` option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a `SELECT` statement to determine which rows belong to a given partition. Consider a partitioned table named `employees`, created and populated using the statements shown here:

```
SET @@SQL_MODE = '';

CREATE TABLE employees (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    fname VARCHAR(25) NOT NULL,
    lname VARCHAR(25) NOT NULL,
    store_id INT NOT NULL,
    department_id INT NOT NULL
)
PARTITION BY RANGE(id) (
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (10),
    PARTITION p2 VALUES LESS THAN (15),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

INSERT INTO employees VALUES
    ('', 'Bob', 'Taylor', 3, 2), ('', 'Frank', 'Williams', 1, 2),
    ('', 'Ellen', 'Johnson', 3, 4), ('', 'Jim', 'Smith', 2, 4),
    ('', 'Mary', 'Jones', 1, 1), ('', 'Linda', 'Black', 2, 3),
    ('', 'Ed', 'Jones', 2, 1), ('', 'June', 'Wilson', 3, 1),
    ('', 'Andy', 'Smith', 1, 3), ('', 'Lou', 'Waters', 2, 4),
    ('', 'Jill', 'Stone', 1, 4), ('', 'Roger', 'White', 3, 2),
    ('', 'Howard', 'Andrews', 1, 2), ('', 'Fred', 'Goldberg', 3, 3),
    ('', 'Barbara', 'Brown', 2, 3), ('', 'Alice', 'Rogers', 2, 2),
    ('', 'Mark', 'Morgan', 3, 3), ('', 'Karen', 'Cole', 3, 2);
```

You can see which rows are stored in partition `p1` like this:

```
mysql> SELECT * FROM employees PARTITION (p1);
+----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+----+-----+-----+-----+-----+
5	Mary	Jones	1	1
6	Linda	Black	2	3
7	Ed	Jones	2	1
8	June	Wilson	3	1
9	Andy	Smith	1	3
+----+-----+-----+-----+-----+
5 rows in set (0.00 sec)
```

The result is the same as obtained by the query `SELECT * FROM employees WHERE id BETWEEN 5 AND 9`.

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, `SELECT * FROM employees PARTITION (p1, p2)` returns all rows from partitions `p1` and `p2` while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a `PARTITION` option to restrict the result to one or more desired partitions. You can use `WHERE` conditions, `ORDER BY` and `LIMIT` options,

and so on. You can also use aggregate functions with `HAVING` and `GROUP BY` options. Each of the following queries produces a valid result when run on the `employees` table as previously defined:

```
mysql> SELECT * FROM employees PARTITION (p0, p2)
->     WHERE lname LIKE 'S%';
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
|  4 | Jim   | Smith |         2 |              4 |
| 11 | Jill  | Stone |         1 |              4 |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
->     FROM employees PARTITION (p0) ORDER BY lname;
+-----+-----+
| id | name          |
+-----+-----+
3	Ellen Johnson
4	Jim Smith
1	Bob Taylor
2	Frank Williams
+-----+-----+
4 rows in set (0.06 sec)

mysql> SELECT store_id, COUNT(department_id) AS c
->     FROM employees PARTITION (p1,p2,p3)
->     GROUP BY store_id HAVING c > 4;
+-----+-----+
| c | store_id |
+-----+-----+
|  5 |         2 |
|  5 |         3 |
+-----+-----+
2 rows in set (0.00 sec)
```

Statements using partition selection can be employed with tables using any of the partitioning types supported in MySQL 5.7. When a table is created using `[LINEAR] HASH` or `[LINEAR] KEY` partitioning and the names of the partitions are not specified, MySQL automatically names the partitions `p0`, `p1`, `p2`, ..., `pN-1`, where `N` is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition `pX` the names `pXsp0`, `pXsp1`, `pXsp2`, ..., `pXspM-1`, where `M` is the number of subpartitions. When executing against this table a `SELECT` (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a `PARTITION` option, as shown here:

```
mysql> CREATE TABLE employees_sub (
->     id INT NOT NULL AUTO_INCREMENT,
->     fname VARCHAR(25) NOT NULL,
->     lname VARCHAR(25) NOT NULL,
->     store_id INT NOT NULL,
->     department_id INT NOT NULL,
->     PRIMARY KEY pk (id, lname)
-> )
->     PARTITION BY RANGE(id)
->     SUBPARTITION BY KEY (lname)
->     SUBPARTITIONS 2 (
->         PARTITION p0 VALUES LESS THAN (5),
->         PARTITION p1 VALUES LESS THAN (10),
->         PARTITION p2 VALUES LESS THAN (15),
->         PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (1.14 sec)

mysql> INSERT INTO employees_sub # re-use data in employees table
->     SELECT * FROM employees;
Query OK, 18 rows affected (0.09 sec)
Records: 18 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
-> FROM employees_sub PARTITION (p2sp1);
+-----+-----+
| id | name          |
+-----+-----+
| 10 | Lou Waters    |
| 14 | Fred Goldberg |
+-----+-----+
2 rows in set (0.00 sec)
```

You may also use a `PARTITION` option in the `SELECT` portion of an `INSERT ... SELECT` statement, as shown here:

```
mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO employees_copy
-> SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM employees_copy;
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
10	Lou	Waters	2	4
11	Jill	Stone	1	4
12	Roger	White	3	2
13	Howard	Andrews	1	2
14	Fred	Goldberg	3	3
+-----+-----+-----+-----+-----+
5 rows in set (0.00 sec)
```

Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:

```
CREATE TABLE stores (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  city VARCHAR(30) NOT NULL
)
PARTITION BY HASH(id)
PARTITIONS 2;

INSERT INTO stores VALUES
  ('', 'Nambucca'), ('', 'Uranga'),
  ('', 'Bellinghen'), ('', 'Grafton');

CREATE TABLE departments (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30) NOT NULL
)
PARTITION BY KEY(id)
PARTITIONS 2;

INSERT INTO departments VALUES
  ('', 'Sales'), ('', 'Customer Service'),
  ('', 'Delivery'), ('', 'Accounting');
```

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. (Note that the `PARTITION` option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias.) For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition `p1` of the `departments` table) at the stores in either of the cities of Nambucca and Bellinghen (partition `p0` of the `stores` table):

```
mysql> SELECT
-> e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,
-> s.city AS City, d.name AS department
```

```

-> FROM employees AS e
-> JOIN stores PARTITION (p1) AS s ON e.store_id=s.id
-> JOIN departments PARTITION (p0) AS d ON e.department_id=d.id
-> ORDER BY e.lname;
+-----+-----+-----+-----+
| Employee ID | Name          | City      | department |
+-----+-----+-----+-----+
14	Fred Goldberg	Bellingen	Delivery
5	Mary Jones	Nambucca	Sales
17	Mark Morgan	Bellingen	Delivery
9	Andy Smith	Nambucca	Delivery
8	June Wilson	Bellingen	Sales
+-----+-----+-----+-----+
5 rows in set (0.00 sec)

```

For general information about joins in MySQL, see [Section 13.2.9.2, “JOIN Syntax”](#).

When the `PARTITION` option is used with `DELETE` statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+
4	Jim	Smith	2	4
8	June	Wilson	3	1
11	Jill	Stone	1	4
+-----+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> DELETE FROM employees PARTITION (p0, p1)
-> WHERE fname LIKE 'j%';
Query OK, 2 rows affected (0.09 sec)

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+
| 11 | Jill  | Stone |         1 |              4 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

Only the two rows in partitions `p0` and `p1` matching the `WHERE` condition were deleted. As you can see from the result when the `SELECT` is run a second time, there remains a row in the table matching the `WHERE` condition, but residing in a different partition (`p2`).

`UPDATE` statements using explicit partition selection behave in the same way; only rows in the partitions referenced by the `PARTITION` option are considered when determining the rows to be updated, as can be seen by executing the following statements:

```

mysql> UPDATE employees PARTITION (p0)
-> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0 Changed: 0 Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+
| 11 | Jill  | Stone |         1 |              4 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> UPDATE employees PARTITION (p2)
-> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 1 row affected (0.09 sec)
Rows matched: 1 Changed: 1 Warnings: 0

```

## Partition Selection

```
mysql> SELECT * FROM employees WHERE fname = 'Jill';
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 11 | Jill  | Stone | 2        | 4              |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

In the same way, when `PARTITION` is used with `DELETE`, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both `INSERT` and `REPLACE` statements, as shown here:

```
mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set
mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)

mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)
```

For statements that write multiple rows to a partitioned table that uses the `InnoDB` storage engine: If any row in the list following `VALUES` cannot be written to one of the partitions specified in the `partition_names` list, the entire statement fails and no rows are written. This is shown for `INSERT` statements in the following example, reusing the `employees` table created previously:

```
mysql> ALTER TABLE employees
-> REORGANIZE PARTITION p3 INTO (
-> PARTITION p3 VALUES LESS THAN (20),
-> PARTITION p4 VALUES LESS THAN (25),
-> PARTITION p5 VALUES LESS THAN MAXVALUE
-> );
Query OK, 6 rows affected (2.09 sec)
Records: 6 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE employees\G
***** 1. row *****
      Table: employees
Create Table: CREATE TABLE `employees` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `fname` varchar(25) NOT NULL,
  `lname` varchar(25) NOT NULL,
  `store_id` int(11) NOT NULL,
  `department_id` int(11) NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=27 DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE (id)
(PARTITION p0 VALUES LESS THAN (5) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (10) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (15) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (20) ENGINE = InnoDB,
PARTITION p4 VALUES LESS THAN (25) ENGINE = InnoDB,
PARTITION p5 VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */
1 row in set (0.00 sec)

mysql> INSERT INTO employees PARTITION (p3, p4) VALUES
-> (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3, p4, p5) VALUES
-> (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
Query OK, 2 rows affected (0.06 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

The preceding is true for both `INSERT` statements and `REPLACE` statements that write multiple rows.

In MySQL 5.7.1 and later, partition selection is disabled for tables employing a storage engine that supplies automatic partitioning, such as [NDB](#). (Bug #14827952)

## 18.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

**Prohibited constructs.** The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see [Section 18.6.3, “Partitioning Limitations Relating to Functions”](#).

**Arithmetic and logical operators.** Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of [\[LINEAR\] KEY](#) partitioning, as discussed elsewhere in this chapter; see [Section 18.2, “Partitioning Types”](#), for more information).

The `DIV` operator is also supported, and the `/` operator is not permitted. (Bug #30188, Bug #33182)

The bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

**HANDLER statements.** Previously, the `HANDLER` statement was not supported with partitioned tables. This limitation is removed beginning with MySQL 5.7.1.

**Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in [Section 5.1.7, “Server SQL Modes”](#), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables.*

**Examples.** The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as `column DIV 0` or `column MOD 0`, as shown here:

```
mysql> CREATE TABLE tn (c1 INT)
->     PARTITION BY LIST(1 DIV c1) (
->     PARTITION p0 VALUES IN (NULL),
->     PARTITION p1 VALUES IN (1)
-> );
Query OK, 0 rows affected (0.05 sec)
```

The default behavior for MySQL is to return `NULL` for the result of a division by zero, without producing any errors:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
Query OK, 3 rows affected (0.00 sec)
```

```
Records: 3 Duplicates: 0 Warnings: 0
```

However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same `INSERT` statement to fail, as shown here:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
ERROR 1365 (22012): Division by 0
```

- Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following `CREATE TABLE` statement can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` mode is in effect:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| NO_UNSIGNED_SUBTRACTION |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.05 sec)
```

If you remove the `NO_UNSIGNED_SUBTRACTION` server SQL mode after creating `tu`, you may no longer be able to access this table:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of

data among partitions to be different in the master's and slave's copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

**Performance considerations.** Some affects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table`.

See also [Maximum number of partitions](#).

- **MyISAM and partition file descriptor usage.** For a partitioned `MyISAM` table, MySQL uses 2 file descriptors for each partition, for each such table that is open. This means that you need many more file descriptors to perform operations on a partitioned `MyISAM` table than on a table which is identical to it except that the latter table is not partitioned, particularly when performing `ALTER TABLE` operations.

Assume a `MyISAM` table `t` with 100 partitions, such as the table created by this SQL statement:

```
CREATE TABLE t (c1 VARCHAR(50))
PARTITION BY KEY (c1) PARTITIONS 100
ENGINE=MYISAM;
```

#### Note

For brevity, we use `KEY` partitioning for the table shown in this example, but file descriptor usage as described here applies to all partitioned `MyISAM` tables, regardless of the type of partitioning that is employed. Partitioned tables using other storage engines such as `InnoDB` are not affected by this issue.

Now assume that you wish to repartition `t` so that it has 101 partitions, using the statement shown here:

```
ALTER TABLE t PARTITION BY KEY (c1) PARTITIONS 101;
```

To process this `ALTER TABLE` statement, MySQL uses 402 file descriptors—that is, two for each of the 100 original partitions, plus two for each of the 101 new partitions. This is because all partitions (old and new) must be opened concurrently during the reorganization of the table data. It is recommended that, if you expect to perform such operations, you should make sure that `--open-files-limit` is not set too low to accommodate them.

- **Table locks.** The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed.
- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` tables.
- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries

on these tables to take advantage of *partition pruning* can improve performance dramatically. See [Section 18.4, “Partition Pruning”](#), for more information.

Previously, index condition pushdown was not supported for partitioned tables. This limitation was removed in MySQL 5.7.3. See [Section 8.2.1.6, “Index Condition Pushdown Optimization”](#).

- **Performance with LOAD DATA.** In MySQL 5.7, `LOAD DATA` uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

#### Maximum number of partitions.

In MySQL 5.7, the maximum possible number of partitions for a given table is 8192. This number includes subpartitions.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see [Section B.5.2.18, “File' Not Found and Similar Errors”](#), for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also [File system operations](#).

#### Query cache not supported.

The query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries.

#### Per-partition key caches.

In MySQL 5.7, key caches are supported for partitioned `MyISAM` tables, using the `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements. Key caches may be defined for one, several, or all partitions, and indexes for one, several, or all partitions may be preloaded into key caches.

#### Foreign keys not supported for partitioned InnoDB tables.

Partitioned tables using the `InnoDB` storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an `InnoDB` table employing user-defined partitioning may contain foreign key references; no `InnoDB` table whose definition contains foreign key references may be partitioned.
2. No `InnoDB` table definition may contain a foreign key reference to a user-partitioned table; no `InnoDB` table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the `InnoDB` storage engine. `CREATE TABLE` and `ALTER TABLE` statements that would result in tables violating these restrictions are not allowed.

**ALTER TABLE ... ORDER BY.** An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.

**Effects on REPLACE statements by modification of primary keys.** It can be desirable in some cases (see [Section 18.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)) to modify a table's primary key. Be aware that, if your application uses `REPLACE` statements and you do this, the results of these statements can be drastically altered. See [Section 13.2.8, “REPLACE Syntax”](#), for more information and an example.

#### FULLTEXT indexes.

Partitioned tables do not support `FULLTEXT` indexes or searches, even for partitioned tables employing the `InnoDB` or `MyISAM` storage engine.

**Spatial columns.** Columns with spatial data types such as `POINT` or `GEOMETRY` cannot be used in partitioned tables.

**Temporary tables.**

Temporary tables cannot be partitioned. (Bug #17497)

**Log tables.** It is not possible to partition the log tables; an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error.

**Data type of partitioning key.**

A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing `ENUM` columns cannot be used. The column or expression value may also be `NULL`. (See [Section 18.2.7, “How MySQL Partitioning Handles NULL”](#).)

There are two exceptions to this restriction:

1. When partitioning by `[LINEAR] KEY`, it is possible to use columns of any valid MySQL data type other than `TEXT` or `BLOB` as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following two `CREATE TABLE` statements are valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;

CREATE TABLE tke
  ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
PARTITION BY LINEAR KEY(c1)
PARTITIONS 6;
```

2. When partitioning by `RANGE COLUMNS` or `LIST COLUMNS`, it is possible to use string, `DATE`, and `DATETIME` columns. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc (c1 INT, c2 DATE)
PARTITION BY RANGE COLUMNS(c2) (
  PARTITION p0 VALUES LESS THAN('1990-01-01'),
  PARTITION p1 VALUES LESS THAN('1995-01-01'),
  PARTITION p2 VALUES LESS THAN('2000-01-01'),
  PARTITION p3 VALUES LESS THAN('2005-01-01'),
  PARTITION p4 VALUES LESS THAN(MAXVALUE)
);

CREATE TABLE lc (c1 INT, c2 CHAR(1))
PARTITION BY LIST COLUMNS(c2) (
  PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
  PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
  PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
);
```

Neither of the preceding exceptions applies to `BLOB` or `TEXT` column types.

**Subqueries.**

A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.

**Issues with subpartitions.**

Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

`SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
);
```

You can create a table having the same columns, partitioned by [KEY](#), using a statement such as this one:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```
mysql> CREATE TABLE ts (
->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY()
-> SUBPARTITIONS 4
-> (
->   PARTITION p0 VALUES LESS THAN (100),
->   PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MySQL server version for the right syntax to use near ' )
mysql> CREATE TABLE ts (
->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY(id)
-> SUBPARTITIONS 4
-> (
->   PARTITION p0 VALUES LESS THAN (100),
->   PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

**DATA DIRECTORY and INDEX DIRECTORY options.** [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) are subject to the following restrictions when used with partitioned tables:

- Table-level [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options are ignored (see Bug #32091).
- On Windows, the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options are not supported for individual partitions or subpartitions of [MyISAM](#) tables. However, you can use [DATA DIRECTORY](#) for individual partitions or subpartitions of [InnoDB](#) tables.

**Repairing and rebuilding partitioned tables.** The statements [CHECK TABLE](#), [OPTIMIZE TABLE](#), [ANALYZE TABLE](#), and [REPAIR TABLE](#) are supported for partitioned tables.

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. See [Section 13.1.6, “ALTER TABLE Syntax”](#), for more information about these two statements.

Starting in MySQL 5.7.2, `ANALYZE`, `CHECK`, `OPTIMIZE`, `REPAIR`, and `TRUNCATE` operations are supported with subpartitions. `REBUILD` was also accepted syntax prior to MySQL 5.7.5, although this had no effect. (Bug #19075411, Bug #73130) See also [Section 13.1.6.1, “ALTER TABLE Partition Operations”](#).

`mysqlcheck`, `myisamchk`, and `myisampack` are not supported with partitioned tables.

**FOR EXPORT option (FLUSH TABLES).** The `FLUSH TABLES` statement's `FOR EXPORT` option is not supported for partitioned `InnoDB` tables in MySQL 5.7.4 and earlier. (Bug #16943907)

## 18.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
```

```

col2 DATE NOT NULL,
col3 INT NOT NULL,
col4 INT NOT NULL,
UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;

```

This example shows the error produced in such cases:

```

mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function

```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```

mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2, col3),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)

```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```

CREATE TABLE t4 (
  col1 INT NOT NULL,
  col2 INT NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col3),
  UNIQUE KEY (col2, col4)
);

```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```

CREATE TABLE t5 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

```

```
CREATE TABLE t6 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col3),
  UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t7 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2, col4),
  UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider the partitioned table created as shown here:

```
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
-> PARTITION BY RANGE(c1) (
-> PARTITION p0 VALUES LESS THAN (10),
-> PARTITION p1 VALUES LESS THAN (20),
-> PARTITION p2 VALUES LESS THAN (30),
-> PARTITION p3 VALUES LESS THAN (40)
-> );
Query OK, 0 rows affected (0.12 sec)
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```
# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0 Duplicates: 0 Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
```

```
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```
mysql> CREATE TABLE np_pk (
->   id INT NOT NULL AUTO_INCREMENT,
->   name VARCHAR(50),
->   added DATE,
->   PRIMARY KEY (id)
-> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```
mysql> ALTER TABLE np_pk
->   PARTITION BY HASH( TO_DAYS(added) )
->   PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk
->   PARTITION BY HASH(id)
->   PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

## 18.6.2 Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

**MERGE storage engine.** User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

**FEDERATED storage engine.** Partitioning of `FEDERATED` tables is not supported; it is not possible to create partitioned `FEDERATED` tables.

**CSV storage engine.** Partitioned tables using the `CSV` storage engine are not supported; it is not possible to create partitioned `CSV` tables.

**InnoDB storage engine.** InnoDB foreign keys and MySQL partitioning are not compatible. Partitioned InnoDB tables cannot have foreign key references, nor can they have columns referenced by foreign keys. InnoDB tables which have or which are referenced by foreign keys cannot be partitioned.

In addition, `ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use the InnoDB storage engine. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see [Section 13.1.6.1, “ALTER TABLE Partition Operations”](#).

**Upgrading partitioned tables.** When performing an upgrade, tables which are partitioned by `KEY` must be dumped and reloaded.

**Same storage engine for all partitions.** All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do *not* specify any engine for *any* partition or subpartition
- Specify the engine for *all* partitions or subpartitions

### 18.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following table are allowed in partitioning expressions.

|                           |                                                                                                  |                                                                                   |
|---------------------------|--------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| <code>ABS()</code>        | <code>CEILING()</code> (see <a href="#">CEILING()</a> and <a href="#">FLOOR()</a> )              | <code>DAY()</code>                                                                |
| <code>DAYOFMONTH()</code> | <code>DAYOFWEEK()</code>                                                                         | <code>DAYOFYEAR()</code>                                                          |
| <code>DATEDIFF()</code>   | <code>EXTRACT()</code> (see <a href="#">EXTRACT()</a> function with <code>WEEK</code> specifier) | <code>FLOOR()</code> (see <a href="#">CEILING()</a> and <a href="#">FLOOR()</a> ) |
| <code>HOURL()</code>      | <code>MICROSECOND()</code>                                                                       | <code>MINUTE()</code>                                                             |
| <code>MOD()</code>        | <code>MONTH()</code>                                                                             | <code>QUARTER()</code>                                                            |
| <code>SECOND()</code>     | <code>TIME_TO_SEC()</code>                                                                       | <code>TO_DAYS()</code>                                                            |
| <code>TO_SECONDS()</code> | <code>UNIX_TIMESTAMP()</code> (with <code>TIMESTAMP</code> columns)                              | <code>WEEKDAY()</code>                                                            |
| <code>YEAR()</code>       |                                                                                                  | <code>YEARWEEK()</code>                                                           |

In MySQL 5.7, partition pruning is supported for the `TO_DAYS()`, `TO_SECONDS()`, `YEAR()`, and `UNIX_TIMESTAMP()` functions. See [Section 18.4, “Partition Pruning”](#), for more information.

**CEILING() and FLOOR().** Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the `INT` types or `DECIMAL`. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) )(
->   PARTITION p0 VALUES IN (1,3,5),
->   PARTITION p1 VALUES IN (2,4,6)
-> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

**EXTRACT() function with WEEK specifier.** The value returned by the `EXTRACT()` function, when used as `EXTRACT(WEEK FROM col)`, depends on the value of the `default_week_format` system variable. For this reason, `EXTRACT()` is not permitted as a partitioning function when it specifies the unit as `WEEK`. (Bug #54483)

See [Section 12.6.2, “Mathematical Functions”](#), for more information about the return types of these functions, as well as [Section 11.2, “Numeric Types”](#).

## 18.6.4 Partitioning and Locking

For storage engines such as [MyISAM](#) that actually execute table-level locks when executing DML or DDL statements, such a statement in older versions of MySQL (5.6.5 and earlier) that affected a partitioned table imposed a lock on the table as a whole; that is, all partitions were locked until the statement was finished. In MySQL 5.7, *partition lock pruning* eliminates unneeded locks in many cases, and most statements reading from or updating a partitioned [MyISAM](#) table cause only the effected partitions to be locked. For example, a [SELECT](#) from a partitioned [MyISAM](#) table locks only those partitions actually containing rows that satisfy the [SELECT](#) statement's [WHERE](#) condition are locked.

For statements effecting partitioned tables using storage engines such as [InnoDB](#), that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning, this is not an issue.

The next few paragraphs discuss the effects of partition lock pruning for various MySQL statements on tables using storage engines that employ table-level locks.

### Effects on DML statements

[SELECT](#) statements (including those containing unions or joins) lock only those partitions that actually need to be read. This also applies to [SELECT ... PARTITION](#).

An [UPDATE](#) prunes locks only for tables on which no partitioning columns are updated.

[REPLACE](#) and [INSERT](#) lock only those partitions having rows to be inserted or replaced. However, if an [AUTO\\_INCREMENT](#) value is generated for any partitioning column then all partitions are locked.

[INSERT ... ON DUPLICATE KEY UPDATE](#) is pruned as long as no partitioning column is updated.

[INSERT ... SELECT](#) locks only those partitions in the source table that need to be read, although all partitions in the target table are locked.

Locks imposed by [LOAD DATA](#) statements on partitioned tables cannot be pruned.

The presence of [BEFORE INSERT](#) or [BEFORE UPDATE](#) triggers using any partitioning column of a partitioned table means that locks on [INSERT](#) and [UPDATE](#) statements updating this table cannot be pruned, since the trigger can alter its values: A [BEFORE INSERT](#) trigger on any of the table's partitioning columns means that locks set by [INSERT](#) or [REPLACE](#) cannot be pruned, since the [BEFORE INSERT](#) trigger may change a row's partitioning columns before the row is inserted, forcing the row into a different partition than it would be otherwise. A [BEFORE UPDATE](#) trigger on a partitioning column means that locks imposed by [UPDATE](#) or [INSERT ... ON DUPLICATE KEY UPDATE](#) cannot be pruned.

### Affected DDL statements

[CREATE VIEW](#) does not cause any locks.

[ALTER TABLE ... EXCHANGE PARTITION](#) prunes locks; only the exchanged table and the exchanged partition are locked.

[ALTER TABLE ... TRUNCATE PARTITION](#) prunes locks; only the partitions to be emptied are locked.

In addition, [ALTER TABLE](#) statements take metadata locks on the table level.

### Other statements

[LOCK TABLES](#) cannot prune partition locks.

`CALL stored_procedure(expr)` supports lock pruning, but evaluating `expr` does not.

`DO` and `SET` statements do not support partitioning lock pruning.

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the [CALL](#) statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation.
- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.
- Events. An event is a task that the server runs according to schedule.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

- For each object type, there are [CREATE](#), [ALTER](#), and [DROP](#) statements that control which objects exist and how they are defined. See [Section 13.1, “Data Definition Statements”](#).
- The [CALL](#) statement is used to invoke stored procedures. See [Section 13.2.1, “CALL Syntax”](#).
- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See [Section 13.6, “MySQL Compound-Statement Syntax”](#).

In MySQL 5.7, metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#).

## 19.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (;) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x   |
+-----+
| 1001 |
+-----+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (“\”) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world! |
+-----+
1 row in set (0.00 sec)
```

## 19.2 Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.7. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.7 installation procedure. If you are upgrading to MySQL 5.7 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

### Additional Resources

- You may find the [Stored Procedures User Forum](#) of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see [Section A.4, “MySQL 5.7 FAQ: Stored Procedures and Functions”](#).
- There are some restrictions on the use of stored routines. See [Section C.1, “Restrictions on Stored Programs”](#).
- Binary logging for stored routines takes place as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

### 19.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see [Section 13.1.12, “CREATE PROCEDURE and](#)

[CREATE FUNCTION Syntax](#)). A procedure is invoked using a `CALL` statement (see [Section 13.2.1, “CALL Syntax”](#)), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see [Section 13.6, “MySQL Compound-Statement Syntax”](#)).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see [Section 13.1.22, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see [Section 13.1.4, “ALTER PROCEDURE Syntax”](#)).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See [Section 5.1.4, “Server System Variables”](#), for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See [Section 23.8.7.54, “mysql\\_real\\_connect\(\)”](#), and [Section 23.8.17, “C API Support for Multiple Statement Execution”](#).

## 19.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.
- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.
- The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

## 19.2.3 Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See [Section 20.19, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See [Section 13.7.5.9, “SHOW CREATE PROCEDURE Syntax”](#).
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See [Section 13.7.5.28, “SHOW PROCEDURE STATUS Syntax”](#).

## 19.2.4 Stored Procedures, Functions, Triggers, and LAST\_INSERT\_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see [Section 12.14, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

## 19.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by `INSERT` or `LOAD DATA` statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

### Important

MySQL triggers activate only for changes made to tables by SQL statements. They do not activate for changes in views, nor by changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by changes in `INFORMATION_SCHEMA` or `performance_schema` tables, because these tables are actually views.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

## Additional Resources

- You may find the [Triggers User Forum](#) of use when working with triggers.
- For answers to commonly asked questions regarding triggers in MySQL, see [Section A.5, “MySQL 5.7 FAQ: Triggers”](#).
- There are some restrictions on the use of triggers; see [Section C.1, “Restrictions on Stored Programs”](#).
- Binary logging for triggers takes place as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

## 19.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement, described in [Section 13.1.16, “CREATE TRIGGER Syntax”](#), and [Section 13.1.26, “DROP TRIGGER Syntax”](#).

Here is a simple example that associates a trigger with a table, to activate for `INSERT` operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is `AFTER`.
- The keyword `INSERT` indicates the trigger event; that is, the type of operation that activates the trigger. In the example, `INSERT` operations cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` operations.
- The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48                |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

As of MySQL 5.7.2, it is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To

affect trigger order, specify a clause after `FOR EACH ROW` that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

For example, the following trigger definition defines another `BEFORE INSERT` trigger for the `account` table:

```
mysql> CREATE TRIGGER ins_transaction BEFORE INSERT ON account
-> FOR EACH ROW PRECEDES ins_sum
-> SET
-> @deposits = @deposits + IF(NEW.amount>0,NEW.amount,0),
-> @withdrawals = @withdrawals + IF(NEW.amount<0,-NEW.amount,0);
Query OK, 0 rows affected (0.02 sec)
```

This trigger, `ins_transaction`, is similar to `ins_sum` but accumulates deposits and withdrawals separately. It has a `PRECEDES` clause that causes it to activate before `ins_sum`; without that clause, it would activate after `ins_sum` because it is created after `ins_sum`.

Before MySQL 5.7.2, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. To work around this, you can define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change will have already occurred.)

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value must be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
->     IF NEW.amount < 0 THEN
->         SET NEW.amount = 0;
->     ELSEIF NEW.amount > 100 THEN
->         SET NEW.amount = 100;
->     END IF;
-> END;//
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK to SAVEPOINT` is permitted because it does not end a transaction.)

See also [Section C.1, "Restrictions on Stored Programs"](#).

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if any `BEFORE` triggers and the row operation execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Triggers can contain direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);

delimiter |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW
BEGIN
  INSERT INTO test2 SET a2 = NEW.a1;
  DELETE FROM test3 WHERE a3 = NEW.a1;
  UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;

|

delimiter ;

INSERT INTO test3 (a3) VALUES
(NULL), (NULL), (NULL), (NULL), (NULL),
(NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
(0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
  -> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

As a result, the four tables contain the following data:

```
mysql> SELECT * FROM test1;
+-----+
| a1 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
+-----+
| 2 |
| 5 |
| 6 |
| 9 |
| 10 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
+-----+
| a4 | b4 |
+-----+
1	3
2	0
3	1
4	2
5	0
6	0
7	1
8	1
9	0
10	0
+-----+
10 rows in set (0.00 sec)
```

## 19.3.2 Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See [Section 20.27, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).
- Use the `SHOW CREATE TRIGGER` statement. See [Section 13.7.5.11, “SHOW CREATE TRIGGER Syntax”](#).
- Use the `SHOW TRIGGERS` statement. See [Section 13.7.5.38, “SHOW TRIGGERS Syntax”](#).

## 19.4 Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- [Section 19.4.1, “Event Scheduler Overview”](#), provides an introduction to and conceptual overview of MySQL Events.
- [Section 19.4.3, “Event Syntax”](#), discusses the SQL statements for creating, altering, and dropping MySQL Events.
- [Section 19.4.4, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the `event` table in the `mysql` database. This table is created during the MySQL 5.7 installation procedure. If you are upgrading to MySQL 5.7 from an earlier version, be sure to update your grant tables to make sure that the `event` table exists. See [Section 4.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

### Additional Resources

- You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events.
- There are some restrictions on the use of events; see [Section C.1, “Restrictions on Stored Programs”](#).
- Binary logging for events takes place as described in [Section 19.7, “Binary Logging of Stored Programs”](#).

#### 19.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* to avoid confusion with triggers of the type discussed in [Section 19.3, “Using Triggers”](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 13.6, “MySQL Compound-Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 13.1.2, “ALTER EVENT Syntax”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see [Section C.1, “Restrictions on Stored Programs”](#).

## 19.4.2 Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. `OFF` is the default value for `event_scheduler`.

When the Event Scheduler is stopped (`event_scheduler` is `OFF`), it can be started by setting the value of `event_scheduler` to `ON`. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is `ON`, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
```

```

    Id: 1
    User: root
    Host: localhost
    db: NULL
Command: Query
    Time: 0
    State: NULL
    Info: show processlist
***** 2. row *****
    Id: 2
    User: event_scheduler
    Host: localhost
    db: NULL
Command: Daemon
    Time: 3
    State: Waiting for next activation
    Info: NULL
2 rows in set (0.00 sec)

```

Event scheduling can be stopped by setting the value of `event_scheduler` to `OFF`.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```

SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;

```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```

SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;

```

Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. **DISABLED** has no numeric equivalent. For this reason, **ON** and **OFF** are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```

mysql> SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
variable and should be set with SET GLOBAL

```

### Important

It is possible to set the Event Scheduler to **DISABLED** only at server startup. If `event_scheduler` is **ON** or **OFF**, you cannot set it to **DISABLED** at runtime. Also, if the Event Scheduler is set to **DISABLED** at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

#### Note

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see [Section 19.4.3, “Event Syntax”](#).

MySQL provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 19.4.4, “Event Metadata”](#), and [Section 20.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

## 19.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 13.1.9, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 13.1.2, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 13.1.19, “DROP EVENT Syntax”](#). Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 13.1.9, “CREATE EVENT Syntax”](#).

An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#).

## 19.4.4 Event Metadata

Metadata about events can be obtained as follows:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 20.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#).
- Use the `SHOW CREATE EVENT` statement. See [Section 13.7.5.7, “SHOW CREATE EVENT Syntax”](#).

- Use the `SHOW EVENTS` statement. See [Section 13.7.5.18, “SHOW EVENTS Syntax”](#).

### Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

| Value         | <code>mysql.event</code> | <code>INFORMATION_SCHEMA.EVENTS</code> | <code>SHOW EVENTS</code> |
|---------------|--------------------------|----------------------------------------|--------------------------|
| Execute at    | UTC                      | ETZ                                    | ETZ                      |
| Starts        | UTC                      | ETZ                                    | ETZ                      |
| Ends          | UTC                      | ETZ                                    | ETZ                      |
| Last executed | UTC                      | ETZ                                    | n/a                      |
| Created       | STZ                      | STZ                                    | n/a                      |
| Last altered  | STZ                      | STZ                                    | n/a                      |

## 19.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See [Section 19.4.6, “The Event Scheduler and MySQL Privileges”](#) for an example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes, run `mysqladmin debug` (see [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At  LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA       : init_scheduler:313
LUA       : init_scheduler:318
WOC       : NO
Workers    : 0
Executed   : 0
Data locked: NO

Event queue status:
Element count  : 1
Data locked    : NO
Attempting lock : NO
LLA           : init_queue:148
```

```
LUA          : init_queue:168
WOC          : NO
Next activation : 0000-00-00 00:00:00
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#). For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

## 19.4.6 The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires the `SUPER` privilege.

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
  ON SCHEDULE
  EVERY 10 SECOND
  DO
  INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails:

```
2013-09-24T12:41:31.261992Z 25 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
```

```
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:31.262022Z 25 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
2013-09-24T12:41:41.271796Z 26 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:41.272761Z 26 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

### Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE
EVERY 7 SECOND
DO
INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 20.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#)) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
  WHERE db = 'myschema'
     AND definer = 'jon@ghidora'
     AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but *not* of statements executed by events; see [Section C.1, “Restrictions on Stored Programs”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

## 19.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

## Additional Resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section A.6, “MySQL 5.7 FAQ: Views”](#).
- There are some restrictions on the use of views; see [Section C.5, “Restrictions on Views”](#).

### 19.5.1 View Syntax

The `CREATE VIEW` statement creates a new view (see [Section 13.1.17, “CREATE VIEW Syntax”](#)). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 13.1.7, “ALTER VIEW Syntax”](#)), or `DROP VIEW` (see [Section 13.1.27, “DROP VIEW Syntax”](#)).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
| 5 | 60 | 300 |
+-----+-----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 5 | 60 | 300 |
+-----+-----+-----+
```

### 19.5.2 View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`.

- For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.
- If no `ALGORITHM` clause is present, `UNDEFINED` is the default algorithm prior to MySQL 5.7.6. As of 5.7.6, the default algorithm is determined by the value of the `derived_merge` flag of the `optimizer_switch` system variable. For additional discussion, see [Optimizing Derived Tables and View References](#).

A reason to specify `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`

- Subquery in the select list
- Assignment to user variables
- Refers only to literal values (in this case, there is no underlying table)

### 19.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. Derived tables can also be specified in multiple-table `UPDATE` and `DELETE` statements, but can only be used for reading data to specify rows to be updated or deleted. Generally, the view references must be updatable, meaning that they may be merged and not materialized. Composite views have more complex rules.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list (fails for `INSERT`, okay for `UPDATE`, `DELETE`)
- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the `FROM` clause
- Subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table (fails for `INSERT`, okay for `UPDATE`, `DELETE`)

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [CREATE TABLE and Generated Columns](#).

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions, such as these:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag.

If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The `IS_UPDATABLE` flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the `IS_UPDATABLE` value, the server keeps track of the updatability of a view and correctly rejects data change operations to views that are not updatable. If the `IS_UPDATABLE` value for a view has become inaccurate due to changes to underlying views, the value can be updated by deleting and recreating the view.

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See [Section 5.1.4, “Server System Variables”](#).

For the following discussion, suppose that these tables and views exist:

```
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (c INTEGER);
CREATE VIEW vmat AS SELECT SUM(x) AS s FROM t1;
CREATE VIEW vup AS SELECT * FROM t2;
CREATE VIEW vjoin AS SELECT * FROM vmat JOIN vup ON vmat.s=vup.c;
```

`INSERT`, `UPDATE`, and `DELETE` statements are permitted as follows:

- **INSERT:** The insert table of an `INSERT` statement may be a view reference that is merged. If the view is a join view, all components of the view must be updatable (not materialized). For a multiple-table updatable view, `INSERT` can work if it inserts into a single table.

This statement is invalid because one component of the join view is nonupdatable:

```
INSERT INTO vjoin (c) VALUES (1);
```

This statement is valid; the view contains no materialized components:

```
INSERT INTO vup (c) VALUES (1);
```

- **UPDATE:** The table or tables to be updated in an `UPDATE` statement may be view references that are merged. If a view is a join view, at least one component of the view must be updatable (this differs from `INSERT`).

In a multiple-table `UPDATE` statement, the updated table references of the statement must be base tables or updatable view references. Nonupdated table references may be materialized views or derived tables.

This statement is valid; column `c` is from the updatable part of the join view:

```
UPDATE vjoin SET c=c+1;
```

This statement is invalid; column `x` is from the nonupdatable part:

```
UPDATE vjoin SET x=x+1;
```

```
UPDATE vjoin SET x=x+1;
```

This statement is valid; the updated table reference of the multiple-table `UPDATE` is an updatable view (`vup`):

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET c=c+1;
```

This statement is invalid; it tries to update a materialized derived table:

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET s=s+1;
```

- **DELETE**: The table or tables to be deleted from in a `DELETE` statement must be merged views. Join views are not allowed (this differs from `INSERT` and `UPDATE`).

This statement is invalid because the view is a join view:

```
DELETE vjoin WHERE ...;
```

This statement is valid because the view is a merged (updatable) view:

```
DELETE vup WHERE ...;
```

This statement is valid because it deletes from a merged (updatable) view:

```
DELETE vup FROM vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...;
```

Additional discussion and examples follow.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```
UPDATE v SET col2 = 0;
```

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

## 19.5.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `select_statement` is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`.

Before MySQL 5.7.6, `WITH CHECK OPTION` testing works like this:

- With `LOCAL`, the view `WHERE` clause is checked, but no underlying views are checked.
- With `CASCADED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCADED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.
- With no check option, the view `WHERE` clause is not checked, and no underlying views are checked.

As of MySQL 5.7.6, `WITH CHECK OPTION` testing is standard-compliant (with changed semantics from previously for `LOCAL` and no check clause):

- With `LOCAL`, the view `WHERE` clause is checked, then checking recurses to underlying views and applies the same rules.
- With `CASCADED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCADED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.
- With no check option, the view `WHERE` clause is not checked, then checking recurses to underlying views, and applies the same rules.

Consider the definitions for the following table and set of views:

```
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. Before MySQL 5.7.6, because `v2` has a `LOCAL` check option, inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against the `v3` check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

As of MySQL 5.7.6, the semantics for `LOCAL` differ from previously: Inserts for `v2` are checked against its `LOCAL` check option, then (unlike before 5.7.6), the check recurses to `v1` and the rules are applied again. The rules for `v1` cause a check failure. The check for `v3` fails as before:

```
mysql> INSERT INTO v2 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v2'
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

## 19.5.5 View Metadata

Metadata about views can be obtained as follows:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 20.29, “The INFORMATION\\_SCHEMA VIEWS Table”](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 13.7.5.13, “SHOW CREATE VIEW Syntax”](#).

## 19.6 Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their `DEFINER` attribute, and, if there is one, their `SQL SECURITY` characteristic.

All stored programs (procedures, functions, triggers, and events) and views can have a `DEFINER` attribute that names a MySQL account. If the `DEFINER` attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have a `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the `SQL SECURITY` characteristic is omitted, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` to call a stored procedure or `SELECT` to select from a view), but when the object executes, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as a `root` account), the object can perform powerful operations *no matter who invokes it*.
- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in `DEFINER` security context and thus executes with the privileges of `'admin'@'localhost'`, the account named in the `DEFINER` attribute. This account must have the `EXECUTE` privilege for `p1` as well as the `UPDATE` privilege for the table `t1`. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

`p2`, unlike `p1`, executes in `INVOKER` security context. The `DEFINER` attribute is irrelevant and `p2` executes with the privileges of the invoking user. `p2` fails if the invoker lacks the `EXECUTE` privilege for `p2` or the `UPDATE` privilege for the table `t1`.

MySQL uses the following rules to control which accounts a user can specify in an object `DEFINER` attribute:

- You can specify a `DEFINER` value other than your own account only if you have the `SUPER` privilege.
- If you do not have the `SUPER` privilege, the only legal user value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

- For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored programs or views while using an account that has the `SUPER` privilege, specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.
- Administrators can prevent users from specifying highly privileged `DEFINER` accounts by not granting them the `SUPER` privilege.
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:
  - A stored procedure or function cannot be referenced by a user who does not have the `EXECUTE` privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` to select from it, `INSERT` to insert into it, and so forth).

However, no such control exists for triggers because users do not reference them directly. A trigger always executes in `DEFINER` context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the `DEFINER` account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the `SUPER` and `TRIGGER` privileges needed to create the trigger are revoked from the account of the user who created it. Administrators should be especially careful about granting users that combination of privileges.

## 19.7 Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 17.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.3.2, “Using Backups for Recovery”](#).

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, triggers, and events), if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave

servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.

- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.7 handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see [Section 17.2.1, “Replication Formats”](#).

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See [Section 5.2.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.7 can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` might be required regardless of whether binary logging is enabled. See [Section 13.1.12, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
    RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
  UPDATE t SET modtime = NOW() WHERE id = p_id;
  RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.
- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 17.4.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is nondeterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes

changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on master and slave servers.
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
->   IF @@server_id=2 THEN dangerous_statement; END IF;
->   RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
```

```
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
  - Updates to transactional tables are not logged.
  - Updates to nontransactional tables are logged because rollback does not cancel them.

- Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

---

# Chapter 20 INFORMATION\_SCHEMA Tables

## Table of Contents

|                                                                                                    |      |

| 20.31    | Extensions to SHOW Statements .....                           | 2760 |

[INFORMATION\\_SCHEMA](#) provides access to database *metadata*, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are *data dictionary* and *system catalog*.

## Usage Notes for the INFORMATION\_SCHEMA Database

[INFORMATION\\_SCHEMA](#) is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The [INFORMATION\\_SCHEMA](#) database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select [INFORMATION\\_SCHEMA](#) as the default database with a [USE](#) statement, you can only read the contents of tables, not perform [INSERT](#), [UPDATE](#), or [DELETE](#) operations on them.

## Example

Here is an example of a statement that retrieves information from [INFORMATION\\_SCHEMA](#):

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name;
```

| table_name | table_type | engine |
|------------|------------|--------|
| fk         | BASE TABLE | InnoDB |
| fk2        | BASE TABLE | InnoDB |
| goto       | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| loop       | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| t          | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| tables     | BASE TABLE | MyISAM |
| v          | VIEW       | NULL   |
| v2         | VIEW       | NULL   |
| v3         | VIEW       | NULL   |
| v56        | VIEW       | NULL   |

```
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

## Character Set Considerations

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character

set ([utf8\\_general\\_ci](#)) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in [INFORMATION\\_SCHEMA](#) string columns can be affected by file system case sensitivity. For more information, see [Section 10.1.7.9, “Collation and INFORMATION\\_SCHEMA Searches”](#).

## INFORMATION\_SCHEMA as Alternative to SHOW Statements

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from [INFORMATION\\_SCHEMA](#) queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of [INFORMATION\\_SCHEMA](#), there are enhancements to `SHOW` as described in [Section 20.31, “Extensions to SHOW Statements”](#).

## Privileges

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges see `NULL`. These restrictions do not apply for `InnoDB` tables; you can see them with only the `PROCESS` privilege.

The same privileges apply to selecting information from [INFORMATION\\_SCHEMA](#) and viewing the same information through `SHOW` statements. In either case, you must have some privilege on an object to see information about it.

## Performance Considerations

[INFORMATION\\_SCHEMA](#) queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about using `EXPLAIN` output to tune [INFORMATION\\_SCHEMA](#) queries, see [Section 8.2.4, “Optimizing INFORMATION\\_SCHEMA Queries”](#).

## Standards Considerations

The implementation for the [INFORMATION\\_SCHEMA](#) table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation,

and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5>.

## Conventions in the INFORMATION\_SCHEMA Reference Sections

The following sections describe each of the tables and columns in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

For information about `INFORMATION_SCHEMA` tables specific to the `InnoDB` storage engine, see [Section 20.30, “INFORMATION\\_SCHEMA Tables for InnoDB”](#).

For answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database, see [Section A.7, “MySQL 5.7 FAQ: INFORMATION\\_SCHEMA”](#).

## 20.1 The INFORMATION\_SCHEMA CHARACTER\_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name         | Remarks         |
|--------------------------------------|--------------------------------|-----------------|
| <code>CHARACTER_SET_NAME</code>      | <code>Charset</code>           |                 |
| <code>DEFAULT_COLLATE_NAME</code>    | <code>Default collation</code> |                 |
| <code>DESCRIPTION</code>             | <code>Description</code>       | MySQL extension |
| <code>MAXLEN</code>                  | <code>Maxlen</code>            | MySQL extension |

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

## 20.2 The INFORMATION\_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

| INFORMATION_SCHEMA Name         | SHOW Name              | Remarks         |
|---------------------------------|------------------------|-----------------|
| <code>COLLATION_NAME</code>     | <code>Collation</code> |                 |
| <code>CHARACTER_SET_NAME</code> | <code>Charset</code>   | MySQL extension |
| <code>ID</code>                 | <code>Id</code>        | MySQL extension |
| <code>IS_DEFAULT</code>         | <code>Default</code>   | MySQL extension |
| <code>IS_COMPILED</code>        | <code>Compiled</code>  | MySQL extension |
| <code>SORTLEN</code>            | <code>Sortlen</code>   | MySQL extension |

- `COLLATION_NAME` is the collation name.
- `CHARACTER_SET_NAME` is the name of the character set with which the collation is associated.
- `ID` is the collation ID.
- `IS_DEFAULT` indicates whether the collation is the default for its character set.
- `IS_COMPILED` indicates whether the character set is compiled into the server.
- `SORTLEN` is related to the amount of memory required to sort strings expressed in the character set.

Collation information is also available from the `SHOW COLLATION` statement. The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
 [WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION
 [LIKE 'wild']
```

## 20.3 The INFORMATION\_SCHEMA COLLATION\_CHARACTER\_SET\_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

| INFORMATION_SCHEMA Name         | SHOW Name              | Remarks |
|---------------------------------|------------------------|---------|
| <code>COLLATION_NAME</code>     | <code>Collation</code> |         |
| <code>CHARACTER_SET_NAME</code> | <code>Charset</code>   |         |

## 20.4 The INFORMATION\_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

| INFORMATION_SCHEMA Name    | SHOW Name          | Remarks          |
|----------------------------|--------------------|------------------|
| <code>TABLE_CATALOG</code> |                    | <code>def</code> |
| <code>TABLE_SCHEMA</code>  |                    |                  |
| <code>TABLE_NAME</code>    |                    |                  |
| <code>COLUMN_NAME</code>   | <code>Field</code> |                  |

| INFORMATION_SCHEMA Name  | SHOW Name  | Remarks         |
|--------------------------|------------|-----------------|
| ORDINAL_POSITION         |            | see notes       |
| COLUMN_DEFAULT           | Default    |                 |
| IS_NULLABLE              | Null       |                 |
| DATA_TYPE                | Type       |                 |
| CHARACTER_MAXIMUM_LENGTH | Type       |                 |
| CHARACTER_OCTET_LENGTH   |            |                 |
| NUMERIC_PRECISION        | Type       |                 |
| NUMERIC_SCALE            | Type       |                 |
| DATETIME_PRECISION       | Type       |                 |
| CHARACTER_SET_NAME       |            |                 |
| COLLATION_NAME           | Collation  |                 |
| COLUMN_TYPE              | Type       | MySQL extension |
| COLUMN_KEY               | Key        | MySQL extension |
| EXTRA                    | Extra      | MySQL extension |
| PRIVILEGES               | Privileges | MySQL extension |
| COLUMN_COMMENT           | Comment    | MySQL extension |
| GENERATION_EXPRESSION    |            | MySQL extension |

**Notes:**

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW`, `SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multibyte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.
- `GENERATION_EXPRESSION` is nonempty for generated columns and displays the expression used to compute column values. For information about generated columns, see [CREATE TABLE and Generated Columns](#). This column was added in MySQL 5.7.6.
- As of MySQL 5.7.6, the `EXTRA` column contains `VIRTUAL GENERATED` or `VIRTUAL STORED` for generated columns.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
  FROM INFORMATION_SCHEMA.COLUMNS
 WHERE table_name = 'tbl_name'
    [AND table_schema = 'db_name']
    [AND column_name LIKE 'wild']

SHOW COLUMNS
  FROM tbl_name
    [FROM db_name]
    [LIKE 'wild']
```

## 20.5 The INFORMATION\_SCHEMA COLUMN\_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks                                         |
|-------------------------|-----------|-------------------------------------------------|
| GRANTEE                 |           | ' <i>user_name</i> '@' <i>host_name</i> ' value |
| TABLE_CATALOG           |           | def                                             |
| TABLE_SCHEMA            |           |                                                 |
| TABLE_NAME              |           |                                                 |
| COLUMN_NAME             |           |                                                 |
| PRIVILEGE_TYPE          |           |                                                 |
| IS_GRANTABLE            |           |                                                 |

**Notes:**

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT, INSERT, UPDATE, REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

## 20.6 The INFORMATION\_SCHEMA ENGINES Table

The `ENGINES` table provides information about storage engines.

| INFORMATION_SCHEMA Name | SHOW Name    | Remarks         |
|-------------------------|--------------|-----------------|
| ENGINE                  | Engine       | MySQL extension |
| SUPPORT                 | Support      | MySQL extension |
| COMMENT                 | Comment      | MySQL extension |
| TRANSACTIONS            | Transactions | MySQL extension |
| XA                      | XA           | MySQL extension |
| SAVEPOINTS              | Savepoints   | MySQL extension |

**Notes:**

- The `ENGINES` table is a nonstandard table. Its contents correspond to the columns of the `SHOW ENGINES` statement. For descriptions of its columns, see [Section 13.7.5.16, “SHOW ENGINES Syntax”](#).

See also [Section 13.7.5.16, “SHOW ENGINES Syntax”](#).

## 20.7 The INFORMATION\_SCHEMA EVENTS Table

The `EVENTS` table provides information about scheduled events, which are discussed in [Section 19.4, “Using the Event Scheduler”](#). The `SHOW Name` values correspond to column names of the `SHOW EVENTS` statement.

| INFORMATION_SCHEMA Name | SHOW Name            | Remarks              |
|-------------------------|----------------------|----------------------|
| EVENT_CATALOG           |                      | def, MySQL extension |
| EVENT_SCHEMA            | Db                   | MySQL extension      |
| EVENT_NAME              | Name                 | MySQL extension      |
| DEFINER                 | Definer              | MySQL extension      |
| TIME_ZONE               | Time zone            | MySQL extension      |
| EVENT_BODY              |                      | MySQL extension      |
| EVENT_DEFINITION        |                      | MySQL extension      |
| EVENT_TYPE              | Type                 | MySQL extension      |
| EXECUTE_AT              | Execute at           | MySQL extension      |
| INTERVAL_VALUE          | Interval value       | MySQL extension      |
| INTERVAL_FIELD          | Interval field       | MySQL extension      |
| SQL_MODE                |                      | MySQL extension      |
| STARTS                  | Starts               | MySQL extension      |
| ENDS                    | Ends                 | MySQL extension      |
| STATUS                  | Status               | MySQL extension      |
| ON_COMPLETION           |                      | MySQL extension      |
| CREATED                 |                      | MySQL extension      |
| LAST_ALTERED            |                      | MySQL extension      |
| LAST_EXECUTED           |                      | MySQL extension      |
| EVENT_COMMENT           |                      | MySQL extension      |
| ORIGINATOR              | Originator           | MySQL extension      |
| CHARACTER_SET_CLIENT    | character_set_client | MySQL extension      |
| COLLATION_CONNECTION    | collation_connection | MySQL extension      |
| DATABASE_COLLATION      | Database Collation   | MySQL extension      |

**Notes:**

- The `EVENTS` table is a nonstandard table.
- `EVENT_CATALOG`: The value of this column is always `def`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The account of the user who created the event, in `'user_name'@'host_name'` format.
- `TIME_ZONE`: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.
- `EVENT_BODY`: The language used for the statements in the event's `DO` clause; in MySQL 5.7, this is always `SQL`.

This column is not to be confused with the column of the same name (now named `EVENT_DEFINITION`) that existed in earlier MySQL versions.

- **EVENT\_DEFINITION**: The text of the SQL statement making up the event's **DO** clause; in other words, the statement executed by this event.
- **EVENT\_TYPE**: The event repetition type, either **ONE TIME** (transient) or **RECURRING** (repeating).
- **EXECUTE\_AT**: For a one-time event, this is the **DATETIME** value specified in the **AT** clause of the **CREATE EVENT** statement used to create the event, or of the last **ALTER EVENT** statement that modified the event. The value shown in this column reflects the addition or subtraction of any **INTERVAL** value included in the event's **AT** clause. For example, if an event is created using **ON SCHEDULE AT CURRENT\_TIMESTAMP + '1:6' DAY\_HOUR**, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be '2006-02-10 20:05:30'.

If the event's timing is determined by an **EVERY** clause instead of an **AT** clause (that is, if the event is recurring), the value of this column is **NULL**.

- **INTERVAL\_VALUE**: For recurring events, this column contains the numeric portion of the event's **EVERY** clause.

For a one-time event (that is, an event whose timing is determined by an **AT** clause), this column is **NULL**.

- **INTERVAL\_FIELD**: For recurring events, this column contains the units portion of the **EVERY** clause governing the timing of the event. Thus, this column contains a value such as 'YEAR', 'QUARTER', 'DAY', and so on.

For a one-time event (that is, an event whose timing is determined by an **AT** clause), this column is **NULL**.

- **SQL\_MODE**: The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see [Section 5.1.7, "Server SQL Modes"](#).
- **STARTS**: For a recurring event whose definition includes a **STARTS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE\_AT** column, this value resolves any expressions used.

If there is no **STARTS** clause affecting the timing of the event, this column is **NULL**.

- **ENDS**: For a recurring event whose definition includes a **ENDS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE\_AT** column, this value resolves any expressions used.

If there is no **ENDS** clause affecting the timing of the event, this column is **NULL**.

- **STATUS**: One of the three values **ENABLED**, **DISABLED**, or **SLAVESIDE\_DISABLED**.

**SLAVESIDE\_DISABLED** indicates that the creation of the event occurred on another MySQL server acting as a replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See [Section 17.4.1.12, "Replication of Invoked Features"](#), for more information.

- **ON\_COMPLETION**: One of the two values **PRESERVE** or **NOT PRESERVE**.
- **CREATED**: The date and time when the event was created. This is a **TIMESTAMP** value.
- **LAST\_ALTERED**: The date and time when the event was last modified. This is a **TIMESTAMP** value. If the event has not been modified since its creation, this column holds the same value as the **CREATED** column.
- **LAST\_EXECUTED**: The date and time when the event last executed. A **DATETIME** value. If the event has never executed, this column is **NULL**.

**LAST\_EXECUTED** indicates when the event started. As a result, the **ENDS** column is never less than **LAST\_EXECUTED**.

- **EVENT\_COMMENT**: The text of a comment, if the event has one. If not, the value of this column is an empty string.
- **ORIGINATOR**: The server ID of the MySQL server on which the event was created; used in replication. The default value is 0.
- **CHARACTER\_SET\_CLIENT**: The session value of the `character_set_client` system variable when the event was created.
- **COLLATION\_CONNECTION**: The session value of the `collation_connection` system variable when the event was created.
- **DATABASE\_COLLATION**: The collation of the database with which the event is associated.

**Example:** Suppose that the user `jon@ghidora` creates an event named `e_daily`, and then modifies it a few minutes later using an `ALTER EVENT` statement, as shown here:

```
DELIMITER |

CREATE EVENT e_daily
ON SCHEDULE
  EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
  BEGIN
    INSERT INTO site_activity.totals (time, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
        FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
  END |

DELIMITER ;

ALTER EVENT e_daily
  ENABLED;
```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME = 'e_daily'
> AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: def
EVENT_SCHEMA: test
EVENT_NAME: e_daily
DEFINER: me@localhost
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
  INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
  DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE:
STARTS: 2008-09-03 12:13:39
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2008-09-03 12:13:39
LAST_ALTERED: 2008-09-03 12:13:39
LAST_EXECUTED: NULL
```

```

EVENT_COMMENT: Saves total number of sessions then clears the
                table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: latin1
COLLATION_CONNECTION: latin1_swedish_ci
DATABASE_COLLATION: latin1_swedish_ci
    
```

Times in the `EVENTS` table are displayed using the event time zone or the current session time zone, as described in [Section 19.4.4, “Event Metadata”](#).

See also [Section 13.7.5.18, “SHOW EVENTS Syntax”](#).

## 20.8 The INFORMATION\_SCHEMA FILES Table

The `FILES` table provides information about the files in which MySQL tablespace data is stored.

`INFORMATION_SCHEMA.FILES` reports data about InnoDB data files as of MySQL 5.7.8. (Previously, this table contained information about MySQL Cluster Disk Data files. See [MySQL Cluster NDB 7.3 and MySQL Cluster NDB 7.4](#)), for more information.)

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| FILE_ID                 |           | MySQL extension |
| FILE_NAME               |           | MySQL extension |
| FILE_TYPE               |           | MySQL extension |
| TABLESPACE_NAME         |           | MySQL extension |
| TABLE_CATALOG           |           | MySQL extension |
| TABLE_SCHEMA            |           | MySQL extension |
| TABLE_NAME              |           | MySQL extension |
| LOGFILE_GROUP_NAME      |           | MySQL extension |
| LOGFILE_GROUP_NUMBER    |           | MySQL extension |
| ENGINE                  |           | MySQL extension |
| FULLTEXT_KEYS           |           | MySQL extension |
| DELETED_ROWS            |           | MySQL extension |
| UPDATE_COUNT            |           | MySQL extension |
| FREE_EXTENTS            |           | MySQL extension |
| TOTAL_EXTENTS           |           | MySQL extension |
| EXTENT_SIZE             |           | MySQL extension |
| INITIAL_SIZE            |           | MySQL extension |
| MAXIMUM_SIZE            |           | MySQL extension |
| AUTOEXTEND_SIZE         |           | MySQL extension |
| CREATION_TIME           |           | MySQL extension |
| LAST_UPDATE_TIME        |           | MySQL extension |
| LAST_ACCESS_TIME        |           | MySQL extension |
| RECOVER_TIME            |           | MySQL extension |
| TRANSACTION_COUNTER     |           | MySQL extension |
| VERSION                 |           | MySQL extension |
| ROW_FORMAT              |           | MySQL extension |
| TABLE_ROWS              |           | MySQL extension |
| AVG_ROW_LENGTH          |           | MySQL extension |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| DATA_LENGTH             |           | MySQL extension |
| MAX_DATA_LENGTH         |           | MySQL extension |
| INDEX_LENGTH            |           | MySQL extension |
| DATA_FREE               |           | MySQL extension |
| CREATE_TIME             |           | MySQL extension |
| UPDATE_TIME             |           | MySQL extension |
| CHECK_TIME              |           | MySQL extension |
| CHECKSUM                |           | MySQL extension |
| STATUS                  |           | MySQL extension |
| EXTRA                   |           | MySQL extension |

## InnoDB Notes

The following notes apply to InnoDB data files. `INFORMATION_SCHEMA.FILES` fields that are not described below are not applicable to InnoDB and report a `NULL` value.

- Data reported by `INFORMATION_SCHEMA.FILES` is reported from the InnoDB in-memory cache for open files. By comparison, `INFORMATION_SCHEMA.INNODB_SYS_DATAFILES` reports data from the InnoDB `SYS_DATAFILES` internal data dictionary table.
- The data reported by `INFORMATION_SCHEMA.FILES` includes temporary table tablespace data. This data is not available in the internal `SYS_DATAFILES` data dictionary table, and is therefore not reported by `INNODB_SYS_DATAFILES`.
- Undo tablespace data is reported by `INFORMATION_SCHEMA.FILES` when separate undo tablespaces are configured using the `innodb_undo_tablespaces` configuration option.
- `FILE_ID` is the tablespace ID, also referred to as the `space_id` or `fil_space_t::id`.
- `FILE_NAME` is the name of the data file. File-per-table and general tablespaces have a `.ibd` file name extension. Undo tablespaces are prefixed by `undo`. The system tablespace is prefixed by `ibdata`. Temporary table tablespaces are prefixed by `ibtmp`. The file name includes the file path, which may be relative to the MySQL data directory (`datadir`).
- `FILE_TYPE` is the tablespace file type. There are three possible file types for InnoDB files. `TABLESPACE` is the file type for any system, general, or file-per-table tablespace file that holds tables, indexes, or other forms of user data. `TEMPORARY` is the file type for temporary table tablespaces. `UNDO LOG` is the file type for undo log tablespaces, which hold undo records. By default, undo records are stored in the system tablespace. Separate undo log tablespaces can be added using the `innodb_undo_tablespaces` option.
- `TABLESPACE_NAME` is the SQL name for the tablespace. A general tablespace name is the `SYS_TABLESPACES.NAME` value. For other tablespace files, names start with `innodb_`, such as `innodb_system`, `innodb_undo`, and `innodb_file_per_table`. The file-per-table tablespace name format is `innodb_file_per_table_##`, where `##` is the tablespace ID.
- `ENGINE` is the storage engine. For InnoDB files, the value is always `InnoDB`.
- `FREE_EXTENTS` is the number of fully free extents in the current data file.
- `TOTAL_EXTENTS` is the number of full extents used in the current data file. Any partial extent at the end of the file is not counted.
- `EXTENT_SIZE` is 1048576 (1MB) for files with a 4k, 8k, or 16k page size. Extent size is 2097152 bytes (2MB) for files with a 32k page size, and 4194304 (4MB) for files

with a 64k page size. `INFORMATION_SCHEMA.FILES` does not report InnoDB page size. Page size is defined by the `innodb_page_size` option. Extent size information can also be retrieved from `INNODB_SYS_TABLESPACES` where `FILES.FILE_ID = INNODB_SYS_TABLESPACES.SPACE_ID`.

- `INITIAL_SIZE` is the initial size of the file, in bytes.
- `MAXIMUM_SIZE` is the maximum number of bytes allowed in the file. The value is `NULL` for all data files except for predefined system tablespace data files. Maximum system tablespace file size is defined by `innodb_data_file_path`. Maximum temporary table tablespace file size is defined by `innodb_temp_data_file_path`. A `NULL` value for a predefined system tablespace data file indicates that a file size limit was not defined explicitly.
- `AUTOEXTEND_SIZE` is the auto-extend size defined by `innodb_data_file_path` for the system tablespace, or defined by `innodb_temp_data_file_path` for temporary table tablespaces.
- `DATA_FREE` is the total amount of free space (in bytes) for the entire tablespace. Predefined system tablespaces, which include the system tablespace and temporary table tablespaces, may have one or more data files.
- `STATUS` is `NORMAL` by default. InnoDB file-per-table tablespaces may report `IMPORTING`, which indicates that the tablespace is not yet available.
- The following query returns all data pertinent to InnoDB tablespaces.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS, TOTAL_EXTENTS,
EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS ENGINE
FROM INFORMATION_SCHEMA.FILES \G
```

## 20.9 The INFORMATION\_SCHEMA GLOBAL\_STATUS and SESSION\_STATUS Tables

### Note

As of MySQL 5.7.6, the value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 5.1.4, “Server System Variables”](#).

### Note

As of MySQL 5.7.6, information available from the tables described here is also available from the Performance Schema. The `INFORMATION_SCHEMA` tables are deprecated in preference to the Performance Schema tables and will be removed in a future MySQL release. For advice on migrating away from the `INFORMATION_SCHEMA` tables to the Performance Schema tables, see [Section 21.17, “Migrating to Performance Schema System and Status Variable Tables”](#).

The `GLOBAL_STATUS` and `SESSION_STATUS` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS` statements (see [Section 13.7.5.35, “SHOW STATUS Syntax”](#)).

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|---------|
| <code>VARIABLE_NAME</code>           | Variable_name          |         |
| <code>VARIABLE_VALUE</code>          | Value                  |         |

**Notes:**

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(1024)`.

## 20.10 The INFORMATION\_SCHEMA GLOBAL\_VARIABLES and SESSION\_VARIABLES Tables

### Note

As of MySQL 5.7.6, the value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 5.1.4, “Server System Variables”](#).

### Note

As of MySQL 5.7.6, information available from the tables described here is also available from the Performance Schema. The `INFORMATION_SCHEMA` tables are deprecated in preference to the Performance Schema tables and will be removed in a future MySQL release. For advice on migrating away from the `INFORMATION_SCHEMA` tables to the Performance Schema tables, see [Section 21.17, “Migrating to Performance Schema System and Status Variable Tables”](#).

The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES` statements (see [Section 13.7.5.39, “SHOW VARIABLES Syntax”](#)).

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|---------|
| <code>VARIABLE_NAME</code>           | Variable_name          |         |
| <code>VARIABLE_VALUE</code>          | Value                  |         |

### Notes:

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(1024)`. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

## 20.11 The INFORMATION\_SCHEMA KEY\_COLUMN\_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

| <code>INFORMATION_SCHEMA</code> Name       | <code>SHOW</code> Name | Remarks |
|--------------------------------------------|------------------------|---------|
| <code>CONSTRAINT_CATALOG</code>            |                        | def     |
| <code>CONSTRAINT_SCHEMA</code>             |                        |         |
| <code>CONSTRAINT_NAME</code>               |                        |         |
| <code>TABLE_CATALOG</code>                 |                        | def     |
| <code>TABLE_SCHEMA</code>                  |                        |         |
| <code>TABLE_NAME</code>                    |                        |         |
| <code>COLUMN_NAME</code>                   |                        |         |
| <code>ORDINAL_POSITION</code>              |                        |         |
| <code>POSITION_IN_UNIQUE_CONSTRAINT</code> |                        |         |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------|
| REFERENCED_TABLE_SCHEMA |           |         |
| REFERENCED_TABLE_NAME   |           |         |
| REFERENCED_COLUMN_NAME  |           |         |

**Notes:**

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY'`, `TABLE_NAME = 't1'`, `COLUMN_NAME = 's3'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = NULL`.
- One row with `CONSTRAINT_NAME = 'CO'`, `TABLE_NAME = 't3'`, `COLUMN_NAME = 's2'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = 1`.

## 20.12 The INFORMATION\_SCHEMA OPTIMIZER\_TRACE Table

The `OPTIMIZER_TRACE` table provides information produced by the optimizer tracing capability. To enable tracking, use the `optimizer_trace` system variable. For details, see [MySQL Internals: Tracing the Optimizer](#).

## 20.13 The INFORMATION\_SCHEMA PARAMETERS Table

The `PARAMETERS` table provides information about stored procedure and function parameters, and about return values for stored functions. Parameter information is similar to the contents of the `param_list` column in the `mysql.proc` table.

| INFORMATION_SCHEMA Name | mysql.proc Name | Remarks          |
|-------------------------|-----------------|------------------|
| SPECIFIC_CATALOG        |                 | def              |
| SPECIFIC_SCHEMA         | db              | routine database |
| SPECIFIC_NAME           | name            | routine name     |

| INFORMATION_SCHEMA Name  | mysql.proc Name | Remarks                                                    |
|--------------------------|-----------------|------------------------------------------------------------|
| ORDINAL_POSITION         |                 | 1, 2, 3, ... for parameters, 0 for function RETURNS clause |
| PARAMETER_MODE           |                 | IN, OUT, INOUT (NULL for RETURNS)                          |
| PARAMETER_NAME           |                 | parameter name (NULL for RETURNS)                          |
| DATA_TYPE                |                 | same as for COLUMNS table                                  |
| CHARACTER_MAXIMUM_LENGTH |                 | same as for COLUMNS table                                  |
| CHARACTER_OCTET_LENGTH   |                 | same as for COLUMNS table                                  |
| NUMERIC_PRECISION        |                 | same as for COLUMNS table                                  |
| NUMERIC_SCALE            |                 | same as for COLUMNS table                                  |
| DATETIME_PRECISION       |                 | same as for COLUMNS table                                  |
| CHARACTER_SET_NAME       |                 | same as for COLUMNS table                                  |
| COLLATION_NAME           |                 | same as for COLUMNS table                                  |
| DTD_IDENTIFIER           |                 | same as for COLUMNS table                                  |
| ROUTINE_TYPE             | type            | same as for ROUTINES table                                 |

**Notes:**

- For successive parameters of a stored procedure or function, the [ORDINAL\\_POSITION](#) values are 1, 2, 3, and so forth. For a stored function, there is also a row that describes the data type for the [RETURNS](#) clause. The return value is not a true parameter, so the row that describes it has these unique characteristics:
  - The [ORDINAL\\_POSITION](#) value is 0.
  - The [PARAMETER\\_NAME](#) and [PARAMETER\\_MODE](#) values are [NULL](#) because the return value has no name and the mode does not apply.

## 20.14 The INFORMATION\_SCHEMA PARTITIONS Table

The [PARTITIONS](#) table provides information about table partitions. See [Chapter 18, Partitioning](#), for more information about partitioning tables.

| INFORMATION_SCHEMA Name       | SHOW Name | Remarks         |
|-------------------------------|-----------|-----------------|
| TABLE_CATALOG                 |           | MySQL extension |
| TABLE_SCHEMA                  |           | MySQL extension |
| TABLE_NAME                    |           | MySQL extension |
| PARTITION_NAME                |           | MySQL extension |
| SUBPARTITION_NAME             |           | MySQL extension |
| PARTITION_ORDINAL_POSITION    |           | MySQL extension |
| SUBPARTITION_ORDINAL_POSITION |           | MySQL extension |
| PARTITION_METHOD              |           | MySQL extension |
| SUBPARTITION_METHOD           |           | MySQL extension |
| PARTITION_EXPRESSION          |           | MySQL extension |
| SUBPARTITION_EXPRESSION       |           | MySQL extension |
| PARTITION_DESCRIPTION         |           | MySQL extension |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| TABLE_ROWS              |           | MySQL extension |
| AVG_ROW_LENGTH          |           | MySQL extension |
| DATA_LENGTH             |           | MySQL extension |
| MAX_DATA_LENGTH         |           | MySQL extension |
| INDEX_LENGTH            |           | MySQL extension |
| DATA_FREE               |           | MySQL extension |
| CREATE_TIME             |           | MySQL extension |
| UPDATE_TIME             |           | MySQL extension |
| CHECK_TIME              |           | MySQL extension |
| CHECKSUM                |           | MySQL extension |
| PARTITION_COMMENT       |           | MySQL extension |
| NODEGROUP               |           | MySQL extension |
| TABLESPACE_NAME         |           | MySQL extension |

**Notes:**

- The `PARTITIONS` table is a nonstandard table.  
Each record in this table corresponds to an individual partition or subpartition of a partitioned table.
- `TABLE_CATALOG`: This column is always `def`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.
- `SUBPARTITION_NAME`: If the `PARTITIONS` table record represents a subpartition, then this column contains the name of subpartition; otherwise it is `NULL`.
- `PARTITION_ORDINAL_POSITION`: All partitions are indexed in the same order as they are defined, with 1 being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.
- `SUBPARTITION_ORDINAL_POSITION`: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.
- `PARTITION_METHOD`: One of the values `RANGE`, `LIST`, `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available partitioning types as discussed in [Section 18.2, "Partitioning Types"](#).
- `SUBPARTITION_METHOD`: One of the values `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available subpartitioning types as discussed in [Section 18.2.6, "Subpartitioning"](#).
- `PARTITION_EXPRESSION`: This is the expression for the partitioning function used in the `CREATE TABLE` or `ALTER TABLE` statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
  c1 INT,
  c2 INT,
  c3 VARCHAR(25)
)
```

```
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The `PARTITION_EXPRESSION` column in a `PARTITIONS` table record for a partition from this table displays `c1 + c2`, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2              |
+-----+
1 row in set (0.09 sec)
```

- `SUBPARTITION_EXPRESSION`: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as `PARTITION_EXPRESSION` does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, then this column is `NULL`.

- `PARTITION_DESCRIPTION`: This column is used for `RANGE` and `LIST` partitions. For a `RANGE` partition, it contains the value set in the partition's `VALUES LESS THAN` clause, which can be either an integer or `MAXVALUE`. For a `LIST` partition, this column contains the values defined in the partition's `VALUES IN` clause, which is a comma-separated list of integer values.

For partitions whose `PARTITION_METHOD` is other than `RANGE` or `LIST`, this column is always `NULL`.

- `TABLE_ROWS`: The number of table rows in the partition.

For partitioned `InnoDB` tables, the row count given in the `TABLE_ROWS` column is only an estimated value used in SQL optimization, and may not always be exact.

- `AVG_ROW_LENGTH`: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as `DATA_LENGTH` divided by `TABLE_ROWS`.

- `DATA_LENGTH`: The total length of all rows stored in this partition or subpartition, in bytes—that is, the total number of bytes stored in the partition or subpartition.

- `MAX_DATA_LENGTH`: The maximum number of bytes that can be stored in this partition or subpartition.

- `INDEX_LENGTH`: The length of the index file for this partition or subpartition, in bytes.

- `DATA_FREE`: The number of bytes allocated to the partition or subpartition but not used.

- `CREATE_TIME`: The time of the partition's or subpartition's creation.

Prior to MySQL 5.7.8, for partitioned `InnoDB` tables, this column was always `NULL`. The correct creation time is shown in MySQL 5.7.8 and later. (Bug #17299181, Bug #69990)

- `UPDATE_TIME`: The time that the partition or subpartition was last modified.

Prior to MySQL 5.7.8, for partitioned `InnoDB` tables, this column was always `NULL`. The correct modification time is shown in MySQL 5.7.8 and later. (Bug #17299181, Bug #69990)

- `CHECK_TIME`: The last time that the table to which this partition or subpartition belongs was checked.

For partitioned `InnoDB` tables, this column is always `NULL`.

- `CHECKSUM`: The checksum value, if any; otherwise, this column is `NULL`.

- `PARTITION_COMMENT`: This column contains the text of any comment made for the partition.

In MySQL 5.7, the maximum length for a partition comment is defined as 1024 characters, and the display width of the `PARTITION_COMMENT` column is also 1024, characters to match this limit (Bug #11748924, Bug #37728).

The default value for this column is an empty string.

- `NODEGROUP`: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always 0.
- `TABLESPACE_NAME`: This column contains the name of the tablespace to which the partition belongs. The value of this column is always `DEFAULT`.
- A nonpartitioned table has one record in `INFORMATION_SCHEMA.PARTITIONS`; however, the values of the `PARTITION_NAME`, `SUBPARTITION_NAME`, `PARTITION_ORDINAL_POSITION`, `SUBPARTITION_ORDINAL_POSITION`, `PARTITION_METHOD`, `SUBPARTITION_METHOD`, `PARTITION_EXPRESSION`, `SUBPARTITION_EXPRESSION`, and `PARTITION_DESCRIPTION` columns are all `NULL`. (The `PARTITION_COMMENT` column in this case is blank.)

## 20.15 The INFORMATION\_SCHEMA PLUGINS Table

The `PLUGINS` table provides information about server plugins.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks         |
|--------------------------------------|------------------------|-----------------|
| <code>PLUGIN_NAME</code>             | Name                   | MySQL extension |
| <code>PLUGIN_VERSION</code>          |                        | MySQL extension |
| <code>PLUGIN_STATUS</code>           | Status                 | MySQL extension |
| <code>PLUGIN_TYPE</code>             | Type                   | MySQL extension |
| <code>PLUGIN_TYPE_VERSION</code>     |                        | MySQL extension |
| <code>PLUGIN_LIBRARY</code>          | Library                | MySQL extension |
| <code>PLUGIN_LIBRARY_VERSION</code>  |                        | MySQL extension |
| <code>PLUGIN_AUTHOR</code>           |                        | MySQL extension |
| <code>PLUGIN_DESCRIPTION</code>      |                        | MySQL extension |
| <code>PLUGIN_LICENSE</code>          | License                | MySQL extension |
| <code>LOAD_OPTION</code>             |                        | MySQL extension |

### Notes:

- The `PLUGINS` table is a nonstandard table.
- `PLUGIN_NAME` is the name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.
- `PLUGIN_VERSION` is the version from the plugin's general type descriptor.
- `PLUGIN_STATUS` indicates the plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.
- `PLUGIN_TYPE` indicates the type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
- `PLUGIN_TYPE_VERSION` is the version from the plugin's type-specific descriptor.
- `PLUGIN_LIBRARY` is the name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in

the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- `PLUGIN_LIBRARY_VERSION` indicates the plugin API interface version.
- `PLUGIN_AUTHOR` names the plugin author.
- `PLUGIN_DESCRIPTION` provides a short description of the plugin.
- `PLUGIN_LICENSE` indicates how the plugin is licensed; for example, `GPL`.
- `LOAD_OPTION` indicates how the plugin was loaded. The value is `OFF`, `ON`, `FORCE`, or `FORCE_PLUS_PERMANENT`. See [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

For plugins installed with `INSTALL PLUGIN`, the `PLUGIN_NAME` and `PLUGIN_LIBRARY` values are also registered in the `mysql.plugin` table.

These statements are equivalent:

```
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

For information about plugin data structures that form the basis of the information in the `PLUGINS` table, see [Section 24.2, “The MySQL Plugin API”](#).

Plugin information is also available using the `SHOW PLUGINS` statement. See [Section 13.7.5.25, “SHOW PLUGINS Syntax”](#).

## 20.16 The INFORMATION\_SCHEMA PROCESSLIST Table

The `PROCESSLIST` table provides information about which threads are running.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| ID                      | Id        | MySQL extension |
| USER                    | User      | MySQL extension |
| HOST                    | Host      | MySQL extension |
| DB                      | db        | MySQL extension |
| COMMAND                 | Command   | MySQL extension |
| TIME                    | Time      | MySQL extension |
| STATE                   | State     | MySQL extension |
| INFO                    | Info      | MySQL extension |

For an extensive description of the table columns, see [Section 13.7.5.29, “SHOW PROCESSLIST Syntax”](#).

### Notes:

- The `PROCESSLIST` table is a nonstandard table.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.

- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.
- Process information is also available from the `performance_schema.threads` table. However, access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST

SHOW FULL PROCESSLIST
```

## 20.17 The INFORMATION\_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILES` and `SHOW PROFILE` statements (see [Section 13.7.5.31](#), “`SHOW PROFILES Syntax`”). The table is empty unless the `profiling` session variable is set to 1.

### Note

This table is deprecated as of MySQL 5.7.2 and will be removed in a future MySQL release. Use the Performance Schema instead; see [Chapter 21](#), *MySQL Performance Schema*.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name           | Remarks |
|--------------------------------------|----------------------------------|---------|
| <code>QUERY_ID</code>                | <code>Query_ID</code>            |         |
| <code>SEQ</code>                     |                                  |         |
| <code>STATE</code>                   | <code>Status</code>              |         |
| <code>DURATION</code>                | <code>Duration</code>            |         |
| <code>CPU_USER</code>                | <code>CPU_user</code>            |         |
| <code>CPU_SYSTEM</code>              | <code>CPU_system</code>          |         |
| <code>CONTEXT_VOLUNTARY</code>       | <code>Context_voluntary</code>   |         |
| <code>CONTEXT_INVOLUNTARY</code>     | <code>Context_involuntary</code> |         |
| <code>BLOCK_OPS_IN</code>            | <code>Block_ops_in</code>        |         |
| <code>BLOCK_OPS_OUT</code>           | <code>Block_ops_out</code>       |         |
| <code>MESSAGES_SENT</code>           | <code>Messages_sent</code>       |         |
| <code>MESSAGES_RECEIVED</code>       | <code>Messages_received</code>   |         |
| <code>PAGE_FAULTS_MAJOR</code>       | <code>Page_faults_major</code>   |         |
| <code>PAGE_FAULTS_MINOR</code>       | <code>Page_faults_minor</code>   |         |
| <code>SWAPS</code>                   | <code>Swaps</code>               |         |
| <code>SOURCE_FUNCTION</code>         | <code>Source_function</code>     |         |
| <code>SOURCE_FILE</code>             | <code>Source_file</code>         |         |
| <code>SOURCE_LINE</code>             | <code>Source_line</code>         |         |

### Notes:

- `QUERY_ID` is a numeric statement identifier.

- [SEQ](#) is a sequence number indicating the display order for rows with the same [QUERY\\_ID](#) value.
- [STATE](#) is the profiling state to which the row measurements apply.
- [DURATION](#) indicates how long statement execution remained in the given state, in seconds.
- [CPU\\_USER](#) and [CPU\\_SYSTEM](#) indicate user and system CPU use, in seconds.
- [CONTEXT\\_VOLUNTARY](#) and [CONTEXT\\_INVOLUNTARY](#) indicate how many voluntary and involuntary context switches occurred.
- [BLOCK\\_OPS\\_IN](#) and [BLOCK\\_OPS\\_OUT](#) indicate the number of block input and output operations.
- [MESSAGES\\_SENT](#) and [MESSAGES\\_RECEIVED](#) indicate the number of communication messages sent and received.
- [PAGE\\_FAULTS\\_MAJOR](#) and [PAGE\\_FAULTS\\_MINOR](#) indicate the number of major and minor page faults.
- [SWAPS](#) indicates how many swaps occurred.
- [SOURCE\\_FUNCTION](#), [SOURCE\\_FILE](#), and [SOURCE\\_LINE](#) provide information indicating where in the source code the profiled state executes.

## 20.18 The INFORMATION\_SCHEMA REFERENTIAL\_CONSTRAINTS Table

The [REFERENTIAL\\_CONSTRAINTS](#) table provides information about foreign keys.

| <a href="#">INFORMATION_SCHEMA</a> Name | <a href="#">SHOW</a> Name | Remarks |
|-----------------------------------------|---------------------------|---------|
| CONSTRAINT_CATALOG                      |                           | def     |
| CONSTRAINT_SCHEMA                       |                           |         |
| CONSTRAINT_NAME                         |                           |         |
| UNIQUE_CONSTRAINT_CATALOG               |                           | def     |
| UNIQUE_CONSTRAINT_SCHEMA                |                           |         |
| UNIQUE_CONSTRAINT_NAME                  |                           |         |
| MATCH_OPTION                            |                           |         |
| UPDATE_RULE                             |                           |         |
| DELETE_RULE                             |                           |         |
| TABLE_NAME                              |                           |         |
| REFERENCED_TABLE_NAME                   |                           |         |

### Notes:

- [TABLE\\_NAME](#) has the same value as [TABLE\\_NAME](#) in [INFORMATION\\_SCHEMA.TABLE\\_CONSTRAINTS](#).
- [CONSTRAINT\\_SCHEMA](#) and [CONSTRAINT\\_NAME](#) identify the foreign key.
- [UNIQUE\\_CONSTRAINT\\_SCHEMA](#), [UNIQUE\\_CONSTRAINT\\_NAME](#), and [REFERENCED\\_TABLE\\_NAME](#) identify the referenced key.
- The only valid value at this time for [MATCH\\_OPTION](#) is [NONE](#).
- The possible values for [UPDATE\\_RULE](#) or [DELETE\\_RULE](#) are [CASCADE](#), [SET NULL](#), [SET DEFAULT](#), [RESTRICT](#), [NO ACTION](#).

## 20.19 The INFORMATION\_SCHEMA ROUTINES Table

The `ROUTINES` table provides information about stored routines (both procedures and functions). The `ROUTINES` table does not include user-defined functions (UDFs).

The column named “`mysql.proc name`” indicates the `mysql.proc` table column that corresponds to the `INFORMATION_SCHEMA.ROUTINES` table column, if any.

| INFORMATION_SCHEMA Name  | mysql.proc Name  | Remarks                                |
|--------------------------|------------------|----------------------------------------|
| SPECIFIC_NAME            | specific_name    |                                        |
| ROUTINE_CATALOG          |                  | def                                    |
| ROUTINE_SCHEMA           | db               |                                        |
| ROUTINE_NAME             | name             |                                        |
| ROUTINE_TYPE             | type             | {PROCEDURE   FUNCTION}                 |
| DATA_TYPE                |                  | same as for <code>COLUMNS</code> table |
| CHARACTER_MAXIMUM_LENGTH |                  | same as for <code>COLUMNS</code> table |
| CHARACTER_OCTET_LENGTH   |                  | same as for <code>COLUMNS</code> table |
| NUMERIC_PRECISION        |                  | same as for <code>COLUMNS</code> table |
| NUMERIC_SCALE            |                  | same as for <code>COLUMNS</code> table |
| DATETIME_PRECISION       |                  | same as for <code>COLUMNS</code> table |
| CHARACTER_SET_NAME       |                  | same as for <code>COLUMNS</code> table |
| COLLATION_NAME           |                  | same as for <code>COLUMNS</code> table |
| DTD_IDENTIFIER           |                  | data type descriptor                   |
| ROUTINE_BODY             |                  | SQL                                    |
| ROUTINE_DEFINITION       | body_utf8        |                                        |
| EXTERNAL_NAME            |                  | NULL                                   |
| EXTERNAL_LANGUAGE        | language         | NULL                                   |
| PARAMETER_STYLE          |                  | SQL                                    |
| IS_DETERMINISTIC         | is_deterministic |                                        |
| SQL_DATA_ACCESS          | sql_data_access  |                                        |
| SQL_PATH                 |                  | NULL                                   |
| SECURITY_TYPE            | security_type    |                                        |
| CREATED                  | created          |                                        |
| LAST_ALTERED             | modified         |                                        |
| SQL_MODE                 | sql_mode         | MySQL extension                        |
| ROUTINE_COMMENT          | comment          | MySQL extension                        |
| DEFINER                  | definer          | MySQL extension                        |
| CHARACTER_SET_CLIENT     |                  | MySQL extension                        |
| COLLATION_CONNECTION     |                  | MySQL extension                        |
| DATABASE_COLLATION       |                  | MySQL extension                        |

### Notes:

- MySQL calculates `EXTERNAL_LANGUAGE` thus:
  - If `mysql.proc.language = 'SQL'`, `EXTERNAL_LANGUAGE` is `NULL`

- Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.
- `CREATED`: The date and time when the routine was created. This is a `TIMESTAMP` value.
- `LAST_ALTERED`: The date and time when the routine was last modified. This is a `TIMESTAMP` value. If the routine has not been modified since its creation, this column holds the same value as the `CREATED` column.
- `SQL_MODE`: The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see [Section 5.1.7, “Server SQL Modes”](#).
- `CHARACTER_SET_CLIENT`: The session value of the `character_set_client` system variable when the routine was created.
- `COLLATION_CONNECTION`: The session value of the `collation_connection` system variable when the routine was created.
- `DATABASE_COLLATION`: The collation of the database with which the routine is associated.
- The `DATA_TYPE`, `CHARACTER_MAXIMUM_LENGTH`, `CHARACTER_OCTET_LENGTH`, `NUMERIC_PRECISION`, `NUMERIC_SCALE`, `DATETIME_PRECISION`, `CHARACTER_SET_NAME`, and `COLLATION_NAME` columns provide information about the data type for the `RETURNS` clause of stored functions. If a stored routine is a stored procedure, these columns all are `NULL`.
- Information about stored function `RETURNS` data types is also available in the `PARAMETERS` table. The return value data type row for a function can be identified as the row that has an `ORDINAL_POSITION` value of 0.

## 20.20 The INFORMATION\_SCHEMA SCHEMATA Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

| <code>INFORMATION_SCHEMA</code> Name    | <code>SHOW</code> Name | Remarks           |
|-----------------------------------------|------------------------|-------------------|
| <code>CATALOG_NAME</code>               |                        | <code>def</code>  |
| <code>SCHEMA_NAME</code>                | Database               |                   |
| <code>DEFAULT_CHARACTER_SET_NAME</code> |                        |                   |
| <code>DEFAULT_COLLATION_NAME</code>     |                        |                   |
| <code>SQL_PATH</code>                   |                        | <code>NULL</code> |

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
[LIKE 'wild']
```

## 20.21 The INFORMATION\_SCHEMA SCHEMA\_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks                                                     |
|--------------------------------------|------------------------|-------------------------------------------------------------|
| <code>GRANTEE</code>                 |                        | <code>'user_name'@'host_name'</code> value, MySQL extension |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks              |
|-------------------------|-----------|----------------------|
| TABLE_CATALOG           |           | def, MySQL extension |
| TABLE_SCHEMA            |           | MySQL extension      |
| PRIVILEGE_TYPE          |           | MySQL extension      |
| IS_GRANTABLE            |           | MySQL extension      |

**Notes:**

- This is a nonstandard table. It takes its values from the `mysql.db` table.

## 20.22 The INFORMATION\_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

| INFORMATION_SCHEMA Name | SHOW Name    | Remarks         |
|-------------------------|--------------|-----------------|
| TABLE_CATALOG           |              | def             |
| TABLE_SCHEMA            |              | = Database      |
| TABLE_NAME              | Table        |                 |
| NON_UNIQUE              | Non_unique   |                 |
| INDEX_SCHEMA            |              | = Database      |
| INDEX_NAME              | Key_name     |                 |
| SEQ_IN_INDEX            | Seq_in_index |                 |
| COLUMN_NAME             | Column_name  |                 |
| COLLATION               | Collation    |                 |
| CARDINALITY             | Cardinality  |                 |
| SUB_PART                | Sub_part     | MySQL extension |
| PACKED                  | Packed       | MySQL extension |
| NULLABLE                | Null         | MySQL extension |
| INDEX_TYPE              | Index_type   | MySQL extension |
| COMMENT                 | Comment      | MySQL extension |

**Notes:**

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
     AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
  FROM db_name
```

## 20.23 The INFORMATION\_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

| INFORMATION_SCHEMA Name | SHOW Name       | Remarks                                                                   |
|-------------------------|-----------------|---------------------------------------------------------------------------|
| TABLE_CATALOG           |                 | def                                                                       |
| TABLE_SCHEMA            | Table_...       |                                                                           |
| TABLE_NAME              | Table_...       |                                                                           |
| TABLE_TYPE              |                 |                                                                           |
| ENGINE                  | Engine          | MySQL extension                                                           |
| VERSION                 | Version         | The version number of the table's <code>.frm</code> file, MySQL extension |
| ROW_FORMAT              | Row_format      | MySQL extension                                                           |
| TABLE_ROWS              | Rows            | MySQL extension                                                           |
| AVG_ROW_LENGTH          | Avg_row_length  | MySQL extension                                                           |
| DATA_LENGTH             | Data_length     | MySQL extension                                                           |
| MAX_DATA_LENGTH         | Max_data_length | MySQL extension                                                           |
| INDEX_LENGTH            | Index_length    | MySQL extension                                                           |
| DATA_FREE               | Data_free       | MySQL extension                                                           |
| AUTO_INCREMENT          | Auto_increment  | MySQL extension                                                           |
| CREATE_TIME             | Create_time     | MySQL extension                                                           |
| UPDATE_TIME             | Update_time     | MySQL extension                                                           |
| CHECK_TIME              | Check_time      | MySQL extension                                                           |
| TABLE_COLLATION         | Collation       | MySQL extension                                                           |
| CHECKSUM                | Checksum        | MySQL extension                                                           |
| CREATE_OPTIONS          | Create_options  | MySQL extension                                                           |
| TABLE_COMMENT           | Comment         | MySQL extension                                                           |

#### Notes:

- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
- `TABLE_TYPE` should be `BASE TABLE` or `VIEW`. The `TABLES` table does not list `TEMPORARY` tables.
- For partitioned tables, the `ENGINE` column shows the name of the storage engine used by all partitions. (Previously, this column showed `PARTITION` for such tables.)
- The `TABLE_ROWS` column is `NULL` if the table is in the `INFORMATION_SCHEMA` database.

For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the `InnoDB` table is partitioned.)

- The `DATA_FREE` column shows the free space in bytes for `InnoDB` tables.
- Prior to MySQL 5.7.8, for partitioned `InnoDB` tables, the `CREATE_TIME` column always showed `NULL`. This column shows the correct table creation time for such tables in MySQL 5.7.8 and later. (Bug #17299181, Bug #69990)
- Beginning with MySQL 5.7.2, `UPDATE_TIME` displays a timestamp value for the last `UPDATE`, `INSERT`, or `DELETE` performed on `InnoDB` tables that are not partitioned. Previously, `UPDATE_TIME` displayed a `NULL` value for `InnoDB` tables. For MVCC, the timestamp value reflects the `COMMIT` time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the `InnoDB` data dictionary cache.

The `UPDATE_TIME` column also shows this information for partitioned `InnoDB` tables in MySQL 5.7.8 and later. Previously this column was always `NULL` for such tables. (Bug #17299181, Bug #69990)

- For partitioned `InnoDB` tables, the `CHECK_TIME` column is always `NULL`.
- We have nothing for the table's default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.
- The `CREATE_OPTIONS` column shows `partitioned` if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  WHERE table_schema = 'db_name'
     [AND table_name LIKE 'wild']

SHOW TABLES
  FROM db_name
     [LIKE 'wild']
```

## 20.24 The INFORMATION\_SCHEMA TABLESPACES Table

The `TABLESPACES` table provides information about active tablespaces.

| INFORMATION_SCHEMA Name         | SHOW Name | Remarks         |
|---------------------------------|-----------|-----------------|
| <code>TABLESPACE_NAME</code>    |           | MySQL extension |
| <code>ENGINE</code>             |           | MySQL extension |
| <code>TABLESPACE_TYPE</code>    |           | MySQL extension |
| <code>LOGFILE_GROUP_NAME</code> |           | MySQL extension |
| <code>EXTENT_SIZE</code>        |           | MySQL extension |
| <code>AUTOEXTEND_SIZE</code>    |           | MySQL extension |
| <code>MAXIMUM_SIZE</code>       |           | MySQL extension |
| <code>NODEGROUP_ID</code>       |           | MySQL extension |
| <code>TABLESPACE_COMMENT</code> |           | MySQL extension |

### Notes:

The `INFORMATION_SCHEMA.TABLESPACES` table does not provide information about `InnoDB` tablespaces. For `InnoDB` tablespace metadata, see `INNODB_SYS_TABLESPACES` and `INNODB_SYS_DATAFILES`. As of MySQL 5.7.8, the `INFORMATION_SCHEMA.FILES` table also provides metadata for `InnoDB` tablespaces.

## 20.25 The INFORMATION\_SCHEMA TABLE\_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

| INFORMATION_SCHEMA Name         | SHOW Name | Remarks          |
|---------------------------------|-----------|------------------|
| <code>CONSTRAINT_CATALOG</code> |           | <code>def</code> |
| <code>CONSTRAINT_SCHEMA</code>  |           |                  |
| <code>CONSTRAINT_NAME</code>    |           |                  |
| <code>TABLE_SCHEMA</code>       |           |                  |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------|
| TABLE_NAME              |           |         |
| CONSTRAINT_TYPE         |           |         |

**Notes:**

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is 0.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

## 20.26 The INFORMATION\_SCHEMA TABLE\_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks                                            |
|-------------------------|-----------|----------------------------------------------------|
| GRANTEE                 |           | ' <i>user_name</i> '@' <i>host_name</i> '<br>value |
| TABLE_CATALOG           |           | def                                                |
| TABLE_SCHEMA            |           |                                                    |
| TABLE_NAME              |           |                                                    |
| PRIVILEGE_TYPE          |           |                                                    |
| IS_GRANTABLE            |           |                                                    |

**Notes:**

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

## 20.27 The INFORMATION\_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. You can see information only for databases and tables for which you have the `TRIGGER` privilege.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------|
| TRIGGER_CATALOG         |           | def     |
| TRIGGER_SCHEMA          |           |         |
| TRIGGER_NAME            | Trigger   |         |
| EVENT_MANIPULATION      | Event     |         |
| EVENT_OBJECT_CATALOG    |           | def     |
| EVENT_OBJECT_SCHEMA     |           |         |

| INFORMATION_SCHEMA Name    | SHOW Name            | Remarks         |
|----------------------------|----------------------|-----------------|
| EVENT_OBJECT_TABLE         | Table                |                 |
| ACTION_ORDER               |                      |                 |
| ACTION_CONDITION           |                      | NULL            |
| ACTION_STATEMENT           | Statement            |                 |
| ACTION_ORIENTATION         |                      | ROW             |
| ACTION_TIMING              | Timing               |                 |
| ACTION_REFERENCE_OLD_TABLE |                      | NULL            |
| ACTION_REFERENCE_NEW_TABLE |                      | NULL            |
| ACTION_REFERENCE_OLD_ROW   |                      | OLD             |
| ACTION_REFERENCE_NEW_ROW   |                      | NEW             |
| CREATED                    | Created              |                 |
| SQL_MODE                   | sql_mode             | MySQL extension |
| DEFINER                    | Definer              | MySQL extension |
| CHARACTER_SET_CLIENT       | character_set_client | MySQL extension |
| COLLATION_CONNECTION       | collation_connection | MySQL extension |
| DATABASE_COLLATION         | Database Collation   | MySQL extension |

**Notes:**

- The names in the “SHOW Name” column refer to the `SHOW TRIGGERS` statement, not `SHOW CREATE TRIGGER`. See [Section 13.7.5.38, “SHOW TRIGGERS Syntax”](#).
- `TRIGGER_SCHEMA` and `TRIGGER_NAME`: The name of the database in which the trigger occurs and the trigger name, respectively.
- `EVENT_MANIPULATION`: The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is `'INSERT'` (a row was inserted), `'DELETE'` (a row was deleted), or `'UPDATE'` (a row was modified).
- `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE`: As noted in [Section 19.3, “Using Triggers”](#), every trigger is associated with exactly one table. These columns indicate the database in which this table occurs, and the table name, respectively.
- `ACTION_ORDER`: The ordinal position of the trigger's action within the list of triggers on the same table with the same `EVENT_MANIPULATION` and `ACTION_TIMING` values. Before MySQL 5.7.2, this value is always 0 because it is not possible for a table to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` values.
- `ACTION_STATEMENT`: The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.
- `ACTION_ORIENTATION`: Always contains the value `'ROW'`.
- `ACTION_TIMING`: Whether the trigger activates before or after the triggering event. The value is `'BEFORE'` or `'AFTER'`.
- `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW`: The old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value `'OLD'` and `ACTION_REFERENCE_NEW_ROW` always contains the value `'NEW'`.
- `CREATED`: The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, `NULL` for triggers created prior to 5.7.2.

- **SQL\_MODE**: The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see [Section 5.1.7, “Server SQL Modes”](#).
- **DEFINER**: The account of the user who created the trigger, in '*user\_name*'@'*host\_name*' format.
- **CHARACTER\_SET\_CLIENT**: The session value of the `character_set_client` system variable when the trigger was created.
- **COLLATION\_CONNECTION**: The session value of the `collation_connection` system variable when the trigger was created.
- **DATABASE\_COLLATION**: The collation of the database with which the trigger is associated.
- The following columns currently always contain NULL: `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, and `ACTION_REFERENCE_NEW_TABLE`.

Example, using the `ins_sum` trigger defined in [Section 19.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
-> WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum'\G
***** 1. row *****
      TRIGGER_CATALOG: def
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: def
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 1
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
      ACTION_REFERENCE_NEW_ROW: NEW
      CREATED: 2013-07-05 07:41:21.26
      SQL_MODE: NO_ENGINE_SUBSTITUTION
      DEFINER: me@localhost
      CHARACTER_SET_CLIENT: utf8
      COLLATION_CONNECTION: utf8_general_ci
      DATABASE_COLLATION: latin1_swedish_ci
```

## 20.28 The INFORMATION\_SCHEMA USER\_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks                                                          |
|-------------------------|-----------|------------------------------------------------------------------|
| GRANTEE                 |           | ' <i>user_name</i> '@' <i>host_name</i> ' value, MySQL extension |
| TABLE_CATALOG           |           | def, MySQL extension                                             |
| PRIVILEGE_TYPE          |           | MySQL extension                                                  |
| IS_GRANTABLE            |           | MySQL extension                                                  |

### Notes:

- This is a nonstandard table. It takes its values from the `mysql.user` table.

## 20.29 The INFORMATION\_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

| INFORMATION_SCHEMA Name           | SHOW Name | Remarks         |
|-----------------------------------|-----------|-----------------|
| <code>TABLE_CATALOG</code>        |           | def             |
| <code>TABLE_SCHEMA</code>         |           |                 |
| <code>TABLE_NAME</code>           |           |                 |
| <code>VIEW_DEFINITION</code>      |           |                 |
| <code>CHECK_OPTION</code>         |           |                 |
| <code>IS_UPDATABLE</code>         |           |                 |
| <code>DEFINER</code>              |           |                 |
| <code>SECURITY_TYPE</code>        |           |                 |
| <code>CHARACTER_SET_CLIENT</code> |           | MySQL extension |
| <code>COLLATION_CONNECTION</code> |           | MySQL extension |

**Notes:**

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column has a value of `NONE`, `CASCADE`, or `LOCAL`.
- MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag.

If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 19.5.3, “Updatable and Insertable Views”](#).)

The `IS_UPDATABLE` flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the `IS_UPDATABLE` value, the server keeps track of the updatability of a view and correctly rejects data change operations to views that are not updatable. If the `IS_UPDATABLE` value for a view has become inaccurate to due to changes to underlying views, the value can be updated by deleting and recreating the view.

- `DEFINER`: The account of the user who created the view, in `'user_name'@'host_name'` format. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.
- `CHARACTER_SET_CLIENT`: The session value of the `character_set_client` system variable when the view was created.
- `COLLATION_CONNECTION`: The session value of the `collation_connection` system variable when the view was created.

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
       -> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `coll` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

## 20.30 INFORMATION\_SCHEMA Tables for InnoDB

This section provides table definitions for InnoDB `INFORMATION_SCHEMA` tables. For related information and examples, see [Section 14.12, “InnoDB INFORMATION\\_SCHEMA Tables”](#).

`INNO_DB INFORMATION_SCHEMA` tables can be used to monitor ongoing InnoDB activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly.

### 20.30.1 The INFORMATION\_SCHEMA INNODB\_CMP and INNODB\_CMP\_RESET Tables

The `INNODB_CMP` and `INNODB_CMP_RESET` tables contain status information on operations related to compressed InnoDB tables.

**Table 20.1 Columns of INNODB\_CMP and INNODB\_CMP\_RESET**

| Column name                  | Description                                                                                                                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PAGE_SIZE</code>       | Compressed page size in bytes.                                                                                                                                                                            |
| <code>COMPRESS_OPS</code>    | Number of times a B-tree page of the size <code>PAGE_SIZE</code> has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out. |
| <code>COMPRESS_OPS_OK</code> | Number of times a B-tree page of the size <code>PAGE_SIZE</code> has been successfully compressed. This count should never exceed <code>COMPRESS_OPS</code> .                                             |
| <code>COMPRESS_TIME</code>   | Total time in seconds spent in attempts to compress B-tree pages of the size <code>PAGE_SIZE</code> .                                                                                                     |
| <code>UNCOMPRESS_OPS</code>  | Number of times a B-tree page of the size <code>PAGE_SIZE</code> has been uncompressed. B-tree pages are uncompressed whenever compression                                                                |

| Column name                  | Description                                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------|
|                              | fails or at first access when the uncompressed page does not exist in the buffer pool.         |
| <code>UNCOMPRESS_TIME</code> | Total time in seconds spent in uncompressing B-tree pages of the size <code>PAGE_SIZE</code> . |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP \G
***** 1. row *****
  page_size: 1024
  compress_ops: 0
  compress_ops_ok: 0
  compress_time: 0
  uncompress_ops: 0
  uncompress_time: 0
***** 2. row *****
  page_size: 2048
  compress_ops: 0
  compress_ops_ok: 0
  compress_time: 0
  uncompress_ops: 0
  uncompress_time: 0
***** 3. row *****
  page_size: 4096
  compress_ops: 0
  compress_ops_ok: 0
  compress_time: 0
  uncompress_ops: 0
  uncompress_time: 0
***** 4. row *****
  page_size: 8192
  compress_ops: 86955
  compress_ops_ok: 81182
  compress_time: 27
  uncompress_ops: 26828
  uncompress_time: 5
***** 5. row *****
  page_size: 16384
  compress_ops: 0
  compress_ops_ok: 0
  compress_time: 0
  uncompress_ops: 0
  uncompress_time: 0
```

**Notes:**

- Use these tables to measure the effectiveness of [InnoDB table compression](#) in your database.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of these tables including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.6.1.4, “Monitoring Compression at Runtime”](#) and [Section 14.12.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB table compression](#), see [Section 14.6, “InnoDB Table and Page Compression”](#).

## 20.30.2 The INFORMATION\_SCHEMA INNODB\_CMP\_PER\_INDEX and INNODB\_CMP\_PER\_INDEX\_RESET Tables

The `INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET` tables contain status information on operations related to [compressed InnoDB tables and indexes](#), with separate statistics for each combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed [InnoDB](#) table, both the table data and all the [secondary indexes](#) are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the [clustered index](#).

**Table 20.2 Columns of INNODB\_CMP\_PER\_INDEX and INNODB\_CMP\_PER\_INDEX\_RESET**

| Column name                     | Description                                                                                                                                                                                                                                                                      |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DATABASE_NAME</a>   | Database containing the applicable table.                                                                                                                                                                                                                                        |
| <a href="#">TABLE_NAME</a>      | Table to monitor for compression statistics.                                                                                                                                                                                                                                     |
| <a href="#">INDEX_NAME</a>      | Index to monitor for compression statistics.                                                                                                                                                                                                                                     |
| <a href="#">COMPRESS_OPS</a>    | Number of compression operations attempted. <a href="#">Pages</a> are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.                                                                                                  |
| <a href="#">COMPRESS_OPS_OK</a> | Number of successful compression operations. Subtract from the <a href="#">COMPRESS_OPS</a> value to get the number of <a href="#">compression failures</a> . Divide by the <a href="#">COMPRESS_OPS</a> value to get the percentage of compression failures.                    |
| <a href="#">COMPRESS_TIME</a>   | Total amount of CPU time, in seconds, used for compressing data in this index.                                                                                                                                                                                                   |
| <a href="#">UNCOMPRESS_OPS</a>  | Number of uncompression operations performed. Compressed <a href="#">InnoDB</a> pages are uncompressed whenever compression <a href="#">fails</a> , or the first time a compressed page is accessed in the <a href="#">buffer pool</a> and the uncompressed page does not exist. |
| <a href="#">UNCOMPRESS_TIME</a> | Total amount of CPU time, in seconds, used for uncompressing data in this index.                                                                                                                                                                                                 |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX \G
***** 1. row *****
  database_name: employees
   table_name: salaries
   index_name: PRIMARY
   compress_ops: 0
compress_ops_ok: 0
   compress_time: 0
uncompress_ops: 23451

**Notes:**

- Use these tables to measure the effectiveness of [InnoDB](#) table [compression](#) for specific tables, indexes, or both.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of these tables including data types and default values.
- You must have the [PROCESS](#) privilege to query these tables.
- Because collecting separate measurements for every index imposes substantial performance overhead, [INNODB\\_CMP\\_PER\\_INDEX](#) and [INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#) statistics are not

gathered by default. You must enable the `innodb_cmp_per_index_enabled` configuration option before performing the operations on compressed tables that you want to monitor.

- For usage information, see [Section 14.6.1.4, “Monitoring Compression at Runtime”](#) and [Section 14.12.1.3, “Using the Compression Information Schema Tables”](#). For general information about InnoDB table compression, see [Section 14.6, “InnoDB Table and Page Compression”](#).

### 20.30.3 The INFORMATION\_SCHEMA INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET Tables

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables contain status information on compressed pages within the InnoDB buffer pool.

**Table 20.3 Columns of INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET**

| Column name                       | Description                                                                                                                                                                                                                                                                         |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>PAGE_SIZE</code>            | Block size in bytes. Each record of this table describes blocks of this size.                                                                                                                                                                                                       |
| <code>BUFFER_POOL_INSTANCE</code> | A unique identifier for the buffer pool instance.                                                                                                                                                                                                                                   |
| <code>PAGES_USED</code>           | Number of blocks of the size <code>PAGE_SIZE</code> that are currently in use.                                                                                                                                                                                                      |
| <code>PAGES_FREE</code>           | Number of blocks of the size <code>PAGE_SIZE</code> that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1.                                                                       |
| <code>RELOCATION_OPS</code>       | Number of times a block of the size <code>PAGE_SIZE</code> has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed block when it tries to form a bigger freed block. Reading from the table <code>INNODB_CMPMEM_RESET</code> resets this count. |
| <code>RELOCATION_TIME</code>      | Total time in microseconds spent in relocating blocks of the size <code>PAGE_SIZE</code> . Reading from the table <code>INNODB_CMPMEM_RESET</code> resets this count.                                                                                                               |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMPMEM \G
***** 1. row *****
      page_size: 1024
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 2. row *****
      page_size: 2048
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 3. row *****
      page_size: 4096
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 4. row *****
      page_size: 8192
buffer_pool_instance: 0
      pages_used: 7673
      pages_free: 15
      relocation_ops: 4638
      relocation_time: 0
***** 5. row *****
      page_size: 16384
```

```
buffer_pool_instance: 0
  pages_used: 0
  pages_free: 0
  relocation_ops: 0
  relocation_time: 0
```

**Notes:**

- Use these tables to measure the effectiveness of [InnoDB table compression](#) in your database.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of these tables including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.6.1.4, “Monitoring Compression at Runtime”](#) and [Section 14.12.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB table compression](#), see [Section 14.6, “InnoDB Table and Page Compression”](#).

## 20.30.4 The INFORMATION\_SCHEMA INNODB\_TRX Table

The `INNODB_TRX` table contains information about every transaction (excluding read-only transactions) currently executing inside [InnoDB](#), including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing, if any.

**Table 20.4 INNODB\_TRX Columns**

| Column name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TRX_ID</code>                | Unique transaction ID number, internal to <a href="#">InnoDB</a> . (Starting in MySQL 5.6, these IDs are not created for transactions that are read-only and non-locking. See <a href="#">Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”</a> for details.)                                                                                                                                                                      |
| <code>TRX_WEIGHT</code>            | The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, <a href="#">InnoDB</a> selects the transaction with the smallest weight as the “victim” to rollback. Transactions that have changed non-transactional tables are considered heavier than others, regardless of the number of altered and locked rows. |
| <code>TRX_STATE</code>             | Transaction execution state. One of <code>RUNNING</code> , <code>LOCK WAIT</code> , <code>ROLLING BACK</code> or <code>COMMITTING</code> .                                                                                                                                                                                                                                                                                                 |
| <code>TRX_STARTED</code>           | Transaction start time.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>TRX_REQUESTED_LOCK_ID</code> | ID of the lock the transaction is currently waiting for (if <code>TRX_STATE</code> is <code>LOCK WAIT</code> , otherwise <code>NULL</code> ). Details about the lock can be found by joining with <code>INNODB_LOCKS</code> on <code>LOCK_ID</code> .                                                                                                                                                                                      |
| <code>TRX_WAIT_STARTED</code>      | Time when the transaction started waiting on the lock (if <code>TRX_STATE</code> is <code>LOCK WAIT</code> , otherwise <code>NULL</code> ).                                                                                                                                                                                                                                                                                                |
| <code>TRX_MYSQL_THREAD_ID</code>   | MySQL thread ID. Can be used for joining with <code>PROCESSLIST</code> on <code>ID</code> . See <a href="#">Potential Inconsistency with PROCESSLIST Data</a> .                                                                                                                                                                                                                                                                            |
| <code>TRX_QUERY</code>             | The SQL query that is being executed by the transaction.                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>TRX_OPERATION_STATE</code>   | The transaction's current operation, or <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                |
| <code>TRX_TABLES_IN_USE</code>     | The number of <a href="#">InnoDB</a> tables used while processing the current SQL statement of this transaction.                                                                                                                                                                                                                                                                                                                           |
| <code>TRX_TABLES_LOCKED</code>     | Number of <a href="#">InnoDB</a> tables that the current SQL statement has row locks on. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.)                                                                                                                                                                                |

| Column name                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TRX_LOCK_STRUCTS           | The number of locks reserved by the transaction.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| TRX_LOCK_MEMORY_BYTES      | Total size taken up by the lock structures of this transaction in memory.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| TRX_ROWS_LOCKED            | Approximate number of rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction.                                                                                                                                                                                                                                                                                                                                  |
| TRX_ROWS_MODIFIED          | The number of modified and inserted rows in this transaction.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| TRX_CONCURRENCY_TICKETS    | A value indicating how much work the current transaction can do before being swapped out, as specified by the <code>innodb_concurrency_tickets</code> option.                                                                                                                                                                                                                                                                                                                                      |
| TRX_ISOLATION_LEVEL        | The isolation level of the current transaction.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| TRX_UNIQUE_CHECKS          | Whether unique checks are turned on or off for the current transaction. (They might be turned off during a bulk data load, for example.)                                                                                                                                                                                                                                                                                                                                                           |
| TRX_FOREIGN_KEY_CHECKS     | Whether foreign key checks are turned on or off for the current transaction. (They might be turned off during a bulk data load, for example.)                                                                                                                                                                                                                                                                                                                                                      |
| TRX_LAST_FOREIGN_KEY_ERROR | Detailed error message for last FK error, or <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| TRX_ADAPTIVE_HASH_LATCHED  | Whether or not the adaptive hash index is locked by the current transaction. (Only a single transaction at a time can modify the adaptive hash index.)                                                                                                                                                                                                                                                                                                                                             |
| TRX_ADAPTIVE_HASH_TIMEOUT  | Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no AHI contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup.                                                                                                                                        |
| TRX_IS_READ_ONLY           | A value of 1 indicates the transaction is read-only. (5.6.4 and up.)                                                                                                                                                                                                                                                                                                                                                                                                                               |
| TRX_AUTOCOMMIT_NON_LOCKING | A value of 1 indicates the transaction is a <code>SELECT</code> statement that does not use the <code>FOR UPDATE</code> or <code>LOCK IN SHARED MODE</code> clauses, and is executing with the <code>autocommit</code> setting turned on so that the transaction will only contain this one statement. (5.6.4 and up.) When this column and <code>TRX_IS_READ_ONLY</code> are both 1, InnoDB optimizes the transaction to reduce the overhead associated with transactions that change table data. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TRX\G
***** 1. row *****
      trx_id: 1510
      trx_state: RUNNING
      trx_started: 2014-11-19 13:24:40
  trx_requested_lock_id: NULL
      trx_wait_started: NULL
      trx_weight: 586739
  trx_mysql_thread_id: 2
      trx_query: DELETE FROM employees.salaries WHERE salary > 65000
  trx_operation_state: updating or deleting
  trx_tables_in_use: 1
  trx_tables_locked: 1
  trx_lock_structs: 3003
  trx_lock_memory_bytes: 450768
  trx_rows_locked: 1407513
  trx_rows_modified: 583736
  trx_concurrency_tickets: 0
```

```

trx_isolation_level: REPEATABLE READ
  trx_unique_checks: 1
  trx_foreign_key_checks: 1
trx_last_foreign_key_error: NULL
  trx_adaptive_hash_latched: 0
  trx_adaptive_hash_timeout: 10000
  trx_is_read_only: 0
trx_autocommit_non_locking: 0
1 row in set (0.00 sec)

```

**Notes:**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 14.12.2.3, “Data Persistence and Consistency for InnoDB Transaction and Locking Tables”](#).
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.12.2.1, “Usage Examples for InnoDB Transaction and Locking Tables”](#).

## 20.30.5 The INFORMATION\_SCHEMA INNODB\_LOCKS Table

The `INNODB_LOCKS` table contains information about each lock that an `InnoDB` transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

**Table 20.5 INNODB\_LOCKS Columns**

| Column name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>LOCK_ID</code>     | Unique lock ID number, internal to <code>InnoDB</code> . Treat it as an opaque string. Although <code>LOCK_ID</code> currently contains <code>TRX_ID</code> , the format of the data in <code>LOCK_ID</code> is not guaranteed to remain the same in future releases. Do not write programs that parse the <code>LOCK_ID</code> value.                                                                                                                                                                                                                                                                                                  |
| <code>LOCK_TRX_ID</code> | ID of the transaction holding this lock. Details about the transaction can be found by joining with <code>INNODB_TRX</code> on <code>TRX_ID</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>LOCK_MODE</code>   | Mode of the lock. One of <code>S</code> , <code>X</code> , <code>IS</code> , <code>IX</code> , <code>S_GAP</code> , <code>X_GAP</code> , <code>IS_GAP</code> , <code>IX_GAP</code> , or <code>AUTO_INC</code> for shared, exclusive, intention shared, intention exclusive row locks, shared and exclusive gap locks, intention shared and intention exclusive gap locks, and auto-increment table level lock, respectively. Refer to the sections <a href="#">Section 14.2.2.1, “InnoDB Lock Modes”</a> and <a href="#">Section 14.2.2, “The InnoDB Transaction Model and Locking”</a> for information on <code>InnoDB</code> locking. |
| <code>LOCK_TYPE</code>   | Type of the lock. One of <code>RECORD</code> or <code>TABLE</code> for record (row) level or table level locks, respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>LOCK_TABLE</code>  | Name of the table that has been locked or contains locked records.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>LOCK_INDEX</code>  | Name of the index if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>LOCK_SPACE</code>  | Tablespace ID of the locked record if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>LOCK_PAGE</code>   | Page number of the locked record if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>LOCK_REC</code>    | Heap number of the locked record within the page if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>LOCK_DATA</code>   | Primary key value(s) of the locked record if <code>LOCK_TYPE= 'RECORD'</code> , otherwise <code>NULL</code> . This column contains the value(s) of the primary key column(s) in the locked row, formatted as a valid SQL string (ready to be copied to SQL commands). If there is no primary key then the <code>InnoDB</code> internal unique row ID number is used. If a gap lock is taken for key values or ranges above the largest                                                                                                                                                                                                  |

| Column name | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | value in the index, <a href="#">LOCK_DATA</a> reports “supremum pseudo-record”. When the page containing the locked record is not in the buffer pool (in the case that it was paged out to disk while the lock was held), <a href="#">InnoDB</a> does not fetch the page from disk, to avoid unnecessary disk operations. Instead, <a href="#">LOCK_DATA</a> is set to <a href="#">NULL</a> . |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCKS \G
***** 1. row *****
  lock_id: 3723:72:3:2
lock_trx_id: 3723
  lock_mode: X
  lock_type: RECORD
lock_table: `mysql`.`t`
lock_index: PRIMARY
lock_space: 72
  lock_page: 3
  lock_rec: 2
  lock_data: 1, 9
***** 2. row *****
  lock_id: 3722:72:3:2
lock_trx_id: 3722
  lock_mode: S
  lock_type: RECORD
lock_table: `mysql`.`t`
lock_index: PRIMARY
lock_space: 72
  lock_page: 3
  lock_rec: 2
  lock_data: 1, 9
```

**Notes:**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 14.12.3, “Data Persistence and Consistency for InnoDB Transaction and Locking Tables”](#).
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For usage information, see [Section 14.12.1, “Usage Examples for InnoDB Transaction and Locking Tables”](#).

## 20.30.6 The INFORMATION\_SCHEMA INNODB\_LOCK\_WAITS Table

The [INNODB\\_LOCK\\_WAITS](#) table contains one or more rows for each blocked [InnoDB](#) transaction, indicating the lock it has requested and any locks that are blocking that request.

**Table 20.6 INNODB\_LOCK\_WAITS Columns**

| Column name                       | Description                                                                                                                                                                                    |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">REQUESTING_TRX_ID</a> | ID of the requesting transaction.                                                                                                                                                              |
| <a href="#">REQUESTED_LOCK_ID</a> | ID of the lock for which a transaction is waiting. Details about the lock can be found by joining with <a href="#">INNODB_LOCKS</a> on <a href="#">LOCK_ID</a> .                               |
| <a href="#">BLOCKING_TRX_ID</a>   | ID of the blocking transaction.                                                                                                                                                                |
| <a href="#">BLOCKING_LOCK_ID</a>  | ID of a lock held by a transaction blocking another transaction from proceeding. Details about the lock can be found by joining with <a href="#">INNODB_LOCKS</a> on <a href="#">LOCK_ID</a> . |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCK_WAITS \G
***** 1. row *****
requesting_trx_id: 3396
requested_lock_id: 3396:91:3:2
  blocking_trx_id: 3395
  blocking_lock_id: 3395:91:3:2
1 row in set (0.00 sec)
```

**Notes:**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 14.12.2.3, “Data Persistence and Consistency for InnoDB Transaction and Locking Tables”](#).
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 14.12.2.1, “Usage Examples for InnoDB Transaction and Locking Tables”](#).

## 20.30.7 The INFORMATION\_SCHEMA INNODB\_SYS\_TABLES Table

The `INNODB_SYS_TABLES` table provides metadata about `InnoDB` tables, equivalent to the information from the `SYS_TABLES` table in the `InnoDB` data dictionary.

For related usage information and examples, see [Section 14.12.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 20.7 INNODB\_SYS\_TABLES Columns**

| Column name                | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TABLE_ID</code>      | An identifier for each <code>InnoDB</code> table that is unique across all databases in the instance.                                                                                                                                                                                                                                                                                                       |
| <code>NAME</code>          | The name of the table. Preceded by the database name where appropriate, for example <code>test/t1</code> . <code>InnoDB</code> system table names are in all uppercase. Names of databases and user tables are in the same case as they were originally defined, possibly influenced by the <code>lower_case_table_names</code> setting.                                                                    |
| <code>FLAG</code>          | This value provides bit level information about table format and storage characteristics including row format, compressed page size (if applicable), and whether or not the <code>DATA DIRECTORY</code> clause was used with <code>CREATE TABLE</code> or <code>ALTER TABLE</code> .                                                                                                                        |
| <code>N_COLS</code>        | The number of columns in the table. The number reported includes three hidden columns that are created by <code>InnoDB</code> ( <code>DB_ROW_ID</code> , <code>DB_TRX_ID</code> , and <code>DB_ROLL_PTR</code> ). The number reported also includes virtual generated columns, if present.                                                                                                                  |
| <code>SPACE</code>         | An identifier for the tablespace where the table resides. 0 means the <code>InnoDB system tablespace</code> . Any other number represents either a <code>file-per-table</code> tablespace or a general tablespace. This identifier stays the same after a <code>TRUNCATE TABLE</code> statement. For file-per-table tablespaces, this identifier is unique for tables across all databases in the instance. |
| <code>FILE_FORMAT</code>   | The table's file format (Antelope or Barracuda).                                                                                                                                                                                                                                                                                                                                                            |
| <code>ROW_FORMAT</code>    | The table's row format (Compact, Redundant, Dynamic, or Compressed).                                                                                                                                                                                                                                                                                                                                        |
| <code>ZIP_PAGE_SIZE</code> | The zip page size. Only applies to tables that use the Compressed row format.                                                                                                                                                                                                                                                                                                                               |

| Column name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SPACE_TYPE  | The type of tablespace to which the table belongs. Possible values include <i>System</i> (for the InnoDB system tablespace), <i>General</i> (for InnoDB general tablespaces created using CREATE TABLESPACE, and <i>Single</i> (for InnoDB file-per-table tablespaces). Tables assigned to the system tablespace using the CREATE TABLE or ALTER TABLE TABLESPACE=innodb_system clause have a <i>General</i> SPACE_TYPE. The SPACE_TYPE column was added in MySQL 5.7.6 with the introduction of InnoDB general tablespaces. For more information, see CREATE TABLESPACE. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE TABLE_ID = 214 \G
***** 1. row *****
TABLE_ID: 214
NAME: test/t1
FLAG: 129
N_COLS: 4
SPACE: 233
FILE_FORMAT: Antelope
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
SPACE_TYPE: General
1 row in set (0.00 sec)
```

**Notes:**

- Use DESCRIBE or SHOW COLUMNS to view additional information about the columns of this table including data types and default values.
- You must have the PROCESS privilege to query this table.

**Interpreting the INNODB\_SYS\_TABLES.FLAG Column Value:**

The INNODB\_SYS\_TABLES.FLAG column provides bit-level information about the table's format and storage characteristics. You can interpret the FLAG column value by adding together the applicable decimal numeric values that are provided in the following table.

**Table 20.8 Bit Position Values for Interpreting INNODB\_SYS\_TABLES FLAG Column Data**

| Bit Position | Description                                                                                                                                                                                   | Decimal Numeric Value                                                                                                                                                                                                                                                                                          |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | This bit is set if the row format is not REDUNDANT. In other words, it is set if the row format is COMPACT, DYNAMIC or COMPRESSED.                                                            | <ul style="list-style-type: none"> <li>• 0 - REDUNDANT</li> <li>• 1 - COMPACT, DYNAMIC or COMPRESSED</li> </ul>                                                                                                                                                                                                |
| 1-4          | These four bits contain a small number that represents the compressed page size of the table. The INNODB_SYS_TABLES.ZIP_PAGE_SIZE field also reports the compressed page size, if applicable. | <ul style="list-style-type: none"> <li>• 0 - Not Compressed</li> <li>• 2 - 1024 Byte Compressed Page Size</li> <li>• 4 - 2048 Byte Compressed Page Size</li> <li>• 6 - 4096 Byte Compressed Page Size</li> <li>• 8 - 8192 Byte Compressed Page Size</li> <li>• 10 - 16384 Byte Compressed Page Size</li> </ul> |
| 5            | This bit is set if the row format is DYNAMIC or COMPRESSED.                                                                                                                                   | <ul style="list-style-type: none"> <li>• 0 - REDUNDANT or COMPACT</li> <li>• 32 - DYNAMIC or COMPRESSED</li> </ul>                                                                                                                                                                                             |

| Bit Position | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Decimal Numeric Value                                                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6            | This bit is set if the <code>DATA DIRECTORY</code> option is used with <code>CREATE TABLE</code> or <code>ALTER TABLE</code> . This bit is set for file-per-table tablespaces that are located in directories other than the default data directory ( <code>datadir</code> ). For these tables, a <code>tablename.isl</code> file is present in the same location as the <code>tablename.frm</code> file. The <code>tablename.isl</code> file stores the actual directory path to the <code>tablename.ibd</code> file-per-table tablespace file. | <ul style="list-style-type: none"> <li>• 0 - Not a remote file-per-table tablespace</li> <li>• 64 - A remote file-per-table tablespace</li> </ul>                                                                                          |
| 7            | This bit is set if the table is assigned to a shared tablespace (either a general tablespace or a system tablespace) using the <code>CREATE TABLE</code> or <code>ALTER TABLE TABLESPACE=tablespace_name</code> option.                                                                                                                                                                                                                                                                                                                          | <ul style="list-style-type: none"> <li>• 0 - Table is located in a default location depending on the value of the <code>innodb_file_per_table</code>.</li> <li>• 128 - The table is explicitly assigned to a shared tablespace.</li> </ul> |

In the following, table `t1` uses `ROW_FORMAT=DYNAMIC` and has a `FLAG` value of 33. Based on the information in the preceding table, we can see that bit position 0 would be set to 1, and bit position 5 would be set to 32 for a table with a `DYNAMIC` row format. These values add up to a `FLAG` value of 33.

```
mysql> use test;
Database changed

mysql> SET GLOBAL innodb_file_format=Barracuda;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (c1 int) ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.02 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
TABLE_ID: 89
NAME: test/t1
FLAG: 33
N_COLS: 4
SPACE: 75
FILE_FORMAT: Barracuda
ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
1 row in set (0.01 sec)
```

## 20.30.8 The INFORMATION\_SCHEMA INNODB\_SYS\_INDEXES Table

The `INNODB_SYS_INDEXES` table provides metadata about `InnoDB` indexes, equivalent to the information in the internal `SYS_INDEXES` table in the `InnoDB` data dictionary.

For related usage information and examples, see [Section 14.12.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 20.9 INNODB\_SYS\_INDEXES Columns**

| Column name           | Description                                                                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>INDEX_ID</code> | An identifier for each index that is unique across all the databases in an instance.                                                                    |
| <code>NAME</code>     | The name of the index. Most indexes created implicitly by <code>InnoDB</code> have consistent names but the index names are not necessarily unique. For |

| Column name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | example, <a href="#">PRIMARY</a> for a primary key index, <a href="#">GEN_CLUST_INDEX</a> for the index representing a primary key when one is not specified, and <a href="#">ID_IND</a> , <a href="#">FOR_IND</a> , and <a href="#">REF_IND</a> for foreign key constraints.                                                                                                                                                                                                                                                                                           |
| <a href="#">TABLE_ID</a>        | An identifier representing the table associated with the index; the same value from <a href="#">INNODB_SYS_TABLES.TABLE_ID</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <a href="#">TYPE</a>            | A numeric identifier signifying the kind of index. 0 = Secondary Index, 1 = Clustered Index, 2 = Unique Index, 3 = Primary Index, 32 = Full-text Index, 64 = Spatial Index, 128 = A secondary index that includes a virtual generated column.                                                                                                                                                                                                                                                                                                                           |
| <a href="#">N_FIELDS</a>        | The number of columns in the index key. For the <a href="#">GEN_CLUST_INDEX</a> indexes, this value is 0 because the index is created using an artificial value rather than a real table column.                                                                                                                                                                                                                                                                                                                                                                        |
| <a href="#">PAGE_NO</a>         | The root page number of the index B-tree. For full-text indexes, the <a href="#">PAGE_NO</a> field is unused and set to -1 ( <a href="#">FIL_NULL</a> ) because the full-text index is laid out in several B-trees (auxiliary tables).                                                                                                                                                                                                                                                                                                                                  |
| <a href="#">SPACE</a>           | An identifier for the tablespace where the index resides. 0 means the <a href="#">InnoDB system tablespace</a> . Any other number represents a table created in <a href="#">file-per-table</a> mode with a separate <a href="#">.ibd</a> file. This identifier stays the same after a <a href="#">TRUNCATE TABLE</a> statement. Because all indexes for a table reside in the same tablespace as the table, this value is not necessarily unique.                                                                                                                       |
| <a href="#">MERGE_THRESHOLD</a> | The merge threshold value for index pages. If the amount of data in an index page falls below the <a href="#">MERGE_THRESHOLD</a> value when a row is deleted or when a row is shortened by an update operation, <a href="#">InnoDB</a> attempts to merge the index page with the neighboring index page. The default threshold value is 50%. The <a href="#">MERGE_THRESHOLD</a> column was added to <a href="#">INNODB_SYS_INDEXES</a> in MySQL 5.7.6. For more information, see <a href="#">Section 14.3.12, “Configuring the Merge Threshold for Index Pages”</a> . |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 34 \G
***** 1. row *****
INDEX_ID: 39
NAME: GEN_CLUST_INDEX
TABLE_ID: 34
TYPE: 1
N_FIELDS: 0
PAGE_NO: 3
SPACE: 23
MERGE_THRESHOLD: 50
***** 2. row *****
INDEX_ID: 40
NAME: i1
TABLE_ID: 34
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 23
MERGE_THRESHOLD: 50
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

## 20.30.9 The INFORMATION\_SCHEMA INNODB\_SYS\_COLUMNS Table

The `INNODB_SYS_COLUMNS` table provides metadata about InnoDB table columns, equivalent to the information from the `SYS_COLUMNS` table in the InnoDB data dictionary.

For related usage information and examples, see [Section 14.12.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 20.10 INNODB\_SYS\_COLUMNS Columns**

| Column name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TABLE_ID</code> | An identifier representing the table associated with the column; the same value from <code>INNODB_SYS_TABLES.TABLE_ID</code> .                                                                                                                                                                                                                                                                                                                                                                  |
| <code>NAME</code>     | The name of each column in each table. These names can be uppercase or lowercase depending on the <code>lower_case_table_names</code> setting. There are no special system-reserved names for columns.                                                                                                                                                                                                                                                                                          |
| <code>POS</code>      | The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps. The <code>POS</code> value for a virtual generated column encodes the column sequence number and ordinal position of the column. For more information, see the <code>POS</code> column description in <a href="#">Section 20.30.16, “The INFORMATION_SCHEMA INNODB_SYS_VIRTUAL Table”</a> . |
| <code>MTYPE</code>    | Stands for “main type”. A numeric identifier for the column type. 1 = <code>VARCHAR</code> , 2 = <code>CHAR</code> , 3 = <code>FIXBINARY</code> , 4 = <code>BINARY</code> , 5 = <code>BLOB</code> , 6 = <code>INT</code> , 7 = <code>SYS_CHILD</code> , 8 = <code>SYS</code> , 9 = <code>FLOAT</code> , 10 = <code>DOUBLE</code> , 11 = <code>DECIMAL</code> , 12 = <code>VARMYSQL</code> , 13 = <code>MYSQL</code> , 14 = <code>GEOMETRY</code> .                                              |
| <code>PRTYPE</code>   | The InnoDB “precise type”, a binary value with bits representing MySQL data type, character set code, and nullability.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>LEN</code>      | The column length, for example 4 for <code>INT</code> and 8 for <code>BIGINT</code> . For character columns in multibyte character sets, this length value is the maximum length in bytes needed to represent a definition such as <code>VARCHAR(N)</code> ; that is, it might be $2*N$ , $3*N$ , and so on depending on the character encoding.                                                                                                                                                |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71 \G
***** 1. row *****
TABLE_ID: 71
  NAME: col1
   POS: 0
  MTYPE: 6
 PRTYPE: 1027
   LEN: 4
***** 2. row *****
TABLE_ID: 71
  NAME: col2
   POS: 1
  MTYPE: 2
 PRTYPE: 524542
   LEN: 10
***** 3. row *****
TABLE_ID: 71
  NAME: col3
   POS: 2
  MTYPE: 1
 PRTYPE: 524303
   LEN: 10
```

**Notes:**

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.

- You must have the [PROCESS](#) privilege to query this table.

### 20.30.10 The INFORMATION\_SCHEMA INNODB\_SYS\_FIELDS Table

The [INNODB\\_SYS\\_FIELDS](#) table provides metadata about the key columns (fields) of [InnoDB](#) indexes, equivalent to the information from the [SYS\\_FIELDS](#) table in the [InnoDB](#) data dictionary.

For related usage information and examples, see [Section 14.12.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 20.11 INNODB\_SYS\_FIELDS Columns**

| Column name              | Description                                                                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">INDEX_ID</a> | An identifier for the index associated with this key field, using the same value as in <a href="#">INNODB_SYS_INDEXES.INDEX_ID</a> .                                                                   |
| <a href="#">NAME</a>     | The name of the original column from the table, using the same value as in <a href="#">INNODB_SYS_COLUMNS.NAME</a> .                                                                                   |
| <a href="#">POS</a>      | The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS where INDEX_ID = 117 \G
***** 1. row *****
INDEX_ID: 117
  NAME: coll
  POS: 0
1 row in set (0.00 sec)
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

### 20.30.11 The INFORMATION\_SCHEMA INNODB\_SYS\_FOREIGN Table

The [INNODB\\_SYS\\_FOREIGN](#) table provides metadata about [InnoDB foreign keys](#), equivalent to the information from the [SYS\\_FOREIGN](#) table in the [InnoDB](#) data dictionary.

For related usage information and examples, see [Section 14.12.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 20.12 INNODB\_SYS\_FOREIGN Columns**

| Column name              | Description                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ID</a>       | The name (not a numeric value) of the foreign key index. Preceded by the database name, for example, <a href="#">test/products_fk</a> .                                                                                                                                                                                                      |
| <a href="#">FOR_NAME</a> | The name of the <a href="#">child table</a> in this foreign key relationship.                                                                                                                                                                                                                                                                |
| <a href="#">REF_NAME</a> | The name of the <a href="#">parent table</a> in this foreign key relationship.                                                                                                                                                                                                                                                               |
| <a href="#">N_COLS</a>   | The number of columns in the foreign key index.                                                                                                                                                                                                                                                                                              |
| <a href="#">TYPE</a>     | A collection of bit flags with information about the foreign key column, ORed together. 1 = <a href="#">ON DELETE CASCADE</a> , 2 = <a href="#">ON UPDATE SET NULL</a> , 4 = <a href="#">ON UPDATE CASCADE</a> , 8 = <a href="#">ON UPDATE SET NULL</a> , 16 = <a href="#">DELETE NO ACTION</a> , 32 = <a href="#">ON UPDATE NO ACTION</a> . |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN \G
***** 1. row *****
      ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
      N_COLS: 1
      TYPE: 1
1 row in set (0.00 sec)
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

## 20.30.12 The INFORMATION\_SCHEMA INNODB\_SYS\_FOREIGN\_COLS Table

The [INNODB\\_SYS\\_FOREIGN\\_COLS](#) table provides status information about the columns of [InnoDB](#) foreign keys, equivalent to the information from the [SYS\\_FOREIGN\\_COLS](#) table in the [InnoDB](#) data dictionary.

For related usage information and examples, see [Section 14.12.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 20.13 INNODB\_SYS\_FOREIGN\_COLS Columns**

| Column name                  | Description                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ID</a>           | The foreign key index associated with this index key field, using the same value as <a href="#">INNODB_SYS_FOREIGN.ID</a> . |
| <a href="#">FOR_COL_NAME</a> | The name of the associated column in the child table.                                                                       |
| <a href="#">REF_COL_NAME</a> | The name of the associated column in the parent table.                                                                      |
| <a href="#">POS</a>          | The ordinal position of this key field within the foreign key index, starting from 0.                                       |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1' \G
***** 1. row *****
      ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
      POS: 0
1 row in set (0.00 sec)
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

## 20.30.13 The INFORMATION\_SCHEMA INNODB\_SYS\_TABLESTATS View

The [INNODB\\_SYS\\_TABLESTATS](#) provides a view of low-level status information about [InnoDB](#) tables. This data is used by the MySQL optimizer to calculate which index to use when querying an [InnoDB](#) table. This information is derived from in-memory data structures rather than corresponding to data stored on disk. There is no corresponding internal [InnoDB](#) system table.

[InnoDB](#) tables are represented in this view if they have been opened since the last server restart, and not aged out of the table cache. Tables for which persistent stats are available are always represented in this view.

Table statistics are only updated for [DELETE](#) or [UPDATE](#) operations that modify indexed columns. Statistics are not updated by operations that only modify non-indexed columns.

For related usage information and examples, see [Section 14.12.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 20.14 INNODB\_SYS\_TABLESTATS Columns**

| Column name                       | Description                                                                                                                                                                                                                                         |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">TABLE_ID</a>          | An identifier representing the table for which statistics are available, using the same value as <a href="#">INNODB_SYS_TABLES.TABLE_ID</a> .                                                                                                       |
| <a href="#">NAME</a>              | The name of the table, using the same value as <a href="#">INNODB_SYS_TABLES.NAME</a> .                                                                                                                                                             |
| <a href="#">STATS_INITIALIZED</a> | The value is <a href="#">Initialized</a> if the statistics are already collected, <a href="#">Uninitialized</a> if not.                                                                                                                             |
| <a href="#">NUM_ROWS</a>          | The current estimated number of rows in the table. Updated after each DML operation. Could be imprecise if uncommitted transactions are inserting into or deleting from the table.                                                                  |
| <a href="#">CLUST_INDEX_SIZE</a>  | Number of pages on disk that store the clustered index, which holds the <a href="#">InnoDB</a> table data in primary key order. This value might be null if no statistics are collected yet for the table.                                          |
| <a href="#">OTHER_INDEX_SIZE</a>  | Number of pages on disk that store all secondary indexes for the table. This value might be null if no statistics are collected yet for the table.                                                                                                  |
| <a href="#">MODIFIED_COUNTER</a>  | The number of rows modified by DML operations, such as <a href="#">INSERT</a> , <a href="#">UPDATE</a> , <a href="#">DELETE</a> , and also cascade operations from foreign keys. This column is reset each time table statistics are recalculated   |
| <a href="#">AUTOINC</a>           | The next number to be issued for any auto-increment-based operation. The rate at which the <a href="#">AUTOINC</a> value changes depends on how many times auto-increment numbers have been requested and how many numbers are granted per request. |
| <a href="#">REF_COUNT</a>         | When this counter reaches zero, the table metadata can be evicted from the table cache.                                                                                                                                                             |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71 \G
***** 1. row *****
      TABLE_ID: 71
        NAME: test/t1
STATS_INITIALIZED: Initialized
      NUM_ROWS: 1
    CLUST_INDEX_SIZE: 1
    OTHER_INDEX_SIZE: 0
    MODIFIED_COUNTER: 1
          AUTOINC: 0
        REF_COUNT: 1
1 row in set (0.00 sec)
```

**Notes:**

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

**20.30.14 The INFORMATION\_SCHEMA INNODB\_SYS\_DATAFILES Table**

The `INNODB_SYS_DATAFILES` table provides data file path information for InnoDB file-per-table and general tablespaces, equivalent to the information in the `SYS_DATAFILES` table in the InnoDB data dictionary.

For related usage information and examples, see [Section 14.12.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

#### Note

As of MySQL 5.7.8, the `INFORMATION_SCHEMA.FILES` table provides data file path information and other metadata about all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, temporary table tablespaces, and undo tablespaces (if present).

**Table 20.15 INNODB\_SYS\_DATAFILES Columns**

| Column name        | Description                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>SPACE</code> | The tablespace Space ID.                                                                                                                                                                                                                                                                                                                                               |
| <code>PATH</code>  | The tablespace data file path (for example, “.\ <code>world\innodb\city.ibd</code> ”). If a <code>file-per-table</code> tablespace is created in a location outside the MySQL data directory using the <code>DATA DIRECTORY</code> clause of the <code>CREATE TABLE</code> statement, the tablespace <code>PATH</code> field shows the fully qualified directory path. |

#### Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57 \G
***** 1. row *****
SPACE: 57
  PATH: ./test/t1.ibd
1 row in set (0.01 sec)
```

#### Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

## 20.30.15 The INFORMATION\_SCHEMA INNODB\_SYS\_TABLESPACES Table

The `INNODB_SYS_TABLESPACES` table provides metadata about InnoDB file-per-table and general tablespaces, equivalent to the information in the `SYS_TABLESPACES` table in the InnoDB data dictionary.

For related usage information and examples, see [Section 14.12.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

#### Note

As of MySQL 5.7.8, the `INFORMATION_SCHEMA.FILES` table provides metadata about all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, temporary table tablespaces, and undo tablespaces (if present).

**Table 20.16 INNODB\_SYS\_TABLESPACES Columns**

| Column name        | Description                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------|
| <code>SPACE</code> | Tablespace Space ID.                                                                           |
| <code>NAME</code>  | The database and table name (for example, <code>world_innodb\city</code> )                     |
| <code>FLAG</code>  | This value provides bit level information about tablespace format and storage characteristics. |

| Column name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FILE_FORMAT    | The tablespace file format. For example, <a href="#">Antelope</a> , <a href="#">Barracuda</a> , or <a href="#">Any</a> ( <a href="#">general tablespaces</a> support any row format). The data in this field is interpreted from the tablespace flags information that resides in the <a href="#">.ibd file</a> . For more information about <a href="#">InnoDB</a> file formats, see <a href="#">Section 14.7, “InnoDB File-Format Management”</a> .                                                                      |
| ROW_FORMAT     | The tablespace row format (Compact or Redundant, Dynamic, or Compressed). The data in this field is interpreted from the tablespace flags information that resides in the <a href="#">.ibd file</a> .                                                                                                                                                                                                                                                                                                                      |
| PAGE_SIZE      | The tablespace page size. The data in this field is interpreted from the tablespace flags information that resides in the <a href="#">.ibd file</a> .                                                                                                                                                                                                                                                                                                                                                                      |
| ZIP_PAGE_SIZE  | The tablespace zip page size. The data in this field is interpreted from the tablespace flags information that resides in the <a href="#">.ibd file</a> .                                                                                                                                                                                                                                                                                                                                                                  |
| SPACE_TYPE     | The type of tablespace. Possible values include <a href="#">General</a> (for <a href="#">InnoDB</a> general tablespaces created using <a href="#">CREATE TABLESPACE</a> and <a href="#">Single</a> (for <a href="#">InnoDB</a> file-per-table tablespaces). The <a href="#">SPACE_TYPE</a> column was added in MySQL 5.7.6 with the introduction of <a href="#">InnoDB</a> general tablespaces. For more information, see <a href="#">CREATE TABLESPACE</a> .                                                              |
| FS_BLOCK_SIZE  | The file system block size, which is the unit size used for hole punching. This column was added in MySQL 5.7.8 with the introduction of the <a href="#">InnoDB transparent page compression</a> feature.                                                                                                                                                                                                                                                                                                                  |
| FILE_SIZE      | The apparent size of the file, which represents the maximum size of the file, uncompressed. This column was added in MySQL 5.7.8 with the introduction of the <a href="#">InnoDB transparent page compression</a> feature.                                                                                                                                                                                                                                                                                                 |
| ALLOCATED_SIZE | The actual size of the file, which is the amount of space allocated on disk. This column was added in MySQL 5.7.8 with the introduction of the <a href="#">InnoDB transparent page compression</a> feature.                                                                                                                                                                                                                                                                                                                |
| COMPRESSION    | The current tablespace setting for page compression ( <a href="#">Zlib</a> , <a href="#">Lz4</a> , or <a href="#">None</a> ). A table may contain a mix of pages with different compression settings. This column was added in MySQL 5.7.8 with the introduction of the <a href="#">InnoDB transparent page compression</a> feature. This column displays incorrect data after a server restart (Bug #78197) and is removed in 5.7.10. Use <a href="#">SHOW CREATE TABLE</a> to view the current page compression setting. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 26 \G
***** 1. row *****
      SPACE: 26
      NAME: test/t1
      FLAG: 0
      FILE_FORMAT: Antelope
      ROW_FORMAT: Compact or Redundant
      PAGE_SIZE: 16384
      ZIP_PAGE_SIZE: 0
      SPACE_TYPE: Single
      FS_BLOCK_SIZE: 4096
      FILE_SIZE: 98304
      ALLOCATED_SIZE: 65536
      COMPRESSION: LZ4
1 row in set (0.00 sec)
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

- Because tablespace flags are always zero for all Antelope file formats (unlike table flags), there is no way to determine from this flag integer if the tablespace row format is Redundant or Compact. As a result, the possible values for the `ROW_FORMAT` field are “Compact or Redundant”, “Compressed”, or “Dynamic.”
- With the introduction of general tablespaces in MySQL 5.7.6, InnoDB system tablespace data (for SPACE 0) is exposed in `INNODB_SYS_TABLESPACES`.

**Interpreting the INNODB\_SYS\_TABLESPACES.FLAG Column Value:**

The `INNODB_SYS_TABLESPACES.FLAG` column provides bit-level information about tablespace format and storage characteristics.

Until MySQL 5.6, table and tablespace flags were the same except for the bit position 0 settings. In MySQL 5.6, support was added for 4K and 8K pages, which required an additional 4 bits to hold the logical page size. Also in MySQL 5.6, support was added for the `CREATE TABLE` and `ALTER TABLE DATA DIRECTORY` clause, which allows file-per-table tablespaces to be stored in a location outside of the MySQL data directory. This feature required an additional bit for both table and tablespace flags, but not at the same position.

You can interpret the tablespace `FLAG` column value by adding together the applicable decimal numeric values that are provided in the following table.

**Table 20.17 Bit Position Values for Interpreting INNODB\_SYS\_TABLESPACES FLAG Column Data**

| Bit Position | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Decimal Numeric Value                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | This bit is set if the row format of tables in the tablespace is <code>DYNAMIC</code> or <code>COMPRESSED</code> . This information can help you distinguish between Antelope and Barracuda file formats but not between <code>REDUNDANT</code> and <code>COMPACT</code> file formats ( <code>DYNAMIC</code> and <code>COMPRESSED</code> row formats require the Barracuda file format). If it is a file-per-table tablespace, you must query <code>INNODB_SYS_TABLES</code> to determine which of the two Antelope row formats is used ( <code>REDUNDANT</code> or <code>COMPACT</code> ). | <ul style="list-style-type: none"> <li>• 0 - <code>REDUNDANT</code> or <code>COMPACT</code> (<code>FILE_FORMAT=Antelope</code>)</li> <li>• 1 - <code>DYNAMIC</code> or <code>COMPRESSED</code> (<code>FILE_FORMAT=Barracuda</code>)</li> </ul>                                                                                                                                                                 |
| 1-4          | These four bits contain a small number that represents the compressed page size (the <code>KEY_BLOCK_SIZE</code> or “physical block size”) of the tablespace.                                                                                                                                                                                                                                                                                                                                                                                                                               | <ul style="list-style-type: none"> <li>• 0 - Not Compressed</li> <li>• 2 - 1024 Byte Compressed Page Size</li> <li>• 4 - 2048 Byte Compressed Page Size</li> <li>• 6 - 4096 Byte Compressed Page Size</li> <li>• 8 - 8192 Byte Compressed Page Size</li> <li>• 10 - 16384 Byte Compressed Page Size</li> <li>• 12 - 32768 Byte Compressed Page Size</li> <li>• 14 - 65536 Byte Compressed Page Size</li> </ul> |

| Bit Position | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Decimal Numeric Value                                                                                                                                                                                                                                                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5            | This bit is set for file-per-table tablespaces if the row format of the table is <a href="#">DYNAMIC</a> or <a href="#">COMPRESSED</a> . General tablespaces that do not contain compressed tables will have the first 6 bits set to zero, including this bit, making it appear to be the Antelope file format. But actually, general tablespaces may contain any combination of <a href="#">REDUNDANT</a> , <a href="#">COMPACT</a> and <a href="#">DYNAMIC</a> tables. For more information about general tablespaces, see <a href="#">CREATE TABLESPACE</a> .         | <ul style="list-style-type: none"> <li>• 0 - <a href="#">REDUNDANT</a> or <a href="#">COMPACT</a></li> <li>• 32 - <a href="#">DYNAMIC</a> or <a href="#">COMPRESSED</a></li> </ul>                                                                                                                                                               |
| 6-9          | These four bits contain a small number that represents the uncompressed page size (logical page size) of the tablespace. The setting is zero if the logical page size is the original <a href="#">InnoDB</a> default page size of 16K.                                                                                                                                                                                                                                                                                                                                   | <ul style="list-style-type: none"> <li>• 192 - 4096 Byte Logical/ Uncompressed Page Size</li> <li>• 256 - 8192 Byte Logical/ Uncompressed Page Size</li> <li>• 0 - 16384 Byte Logical/ Uncompressed Page size</li> <li>• 384 - 32768 Byte Logical/ Uncompressed Page Size</li> <li>• 448 - 65536 Byte Logical/ Uncompressed Page Size</li> </ul> |
| 10           | This bit is set if the <a href="#">DATA DIRECTORY</a> option is used with <a href="#">CREATE TABLE</a> or <a href="#">ALTER TABLE</a> . This bit is set for file-per-table tablespaces that are located in directories other than the default data directory ( <a href="#">datadir</a> ). For these tables, a <a href="#">tablename.isl</a> file is present in the same location as the <a href="#">tablename.frm</a> file. The <a href="#">tablename.isl</a> file stores the actual directory path to the <a href="#">tablename.ibd</a> file-per-table tablespace file. | <ul style="list-style-type: none"> <li>• 0 - Not a remote file-per-table tablespace</li> <li>• 1024 - A remote file-per-table tablespace</li> </ul>                                                                                                                                                                                              |
| 11           | This bit is set if the tablespace is a shared general tablespace created using <a href="#">CREATE TABLESPACE</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <ul style="list-style-type: none"> <li>• 0 - Table is located in a default location depending on the value of the <a href="#">innodb_file_per_table</a> setting.</li> <li>• 2048 - The table was explicitly assigned to a shared tablespace.</li> </ul>                                                                                          |
| 12           | This bit is set if the tablespace is dedicated to temporary tables. In MySQL 5.7, only the predefined <a href="#">ibtmp1</a> tablespace uses this flag.                                                                                                                                                                                                                                                                                                                                                                                                                  | <ul style="list-style-type: none"> <li>• 0 - The tablespace does not contain temporary tables, so it is not recreated upon startup.</li> <li>• 4096 - The tablespace contains temporary tables and is recreated on startup.</li> </ul>                                                                                                           |

In the following example, table `t1` is created with `innodb_file_per_table=ON`, which creates table `t1` in its own tablespace. When querying `INNODB_SYS_TABLESPACES`, we see that the tablespace has a `FLAG` value of 33. To determine how this value is arrived at, review the bit values described in the preceding table. Bit 0 has a value of 1 because table `t1` uses the [DYNAMIC](#) row format. Bit 5 has

a value of 32 because the tablespace is a file-per-table tablespace that uses a [DYNAMIC](#) row format. Bit position 6-9 is 0 because [innodb\\_page\\_size](#) is set to the default 16K value. The other bit values are not applicable and are therefore set to 0. The values for bit position 0 and bit position 5 add up to a [FLAG](#) value of 33.

```
mysql> use test;
Database changed

mysql> SHOW VARIABLES LIKE 'innodb_file_per_table';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_file_per_table | ON |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW VARIABLES LIKE 'innodb_page_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_page_size | 16384 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET GLOBAL innodb_file_format=Barracuda;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (c1 int) ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.02 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
      SPACE: 75
      NAME: test/t1
      FLAG: 33
      FILE_FORMAT: Barracuda
      ROW_FORMAT: Dynamic
      PAGE_SIZE: 16384
      ZIP_PAGE_SIZE: 0
1 row in set (0.00 sec)
```

## 20.30.16 The INFORMATION\_SCHEMA INNODB\_SYS\_VIRTUAL Table

The [INNODB\\_SYS\\_VIRTUAL](#) table provides metadata about [InnoDB](#) virtual generated columns and columns upon which virtual generated columns are based, equivalent to information in the [SYS\\_VIRTUAL](#) table in the [InnoDB](#) data dictionary.

A row appears in the [INNODB\\_SYS\\_VIRTUAL](#) table for each column upon which a virtual generated column is based.

**Table 20.18 INNODB\_SYS\_VIRTUAL Columns**

| Column name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">TABLE_ID</a> | An identifier representing the table associated with the virtual column; the same value as <a href="#">INNODB_SYS_TABLES.TABLE_ID</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <a href="#">POS</a>      | The position value of the virtual generated column. The value is large because it encodes the column sequence number and ordinal position. The formula used to calculate the value uses a bitwise operation. The formula is <code>((nth virtual generated column for the InnoDB instance + 1) &lt;&lt; 16) + the ordinal position of the virtual generated column</code> . For example, if the first virtual generated column in the <a href="#">InnoDB</a> instance is the third column of the table, the formula is <code>(0 + 1) &lt;&lt; 16) + 2</code> . The first virtual generated column in the <a href="#">InnoDB</a> instance is always number 0. As the third column in the table, the ordinal position of the virtual generated column is 2. Ordinal positions are counted from 0. |

| Column name              | Description                                                                         |
|--------------------------|-------------------------------------------------------------------------------------|
| <a href="#">BASE_POS</a> | The ordinal position of the columns upon which a virtual generated column is based. |

**Example:**

```
mysql> CREATE TABLE `t1` (
  ->   `a` int(11) DEFAULT NULL,
  ->   `b` int(11) DEFAULT NULL,
  ->   `c` int(11) GENERATED ALWAYS AS (a+b) VIRTUAL,
  ->   `h` varchar(10) DEFAULT NULL
  -> ) ENGINE=InnoDB DEFAULT CHARSET=latin1;

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_VIRTUAL
  -> WHERE TABLE_ID IN (SELECT TABLE_ID FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE "t1")
+-----+-----+-----+
| TABLE_ID | POS  | BASE_POS |
+-----+-----+-----+
|         45 | 65538 |         0 |
|         45 | 65538 |         1 |
+-----+-----+-----+
```

**Notes:**

- If a constant value is assigned to a virtual generated column, as in the following example, an entry for the column does not appear in the [INNODB\\_SYS\\_VIRTUAL](#) table. For an entry to appear, a virtual generated column must have a base column.

```
mysql> CREATE TABLE `t1` (
  ->   `a` int(11) DEFAULT NULL,
  ->   `b` int(11) DEFAULT NULL,
  ->   `c` int(11) GENERATED ALWAYS AS (5) VIRTUAL
  -> ) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

However, metadata for such a column appears in the [INNODB\\_SYS\\_COLUMNS](#) table.

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

### 20.30.17 The INFORMATION\_SCHEMA INNODB\_BUFFER\_PAGE Table

The [INNODB\\_BUFFER\\_PAGE](#) table holds information about each [page](#) in the [InnoDB buffer pool](#).

For related usage information and examples, see [Section 14.12.5, "InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables"](#).

**Warning**

Querying the [INNODB\\_BUFFER\\_PAGE](#) table can introduce significant performance overhead. Do not query this table on a production system unless you are aware of the performance impact that your query may have and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and query the [INNODB\\_BUFFER\\_PAGE](#) table on the test instance.

**Table 20.19 INNODB\_BUFFER\_PAGE Columns**

| Column name              | Description                                                                          |
|--------------------------|--------------------------------------------------------------------------------------|
| <a href="#">POOL_ID</a>  | Buffer Pool ID. An identifier to distinguish between multiple buffer pool instances. |
| <a href="#">BLOCK_ID</a> | Buffer Pool Block ID.                                                                |

| Column name         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SPACE               | Tablespace ID. Uses the same value as in <code>INNODB_SYS_TABLES.SPACE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| PAGE_NUMBER         | Page number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PAGE_TYPE           | Page type. One of <code>ALLOCATED</code> (Freshly allocated page), <code>INDEX</code> (B-tree node), <code>UNDO_LOG</code> (Undo log page), <code>INODE</code> (Index node), <code>IBUF_FREE_LIST</code> (Insert buffer free list), <code>IBUF_BITMAP</code> (Insert buffer bitmap), <code>SYSTEM</code> (System page), <code>TRX_SYSTEM</code> (Transaction system data), <code>FILE_SPACE_HEADER</code> (File space header), <code>EXTENT_DESCRIPTOR</code> (Extent descriptor page), <code>BLOB</code> (Uncompressed BLOB page), <code>COMPRESSED_BLOB</code> (First compressed BLOB page), <code>COMPRESSED_BLOB2</code> (Subsequent comp BLOB page), <code>IBUF_INDEX</code> (Insert buffer index), <code>UNKNOWN</code> (unknown). |
| FLUSH_TYPE          | Flush type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| FIX_COUNT           | Number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| IS_HASHED           | Whether hash index has been built on this page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| NEWEST_MODIFICATION | Log Sequence Number of the youngest modification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| OLDEST_MODIFICATION | Log Sequence Number of the oldest modification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ACCESS_TIME         | An abstract number used to judge the first access time of the page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| TABLE_NAME          | Name of the table the page belongs to. This column is only applicable to pages of type <code>INDEX</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| INDEX_NAME          | Name of the index the page belongs to. It can be the name of a clustered index or a secondary index. This column is only applicable to pages of type <code>INDEX</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| NUMBER_RECORDS      | Number of records within the page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DATA_SIZE           | Sum of the sizes of the records. This column is only applicable to pages of type <code>INDEX</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| COMPRESSED_SIZE     | Compressed page size. Null for pages that are not compressed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PAGE_STATE          | Page state. A page with valid data has one of the following states: <code>FILE_PAGE</code> (buffers a page of data from a file), <code>MEMORY</code> (buffers a page from an in-memory object), <code>COMPRESSED</code> . Other possible states (managed by <code>InnoDB</code> ) are: <code>NULL</code> , <code>READY_FOR_USE</code> , <code>NOT_USED</code> , <code>REMOVE_HASH</code> .                                                                                                                                                                                                                                                                                                                                               |
| IO_FIX              | Specifies whether any I/O is pending for this page: <code>IO_NONE</code> = no pending I/O, <code>IO_READ</code> = read pending, <code>IO_WRITE</code> = write pending.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| IS_OLD              | Specifies whether or not the block is in the sublist of old blocks in the LRU list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| FREE_PAGE_CLOCK     | The value of the <code>freed_page_clock</code> counter when the block was the last placed at the head of the LRU list. The <code>freed_page_clock</code> counter tracks the number of blocks removed from the end of the LRU list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE LIMIT 1\G
***** 1. row *****
      POOL_ID: 0
      BLOCK_ID: 0
        SPACE: 97
PAGE_NUMBER: 2473
   PAGE_TYPE: INDEX
    FLUSH_TYPE: 1
     FIX_COUNT: 0
```

```

      IS_HASHED: YES
NEWEST_MODIFICATION: 733855581
OLDEST_MODIFICATION: 0
      ACCESS_TIME: 3378385672
      TABLE_NAME: `employees`.`salaries`
      INDEX_NAME: PRIMARY
      NUMBER_RECORDS: 468
      DATA_SIZE: 14976
COMPRESSED_SIZE: 0
      PAGE_STATE: FILE_PAGE
      IO_FIX: IO_NONE
      IS_OLD: YES
      FREE_PAGE_CLOCK: 66
1 row in set (0.03 sec)

```

**Notes:**

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The [INNODB\\_BUFFER\\_PAGE](#) table reports information about these pages until they are evicted from the buffer pool. For more information about how the [InnoDB](#) manages buffer pool data, see [Section 8.10.1, “The InnoDB Buffer Pool”](#).

## 20.30.18 The INFORMATION\_SCHEMA INNODB\_BUFFER\_PAGE\_LRU Table

The [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table holds information about the pages in the [InnoDB buffer pool](#), in particular how they are ordered in the LRU list that determines which pages to [evict](#) from the buffer pool when it becomes full.

The [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table has the same columns as the [INNODB\\_BUFFER\\_PAGE](#) table, except that the [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table has an [LRU\\_POSITION](#) column instead of a [BLOCK\\_ID](#) column.

For related usage information and examples, see [Section 14.12.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

**Warning**

Querying the [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table can introduce significant performance overhead. Do not query this table on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and query the [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table on the test instance.

**Table 20.20 INNODB\_BUFFER\_PAGE\_LRU Columns**

| Column name                  | Description                                                                          |
|------------------------------|--------------------------------------------------------------------------------------|
| <a href="#">POOL_ID</a>      | Buffer Pool ID. An identifier to distinguish between multiple buffer pool instances. |
| <a href="#">LRU_POSITION</a> | The position of the page in the LRU list.                                            |
| <a href="#">SPACE</a>        | Tablespace ID. Uses the same value as in <a href="#">INNODB_SYS_TABLES.SPACE</a> .   |
| <a href="#">PAGE_NUMBER</a>  | Page number.                                                                         |

| Column name         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PAGE_TYPE           | Page type. One of <code>ALLOCATED</code> (Freshly allocated page), <code>INDEX</code> (B-tree node), <code>UNDO_LOG</code> (Undo log page), <code>INODE</code> (Index node), <code>IBUF_FREE_LIST</code> (Insert buffer free list), <code>IBUF_BITMAP</code> (Insert buffer bitmap), <code>SYSTEM</code> (System page), <code>TRX_SYSTEM</code> (Transaction system data), <code>FILE_SPACE_HEADER</code> (File space header), <code>EXTENT_DESCRIPTOR</code> (Extent descriptor page), <code>BLOB</code> (Uncompressed BLOB page), <code>COMPRESSED_BLOB</code> (First compressed BLOB page), <code>COMPRESSED_BLOB2</code> (Subsequent comp BLOB page), <code>IBUF_INDEX</code> (Insert buffer index), <code>UNKNOWN</code> (unknown). |
| FLUSH_TYPE          | Flush type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| FIX_COUNT           | Number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| IS_HASHED           | Whether hash index has been built on this page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| NEWEST_MODIFICATION | Log Sequence Number of the youngest modification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| OLDEST_MODIFICATION | Log Sequence Number of the oldest modification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ACCESS_TIME         | An abstract number used to judge the first access time of the page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| TABLE_NAME          | Name of the table the page belongs to. This column is only applicable to pages of type <code>INDEX</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| INDEX_NAME          | Name of the index the page belongs to. It can be the name of a clustered index or a secondary index. This column is only applicable to pages of type <code>INDEX</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| NUMBER_RECORDS      | Number of records within the page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DATA_SIZE           | Sum of the sizes of the records. This column is only applicable to pages of type <code>INDEX</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| COMPRESSED_SIZE     | Compressed page size. Null for pages that are not compressed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PAGE_STATE          | Page state. A page with valid data has one of the following states: <code>FILE_PAGE</code> (buffers a page of data from a file), <code>MEMORY</code> (buffers a page from an in-memory object), <code>COMPRESSED</code> . Other possible states (managed by InnoDB) are: <code>NULL</code> , <code>READY_FOR_USE</code> , <code>NOT_USED</code> , <code>REMOVE_HASH</code> .                                                                                                                                                                                                                                                                                                                                                             |
| IO_FIX              | Specifies whether any I/O is pending for this page: <code>IO_NONE</code> = no pending I/O, <code>IO_READ</code> = read pending, <code>IO_WRITE</code> = write pending.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| IS_OLD              | Specifies whether or not the block is in the sublist of old blocks in the LRU list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| FREE_PAGE_CLOCK     | The value of the <code>freed_page_clock</code> counter when the block was the last placed at the head of the LRU list. The <code>freed_page_clock</code> counter tracks the number of blocks removed from the end of the LRU list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU LIMIT 1\G
***** 1. row *****
      POOL_ID: 0
    LRU_POSITION: 0
         SPACE: 97
    PAGE_NUMBER: 1984
     PAGE_TYPE: INDEX
     FLUSH_TYPE: 1
     FIX_COUNT: 0
     IS_HASHED: YES
NEWEST_MODIFICATION: 719490396
OLDEST_MODIFICATION: 0
     ACCESS_TIME: 3378383796
     TABLE_NAME: `employees`.`salaries`
```

```

INDEX_NAME: PRIMARY
NUMBER_RECORDS: 468
DATA_SIZE: 14976
COMPRESSED_SIZE: 0
COMPRESSED: NO
IO_FIX: IO_NONE
IS_OLD: YES
FREE_PAGE_CLOCK: 0
1 row in set (0.02 sec)

```

## Notes

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the [PROCESS](#) privilege to query this table.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes time the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
- Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table reports information about these pages until they are evicted from the buffer pool. For more information about how the [InnoDB](#) manages buffer pool data, see [Section 8.10.1, “The InnoDB Buffer Pool”](#).

## 20.30.19 The INFORMATION\_SCHEMA INNODB\_BUFFER\_POOL\_STATS Table

The [INNODB\\_BUFFER\\_POOL\\_STATS](#) table provides much of the same buffer pool information provided in [SHOW ENGINE INNODB STATUS](#) output. Much of the same information may also be obtained using [InnoDB](#) buffer pool [server status variables](#).

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the [sublists](#) at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of [eviction](#).

For related usage information and examples, see [Section 14.12.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

**Table 20.21 INNODB\_BUFFER\_POOL\_STATS Columns**

| Column name                        | Description                                                                                                                    |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">POOL_ID</a>            | Buffer Pool ID. A unique identifier to distinguish between multiple buffer pool instances.                                     |
| <a href="#">POOL_SIZE</a>          | The <a href="#">InnoDB</a> buffer pool size in pages.                                                                          |
| <a href="#">FREE_BUFFERS</a>       | The number of free pages in the <a href="#">InnoDB</a> buffer pool                                                             |
| <a href="#">DATABASE_PAGES</a>     | The number of pages in the <a href="#">InnoDB</a> buffer pool containing data. The number includes both dirty and clean pages. |
| <a href="#">OLD_DATABASE_PAGES</a> | The number of pages in the <code>old</code> buffer pool sublist.                                                               |

| Column name                      | Description                                                                                                                                                      |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MODIFIED_DATABASE_PAGES          | The number of modified (dirty) database pages                                                                                                                    |
| PENDING_DECOMPRESS               | The number of pages pending decompression                                                                                                                        |
| PENDING_READS                    | The number of pending reads                                                                                                                                      |
| PENDING_FLUSH_LRU                | The number of pages pending flush in the LRU                                                                                                                     |
| PENDING_FLUSH_LIST               | The number of pages pending flush in the flush list                                                                                                              |
| PAGES_MADE_YOUNG                 | The number of pages made young                                                                                                                                   |
| PAGES_NOT_MADE_YOUNG             | The number of pages not made young                                                                                                                               |
| PAGES_MADE_YOUNG_RATE            | The number of pages made young per second (pages made young since the last printout / time elapsed)                                                              |
| PAGES_MADE_NOT_YOUNG_RATE        | The number of pages not made young per second (pages not made young since the last printout / time elapsed)                                                      |
| NUMBER_PAGES_READ                | The number of pages read                                                                                                                                         |
| NUMBER_PAGES_CREATED             | The number of pages created                                                                                                                                      |
| NUMBER_PAGES_WRITTEN             | The number of pages written                                                                                                                                      |
| PAGES_READ_RATE                  | The number of pages read per second (pages read since the last printout / time elapsed)                                                                          |
| PAGES_CREATE_RATE                | The number of pages created per second (pages created since the last printout / time elapsed)                                                                    |
| PAGES_WRITTEN_RATE               | The number of pages written per second (pages written since the last printout / time elapsed)                                                                    |
| NUMBER_PAGES_GET                 | The number of logical read requests.                                                                                                                             |
| HIT_RATE                         | The buffer pool hit rate                                                                                                                                         |
| YOUNG_MAKE_PER_THOUSAND_GETS     | The number of pages made young per thousand gets                                                                                                                 |
| NOT_YOUNG_MAKE_PER_THOUSAND_GETS | The number of pages not made young per thousand gets                                                                                                             |
| NUMBER_PAGES_READ_AHEAD          | The number of pages read ahead                                                                                                                                   |
| NUMBER_READ_AHEAD_EVICTED        | The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries. |
| READ_AHEAD_RATE                  | The read ahead rate per second (pages read ahead since the last printout / time elapsed)                                                                         |
| READ_AHEAD_EVICTED_RATE          | The number of read ahead pages evicted without access per second (read ahead pages not accessed since the last printout / time elapsed)                          |
| LRU_IO_TOTAL                     | LRU IO total                                                                                                                                                     |
| LRU_IO_CURRENT                   | LRU IO for the current interval                                                                                                                                  |
| UNCOMPRESS_TOTAL                 | Total number of pages decompressed                                                                                                                               |
| UNCOMPRESS_CURRENT               | The number of pages decompressed in the current interval                                                                                                         |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS\G
***** 1. row *****
      POOL_ID: 0
      POOL_SIZE: 8192
      FREE_BUFFERS: 1
      DATABASE_PAGES: 8085
      OLD_DATABASE_PAGES: 2964
      MODIFIED_DATABASE_PAGES: 0
      PENDING_DECOMPRESS: 0
      PENDING_READS: 0
```

```

PENDING_FLUSH_LRU: 0
PENDING_FLUSH_LIST: 0
PAGES_MADE_YOUNG: 22821
PAGES_NOT_MADE_YOUNG: 3544303
PAGES_MADE_YOUNG_RATE: 357.62602199870594
PAGES_MADE_NOT_YOUNG_RATE: 0
NUMBER_PAGES_READ: 2389
NUMBER_PAGES_CREATED: 12385
NUMBER_PAGES_WRITTEN: 13111
PAGES_READ_RATE: 0
PAGES_CREATE_RATE: 0
PAGES_WRITTEN_RATE: 0
NUMBER_PAGES_GET: 33322210
HIT_RATE: 1000
YOUNG_MAKE_PER_THOUSAND_GETS: 18
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
NUMBER_PAGES_READ_AHEAD: 2024
NUMBER_READ_AHEAD_EVICTED: 0
READ_AHEAD_RATE: 0
READ_AHEAD_EVICTED_RATE: 0
LRU_IO_TOTAL: 0
LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0
1 row in set (0.00 sec)

```

**Notes:**

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

### 20.30.20 The INFORMATION\_SCHEMA INNODB\_METRICS Table

This [INFORMATION\\_SCHEMA](#) table presents a wide variety of [InnoDB](#) performance information, complementing the specific focus areas of the [PERFORMANCE\\_SCHEMA](#) tables for [InnoDB](#). With simple queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the [InnoDB](#) source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

By default, relatively little data is collected. To start, stop, and reset counters, you set one of the configuration options [innodb\\_monitor\\_enable](#), [innodb\\_monitor\\_disable](#), [innodb\\_monitor\\_reset](#), or [innodb\\_monitor\\_reset\\_all](#), using the name of the counter, the name of the module, a wildcard match for such a name using the “%” character, or the special keyword [all](#).

For usage information, see [Section 14.12.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

**Table 20.22 INNODB\_METRICS Columns**

| Column name               | Description                                                                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">NAME</a>      | Unique name for the counter.                                                                                                                                                            |
| <a href="#">SUBSYSTEM</a> | The aspect of <a href="#">InnoDB</a> that the metric applies to. See the list following the table for the corresponding module names to use with the <a href="#">SET GLOBAL</a> syntax. |
| <a href="#">COUNT</a>     | Value since the counter is enabled.                                                                                                                                                     |

| Column name                     | Description                                                                                                                                                                                                                                                                                               |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">MAX_COUNT</a>       | Maximum value since the counter is enabled.                                                                                                                                                                                                                                                               |
| <a href="#">MIN_COUNT</a>       | Minimum value since the counter is enabled.                                                                                                                                                                                                                                                               |
| <a href="#">AVG_COUNT</a>       | Average value since the counter is enabled.                                                                                                                                                                                                                                                               |
| <a href="#">COUNT_RESET</a>     | Counter value since it was last reset. (The <a href="#">_RESET</a> fields act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in the <a href="#">COUNT</a> , <a href="#">MAX_COUNT</a> , and so on fields.) |
| <a href="#">MAX_COUNT_RESET</a> | Maximum counter value since it was last reset.                                                                                                                                                                                                                                                            |
| <a href="#">MIN_COUNT_RESET</a> | Minimum counter value since it was last reset.                                                                                                                                                                                                                                                            |
| <a href="#">AVG_COUNT_RESET</a> | Average counter value since it was last reset.                                                                                                                                                                                                                                                            |
| <a href="#">TIME_ENABLED</a>    | Timestamp of last start.                                                                                                                                                                                                                                                                                  |
| <a href="#">TIME_DISABLED</a>   | Timestamp of last stop.                                                                                                                                                                                                                                                                                   |
| <a href="#">TIME_ELAPSED</a>    | Elapsed time in seconds since the counter started.                                                                                                                                                                                                                                                        |
| <a href="#">TIME_RESET</a>      | Timestamp of last stop.                                                                                                                                                                                                                                                                                   |
| <a href="#">STATUS</a>          | Whether the counter is still running ( <a href="#">enabled</a> ) or stopped ( <a href="#">disabled</a> ).                                                                                                                                                                                                 |
| <a href="#">TYPE</a>            | Whether the item is a cumulative counter, or measures the current value of some resource.                                                                                                                                                                                                                 |
| <a href="#">COMMENT</a>         | Counter description.                                                                                                                                                                                                                                                                                      |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.046153846153846156
    COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
    TIME_ELAPSED: 65
    TIME_RESET: NULL
      STATUS: enabled
      TYPE: status_counter
    COMMENT: Number of rows inserted
1 row in set (0.00 sec)
```

**Notes:**

- You must have the [PROCESS](#) privilege to query this table.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.

## 20.30.21 The INFORMATION\_SCHEMA INNODB\_FT\_CONFIG Table

The [INNODB\\_FT\\_CONFIG](#) table displays metadata about the [FULLTEXT](#) index and associated processing for an [InnoDB](#) table.

Before you query this table, set the configuration variable [innodb\\_ft\\_aux\\_table](#) to the name (including the database name) of the table that contains the [FULLTEXT](#) index, for example [test/articles](#).

For related usage information and examples, see [Section 14.12.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

**Table 20.23 INNODB\_FT\_CONFIG Columns**

| Column name        | Description                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>KEY</code>   | The name designating an item of metadata for an <code>InnoDB</code> table containing a <code>FULLTEXT</code> index.                                                                          |
| <code>VALUE</code> | The value associated with the corresponding <code>KEY</code> column, reflecting some limit or current value for an aspect of a <code>FULLTEXT</code> index for an <code>InnoDB</code> table. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY                | VALUE                |
+-----+-----+
optimize_checkpoint_limit	180
synced_doc_id	0
stopword_table_name	test/my_stopwords
use_stopword	1
+-----+-----+
```

**Notes:**

- This table is only intended for internal configuration. It is not intended for statistical information purposes.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- The values for the `KEY` column might evolve depending on the needs for performance tuning and debugging for `InnoDB` full-text processing. The key values include:
  - `optimize_checkpoint_limit`: The number of seconds after which an `OPTIMIZE TABLE` run will stop.
  - `synced_doc_id`: The next `DOC_ID` to be issued.
  - `stopword_table_name`: The `database/table` name for a user defined stopword table. This field appears empty if there is no user-defined stopword table.
  - `use_stopword`: Indicates whether or not a stopword table is used, which is defined when the `FULLTEXT` index is created.
- For more information about `InnoDB FULLTEXT` search, see [Section 14.2.7.3, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

## 20.30.22 The INFORMATION\_SCHEMA INNODB\_FT\_DEFAULT\_STOPWORD Table

The `INNODB_FT_DEFAULT_STOPWORD` table holds a list of `stopwords` that are used by default when creating a `FULLTEXT` index on an `InnoDB` table. For information about the default `InnoDB` stopword list and how to define your own stopword lists, see [Section 12.9.4, “Full-Text Stopwords”](#).

For related usage information and examples, see [Section 14.12.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

Table 20.24 INNODB\_FT\_DEFAULT\_STOPWORD Columns

| Column name | Description                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value       | A word that is used by default as a stopword for <code>FULLTEXT</code> indexes on <code>InnoDB</code> tables. Not used if you override the default stopword processing with either the <code>innodb_ft_server_stopword_table</code> or the <code>innodb_ft_user_stopword_table</code> option. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
+-----+
| value |
+-----+
| a     |
| about |
| an    |

| who   |
| will  |
| with  |
| und   |
| the   |
| www   |
+-----+
36 rows in set (0.00 sec)
```

**Notes:**

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For more information about `InnoDB FULLTEXT` search, see [Section 14.2.7.3, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

**20.30.23 The INFORMATION\_SCHEMA INNODB\_FT\_INDEX\_TABLE Table**

The `INNODB_FT_INDEX_TABLE` table displays information about the inverted index used to process text searches against the `FULLTEXT` index of an `InnoDB` table.

For related usage information and examples, see [Section 14.12.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

Before you query this table, set the configuration variable `innodb_ft_aux_table` to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

**Table 20.25 INNODB\_FT\_INDEX\_TABLE Columns**

| Column name               | Description                                                                                                                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD</code>         | A word extracted from the text of the columns that are part of a <code>FULLTEXT</code> .                                                                                                                                                                        |
| <code>FIRST_DOC_ID</code> | The first document ID that this word appears in the <code>FULLTEXT</code> index.                                                                                                                                                                                |
| <code>LAST_DOC_ID</code>  | The last document ID that this word appears in the <code>FULLTEXT</code> index.                                                                                                                                                                                 |
| <code>DOC_COUNT</code>    | The number of rows this word appears in the <code>FULLTEXT</code> index. The same word can occur several times within the cache table, once for each combination of <code>DOC_ID</code> and <code>POSITION</code> values.                                       |
| <code>DOC_ID</code>       | The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column. |
| <code>POSITION</code>     | The position of this particular instance of the word within the relevant document identified by the <code>DOC_ID</code> value.                                                                                                                                  |

**Notes:**

- This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table`. The following example demonstrates how to use the `innodb_ft_aux_table` option to show information about a `FULLTEXT` index for a specified table. Before information for newly inserted rows appears in `INNODB_FT_INDEX_TABLE`, the `FULLTEXT` index cache must be flushed to disk. This is accomplished by running an `OPTIMIZE TABLE` operation on the indexed table with `innodb_optimize_fulltext_only=ON`.

```
mysql> use test;

mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.00 sec)

mysql> OPTIMIZE TABLE articles;
+-----+-----+-----+-----+
| Table          | Op       | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.articles | optimize | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> USE INFORMATION_SCHEMA;

mysql> SELECT word, doc_count, doc_id, position FROM INNODB_FT_INDEX_TABLE LIMIT 5;
+-----+-----+-----+-----+
| word      | doc_count | doc_id | position |
+-----+-----+-----+-----+
1001	1	4	0
after	1	2	22
comparison	1	5	44
configured	1	6	20
database	2	1	31
+-----+-----+-----+-----+
```

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 14.2.7.3, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

## 20.30.24 The INFORMATION\_SCHEMA INNODB\_FT\_INDEX\_CACHE Table

**INNODB\_FT\_INDEX\_CACHE:** Contains token information about newly inserted rows in a [FULLTEXT](#) index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when [OPTIMIZE TABLE](#) is run, when the server is shut down, or when the cache size exceeds a limit defined by [innodb\\_ft\\_cache\\_size](#) or [innodb\\_ft\\_total\\_cache\\_size](#).

Before you query this table, set the configuration variable [innodb\\_ft\\_aux\\_table](#) to the name (including the database name) of the table that contains the [FULLTEXT](#) index, for example [test/articles](#).

For related usage information and examples, see [Section 14.12.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

**Table 20.26 INNODB\_FT\_INDEX\_CACHE Columns**

| Column name                  | Description                                                                                                                                                                                                                                                                       |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">WORD</a>         | A word extracted from the text of a newly inserted row.                                                                                                                                                                                                                           |
| <a href="#">FIRST_DOC_ID</a> | The first document ID that this word appears in the <a href="#">FULLTEXT</a> index.                                                                                                                                                                                               |
| <a href="#">LAST_DOC_ID</a>  | The last document ID that this word appears in the <a href="#">FULLTEXT</a> index.                                                                                                                                                                                                |
| <a href="#">DOC_COUNT</a>    | The number of rows this word appears in the <a href="#">FULLTEXT</a> index. The same word can occur several times within the cache table, once for each combination of <a href="#">DOC_ID</a> and <a href="#">POSITION</a> values.                                                |
| <a href="#">DOC_ID</a>       | The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <a href="#">InnoDB</a> when the table does not contain a suitable column.                     |
| <a href="#">POSITION</a>     | The position of this particular instance of the word within the relevant document identified by the <a href="#">DOC_ID</a> value. The value does not represent an absolute position; it is an offset added to the <a href="#">POSITION</a> of the previous instance of that word. |

### Notes:

- This table initially appears empty, until you set the value of the configuration variable [innodb\\_ft\\_aux\\_table](#). The following example demonstrates how to use the [innodb\\_ft\\_aux\\_table](#) option to show information about a [FULLTEXT](#) index for a specified table.

```

mysql> USE test;

mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
Query OK, 0 rows affected (0.00 sec)

mysql> USE INFORMATION_SCHEMA;

mysql> SELECT word, doc_count, doc_id, position FROM INNODB_FT_INDEX_CACHE LIMIT 5;
+-----+-----+-----+-----+
| word      | doc_count | doc_id | position |
+-----+-----+-----+-----+
1001	1	4	0
after	1	2	22
comparison	1	5	44
configured	1	6	20
database	2	1	31
+-----+-----+-----+-----+

```

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 14.2.7.3, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

## 20.30.25 The INFORMATION\_SCHEMA INNODB\_FT\_DELETED Table

The [INNODB\\_FT\\_DELETED](#) table records rows that are deleted from the [FULLTEXT](#) index for an [InnoDB](#) table. To avoid expensive index reorganization during DML operations for an [InnoDB FULLTEXT](#) index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue the [OPTIMIZE TABLE](#) statement for the [InnoDB](#) table. See [Optimizing InnoDB Full-Text Indexes](#) for more information.

This table initially appears empty, until you set the value of the configuration variable [innodb\\_ft\\_aux\\_table](#) to the name (including the database name) of the table that contains the [FULLTEXT](#) index, for example [test/articles](#).

For related usage information and examples, see [Section 14.12.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

**Table 20.27 INNODB\_FT\_DELETED Columns**

| Column name            | Description                                                                                                                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">DOC_ID</a> | The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <a href="#">InnoDB</a> when the table does |

| Column name | Description                                                                                                                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | not contain a suitable column. This value is used to skip rows in the <code>innodb_ft_index_table</code> table, when you do text searches before data for deleted rows is physically removed from the <code>FULLTEXT</code> index by an <code>OPTIMIZE TABLE</code> statement. See <a href="#">Optimizing InnoDB Full-Text Indexes</a> for more information. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_BEING_DELETED;
+-----+
| DOC_ID |
+-----+
|      6 |
|      7 |
|      8 |
+-----+
```

**Notes:**

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For more information about `InnoDB FULLTEXT` search, see [Section 14.2.7.3, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

## 20.30.26 The INFORMATION\_SCHEMA INNODB\_FT\_BEING\_DELETED Table

The `INNODB_FT_BEING_DELETED` table is a snapshot of the `INNODB_FT_DELETED` table that is only used during an `OPTIMIZE TABLE` maintenance operation. When `OPTIMIZE TABLE` is run, the `INNODB_FT_BEING_DELETED` table is emptied, and `DOC_ID`s are removed from the `INNODB_FT_DELETED` table. Because the contents of `INNODB_FT_BEING_DELETED` typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running `OPTIMIZE TABLE` on tables with `FULLTEXT` indexes, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table`. The output appears similar to the example provided for the `INNODB_FT_DELETED` table.

For related usage information and examples, see [Section 14.12.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

**Table 20.28 INNODB\_FT\_BEING\_DELETED Columns**

| Column name         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>DOC_ID</code> | The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column. This value is used to skip rows in the <code>innodb_ft_index_table</code> table, when you do text searches before data for deleted rows is physically removed from the <code>FULLTEXT</code> index by an <code>OPTIMIZE TABLE</code> statement. See <a href="#">Optimizing InnoDB Full-Text Indexes</a> for more information. |

**Notes:**

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.

- You must have the `PROCESS` privilege to query this table.
- For more information about `InnoDB FULLTEXT` search, see [Section 14.2.7.3, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

### 20.30.27 The INFORMATION\_SCHEMA INNODB\_TEMP\_TABLE\_INFO Table

`INNODB_TEMP_TABLE_INFO` contains metadata about active `InnoDB` temporary tables. With the exception of optimized internal temporary tables used by `InnoDB`, `INNODB_TEMP_TABLE_INFO` reports on all user and system-created temporary tables that are active within a given `InnoDB` instance. The table is maintained in memory and not persisted to disk.

Prior to the introduction of the `INNODB_TEMP_TABLE_INFO` table in MySQL 5.7.1, `InnoDB` temporary table metadata was stored in `InnoDB` system tables.

For usage information and examples, see [Section 14.12.7, “InnoDB INFORMATION\\_SCHEMA Temporary Table Information Table”](#).

**Table 20.29** INNODB\_TEMP\_TABLE\_INFO Columns

| Column name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TABLE_ID</code>        | The table ID of the active temporary table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>NAME</code>            | The name of the active temporary table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>N_COLS</code>          | The number of columns in the temporary table. The number always includes three hidden columns created by <code>InnoDB</code> ( <code>DB_ROW_ID</code> , <code>DB_TRX_ID</code> , and <code>DB_ROLL_PTR</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>SPACE</code>           | The tablespace identifier (a numerical value) for the tablespace in which the temporary table resides. As of MySQL 5.7.1, all non-compressed <code>InnoDB</code> temporary tables reside in a shared temporary table tablespace, as defined by <code>innodb_temp_data_file_path</code> . By default the shared temporary tablespace is named <code>ibtmp1</code> and located in the <code>data</code> directory. Compressed temporary tables reside in separate per-table tablespaces located in the temporary file directory, as defined by <code>tmpdir</code> . The <code>SPACE</code> ID is always a non-zero value and is dynamically generated on server restart. |
| <code>PER_TABLE_SPACE</code> | A value of <code>TRUE</code> indicates that the temporary table resides in a separate per-table tablespace. A value of <code>FALSE</code> indicates that the temporary table resides in the shared temporary tablespace.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>IS_COMPRESSED</code>   | A value of <code>TRUE</code> indicates that the temporary table is compressed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Example:**

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 32
         NAME: #sqlaf56_2_0
        N_COLS: 4
         SPACE: 19
PER_TABLE_TABLESPACE: FALSE
      IS_COMPRESSED: FALSE
1 row in set (0.00 sec)
```

**Notes:**

- This table is primarily useful for expert level monitoring.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.

- You must have the `PROCESS` privilege to query this table.

## 20.31 Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS                |
| COLLATIONS                    |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                      |
| COLUMN_PRIVILEGES             |
| ENGINES                      |
| EVENTS                       |
| FILES                         |
| GLOBAL_STATUS                 |
| GLOBAL_VARIABLES              |
| KEY_COLUMN_USAGE              |
| PARTITIONS                    |
| PLUGINS                      |
| PROCESSLIST                   |
| REFERENTIAL_CONSTRAINTS      |
| ROUTINES                     |
| SCHEMATA                      |
| SCHEMA_PRIVILEGES             |
| SESSION_STATUS                |
| SESSION_VARIABLES             |
| STATISTICS                    |
| TABLES                      |
| TABLE_CONSTRAINTS            |
| TABLE_PRIVILEGES             |
| TRIGGERS                      |
| USER_PRIVILEGES               |
| VIEWS                         |
+-----+
27 rows in set (0.00 sec)
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed also permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
```

```
SHOW TRIGGERS
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
big5	Big5 Traditional Chinese	big5_chinese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
cp850	DOS West European	cp850_general_ci	1
hp8	HP West European	hp8_english_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
...			
```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string `'japanese'`:

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3
+-----+-----+-----+-----+
```

This statement displays the multibyte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
big5	Big5 Traditional Chinese	big5_chinese_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
utf8	UTF-8 Unicode	utf8_general_ci	3
ucs2	UCS-2 Unicode	ucs2_general_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3
+-----+-----+-----+-----+
```

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level. The Performance Schema has these characteristics:

- The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the [PERFORMANCE\\_SCHEMA](#) storage engine and the [performance\\_schema](#) database. The Performance Schema focuses primarily on performance data. This differs from [INFORMATION\\_SCHEMA](#), which serves for inspection of metadata.
- The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Event collection provides access to information about synchronization calls (such as for mutexes) file and table I/O, table locks, and so forth for the server and for several storage engines.

- Performance Schema events are distinct from events written to the server's binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).
- Performance Schema events are specific to a given instance of the MySQL Server. Performance Schema tables are considered local to the server, and changes to them are not replicated or written to the binary log.
- Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took. Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.
- The `PERFORMANCE_SCHEMA` storage engine collects event data using “instrumentation points” in server source code.
- Collected events are stored in tables in the `performance_schema` database. These tables can be queried using `SELECT` statements like other tables.
- Performance Schema configuration can be modified dynamically by updating tables in the `performance_schema` database through SQL statements. Configuration changes affect data collection immediately.
- Tables in the `performance_schema` database are views or temporary tables that use no persistent on-disk storage.
- Monitoring is available on all platforms supported by MySQL.

Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also [Section C.8, “Restrictions on Performance Schema”](#).

- Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

- Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by `EXPLAIN`) to change.
- Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.
- The parser is unchanged. There are no new keywords or statements.
- Execution of server code proceeds normally even if the Performance Schema fails internally.
- When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.
- It is easy to add new instrumentation points.
- Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code will continue to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

#### Note

The MySQL `sys` schema is a set of objects that provides convenient access to data collected by the Performance Schema. The `sys` schema is installed by

default as of MySQL 5.7.7. For usage instructions, see [Chapter 22, MySQL sys Schema](#).

## 21.1 Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see [Section 21.16, “Using the Performance Schema to Diagnose Problems”](#).

For the Performance Schema to be available, support for it must have been configured when MySQL was built. You can verify whether this is the case by checking the server's help output. If the Performance Schema is available, the output will mention several variables with names that begin with `performance_schema`:

```
shell> mysqld --verbose --help
...
--performance_schema
           Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
           Number of rows in events_waits_history_long.
...
```

If such variables do not appear in the output, your server has not been built to support the Performance Schema. In this case, see [Section 21.2, “Performance Schema Configuration”](#).

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

When the server starts, it sees `performance_schema` and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
mysql> SHOW VARIABLES LIKE 'performance_schema';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON   |
+-----+-----+
```

A value of `ON` means that the Performance Schema initialized successfully and is ready for use. A value of `OFF` means that some error occurred. Check the server error log for information about what went wrong.

The Performance Schema is implemented as a storage engine. If this engine is available (which you should already have checked earlier), you should see it listed with a `SUPPORT` value of `YES` in the output from the `INFORMATION_SCHEMA.ENGINES` table or the `SHOW ENGINES` statement:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE='PERFORMANCE_SCHEMA'\G
***** 1. row *****
ENGINE: PERFORMANCE_SCHEMA
SUPPORT: YES
COMMENT: Performance Schema
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO

mysql> SHOW ENGINES\G
...
```

```

Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
Transactions: NO
  XA: NO
Savepoints: NO
...

```

The `PERFORMANCE_SCHEMA` storage engine operates on tables in the `performance_schema` database. You can make `performance_schema` the default database so that references to its tables need not be qualified with the database name:

```
mysql> USE performance_schema;
```

Many examples in this chapter assume `performance_schema` as the default database.

Performance Schema tables are stored in the `performance_schema` database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from the `INFORMATION_SCHEMA` database or by using `SHOW` statements. For example, use either of these statements to see what Performance Schema tables exist:

```

mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_SCHEMA = 'performance_schema';
+-----+
| TABLE_NAME |
+-----+
| accounts |
| cond_instances |
| events_stages_current |
| events_stages_history |
| events_stages_history_long |
| events_stages_summary_by_account_by_event_name |
| events_stages_summary_by_host_by_event_name |
| events_stages_summary_by_thread_by_event_name |
| events_stages_summary_by_user_by_event_name |
| events_stages_summary_global_by_event_name |
| events_statements_current |
| events_statements_history |
| events_statements_history_long |
| ... |
| file_instances |
| file_summary_by_event_name |
| file_summary_by_instance |
| host_cache |
| hosts |
| memory_summary_by_account_by_event_name |
| memory_summary_by_host_by_event_name |
| memory_summary_by_thread_by_event_name |
| memory_summary_by_user_by_event_name |
| memory_summary_global_by_event_name |
| metadata_locks |
| mutex_instances |
| objects_summary_global_by_type |
| performance_timers |
| replication_connection_configuration |
| replication_connection_status |
| replication_applier_configuration |
| replication_applier_status |
| replication_applier_status_by_coordinator |
| replication_applier_status_by_worker |
| rlock_instances |
| session_account_connect_attrs |
| session_connect_attrs |
| setup_actors |
| setup_consumers |
| setup_instruments |
| setup_objects |
| setup_timers |

```

```

| socket_instances
| socket_summary_by_event_name
| socket_summary_by_instance
| table_handles
| table_io_waits_summary_by_index_usage
| table_io_waits_summary_by_table
| table_lock_waits_summary_by_table
| threads
| users
+-----+
mysql> SHOW TABLES FROM performance_schema;
+-----+
| Tables_in_performance_schema
+-----+
| accounts
| cond_instances
| events_stages_current
| events_stages_history
| events_stages_history_long
| ...

```

The number of Performance Schema tables is expected to increase over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```

mysql> SHOW CREATE TABLE setup_timers\G
***** 1. row *****
      Table: setup_timers
Create Table: CREATE TABLE `setup_timers` (
  `NAME` varchar(64) NOT NULL,
  `TIMER_NAME` enum('CYCLE','NANOSECOND','MICROSECOND','MILLISECOND','TICK')
  NOT NULL
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8

```

Table structure is also available by selecting from tables such as `INFORMATION_SCHEMA.COLUMNS` or by using statements such as `SHOW COLUMNS`.

Tables in the `performance_schema` database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration) information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see [Section 21.9, “Performance Schema Table Descriptions”](#).

Initially, not all instruments and consumers are enabled, so the performance schema does not collect all events. To turn all of these on and enable event timing, execute two statements (the row counts may differ depending on MySQL version):

```

mysql> UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES';
Query OK, 560 rows affected (0.04 sec)
mysql> UPDATE setup_consumers SET ENABLED = 'YES';
Query OK, 10 rows affected (0.00 sec)

```

To see what the server is doing at the moment, examine the `events_waits_current` table. It contains one row per thread showing each thread's most recent monitored event:

```

mysql> SELECT * FROM events_waits_current\G
***** 1. row *****
      THREAD_ID: 0
      EVENT_ID: 5523
      EVENT_NAME: wait/synch/mutex/mysys/THR_LOCK::mutex
      SOURCE: thr_lock.c:525

```

```

TIMER_START: 201660494489586
TIMER_END: 201660494576112
TIMER_WAIT: 86526
  SPINS: NULL
OBJECT_SCHEMA: NULL
OBJECT_NAME: NULL
OBJECT_TYPE: NULL
OBJECT_INSTANCE_BEGIN: 142270668
NESTING_EVENT_ID: NULL
  OPERATION: lock
NUMBER_OF_BYTES: NULL
  FLAGS: 0
...

```

This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on `THR_LOCK::mutex`, a mutex in the `mysys` subsystem. The first few columns provide the following information:

- The ID columns indicate which thread the event comes from and the event number.
- `EVENT_NAME` indicates what was instrumented and `SOURCE` indicates which source file contains the instrumented code.
- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the `TIMER_END` and `TIMER_WAIT` values are `NULL`. Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The `events_waits_history` and `events_waits_history_long` tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```

mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
-> FROM events_waits_history WHERE THREAD_ID = 13
-> ORDER BY EVENT_ID;
+-----+-----+-----+
| EVENT_ID | EVENT_NAME                                     | TIMER_WAIT |
+-----+-----+-----+
86	wait/synch/mutex/mysys/THR_LOCK::mutex	686322
87	wait/synch/mutex/mysys/THR_LOCK_malloc	320535
88	wait/synch/mutex/mysys/THR_LOCK_malloc	339390
89	wait/synch/mutex/mysys/THR_LOCK_malloc	377100
90	wait/synch/mutex/sql/LOCK_plugin	614673
91	wait/synch/mutex/sql/LOCK_open	659925
92	wait/synch/mutex/sql/THD::LOCK_thd_data	494001
93	wait/synch/mutex/mysys/THR_LOCK_malloc	222489
94	wait/synch/mutex/mysys/THR_LOCK_malloc	214947
95	wait/synch/mutex/mysys/LOCK_alarm	312993
+-----+-----+-----+

```

As new events are added to a history table, older events are discarded if the table is full.

Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the `COUNT_STAR` or `SUM_TIMER_WAIT` column, which correspond to a `COUNT(*)` or `SUM(TIMER_WAIT)` value, respectively, calculated over all events:

```

mysql> SELECT EVENT_NAME, COUNT_STAR
-> FROM events_waits_summary_global_by_event_name
-> ORDER BY COUNT_STAR DESC LIMIT 10;
+-----+-----+
| EVENT_NAME                                     | COUNT_STAR |
+-----+-----+

```

```

+-----+-----+
wait/synch/mutex/mysys/THR_LOCK_malloc	6419
wait/io/file/sql/FRM	452
wait/synch/mutex/sql/LOCK_plugin	337
wait/synch/mutex/mysys/THR_LOCK_open	187
wait/synch/mutex/mysys/LOCK_alarm	147
wait/synch/mutex/sql/THD::LOCK_thd_data	115
wait/io/file/myisam/kfile	102
wait/synch/mutex/sql/LOCK_global_system_variables	89
wait/synch/mutex/mysys/THR_LOCK::mutex	89
wait/synch/mutex/sql/LOCK_open	88
+-----+-----+

mysql> SELECT EVENT_NAME, SUM_TIMER_WAIT
-> FROM events_waits_summary_global_by_event_name
-> ORDER BY SUM_TIMER_WAIT DESC LIMIT 10;

+-----+-----+
| EVENT_NAME | SUM_TIMER_WAIT |
+-----+-----+
wait/io/file/sql/MYSQL_LOG	1599816582
wait/synch/mutex/mysys/THR_LOCK_malloc	1530083250
wait/io/file/sql/binlog_index	1385291934
wait/io/file/sql/FRM	1292823243
wait/io/file/myisam/kfile	411193611
wait/io/file/myisam/dfile	322401645
wait/synch/mutex/mysys/LOCK_alarm	145126935
wait/io/file/sql/casetest	104324715
wait/synch/mutex/sql/LOCK_plugin	86027823
wait/io/file/sql/pid	72591750
+-----+-----+

```

These results show that the `THR_LOCK_malloc` mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

#### Note

The `THR_LOCK_malloc` mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.

Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the `file_instances` table lists instances of instruments for file I/O operations and their associated files:

```

mysql> SELECT * FROM file_instances\G
***** 1. row *****
FILE_NAME: /opt/mysql-log/60500/binlog.000007
EVENT_NAME: wait/io/file/sql/binlog
OPEN_COUNT: 0
***** 2. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/tables_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
***** 3. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/columns_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
...

```

Setup tables are used to configure and display monitoring characteristics. For example, to see which event timers are selected, query the `setup_timers` tables:

```

mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| idle | MICROSECOND |

```

|             |            |
|-------------|------------|
| wait        | CYCLE      |
| stage       | NANOSECOND |
| statement   | NANOSECOND |
| transaction | NANOSECOND |

`setup_instruments` lists the set of instruments for which events can be collected and shows which of them are enabled:

```
mysql> SELECT * FROM setup_instruments;
```

| NAME                                              | ENABLED | TIMED |
|---------------------------------------------------|---------|-------|
| ...                                               |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...                                               |         |       |
| wait/synch/rwlock/sql/LOCK_grant                  | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger         | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect       | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave         | YES     | YES   |
| ...                                               |         |       |
| wait/io/file/sql/binlog                           | YES     | YES   |
| wait/io/file/sql/binlog_index                     | YES     | YES   |
| wait/io/file/sql/casetest                         | YES     | YES   |
| wait/io/file/sql/dbopt                            | YES     | YES   |
| ...                                               |         |       |

To understand how to interpret instrument names, see [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

To control whether events are collected for an instrument, set its `ENABLED` value to `YES` or `NO`. For example:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME = 'wait/synch/mutex/sql/LOCK_mysql_create_db';
```

The Performance Schema uses collected events to update tables in the `performance_schema` database, which act as “consumers” of event information. The `setup_consumers` table lists the available consumers and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
```

| NAME                             | ENABLED |
|----------------------------------|---------|
| events_stages_current            | NO      |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | YES     |
| events_statements_history_long   | NO      |
| events_transactions_current      | NO      |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |
| events_waits_current             | NO      |
| events_waits_history             | NO      |
| events_waits_history_long        | NO      |
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| statements_digest                | YES     |

To control whether the Performance Schema maintains a consumer as a destination for event information, set its `ENABLED` value.

For more information about the setup tables and how to use them to control event collection, see [Section 21.2.3.2, “Performance Schema Event Filtering”](#).

There are some miscellaneous tables that do not fall into any of the previous groups. For example, `performance_timers` lists the available event timers and their characteristics. For information about timers, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

## 21.2 Performance Schema Configuration

To use the MySQL Performance Schema, these configuration considerations apply:

- The Performance Schema must be configured into MySQL Server at build time to make it available. Performance Schema support is included in binary MySQL distributions. If you are building from source, you must ensure that it is configured into the build as described in [Section 21.2.1, “Performance Schema Build Configuration”](#).
- The Performance Schema must be enabled at server startup to enable event collection to occur. Specific Performance Schema features can be enabled at server startup or at runtime to control which types of event collection occur. See [Section 21.2.2, “Performance Schema Startup Configuration”](#), [Section 21.2.3, “Performance Schema Runtime Configuration”](#), and [Section 21.2.3.2, “Performance Schema Event Filtering”](#).

### 21.2.1 Performance Schema Build Configuration

For the Performance Schema to be available, it must be configured into the MySQL server at build time. Binary MySQL distributions provided by Oracle Corporation are configured to support the Performance Schema. If you use a binary MySQL distribution from another provider, check with the provider whether the distribution has been appropriately configured.

If you build MySQL from a source distribution, enable the Performance Schema by running `CMake` with the `WITH_PERFSCHEMA_STORAGE_ENGINE` option enabled:

```
shell> cmake . -DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

Configuring MySQL with the `-DWITHOUT_PERFSCHEMA_STORAGE_ENGINE=1` option prevents inclusion of the Performance Schema, so if you want it included, do not use this option. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

As of MySQL 5.7.3, it is also possible to enable the Performance Schema but exclude certain parts of the instrumentation. For example, to enable the Performance Schema but exclude stage and statement instrumentation, do this:

```
shell> cmake . -DWITH_PERFSCHEMA_STORAGE_ENGINE=1 \  
-DDISABLE_PSI_STAGE=1 \  
-DDISABLE_PSI_STATEMENT=1
```

For more information, see the descriptions of the `DISABLE_PSI_XXX` `CMake` options in [Section 2.9.4, “MySQL Source-Configuration Options”](#).

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that may not have all the current tables), run `mysql_upgrade` after starting the server to ensure that the `performance_schema` database exists with all current tables. Then restart the server. One indication that you need to do this is the presence of messages such as the following in the error log:

```
[ERROR] Native table 'performance_schema'.'events_waits_history'  
has the wrong structure  
[ERROR] Native table 'performance_schema'.'events_waits_history_long'
```

```
has the wrong structure
...
```

To verify whether a server was built with Performance Schema support, check its help output. If the Performance Schema is available, the output will mention several variables with names that begin with `performance_schema`:

```
shell> mysqld --verbose --help
...
--performance_schema
           Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
           Number of rows in events_waits_history_long.
...
```

You can also connect to the server and look for a line that names the `PERFORMANCE_SCHEMA` storage engine in the output from `SHOW ENGINES`:

```
mysql> SHOW ENGINES\G
...
      Engine: PERFORMANCE_SCHEMA
      Support: YES
      Comment: Performance Schema
Transactions: NO
           XA: NO
      Savepoints: NO
...
```

If the Performance Schema was not configured into the server at build time, no row for `PERFORMANCE_SCHEMA` will appear in the output from `SHOW ENGINES`. You might see `performance_schema` listed in the output from `SHOW DATABASES`, but it will have no tables and you will not be able to use it.

A line for `PERFORMANCE_SCHEMA` in the `SHOW ENGINES` output means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

### 21.2.2 Performance Schema Startup Configuration

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets `performance_schema` to `OFF`, and the server runs without instrumentation.

The Performance Schema also permits instrument and consumer configuration at server startup.

To control an instrument at server startup, use an option of this form:

```
--performance-schema-instrument='instrument_name=value'
```

Here, `instrument_name` is an instrument name such as `wait/synch/mutex/sql/LOCK_open`, and `value` is one of these values:

- `OFF`, `FALSE`, or `0`: Disable the instrument

- `ON`, `TRUE`, or `1`: Enable and time the instrument
- `COUNTED`: Enable and count (rather than time) the instrument

Each `--performance-schema-instrument` option can specify only one instrument name, but multiple instances of the option can be given to configure multiple instruments. In addition, patterns are permitted in instrument names to configure instruments that match the pattern. To configure all condition synchronization instruments as enabled and counted, use this option:

```
--performance-schema-instrument='wait/synch/cond/%=COUNTED'
```

To disable all instruments, use this option:

```
--performance-schema-instrument='%=OFF'
```

Exception: The `memory/performance_schema/%` instruments are built in and cannot be disabled at startup.

Longer instrument name strings take precedence over shorter pattern names, regardless of order. For information about specifying patterns to select instruments, see [Section 21.2.3.4, “Naming Instruments or Consumers for Filtering Operations”](#).

An unrecognized instrument name is ignored. It is possible that a plugin installed later may create the instrument, at which time the name is recognized and configured.

To control a consumer at server startup, use an option of this form:

```
--performance-schema-consumer-consumer_name=value
```

Here, `consumer_name` is a consumer name such as `events_waits_history`, and `value` is one of these values:

- `OFF`, `FALSE`, or `0`: Do not collect events for the consumer
- `ON`, `TRUE`, or `1`: Collect events for the consumer

For example, to enable the `events_waits_history` consumer, use this option:

```
--performance-schema-consumer-events-waits-history=ON
```

The permitted consumer names can be found by examining the `setup_consumers` table. Patterns are not permitted. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

The Performance Schema includes several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
performance_schema	ON
performance_schema_accounts_size	100
performance_schema_digests_size	200
performance_schema_events_stages_history_long_size	10000
performance_schema_events_stages_history_size	10
performance_schema_events_statements_history_long_size	10000
performance_schema_events_statements_history_size	10
performance_schema_events_waits_history_long_size	10000
performance_schema_events_waits_history_size	10
+-----+-----+
```

```
performance_schema_hosts_size	100
performance_schema_max_cond_classes	80
performance_schema_max_cond_instances	1000
...

```

The `performance_schema` variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

#### Note

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. Before MySQL 5.7.6, it may be necessary to tune the values of Performance Schema system variables to find the number of instances that balances insufficient instrumentation against excessive memory consumption. As of MySQL 5.7.6, the Performance Schema autoscales many parameters to use memory only as required; see [Section 21.14, “The Performance Schema Memory-Allocation Model”](#).

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a `my.cnf` file to change the sizes of the history tables for wait events:

```
[mysqld]
performance_schema
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000

```

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For example, it sizes the parameters that control the sizes of the events waits tables this way. As of MySQL 5.7.6, the Performance Schema allocates memory incrementally, scaling its memory use to actual server load, instead of allocating all the memory it needs during server startup. Consequently, many sizing parameters need not be set at all. To see which parameters are autosized or autoscaled, use `mysqld --verbose --help` and examine the option descriptions, or see [Section 21.12, “Performance Schema System Variables”](#).

For each autosized parameter that is not set at server startup (or is set to `-1`), the Performance Schema determines how to set its value based on the value of the following system values, which are considered as “hints” about how you have configured your MySQL server:

```
max_connections
open_files_limit
table_definition_cache
table_open_cache

```

To override autosizing or autoscaling for a given parameter, set it to a value other than `-1` at startup. In this case, the Performance Schema assigns it the specified value.

At runtime, `SHOW VARIABLES` displays the actual values that autosized parameters were set to. Autoscaled parameters display with a value of `-1`.

If the Performance Schema is disabled, its autosized and autoscaled parameters remain set to `-1` and `SHOW VARIABLES` displays `-1`.

## 21.2.3 Performance Schema Runtime Configuration

Performance Schema setup tables contain information about monitoring configuration:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_SCHEMA = 'performance_schema'
-> AND TABLE_NAME LIKE 'setup%';
+-----+
| TABLE_NAME |
+-----+
| setup_actors |
| setup_consumers |
| setup_instruments |
| setup_objects |
| setup_timers |
+-----+
```

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see [Section 21.9.2, “Performance Schema Setup Tables”](#).

To see which event timers are selected, query the `setup_timers` tables:

```
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
idle	MICROSECOND
wait	CYCLE
stage	NANOSECOND
statement	NANOSECOND
transaction	NANOSECOND
+-----+-----+
```

The `NAME` value indicates the type of instrument to which the timer applies, and `TIMER_NAME` indicates which timer applies to those instruments. The timer applies to instruments where their name begins with a component matching the `NAME` value.

To change the timer, update the `NAME` value. For example, to use the `NANOSECOND` timer for the `wait` timer:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'NANOSECOND'
-> WHERE NAME = 'wait';
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
idle	MICROSECOND
wait	NANOSECOND
stage	NANOSECOND
statement	NANOSECOND
transaction	NANOSECOND
+-----+-----+
```

For discussion of timers, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. Other setup tables enable further modification of the monitoring configuration. [Section 21.2.3.2, “Performance Schema Event Filtering”](#), discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like these changes to take effect each time the server starts, put the statements in a file and start the server with the `--init-file=file_name` option. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a different kind of monitoring, such as casual server health monitoring, incident investigation, application behavior

troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the `--init-file` argument when you start the server.

### 21.2.3.1 Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

#### Performance Schema Timers

Two Performance Schema tables provide timer information:

- `performance_timers` lists the available timers and their characteristics.
- `setup_timers` indicates which timers are used for which instruments.

Each timer row in `setup_timers` must refer to one of the timers listed in `performance_timers`.

Timers vary in precision and amount of overhead. To see what timers are available and their characteristics, check the `performance_timers` table:

```
mysql> SELECT * FROM performance_timers;
```

| TIMER_NAME  | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
|-------------|-----------------|------------------|----------------|
| CYCLE       | 2389029850      | 1                | 72             |
| NANOSECOND  | 1000000000      | 1                | 112            |
| MICROSECOND | 1000000         | 1                | 136            |
| MILLISECOND | 1036            | 1                | 168            |
| TICK        | 105             | 1                | 2416           |

The columns have these meanings:

- The `TIMER_NAME` column shows the names of the available timers. `CYCLE` refers to the timer that is based on the CPU (processor) cycle counter. The timers in `setup_timers` that you can use are those that do not have `NULL` in the other columns. If the values associated with a given timer name are `NULL`, that timer is not supported on your platform.
- `TIMER_FREQUENCY` indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds. For `TICK`, the frequency may vary by platform (for example, some use 100 ticks/second, others 1000 ticks/second).
- `TIMER_RESOLUTION` indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.
- `TIMER_OVERHEAD` is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

To see which timers are in effect or to change timers, access the `setup_timers` table:

```
mysql> SELECT * FROM setup_timers;
```

| NAME  | TIMER_NAME  |
|-------|-------------|
| idle  | MICROSECOND |
| wait  | CYCLE       |
| stage | NANOSECOND  |

```

| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+

mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
-> WHERE NAME = 'idle';
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
idle	MICROSECOND
wait	CYCLE
stage	NANOSECOND
statement	NANOSECOND
transaction	NANOSECOND
+-----+-----+

```

By default, the Performance Schema uses the best timer available for each instrument type, but you can select a different one.

To time wait events, the most important criterion is to reduce overhead, at the possible expense of the timer accuracy, so using the [CYCLE](#) timer is the best.

The time a statement (or stage) takes to execute is in general orders of magnitude larger than the time it takes to execute a single wait. To time statements, the most important criterion is to have an accurate measure, which is not affected by changes in processor frequency, so using a timer which is not based on cycles is the best. The default timer for statements is [NANOSECOND](#). The extra “overhead” compared to the [CYCLE](#) timer is not significant, because the overhead caused by calling a timer twice (once when the statement starts, once when it ends) is orders of magnitude less compared to the CPU time used to execute the statement itself. Using the [CYCLE](#) timer has no benefit here, only drawbacks.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using the cycle counter is much cheaper than getting the actual time of day. For example, the standard [gettimeofday\(\)](#) function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:

- End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.
- Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor's cycle rate fluctuates, conversion from cycles to real-time units is subject to error.
- Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is [RDTSC](#) (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.
- Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

MySQL works with cycle counters on x386 (Windows, OS X, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

## Performance Schema Timer Representation in Events

Rows in Performance Schema tables that store current events and historical events have three columns to represent timing information: [TIMER\\_START](#) and [TIMER\\_END](#) indicate when an event started and finished, and [TIMER\\_WAIT](#) indicates event duration.

The `setup_instruments` table has an `ENABLED` column to indicate the instruments for which to collect events. The table also has a `TIMED` column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

Internally, times within events are stored in units given by the timer in effect when event timing begins. For display when events are retrieved from Performance Schema tables, times are shown in picoseconds (trillionths of a second) to normalize them to a standard unit, regardless of which timer is selected.

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The timer baseline (“time zero”) occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major precision loss. The result is that the time unit is “picoseconds.” This precision is spurious, but the decision enables overhead to be minimized.

Before MySQL 5.7.8, while a wait, stage, statement, or transaction event is executing, the respective current-event tables display the event with `TIMER_START` populated, but with `TIMER_END` and `TIMER_WAIT` set to `NULL`:

```
events_waits_current
events_stages_current
events_statements_current
events_transactions_current
```

As of MySQL 5.7.8, current-event timing provides more information. To make it possible to determine how long a not-yet-completed event has been running, the timer columns are set as follows:

- `TIMER_START` is populated (unchanged from previous behavior)
- `TIMER_END` is populated with the current timer value
- `TIMER_WAIT` is populated with the time elapsed so far (`TIMER_END - TIMER_START`)

Events that have not yet completed have an `END_EVENT_ID` value of `NULL`. To assess time elapsed so far for an event, use the `TIMER_WAIT` column. Therefore, to identify events that have not yet completed and have taken longer than `N` picoseconds thus far, monitoring applications can use this expression in queries:

```
WHERE END_EVENT_ID IS NULL AND TIMER_WAIT > N
```

Event identification as just described assumes that the corresponding instruments have [ENABLED](#) and [TIMED](#) set to [YES](#) and that the relevant consumers are enabled.

### 21.2.3.2 Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The [setup\\_instruments](#) table lists the instruments for which events can be collected, whether they are enabled, and (for enabled instruments) whether to collect timing information:

```
mysql> SELECT * FROM setup_instruments;
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
...
wait/synch/mutex/sql/LOCK_global_read_lock	YES	YES
wait/synch/mutex/sql/LOCK_global_system_variables	YES	YES
wait/synch/mutex/sql/LOCK_lock_db	YES	YES
wait/synch/mutex/sql/LOCK_manager	YES	YES
...

```

The [setup\\_instruments](#) table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 21.2.3.3, “Event Pre-Filtering”](#).

- Performance Schema tables are the destinations for events and consume events. The [setup\\_consumers](#) table lists the types of consumers to which event information can be sent and whether they are enabled:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
events_transactions_current	NO
events_transactions_history	NO
events_transactions_history_long	NO
events_waits_current	NO
events_waits_history	NO
events_waits_history_long	NO
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES
+-----+-----+

```

Filtering can be done at different stages of performance monitoring:

- Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. To do this, enable or disable instruments or consumers. Pre-filtering is done by the Performance Schema and has a global effect that applies to all users.

Reasons to use pre-filtering:

- To reduce overhead. Performance Schema overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.

- To avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.
- To avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.
- **Post-filtering.** This involves the use of `WHERE` clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. Post-filtering is performed on a per-user basis because individual users select which of the available events are of interest.

Reasons to use post-filtering:

- To avoid making decisions for individual users about which event information is of interest.
- To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see [Section 21.3, “Performance Schema Queries”](#).

### 21.2.3.3 Event Pre-Filtering

Pre-filtering is done by the Performance Schema and has a global effect that applies to all users. Pre-filtering can be applied to either the producer or consumer stage of event processing:

- To configure pre-filtering at the producer stage, several tables can be used:
  - `setup_instruments` indicates which instruments are available. An instrument disabled in this table produces no events regardless of the contents of the other production-related setup tables. An instrument enabled in this table is permitted to produce events, subject to the contents of the other tables.
  - `setup_objects` controls whether the Performance Schema monitors particular table and stored program objects.
  - `threads` indicates whether monitoring is enabled for each server thread.
  - `setup_actors` determines the initial monitoring state for new foreground threads.
- To configure pre-filtering at the consumer stage, modify the `setup_consumers` table. This determines the destinations to which events are sent. `setup_consumers` also implicitly affects event production. If a given event will not be sent to any destination (that is, will not be consumed), the Performance Schema does not produce it.

Modifications to any of these tables affect monitoring immediately, with some exceptions:

- Modifications to some instruments in the `setup_instruments` table are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.
- Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads.

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by

newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use `TRUNCATE TABLE` to empty the history tables.

After making instrumentation changes, you might want to truncate the summary tables to clear aggregate information for previously collected events. Except for `events_statements_summary_by_digest` and the memory summary tables, the effect of `TRUNCATE TABLE` for summary tables is to reset the summary columns to 0 or `NULL`, not to remove rows.

The following sections describe how to use specific tables to control Performance Schema pre-filtering.

## Pre-Filtering by Instrument

The `setup_instruments` table lists the available instruments:

```
mysql> SELECT * FROM setup_instruments;
```

| NAME                                              | ENABLED | TIMED |
|---------------------------------------------------|---------|-------|
| ...                                               |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...                                               |         |       |
| wait/synch/rwlock/sql/LOCK_grant                  | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger         | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect       | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave         | YES     | YES   |
| ...                                               |         |       |
| wait/io/file/sql/binlog                           | YES     | YES   |
| wait/io/file/sql/binlog_index                     | YES     | YES   |
| wait/io/file/sql/casetest                         | YES     | YES   |
| wait/io/file/sql/dbopt                            | YES     | YES   |
| ...                                               |         |       |

To control whether an instrument is enabled, set its `ENABLED` column to `YES` or `NO`. To configure whether to collect timing information for an enabled instrument, set its `TIMED` value to `YES` or `NO`. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 21.2.3.1, “Performance Schema Event Timing”](#).

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 21.2.3.3, “Event Pre-Filtering”](#).

The following examples demonstrate possible operations on the `setup_instruments` table. These changes, like other pre-filtering operations, affect all users. Some of these queries use the `LIKE` operator and a pattern match instrument names. For additional information about specifying patterns to select instruments, see [Section 21.2.3.4, “Naming Instruments or Consumers for Filtering Operations”](#).

- Disable all instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO';
```

Now no events will be collected.

- Disable all file instruments, adding them to the current set of disabled instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME LIKE 'wait/io/file/%';
```

- Disable only file instruments, enable all other instruments:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = IF(NAME LIKE 'wait/io/file/%', 'NO', 'YES');
```

- Enable all but those instruments in the `mysys` library:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%' THEN 'YES' ELSE 'NO' END;
```

- Disable a specific instrument:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- To toggle the state of an instrument, “flip” its `ENABLED` value:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES')
-> WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- Disable timing for all events:

```
mysql> UPDATE setup_instruments SET TIMED = 'NO';
```

## Pre-Filtering by Object

The `setup_objects` table controls whether the Performance Schema monitors particular table and stored program objects. The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM setup_objects;
```

| OBJECT_TYPE | OBJECT_SCHEMA      | OBJECT_NAME | ENABLED | TIMED |
|-------------|--------------------|-------------|---------|-------|
| EVENT       | mysql              | %           | NO      | NO    |
| EVENT       | performance_schema | %           | NO      | NO    |
| EVENT       | information_schema | %           | NO      | NO    |
| EVENT       | %                  | %           | YES     | YES   |
| FUNCTION    | mysql              | %           | NO      | NO    |
| FUNCTION    | performance_schema | %           | NO      | NO    |
| FUNCTION    | information_schema | %           | NO      | NO    |
| FUNCTION    | %                  | %           | YES     | YES   |
| PROCEDURE   | mysql              | %           | NO      | NO    |
| PROCEDURE   | performance_schema | %           | NO      | NO    |
| PROCEDURE   | information_schema | %           | NO      | NO    |
| PROCEDURE   | %                  | %           | YES     | YES   |
| TABLE       | mysql              | %           | NO      | NO    |
| TABLE       | performance_schema | %           | NO      | NO    |
| TABLE       | information_schema | %           | NO      | NO    |
| TABLE       | %                  | %           | YES     | YES   |
| TRIGGER     | mysql              | %           | NO      | NO    |
| TRIGGER     | performance_schema | %           | NO      | NO    |
| TRIGGER     | information_schema | %           | NO      | NO    |
| TRIGGER     | %                  | %           | YES     | YES   |

Modifications to the `setup_objects` table affect object monitoring immediately.

The `OBJECT_TYPE` column indicates the type of object to which a row applies. `TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

The `OBJECT_SCHEMA` and `OBJECT_NAME` columns should contain a literal schema or object name, or `'%'` to match any name.

The `ENABLED` column indicates whether matching objects are monitored, and `TIMED` indicates whether to collect timing information. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 21.2.3.1, “Performance Schema Event Timing”](#).

The effect of the default object configuration is to instrument all objects except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For rows that match a given `OBJECT_TYPE`, the Performance Schema checks rows in this order:

- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='literal'`.
- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='%'`.
- Rows with `OBJECT_SCHEMA='%'` and `OBJECT_NAME='%'`.

For example, with a table `db1.t1`, the Performance Schema looks in `TABLE` rows for a match for `'db1'` and `'t1'`, then for `'db1'` and `'%'`, then for `'%'` and `'%'`. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

For table-related events, the Performance Schema combines the contents of `setup_objects` with `setup_instruments` to determine whether to enable instruments and whether to time enabled instruments:

- For tables that match a row in `setup_objects`, table instruments produce events only if `ENABLED` is `YES` in both `setup_instruments` and `setup_objects`.
- The `TIMED` values in the two tables are combined, so that timing information is collected only when both values are `YES`.

For stored program objects, the Performance Schema takes the `ENABLED` and `TIMED` columns directly from the `setup_objects` row. There is no combining of values with `setup_instruments`.

Suppose that `setup_objects` contains the following `TABLE` rows that apply to `db1`, `db2`, and `db3`:

| OBJECT_TYPE | OBJECT_SCHEMA | OBJECT_NAME | ENABLED | TIMED |
|-------------|---------------|-------------|---------|-------|
| TABLE       | db1           | t1          | YES     | YES   |
| TABLE       | db1           | t2          | NO      | NO    |
| TABLE       | db2           | %           | YES     | YES   |
| TABLE       | db3           | %           | NO      | NO    |
| TABLE       | %             | %           | YES     | YES   |

If an object-related instrument in `setup_instruments` has an `ENABLED` value of `NO`, events for the object are not monitored. If the `ENABLED` value is `YES`, event monitoring occurs according to the `ENABLED` value in the relevant `setup_objects` row:

- `db1.t1` events are monitored
- `db1.t2` events are not monitored
- `db2.t3` events are monitored
- `db3.t4` events are not monitored

- `db4.t5` events are monitored

Similar logic applies for combining the `TIMED` columns from the `setup_instruments` and `setup_objects` tables to determine whether to collect event timing information.

If a persistent table and a temporary table have the same name, matching against `setup_objects` rows occurs the same way for both. It is not possible to enable monitoring for one table but not the other. However, each table is instrumented separately.

## Pre-Filtering by Thread

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it. For the Performance Schema to monitor a thread, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

The `threads` table also indicates for each server thread whether to perform historical event logging. This includes wait, stage, statement, and transaction events and affects logging to these tables:

```
events_waits_history
events_waits_history_long
events_stages_history
events_stages_history_long
events_statements_history
events_statements_history_long
events_transactions_history
events_transactions_history_long
```

For historical event logging to occur, these things must be true:

- The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be `YES`.
- The `threads.HISTORY` column must be `YES`.
- Logging occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

For foreground threads (resulting from client connections), the initial values of the `INSTRUMENTED` and `HISTORY` columns in `threads` table rows are determined by whether the user account associated with a thread matches any row in the `setup_actors` table. The values come from the `ENABLED` and `HISTORY` columns of the matching `setup_actors` table row.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial `setup_actors` contents look like this:

```
mysql> SELECT * FROM setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

The `HOST` and `USER` columns should contain a literal host or user name, or `'%'` to match any name.

The `ENABLED` and `HISTORY` columns indicate whether to enable instrumentation and historical event logging for matching threads, subject to the other conditions described previously.

When the Performance Schema checks for a match for each new foreground thread in `setup_actors`, it tries to find more specific matches first, using the `USER` and `HOST` columns (`ROLE` is unused):

- Rows with `USER='literal'` and `HOST='literal'`.
- Rows with `USER='literal'` and `HOST='%'`.
- Rows with `USER='%'` and `HOST='literal'`.
- Rows with `USER='%'` and `HOST='%'`.

The order in which matching occurs matters because different matching `setup_actors` rows can have different `USER` and `HOST` values. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (combination of host and user), based on the `ENABLED` and `HISTORY` column values:

- When the best match is a row with `ENABLED=YES`, the `INSTRUMENTED` value for the thread becomes `YES`. When the best match is a row with `HISTORY=YES`, the `HISTORY` value for the thread becomes `YES`.
- When the best match is a row with `ENABLED=NO`, the `INSTRUMENTED` value for the thread becomes `NO`. When the best match is a row with `HISTORY=NO`, the `HISTORY` value for the thread becomes `NO`.
- When no match is found, the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

The `ENABLED` and `HISTORY` columns in `setup_actors` rows can be set to `YES` or `NO` independent of one another. This means you can enable instrumentation separately from whether you collect historical events.

Before MySQL 5.7.6, there is no `ENABLED` column. The `INSTRUMENTED` value for the thread becomes `YES` if any row matches, `NO` otherwise.

Before MySQL 5.7.8, there is no `HISTORY` column. The Performance Schema logs historical events either for all threads or no threads, depending on which history consumers are enabled or disabled.

By default, monitoring and historical event collection are enabled for all new foreground threads because the `setup_actors` table initially contains a row with `'%'` for both `HOST` and `USER`. To perform more limited matching such as to enable monitoring only for some foreground threads, you must change this row because it matches any connection, and add rows for more specific `HOST/USER` combinations.

Suppose that you modify `setup_actors` as follows:

```
UPDATE setup_actors SET ENABLED = 'NO', HISTORY = 'NO'
WHERE HOST = '%' AND USER = '%';
INSERT INTO setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('localhost','joe','%','YES','YES');
INSERT INTO setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('hosta.example.com','joe','%','YES','NO');
INSERT INTO setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('%','sam','%','NO','YES');
```

The `UPDATE` statement changes the default match to disable instrumentation and historical event collection. The `INSERT` statements add rows for more specific matches.

Now the Performance Schema determines how to set the `INSTRUMENTED` and `HISTORY` values for new connection threads as follows:

- If `joe` connects from the local host, the connection matches the first inserted row. The `INSTRUMENTED` and `HISTORY` values for the thread become `YES`.
- If `joe` connects from `hosta.example.com`, the connection matches the second inserted row. The `INSTRUMENTED` value for the thread becomes `YES` and the `HISTORY` value becomes `NO`.
- If `joe` connects from any other host, there is no match. The `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.
- If `sam` connects from any host, the connection matches the third inserted row. The `INSTRUMENTED` value for the thread becomes `NO` and the `HISTORY` value becomes `YES`.
- For any other connection, the row with `HOST` and `USER` set to `'%'` matches. This row now has `ENABLED` and `HISTORY` set to `NO`, so the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

## Pre-Filtering by Consumer

The `setup_consumers` table lists the available consumer types and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
```

| NAME                             | ENABLED |
|----------------------------------|---------|
| events_stages_current            | NO      |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | YES     |
| events_statements_history_long   | NO      |
| events_transactions_current      | NO      |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |
| events_waits_current             | NO      |
| events_waits_history             | NO      |
| events_waits_history_long        | NO      |
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| statements_digest                | YES     |

Modify the `setup_consumers` table to affect pre-filtering at the consumer stage and determine the destinations to which events are sent. To enable or disable a consumer, set its `ENABLED` value to `YES` or `NO`.

Modifications to the `setup_consumers` table affect monitoring immediately.

If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about historical event information, disable the history consumers:

```
mysql> UPDATE setup_consumers
-> SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following principles apply:

- Destinations associated with a consumer receive no events unless the Performance Schema checks the consumer and the consumer is enabled.
- A consumer is checked only if all consumers it depends on (if any) are enabled.

- If a consumer is not checked, or is checked but is disabled, other consumers that depend on it are not checked.
- Dependent consumers may have their own dependent consumers.
- If an event would not be sent to any destination, the Performance Schema does not produce it.

The following lists describe the available consumer values. For discussion of several representative consumer configurations and their effect on instrumentation, see [Example Consumer Configurations](#).

### Global and Thread Consumers

- `global_instrumentation` is the highest level consumer. If `global_instrumentation` is `NO`, it disables global instrumentation. All other settings are lower level and are not checked; it does not matter what they are set to. No global or per thread information is maintained and no individual events are collected in the current-events or event-history tables. If `global_instrumentation` is `YES`, the Performance Schema maintains information for global states and also checks the `thread_instrumentation` consumer.
- `thread_instrumentation` is checked only if `global_instrumentation` is `YES`. Otherwise, if `thread_instrumentation` is `NO`, it disables thread-specific instrumentation and all lower-level settings are ignored. No information is maintained per thread and no individual events are collected in the current-events or event-history tables. If `thread_instrumentation` is `YES`, the Performance Schema maintains thread-specific information and also checks `events_xxx_current` consumers.

### Wait Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_waits_current`, if `NO`, disables collection of individual wait events in the `events_waits_current` table. If `YES`, it enables wait event collection and the Performance Schema checks the `events_waits_history` and `events_waits_history_long` consumers.
- `events_waits_history` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history` table.
- `events_waits_history_long` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history_long` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history_long` table.

### Stage Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_stages_current`, if `NO`, disables collection of individual stage events in the `events_stages_current` table. If `YES`, it enables stage event collection and the Performance Schema checks the `events_stages_history` and `events_stages_history_long` consumers.
- `events_stages_history` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history` table.
- `events_stages_history_long` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history_long` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history_long` table.

### Statement Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_statements_current`, if `NO`, disables collection of individual statement events in the `events_statements_current` table. If `YES`, it enables statement event collection and the Performance Schema checks the `events_statements_history` and `events_statements_history_long` consumers.
- `events_statements_history` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history` table.
- `events_statements_history_long` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history_long` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history_long` table.

### Transaction Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_transactions_current`, if `NO`, disables collection of individual transaction events in the `events_transactions_current` table. If `YES`, it enables transaction event collection and the Performance Schema checks the `events_transactions_history` and `events_transactions_history_long` consumers.
- `events_transactions_history` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history` table.
- `events_transactions_history_long` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history_long` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history_long` table.

### Statement Digest Consumer

This consumer requires `global_instrumentation` to be `YES` or it is not checked. There is no dependency on the statement event consumers, so you can obtain statistics per digest without having to collect statistics in `events_statements_current`, which is advantageous in terms of overhead. Conversely, you can get detailed statements in `events_statements_current` without digests (the `DIGEST` and `DIGEST_TEXT` columns will be `NULL`).

## Example Consumer Configurations

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following discussion describes how consumers work, showing specific configurations and their effects as consumer settings are enabled progressively from high to low. The consumer values shown are representative. The general principles described here apply to other consumer values that may be available.

The configuration descriptions occur in order of increasing functionality and overhead. If you do not need the information provided by enabling lower-level settings, disable them and the Performance Schema will execute less code on your behalf and you will have less information to sift through.

The `setup_consumers` table contains the following hierarchy of values:

```
global_instrumentation
thread_instrumentation
  events_waits_current
  events_waits_history
  events_waits_history_long
```

```

events_stages_current
  events_stages_history
  events_stages_history_long
events_statements_current
  events_statements_history
  events_statements_history_long
events_transactions_current
  events_transactions_history
  events_transactions_history_long
statements_digest

```

### Note

In the consumer hierarchy, the consumers for waits, stages, statements, and transactions are all at the same level. This differs from the event nesting hierarchy, for which wait events nest within stage events, which nest within statement events, which nest within transaction events.

If a given consumer setting is **NO**, the Performance Schema disables the instrumentation associated with the consumer and ignores all lower-level settings. If a given setting is **YES**, the Performance Schema enables the instrumentation associated with it and checks the settings at the next lowest level. For a description of the rules for each consumer, see [Pre-Filtering by Consumer](#).

For example, if `global_instrumentation` is enabled, `thread_instrumentation` is checked. If `thread_instrumentation` is enabled, the `events_xxx_current` consumers are checked. If of these `events_waits_current` is enabled, `events_waits_history` and `events_waits_history_long` are checked.

Each of the following configuration descriptions indicates which setup elements the Performance Schema checks and which output tables it maintains (that is, for which tables it collects information).

## No Instrumentation

Server configuration state:

```

mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                | ENABLED |
+-----+-----+
| global_instrumentation | NO      |
| ...                  |         |
+-----+-----+

```

In this configuration, nothing is instrumented.

Setup elements checked:

- Table `setup_consumers`, consumer `global_instrumentation`

Output tables maintained:

- None

## Global Instrumentation Only

Server configuration state:

```

mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                | ENABLED |
+-----+-----+
| global_instrumentation | YES     |
| thread_instrumentation  | NO      |
+-----+-----+

```

```
...  
+-----+-----+
```

In this configuration, instrumentation is maintained only for global states. Per-thread instrumentation is disabled.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `thread_instrumentation`
- Table `setup_instruments`
- Table `setup_objects`
- Table `setup_timers`

Additional output tables maintained, relative to the preceding configuration:

- `mutex_instances`
- `rwlock_instances`
- `cond_instances`
- `file_instances`
- `users`
- `hosts`
- `accounts`
- `socket_summary_by_event_name`
- `file_summary_by_instance`
- `file_summary_by_event_name`
- `objects_summary_global_by_type`
- `memory_summary_global_by_event_name`
- `table_lock_waits_summary_by_table`
- `table_io_waits_summary_by_index_usage`
- `table_io_waits_summary_by_table`
- `events_waits_summary_by_instance`
- `events_waits_summary_global_by_event_name`
- `events_stages_summary_global_by_event_name`
- `events_statements_summary_global_by_event_name`
- `events_transactions_summary_global_by_event_name`

### Global and Thread Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
```

| NAME                        | ENABLED |
|-----------------------------|---------|
| global_instrumentation      | YES     |
| thread_instrumentation      | YES     |
| events_waits_current        | NO      |
| ...                         |         |
| events_stages_current       | NO      |
| ...                         |         |
| events_statements_current   | NO      |
| ...                         |         |
| events_transactions_current | NO      |
| ...                         |         |

In this configuration, instrumentation is maintained globally and per thread. No individual events are collected in the current-events or event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumers `events_XXX_current`, where `XXX` is `waits`, `stages`, `statements`, `transactions`
- Table `setup_actors`
- Column `threads.instrumented`

Additional output tables maintained, relative to the preceding configuration:

- `events_XXX_summary_by_YYY_by_event_name`, where `XXX` is `waits`, `stages`, `statements`, `transactions`; and `YYY` is `thread`, `user`, `host`, `account`

## Global, Thread, and Current-Event Instrumentation

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
```

| NAME                             | ENABLED |
|----------------------------------|---------|
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| events_waits_current             | YES     |
| events_waits_history             | NO      |
| events_waits_history_long        | NO      |
| events_stages_current            | YES     |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | YES     |
| events_statements_history_long   | NO      |
| events_transactions_current      | YES     |
| events_transactions_history      | YES     |
| events_transactions_history_long | NO      |
| ...                              |         |

In this configuration, instrumentation is maintained globally and per thread. Individual events are collected in the current-events table, but not in the event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Consumers `events_XXX_history`, where `XXX` is `waits`, `stages`, `statements`, `transactions`
- Consumers `events_XXX_history_long`, where `XXX` is `waits`, `stages`, `statements`, `transactions`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

### Global, Thread, Current-Event, and Event-History instrumentation

The preceding configuration collects no event history because the `events_xxx_history` and `events_xxx_history_long` consumers are disabled. Those consumers can be enabled separately or together to collect event history per thread, globally, or both.

This configuration collects event history per thread, but not globally:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
global_instrumentation	YES
thread_instrumentation	YES
events_waits_current	YES
events_waits_history	YES
events_waits_history_long	NO
events_stages_current	YES
events_stages_history	YES
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	NO
...	
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history globally, but not per thread:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
global_instrumentation	YES
thread_instrumentation	YES
events_waits_current	YES
events_waits_history	NO
events_waits_history_long	YES
events_stages_current	YES
events_stages_history	NO
events_stages_history_long	YES
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	YES
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	YES
...	
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history per thread and globally:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
global_instrumentation	YES
thread_instrumentation	YES
events_waits_current	YES
events_waits_history	YES
events_waits_history_long	YES
events_stages_current	YES
events_stages_history	YES
events_stages_history_long	YES
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	YES
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	YES
...	
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

### 21.2.3.4 Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = 'NO'
-> WHERE NAME = 'wait/synch/mutex/myisammrg/MYRG_INFO::mutex';

mysql> UPDATE setup_consumers
-> SET ENABLED = 'NO' WHERE NAME = 'events_waits_current';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```
mysql> UPDATE setup_instruments
-> SET ENABLED = 'NO'
-> WHERE NAME LIKE 'wait/synch/mutex/%';

mysql> UPDATE setup_consumers
-> SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```
... WHERE NAME LIKE 'wait/io/file/%';
```

A pattern of `%/file/%` will match other instruments that have a component of `/file/` anywhere in the name. Even less suitable is the pattern `%file%` because it will match instruments with `file` anywhere in the name, such as `wait/synch/mutex/sql/LOCK_des_key_file`.

To check which instrument or consumer names a pattern matches, perform a simple test:

```
mysql> SELECT NAME FROM setup_instruments WHERE NAME LIKE 'pattern';
mysql> SELECT NAME FROM setup_consumers WHERE NAME LIKE 'pattern';
```

For information about the types of names that are supported, see [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

### 21.2.3.5 Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the `setup_instruments` table. For example, to see what file-related events are instrumented for the InnoDB storage engine, use this query:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'wait/io/file/innodb/%';
```

| NAME                                 | ENABLED | TIMED |
|--------------------------------------|---------|-------|
| wait/io/file/innodb/innodb_data_file | YES     | YES   |
| wait/io/file/innodb/innodb_log_file  | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file | YES     | YES   |

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

- What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.
- It is not practical to list all the instruments because there are hundreds of them.
- As described earlier, it is possible to find out by querying the `setup_instruments` table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

## 21.3 Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate `WHERE` clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In [Section 21.2.3.3, “Event Pre-Filtering”](#), an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a `WHERE` clause to queries to restrict event selection appropriately:

```
mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
-> FROM events_waits_history
-> WHERE EVENT_NAME LIKE 'wait/io/file/%'
-> AND NUMBER_OF_BYTES IS NOT NULL;
```

| THREAD_ID | NUMBER_OF_BYTES |
|-----------|-----------------|
| 11        | 66              |
| 11        | 47              |
| 11        | 139             |
| 5         | 24              |
| 5         | 834             |

## 21.4 Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of components separated by `' / '` characters. Example names:

```
wait/io/file/myisam/log
wait/io/file/mysys/charset
wait/lock/table/sql/handler
wait/synch/cond/mysys/COND_alarm
wait/synch/cond/sql/BINLOG::update_cond
wait/synch/mutex/mysys/BITMAP_mutex
wait/synch/mutex/sql/LOCK_delete
wait/synch/rwlock/sql/Query_cache_query::lock
stage/sql/closing_tables
stage/sql/Sorting_result
statement/com/Execute
statement/com/Query
statement/sql/create_table
statement/sql/lock_tables
```

The instrument name space has a tree-like structure. The components of an instrument name from left to right provide a progression from more general to more specific. The number of components a name has depends on the type of instrument.

The interpretation of a given component in a name depends on the components to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

```
wait/io/file/myisam/log
wait/synch/cond/myisam/MI_SORT_INFO::cond
```

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level component of an instrument prefix indicates the type of instrument. This component also determines which event timer in the `setup_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major component (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC::MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.

### Top-Level Instrument Components

- `idle`: An instrumented idle event. This instrument has no further components.
- `memory`: An instrumented memory event.
- `stage`: An instrumented stage event.
- `statement`: An instrumented statement event.
- `transaction`: An instrumented transaction event. This instrument has no further components.
- `wait`: An instrumented wait event.

### Idle Instrument Components

- `idle`

The idle instrument. The Performance Schema generates idle events as discussed in the description of the `socket_instances.STATE` column in [Section 21.9.3.5, “The socket\\_instances Table”](#).

### Memory Instrument Components

Most memory instrumentation is disabled by default, and can be enabled or disabled dynamically by updating the `ENABLED` column of the relevant instruments in the `setup_instruments` table. Memory instruments have names of the form `memory/code_area/instrument_name` where `code_area` is a value such as `sql` or `myisam`, and `instrument_name` is the instrument detail.

Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for internal buffers in the Performance Schema. The `memory/performance_schema/` instruments are built in, always enabled, and cannot be disabled at startup or runtime. The built-in memory instruments are displayed only in the `memory_summary_global_by_event_name` table. For more information, see [Section 21.14, “The Performance Schema Memory-Allocation Model”](#).

### Stage Instrument Components

Stage instruments have names of the form `stage/code_area/stage_name`, where `code_area` is a value such as `sql` or `myisam`, and `stage_name` indicates the stage of statement processing, such as `Sorting result` or `Sending data`. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table.

### Statement Instrument Components

- `statement/abstract/*`: An abstract instrument for statement operations. Abstract instruments are used during the early stages of statement classification before the exact statement type is known, then changed to a more specific statement instrument when the type is known. For a description of this process, see [Section 21.9.6, “Performance Schema Statement Event Tables”](#).
- `statement/com`: An instrumented command operation. These have names corresponding to `COM_xxx` operations (see the `mysql_com.h` header file and `sql/sql_parse.cc`). For example, the `statement/com/Connect` and `statement/com/Init DB` instruments correspond to the `COM_CONNECT` and `COM_INIT_DB` commands.
- `statement/scheduler/event`: A single instrument to track all events executed by the Event Scheduler. This instrument comes into play when a scheduled event begins executing.
- `statement/sp`: An instrumented internal instruction executed by a stored program. For example, the `statement/sp/cfetch` and `statement/sp/freturn` instruments are used cursor fetch and function return instructions.
- `statement/sql`: An instrumented SQL statement operation. For example, the `statement/sql/create_db` and `statement/sql/select` instruments are used for `CREATE DATABASE` and `SELECT` statements.

### Wait Instrument Components

- `wait/io`

An instrumented I/O operation.

- `wait/io/file`

An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.

- `wait/io/socket`

An instrumented socket operation. Socket instruments have names of the form `wait/io/socket/sql/socket_type`. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively. When a listening socket detects a connection, the server transfers the connection to

a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

- `wait/io/table`

An instrumented table I/O operation. These include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete. For a view, waits are associated with base tables referenced by the view.

Unlike most waits, a table I/O wait can include other waits. For example, table I/O might include file I/O or memory operations. Thus, `events_waits_current` for a table I/O wait usually has two rows. For more information, see [Section 21.6, “Performance Schema Atom and Molecule Events”](#).

Some row operations might cause multiple table I/O waits. For example, an insert might activate a trigger that causes an update.

- `wait/lock`

An instrumented lock operation.

- `wait/lock/table`

An instrumented table lock operation.

- `wait/lock/metadata/sql/mdl`

An instrumented metadata lock operation (disabled by default).

- `wait/synch`

An instrumented synchronization object. For synchronization objects, the `TIMER_WAIT` time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

- `wait/synch/cond`

A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

- `wait/synch/mutex`

A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

- `wait/synch/rwlock`

A [read/write lock](#) object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

- `wait/synch/sxlock`

A shared-exclusive (SX) lock is a type of [rwlock](#) lock object that provides write access to a common resource while permitting inconsistent reads by other threads. `sxlocks` were introduced in MySQL 5.7 to optimize concurrency and improve scalability for read-write workloads.

## 21.5 Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

---

```
mysql> SHOW STATUS LIKE 'perf%';
```

| Variable_name                                 | Value |
|-----------------------------------------------|-------|
| Performance_schema_accounts_lost              | 0     |
| Performance_schema_cond_classes_lost          | 0     |
| Performance_schema_cond_instances_lost        | 0     |
| Performance_schema_digest_lost                | 0     |
| Performance_schema_file_classes_lost          | 0     |
| Performance_schema_file_handles_lost          | 0     |
| Performance_schema_file_instances_lost        | 0     |
| Performance_schema_hosts_lost                 | 0     |
| Performance_schema_locker_lost                | 0     |
| Performance_schema_memory_classes_lost        | 0     |
| Performance_schema_metadata_lock_lost         | 0     |
| Performance_schema_mutex_classes_lost         | 0     |
| Performance_schema_mutex_instances_lost       | 0     |
| Performance_schema_nested_statement_lost      | 0     |
| Performance_schema_program_lost               | 0     |
| Performance_schema_rwlock_classes_lost        | 0     |
| Performance_schema_rwlock_instances_lost      | 0     |
| Performance_schema_session_connect_attrs_lost | 0     |
| Performance_schema_socket_classes_lost        | 0     |
| Performance_schema_socket_instances_lost      | 0     |
| Performance_schema_stage_classes_lost         | 0     |
| Performance_schema_statement_classes_lost     | 0     |
| Performance_schema_table_handles_lost         | 0     |
| Performance_schema_table_instances_lost       | 0     |
| Performance_schema_thread_classes_lost        | 0     |
| Performance_schema_thread_instances_lost      | 0     |
| Performance_schema_users_lost                 | 0     |

The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- `Performance_schema_xxx_classes_lost` indicates how many instruments of type `xxx` could not be loaded.
- `Performance_schema_xxx_instances_lost` indicates how many instances of object type `xxx` could not be created.
- `Performance_schema_xxx_handles_lost` indicates how many instances of object type `xxx` could not be opened.
- `Performance_schema_locker_lost` indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments `Performance_schema_mutex_classes_lost`. The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it will not be collected. If the instrument can be allocated, it can be used for initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there will be only one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers will increase the maximum number of instances that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments `Performance_schema_mutex_instances_lost`.

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named `plugin_a` contains 40 mutex instruments.

- The plugin named `plugin_b` contains 20 mutex instruments.

The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:

```
INSTALL PLUGIN plugin_a
```

The server now has  $150+40 = 190$  mutex instruments.

```
UNINSTALL PLUGIN plugin_a;
```

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

```
INSTALL PLUGIN plugin_a;
```

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

```
INSTALL PLUGIN plugin_b;
```

The server has room for  $200-190 = 10$  instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The `Performance_schema_mutex_classes_lost` indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf%mutex_classes_lost";
+-----+-----+
| Variable_name                | Value |
+-----+-----+
| Performance_schema_mutex_classes_lost | 10    |
+-----+-----+
1 row in set (0.10 sec)
```

The instrumentation still works and collects (partial) data for `plugin_b`.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the `setup_instruments` table.
- `Performance_schema_mutex_classes_lost` increases by 1.
- `Performance_schema_mutex_instances_lost` does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of `Performance_schema_mutex_classes_lost` greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with `--performance_schema_max_mutex_classes=N`, where `N` is less than the default value. The default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but this can be reduced if some plugins are never loaded. For example, you might choose not to load some of the storage engines in the distribution.
- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for the plugin's instrumentation memory requirements when you start the server. Because it comes from a third party, the instrument memory consumption of this engine is not accounted for in the default value chosen for `performance_schema_max_mutex_classes`.

If the server has insufficient resources for the plugin's instruments and you do not explicitly allocate more using `--performance_schema_max_mutex_classes=N`, loading the plugin leads to starvation of instruments.

If the value chosen for `performance_schema_max_mutex_classes` is too small, no error is reported in the error log and there is no failure at runtime. However, the content of the tables in the `performance_schema` database will miss events. The `Performance_schema_mutex_classes_lost` status variable is the only visible sign to indicate that some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting instances. For example, `wait/synch/mutex/sql/LOCK_delete` is the name of a mutex instrument in the `setup_instruments` table. This single instrument is used when creating a mutex in the code (in `THD::LOCK_delete`) however many instances of the mutex are needed as the server runs. In this case, `LOCK_delete` is a mutex that is per connection (`THD`), so if a server has 1000 connections, there are 1000 threads, and 1000 instrumented `LOCK_delete` mutex instances (`THD::LOCK_delete`).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes are created with instrumentation, and some are created without instrumentation. If the server can create only 800 instances, 200 instances are lost. The server continues to run, but increments `Performance_schema_mutex_instances_lost` by 200 to indicate that instances could not be created.

A value of `Performance_schema_mutex_instances_lost` greater than 0 can happen when the code initializes more mutexes at runtime than were allocated for `--performance_schema_max_mutex_instances=N`.

The bottom line is that if `SHOW STATUS LIKE 'perf%'` says that nothing was lost (all values are zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the data is incomplete, and the Performance Schema could not record everything given the insufficient amount of memory it was given to use. In this case, the specific `Performance_schema_xxx_lost` variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you do not care about performance data for file I/O, you can start the server with all Performance Schema parameters related to file I/O set to 0. No memory will be allocated for file-related classes, instances, or handles, and all file events will be lost.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.size
Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.count
Status: 10000
***** 5. row *****
  Type: performance_schema
  Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
  Type: performance_schema
  Name: performance_schema.memory
Status: 26459600
```

...

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements. For a description of the field meanings, see [Section 13.7.5.15, “SHOW ENGINE Syntax”](#).

## 21.6 Performance Schema Atom and Molecule Events

For a table I/O event, there are usually two rows in `events_waits_current`, not one. For example, a row fetch might result in rows like this:

| Row# | EVENT_NAME                | TIMER_START | TIMER_END |
|------|---------------------------|-------------|-----------|
| 1    | wait/io/file/myisam/dfile | 10001       | 10002     |
| 2    | wait/io/table/sql/handler | 10000       | NULL      |

The row fetch causes a file read. In the example, the table I/O fetch event started before the file I/O event but has not finished (its `TIMER_END` value is `NULL`). The file I/O event is “nested” within the table I/O event.

This occurs because, unlike other “atomic” wait events such as for mutexes or file I/O, table I/O events are “molecular” and include (overlap with) other events. In `events_waits_current`, the table I/O event usually has two rows:

- One row for the most recent table I/O wait event
- One row for the most recent wait event of any kind

Usually, but not always, the “of any kind” wait event differs from the table I/O event. As each subsidiary event completes, it disappears from `events_waits_current`. At this point, and until the next subsidiary event begins, the table I/O wait is also the most recent wait of any kind.

## 21.7 Performance Schema Statement Digests

The MySQL server is capable of maintaining statement digest information. The digesting process converts a SQL statement to normalized form and computes a hash value for the result. Normalization permits statements that are similar to be grouped and summarized to expose information about the types of statements the server is executing and how often they occur. This section describes how statement normalizing occurs and how it can be useful.

### Note

Before MySQL 5.7.4, statement digesting was a function of the Performance Schema. As of 5.7.4, digesting occurs at the SQL level regardless of whether the Performance Schema is available, so that other server functions such as query rewrite plugins have access to statement digests.

In the Performance Schema, statement digesting involves these components:

- A `statement_digest` consumer in the `setup_consumers` table controls whether the Performance Schema maintains digest information.
- The statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`) have columns that contain digests and the corresponding digest hash values:
  - `DIGEST_TEXT` is the text of the normalized statement digest.
  - `DIGEST` is the digest MD5 hash value.

The maximum space available for digest computation is 1024 bytes by default. As of MySQL 5.7.8, this value can be changed at server startup by setting the `performance_schema_max_digest_length` system variable. In MySQL 5.7.6 and 5.7.7, use `max_digest_length` instead. Before 5.7.6, the value cannot be changed.

- The statement event tables also have a `SQL_TEXT` column that contains the original SQL statement. The maximum space available for statement display is 1024 bytes by default. As of MySQL 5.7.6, this value can be changed at server startup by setting the `performance_schema_max_sql_text_length` system variable. Before 5.7.6, the value cannot be changed.
- An `events_statements_summary_by_digest` table provides aggregated statement digest information.

Normalizing a statement transforms the statement text to a more standardized digest string representation that preserves the general statement structure while removing information not essential to the structure:

- Object identifiers such as database and table names are preserved.
- Literal values are converted to parameter markers. A normalized statement does not retain information such as names, passwords, dates, and so forth.
- Comments are removed and whitespace is adjusted.

Consider these statements:

```
SELECT * FROM orders WHERE customer_id=10 AND quantity>20
SELECT * FROM orders WHERE customer_id = 20 AND quantity > 100
```

To normalize these statements, the Performance Schema replaces data values by `?` and adjusts whitespace. Both statements yield the same normalized form and thus are considered “the same”:

```
SELECT * FROM orders WHERE customer_id = ? AND quantity > ?
```

The normalized statement contains less information but is still representative of the original statement. Other similar statements that have different comparison values have the same normalized form.

Now consider these statements:

```
SELECT * FROM customers WHERE customer_id = 1000
SELECT * FROM orders WHERE customer_id = 1000
```

In this case, the statements are not “the same.” The object identifiers differ, so the statements yield different normalized forms:

```
SELECT * FROM customers WHERE customer_id = ?
SELECT * FROM orders WHERE customer_id = ?
```

If normalization produces a statement that exceeds the space available in the digest buffer, the text ends with “...”. Long statements that differ only in the part that occurs following the “...” are considered to be the same. Consider these statements:

```
SELECT * FROM mytable WHERE cola = 10 AND colb = 20
SELECT * FROM mytable WHERE cola = 10 AND colc = 20
```

If the cutoff happened to be right after the `AND`, both statements would have this normalized form:

```
SELECT * FROM mytable WHERE cola = ? AND ...
```

In this case, the difference in the second column name is lost and both statements are considered the same.

For each normalized statement, the Performance Schema computes a hash digest value and stores the statement and its MD5 hash value in the `DIGEST_TEXT` and `DIGEST` columns of the statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`). In addition, information for statements with the same `SCHEMA_NAME` and `DIGEST` values are aggregated in the `events_statements_summary_by_digest` summary table. The Performance Schema uses MD5 hash values because they are fast to compute and have a favorable statistical distribution that minimizes collisions.

The statement digest summary table provides a profile of the statements executed by the server. It shows what kinds of statements an application is executing and how often. An application developer can use this information together with other information in the table to assess the application's performance characteristics. For example, table columns that show wait times, lock times, or index use may highlight types of queries that are inefficient. This gives the developer insight into which parts of the application need attention.

The `events_statements_summary_by_digest` summary table has a fixed size, so when it becomes full, statements that have `SCHEMA_NAME` and `DIGEST` values not matching existing values in the table are grouped in a special row with `SCHEMA_NAME` and `DIGEST` set to `NULL`. This permits all statements to be counted. However, if the special row accounts for a significant percentage of the statements executed, it might be desirable to increase the size of the summary table by setting the `performance_schema_digests_size` system variable to a larger value at server startup. If no `performance_schema_digests_size` value is given, the Performance Schema estimates the value to use at startup.

The `performance_schema_max_digest_length` system variable determines the maximum number of bytes available in the digest buffer for digest computation. However, the display length of statement digests may be longer than the available buffer size due to encoding of statement components such as keywords and literal values in digest buffer. Consequently, values selected from the `DIGEST_TEXT` column of statement event tables may appear to exceed the `performance_schema_max_digest_length` value.

For applications that generate very long statements that differ only at the end, increasing `performance_schema_max_digest_length` enables computation of digests that distinguish statements that would otherwise aggregate to the same digest. Conversely, decreasing `performance_schema_max_digest_length` causes the server to devote less memory to digest storage but increases the likelihood of longer statements aggregating to the same digest. Administrators should keep in mind that larger values result in correspondingly increased memory requirements, particularly for workloads that involve large numbers of simultaneous sessions (`performance_schema_max_digest_length` bytes are allocated per session).

To assess the amount of memory used for SQL statement storage and digest computation, use the `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` statement, or monitor these instruments:

```
mysql> SELECT NAME FROM setup_instruments
-> WHERE NAME LIKE '%.sqltext';
+-----+-----+
| NAME                                     |     |
+-----+-----+
memory/performance_schema/events_statements_history.sqltext	
memory/performance_schema/events_statements_current.sqltext	
memory/performance_schema/events_statements_history_long.sqltext	
+-----+-----+

mysql> SELECT NAME FROM setup_instruments
-> WHERE NAME LIKE 'memory/performance_schema/%.tokens';
+-----+-----+
| NAME                                     |     |
+-----+-----+
```

|                                                                      |
|----------------------------------------------------------------------|
| memory/performance_schema/events_statements_history.tokens           |
| memory/performance_schema/events_statements_current.tokens           |
| memory/performance_schema/events_statements_summary_by_digest.tokens |
| memory/performance_schema/events_statements_history_long.tokens      |

## 21.8 Performance Schema General Table Characteristics

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Most tables in the `performance_schema` database are read only and cannot be modified. Some of the setup tables have columns that can be modified to affect Performance Schema operation; some also permit rows to be inserted or deleted. Truncation is permitted to clear collected events, so `TRUNCATE TABLE` can be used on tables containing those kinds of information, such as tables named with a prefix of `events_waits_`.

`TRUNCATE TABLE` can also be used with summary tables, but except for `events_statements_summary_by_digest` and the memory summary tables, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows.

Privileges are as for other databases and tables:

- To retrieve from `performance_schema` tables, you must have the `SELECT` privilege.
- To change those columns that can be modified, you must have the `UPDATE` privilege.
- To truncate tables that can be truncated, you must have the `DROP` privilege.

## 21.9 Performance Schema Table Descriptions

Tables in the `performance_schema` database can be grouped as follows:

- Setup tables. These tables are used to configure and display monitoring characteristics.
- Current events tables. The `events_waits_current` table contains the most recent event for each thread. Other similar tables contain current events at different levels of the event hierarchy: `events_stages_current` for stage events, `events_statements_current` for statement events, and `events_transactions_current` for transaction events.
- History tables. These tables have the same structure as the current events tables, but contain more rows. For example, for wait events, `events_waits_history` table contains the most recent 10 events per thread. `events_waits_history_long` contains the most recent 10,000 events. Other similar tables exist for stage, statement, and transaction histories.

To change the sizes of the history tables, set the appropriate system variables at server startup. For example, to set the sizes of the wait event history tables, set `performance_schema_events_waits_history_size` and `performance_schema_events_waits_history_long_size`.

- Summary tables. These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.
- Instance tables. These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.
- Miscellaneous tables. These do not fall into any of the other table groups.

### 21.9.1 Performance Schema Table Index

The following table lists each Performance Schema table and provides a short description of each one.

**Table 21.1 Performance Schema Tables**

| Table Name                                           | Description                                     |
|------------------------------------------------------|-------------------------------------------------|
| accounts                                             | Connection statistics per client account        |
| cond_instances                                       | synchronization object instances                |
| events_stages_current                                | Current stage events                            |
| events_stages_history                                | Most recent stage events for each thread        |
| events_stages_history_long                           | Most recent stage events overall                |
| events_stages_summary_by_account_by_event_name       | Stage events per account and event name         |
| events_stages_summary_by_host_by_event_name          | Stage events per host name and event name       |
| events_stages_summary_by_thread_by_event_name        | Stage waits per thread and event name           |
| events_stages_summary_by_user_by_event_name          | Stage events per user name and event name       |
| events_stages_summary_global_by_event_name           | Stage waits per event name                      |
| events_statements_current                            | Current statement events                        |
| events_statements_history                            | Most recent statement events for each thread    |
| events_statements_history_long                       | Most recent statement events overall            |
| events_statements_summary_by_account_by_event_name   | Statement events per account and event name     |
| events_statements_summary_by_digest                  | Statement events per schema and digest value    |
| events_statements_summary_by_host_by_event_name      | Statement events per host name and event name   |
| events_statements_summary_by_program                 | Statement events per stored program             |
| events_statements_summary_by_thread_by_event_name    | Statement events per thread and event name      |
| events_statements_summary_by_user_by_event_name      | Statement events per user name and event name   |
| events_statements_summary_global_by_event_name       | Statement events per event name                 |
| events_transactions_current                          | Current transaction events                      |
| events_transactions_history                          | Most recent transaction events for each thread  |
| events_transactions_history_long                     | Most recent transaction events overall          |
| events_transactions_summary_by_account_by_event_name | Transaction events per account and event name   |
| events_transactions_summary_by_host_by_event_name    | Transaction events per host name and event name |
| events_transactions_summary_by_thread_by_event_name  | Transaction events per thread and event name    |
| events_transactions_summary_by_user_by_event_name    | Transaction events per user name and event name |
| events_transactions_summary_global_by_event_name     | Transaction events per event name               |
| events_waits_current                                 | Current wait events                             |
| events_waits_history                                 | Most recent wait events for each thread         |
| events_waits_history_long                            | Most recent wait events overall                 |
| events_waits_summary_by_account_by_event_name        | Wait events per account and event name          |
| events_waits_summary_by_host_by_event_name           | Wait events per host name and event name        |

Performance Schema Table Index

| Table Name                                                   | Description                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------|
| <a href="#">events_waits_summary_by_instance</a>             | Wait events per instance                                            |
| <a href="#">events_waits_summary_by_thread_by_event_name</a> | Wait events per thread and event name                               |
| <a href="#">events_waits_summary_by_user_by_event_name</a>   | Wait events per user name and event name                            |
| <a href="#">events_waits_summary_global_by_event_name</a>    | Wait events per event name                                          |
| <a href="#">file_instances</a>                               | File instances                                                      |
| <a href="#">file_summary_by_event_name</a>                   | File events per event name                                          |
| <a href="#">file_summary_by_instance</a>                     | File events per file instance                                       |
| <a href="#">global_status</a>                                | Global status variables                                             |
| <a href="#">global_variables</a>                             | Global system variables                                             |
| <a href="#">host_cache</a>                                   | Information from the internal host cache                            |
| <a href="#">hosts</a>                                        | Connection statistics per client host name                          |
| <a href="#">memory_summary_by_account_by_event_name</a>      | Memory operations per account and event name                        |
| <a href="#">memory_summary_by_host_by_event_name</a>         | Memory operations per host and event name                           |
| <a href="#">memory_summary_by_thread_by_event_name</a>       | Memory operations per thread and event name                         |
| <a href="#">memory_summary_by_user_by_event_name</a>         | Memory operations per user and event name                           |
| <a href="#">memory_summary_global_by_event_name</a>          | Memory operations globally per event name                           |
| <a href="#">metadata_locks</a>                               | Metadata locks and lock requests                                    |
| <a href="#">mutex_instances</a>                              | Mutex synchronization object instances                              |
| <a href="#">objects_summary_global_by_type</a>               | Object summaries                                                    |
| <a href="#">performance_timers</a>                           | Which event timers are available                                    |
| <a href="#">prepared_statements_instances</a>                | Prepared statement instances and statistics                         |
| <a href="#">replication_connection_configuration</a>         | Configuration parameters for connecting to the master               |
| <a href="#">replication_connection_status</a>                | Current status of the connection to the master                      |
| <a href="#">replication_applier_configuration</a>            | Configuration parameters for the transaction applier on the slave   |
| <a href="#">replication_applier_status</a>                   | Current status of the transaction applier on the slave              |
| <a href="#">replication_applier_status_by_coordinator</a>    | SQL or coordinator thread applier status                            |
| <a href="#">replication_applier_status_by_worker</a>         | Worker thread applier status (empty unless slave is multi-threaded) |
| <a href="#">rwlock_instances</a>                             | Lock synchronization object instances                               |
| <a href="#">session_account_connect_attrs</a>                | Connection attributes per for the current session                   |
| <a href="#">session_connect_attrs</a>                        | Connection attributes for all sessions                              |
| <a href="#">session_status</a>                               | Status variables for current session                                |
| <a href="#">session_variables</a>                            | System variables for current session                                |
| <a href="#">setup_actors</a>                                 | How to initialize monitoring for new foreground threads             |
| <a href="#">setup_consumers</a>                              | Consumers for which event information can be stored                 |

| Table Name                                         | Description                                                       |
|----------------------------------------------------|-------------------------------------------------------------------|
| <code>setup_instruments</code>                     | Classes of instrumented objects for which events can be collected |
| <code>setup_objects</code>                         | Which objects should be monitored                                 |
| <code>setup_timers</code>                          | Current event timer                                               |
| <code>socket_instances</code>                      | Active connection instances                                       |
| <code>socket_summary_by_event_name</code>          | Socket waits and I/O per event name                               |
| <code>socket_summary_by_instance</code>            | Socket waits and I/O per instance                                 |
| <code>status_by_account</code>                     | Session status variables per account                              |
| <code>status_by_host</code>                        | Session status variables per host name                            |
| <code>status_by_thread</code>                      | Session status variables per session                              |
| <code>status_by_user</code>                        | Session status variables per user name                            |
| <code>table_handles</code>                         | Table locks and lock requests                                     |
| <code>table_io_waits_summary_by_index_usage</code> | Table I/O waits per index                                         |
| <code>table_io_waits_summary_by_table</code>       | Table I/O waits per table                                         |
| <code>table_lock_waits_summary_by_table</code>     | Table lock waits per table                                        |
| <code>threads</code>                               | Information about server threads                                  |
| <code>users</code>                                 | Connection statistics per client user name                        |
| <code>user_variables_by_thread</code>              | User-defined variables per thread                                 |
| <code>variables_by_thread</code>                   | Session system variables per session                              |

## 21.9.2 Performance Schema Setup Tables

The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the `UPDATE` privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- `setup_actors`: How to initialize monitoring for new foreground threads
- `setup_consumers`: The destinations to which event information can be sent and stored
- `setup_instruments`: The classes of instrumented objects for which events can be collected
- `setup_objects`: Which objects should be monitored
- `setup_timers`: The current event timer

### 21.9.2.1 The `setup_actors` Table

The `setup_actors` table contains information that determines whether to enable monitoring and historical event logging for new foreground server threads (threads associated with client connections). This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_actors_size` system variable at server startup.

For each new foreground thread, the Performance Schema matches the user and host for the thread against the rows of the `setup_actors` table. If a row from that table matches, its `ENABLED` and `HISTORY` column values are used to set the the `INSTRUMENTED` and `HISTORY` columns, respectively,

of the `threads` table row for the thread. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (combination of host and user). If there is no match, the `INSTRUMENTED` and `HISTORY` columns for the thread are set to `NO`.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial contents of the `setup_actors` table match any user and host combination, so monitoring and historical event collection are enabled by default for all foreground threads:

```
mysql> SELECT * FROM setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

For information about how to use the `setup_actors` table to affect event monitoring, see [Pre-Filtering by Thread](#).

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

The `setup_actors` table has these columns:

- `HOST`

The host name. This should be a literal name, or `'%'` to mean “any host.”

- `USER`

The user name. This should be a literal name, or `'%'` to mean “any user.”

- `ROLE`

Unused.

- `ENABLED`

Whether to enable instrumentation for foreground threads matched by the row. The value is `YES` or `NO`.

This column was added in MySQL 5.7.6. For earlier versions in which it is not present, the Performance Schema enables instrumentation only for foreground threads matched by some row in the table; instrumentation is implicitly disabled for nonmatching threads.

- `HISTORY`

Whether to log historical events for foreground threads matched by the row. The value is `YES` or `NO`.

This column was added in MySQL 5.7.8. For earlier versions in which it is not present, the Performance Schema logs historical events either for all threads or no threads, depending on which history consumers are enabled or disabled.

## 21.9.2.2 The `setup_consumers` Table

The `setup_consumers` table lists the types of consumers for which event information can be stored and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME | ENABLED |
+-----+-----+
```

|                                  |     |
|----------------------------------|-----|
| events_stages_current            | NO  |
| events_stages_history            | NO  |
| events_stages_history_long       | NO  |
| events_statements_current        | YES |
| events_statements_history        | YES |
| events_statements_history_long   | NO  |
| events_transactions_current      | NO  |
| events_transactions_history      | NO  |
| events_transactions_history_long | NO  |
| events_waits_current             | NO  |
| events_waits_history             | NO  |
| events_waits_history_long        | NO  |
| global_instrumentation           | YES |
| thread_instrumentation           | YES |
| statements_digest                | YES |

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. For detailed information about the effect of enabling different consumers, see [Pre-Filtering by Consumer](#).

Modifications to the `setup_consumers` table affect monitoring immediately.

The `setup_consumers` table has these columns:

- `NAME`

The consumer name.

- `ENABLED`

Whether the consumer is enabled. The value is `YES` or `NO`. This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

### 21.9.2.3 The `setup_instruments` Table

The `setup_instruments` table lists classes of instrumented objects for which events can be collected:

```
mysql> SELECT * FROM setup_instruments;
```

| NAME                                              | ENABLED | TIMED |
|---------------------------------------------------|---------|-------|
| ...                                               |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...                                               |         |       |
| wait/synch/rwlock/sql/LOCK_grant                  | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger         | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect       | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave         | YES     | YES   |
| ...                                               |         |       |
| wait/io/file/sql/binlog                           | YES     | YES   |
| wait/io/file/sql/binlog_index                     | YES     | YES   |
| wait/io/file/sql/casetest                         | YES     | YES   |
| wait/io/file/sql/dbopt                            | YES     | YES   |
| ...                                               |         |       |

Each instrument added to the source code provides a row for this table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the `*_instances` tables.

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect.

This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

For more information about the role of the `setup_instruments` table in event filtering, see [Section 21.2.3.3, “Event Pre-Filtering”](#).

The `setup_instruments` table has these columns:

- `NAME`

The instrument name. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#). Events produced from execution of an instrument have an `EVENT_NAME` value that is taken from the instrument `NAME` value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

- `ENABLED`

Whether the instrument is enabled. The value is `YES` or `NO`. This column can be modified. A disabled instrument produces no events.

- `TIMED`

Whether the instrument is timed. This column can be modified.

For memory instruments, the `TIMED` column in `setup_instruments` is ignored because memory operations are not timed.

If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

## 21.9.2.4 The `setup_objects` Table

The `setup_objects` table controls whether the Performance Schema monitors particular objects. This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_objects_size` system variable at server startup.

The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM setup_objects;
```

| OBJECT_TYPE | OBJECT_SCHEMA      | OBJECT_NAME | ENABLED | TIMED |
|-------------|--------------------|-------------|---------|-------|
| EVENT       | mysql              | %           | NO      | NO    |
| EVENT       | performance_schema | %           | NO      | NO    |
| EVENT       | information_schema | %           | NO      | NO    |
| EVENT       | %                  | %           | YES     | YES   |
| FUNCTION    | mysql              | %           | NO      | NO    |
| FUNCTION    | performance_schema | %           | NO      | NO    |
| FUNCTION    | information_schema | %           | NO      | NO    |
| FUNCTION    | %                  | %           | YES     | YES   |
| PROCEDURE   | mysql              | %           | NO      | NO    |
| PROCEDURE   | performance_schema | %           | NO      | NO    |
| PROCEDURE   | information_schema | %           | NO      | NO    |
| PROCEDURE   | %                  | %           | YES     | YES   |
| TABLE       | mysql              | %           | NO      | NO    |
| TABLE       | performance_schema | %           | NO      | NO    |
| TABLE       | information_schema | %           | NO      | NO    |
| TABLE       | %                  | %           | YES     | YES   |
| TRIGGER     | mysql              | %           | NO      | NO    |
| TRIGGER     | performance_schema | %           | NO      | NO    |
| TRIGGER     | information_schema | %           | NO      | NO    |
| TRIGGER     | %                  | %           | YES     | YES   |

Modifications to the `setup_objects` table affect object monitoring immediately.

For object types listed in `setup_objects`, the Performance Schema uses the table to how to monitor them. Object matching is based on the `OBJECT_SCHEMA` and `OBJECT_NAME` columns. Objects for which there is no match are not monitored.

The effect of the default object configuration is to instrument all tables except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For example, with a table `db1.t1`, it looks for a match for `'db1'` and `'t1'`, then for `'db1'` and `'%'`, then for `'%'` and `'%'`. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

Rows can be inserted into or deleted from `setup_objects` by users with the `INSERT` or `DELETE` privilege on the table. For existing rows, only the `ENABLED` and `TIMED` columns can be modified, by users with the `UPDATE` privilege on the table.

For more information about the role of the `setup_objects` table in event filtering, see [Section 21.2.3.3, “Event Pre-Filtering”](#).

The `setup_objects` table has these columns:

- `OBJECT_TYPE`

The type of object to instrument. The value is one of `'EVENT'` (Event Scheduler event), `'FUNCTION'` (stored function), `'PROCEDURE'` (stored procedure), `'TABLE'` (base table), or `'TRIGGER'` (trigger). Before MySQL 5.7.2, the value is always `'TABLE'`.

`TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

- `OBJECT_SCHEMA`

The schema that contains the object. This should be a literal name, or `'%'` to mean “any schema.”

- `OBJECT_NAME`

The name of the instrumented object. This should be a literal name, or `'%'` to mean “any object.”

- `ENABLED`

Whether events for the object are instrumented. The value is `YES` or `NO`. This column can be modified.

- `TIMED`

Whether events for the object are timed. This column can be modified.

### 21.9.2.5 The `setup_timers` Table

The `setup_timers` table shows the currently selected event timers:

```
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
idle	MICROSECOND
wait	CYCLE
stage	NANOSECOND
statement	NANOSECOND
```

```
| transaction | NANOSECOND |
+-----+-----+
```

The `setup_timers.TIMER_NAME` value can be changed to select a different timer. The value can be any of the values in the `performance_timers.TIMER_NAME` column. For an explanation of how event timing occurs, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The `setup_timers` table has these columns:

- `NAME`

The type of instrument the timer is used for.

- `TIMER_NAME`

The timer that applies to the instrument type. This column can be modified.

## 21.9.3 Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- `cond_instances`: Condition synchronization object instances
- `file_instances`: File instances
- `mutex_instances`: Mutex synchronization object instances
- `rwlock_instances`: Lock synchronization object instances
- `socket_instances`: Active connection instances

These tables list instrumented synchronization objects, files, and connections. There are three types of synchronization objects: `cond`, `mutex`, and `rwlock`. Each instance table has an `EVENT_NAME` or `NAME` column to indicate the instrument associated with each row. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see [Section 21.16, “Using the Performance Schema to Diagnose Problems”](#)

### 21.9.3.1 The `cond_instances` Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other thread, or threads, will cause the condition to happen.

The `cond_instances` table has these columns:

- `NAME`

The instrument name associated with the condition.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented condition.

### 21.9.3.2 The `file_instances` Table

The `file_instances` table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it will not be in `file_instances`. When a file is deleted from the disk, it is also removed from the `file_instances` table.

The `file_instances` table has these columns:

- `FILE_NAME`

The file name.

- `EVENT_NAME`

The instrument name associated with the file.

- `OPEN_COUNT`

The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but `OPEN_COUNT` will be 0. To list all the files currently opened by the server, use `WHERE OPEN_COUNT > 0`.

### 21.9.3.3 The `mutex_instances` Table

The `mutex_instances` table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads will compete against each other, so that the first query to obtain a lock on the mutex will cause the other query to wait until the first is done and unlocks the mutex.

The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.

The `mutex_instances` table has these columns:

- `NAME`

The instrument name associated with the mutex.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented mutex.

- `LOCKED_BY_THREAD_ID`

When a thread currently has a mutex locked, `LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

For every mutex instrumented in the code, the Performance Schema provides the following information.

- The `setup_instruments` table lists the name of the instrumentation point, with the prefix `wait/synch/mutex/`.
- When some code creates a mutex, a row is added to the `mutex_instances` table. The `OBJECT_INSTANCE_BEGIN` column is a property that uniquely identifies the mutex.

- When a thread attempts to lock a mutex, the `events_waits_current` table shows a row for that thread, indicating that it is waiting on a mutex (in the `EVENT_NAME` column), and indicating which mutex is waited on (in the `OBJECT_INSTANCE_BEGIN` column).
- When a thread succeeds in locking a mutex:
  - `events_waits_current` shows that the wait on the mutex is completed (in the `TIMER_END` and `TIMER_WAIT` columns)
  - The completed wait event is added to the `events_waits_history` and `events_waits_history_long` tables
  - `mutex_instances` shows that the mutex is now owned by the thread (in the `THREAD_ID` column).
- When a thread unlocks a mutex, `mutex_instances` shows that the mutex now has no owner (the `THREAD_ID` column is `NULL`).
- When a mutex object is destroyed, the corresponding row is removed from `mutex_instances`.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

- `events_waits_current`, to see what mutex a thread is waiting for
- `mutex_instances`, to see which other thread currently owns a mutex

### 21.9.3.4 The `rwlock_instances` Table

The `rwlock_instances` table lists all the `rwlock` (read write lock) instances seen by the Performance Schema while the server executes. An `rwlock` is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules. The resource is said to be “protected” by the `rwlock`. The access is either shared (many threads can have a read lock at the same time), exclusive (only one thread can have a write lock at a given time), or shared-exclusive (a thread can have a write lock while permitting inconsistent reads by other threads). Shared-exclusive access is otherwise known as an `sxlock` and was introduced in MySQL 5.7 to optimize concurrency and improve scalability for read-write workloads.

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, exclusive mode, shared-exclusive mode or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

- `NAME`

The instrument name associated with the lock.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented lock.

- `WRITE_LOCKED_BY_THREAD_ID`

When a thread currently has an `rwlock` locked in exclusive (write) mode, `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

- `READ_LOCKED_BY_COUNT`

When a thread currently has an `rwlock` locked in shared (read) mode, `READ_LOCKED_BY_COUNT` is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an `rwlock`, and see how many readers are currently active.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- `events_waits_current`, to see what `rwlock` a thread is waiting for
- `rwlock_instances`, to see which other thread currently owns an `rwlock`

There is a limitation: The `rwlock_instances` can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

### 21.9.3.5 The `socket_instances` Table

The `socket_instances` table provides a real-time snapshot of the active connections to the MySQL server. The table contains one row per TCP/IP or Unix socket file connection. Information available in this table provides a real-time snapshot of the active connections to the server. (Additional information is available in socket summary tables, including network activity such as socket operations and number of bytes transmitted and received; see [Section 21.9.14.9, “Socket Summary Tables”](#)).

```
mysql> SELECT * FROM socket_instances\G
***** 1. row *****
      EVENT_NAME: wait/io/socket/sql/server_unix_socket
OBJECT_INSTANCE_BEGIN: 4316619408
      THREAD_ID: 1
      SOCKET_ID: 16
        IP:
        PORT: 0
      STATE: ACTIVE
***** 2. row *****
      EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 4316644608
      THREAD_ID: 21
      SOCKET_ID: 39
        IP: 127.0.0.1
        PORT: 55233
      STATE: ACTIVE
***** 3. row *****
      EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
OBJECT_INSTANCE_BEGIN: 4316699040
      THREAD_ID: 1
      SOCKET_ID: 14
        IP: 0.0.0.0
        PORT: 50603
      STATE: ACTIVE
```

Socket instruments have names of the form `wait/io/socket/sql/socket_type` and are used like this:

1. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively.
2. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.
3. When a connection terminates, the row in `socket_instances` corresponding to it is deleted.

The `socket_instances` table has these columns:

- `EVENT_NAME`

The name of the `wait/io/socket/*` instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

- `OBJECT_INSTANCE_BEGIN`

This column uniquely identifies the socket. The value is the address of an object in memory.

- `THREAD_ID`

The internal thread identifier assigned by the server. Each socket is managed by a single thread, so each socket can be mapped to a thread which can be mapped to a server process.

- `SOCKET_ID`

The internal file handle assigned to the socket.

- `IP`

The client IP address. The value may be either an IPv4 or IPv6 address, or blank to indicate a Unix socket file connection.

- `PORT`

The TCP/IP port number, in the range from 0 to 65535.

- `STATE`

The socket status, either `IDLE` or `ACTIVE`. Wait times for active sockets are tracked using the corresponding socket instrument. Wait times for idle sockets are tracked using the `idle` instrument.

A socket is idle if it is waiting for a request from the client. When a socket becomes idle, the event row in `socket_instances` that is tracking the socket switches from a status of `ACTIVE` to `IDLE`. The `EVENT_NAME` value remains `wait/io/socket/*`, but timing for the instrument is suspended. Instead, an event is generated in the `events_waits_current` table with an `EVENT_NAME` value of `idle`.

When the next request is received, the `idle` event terminates, the socket instance switches from `IDLE` to `ACTIVE`, and timing of the socket instrument resumes.

The `IP:PORT` column combination value identifies the connection. This combination value is used in the `OBJECT_NAME` column of the `events_waits_XXX` tables, to identify the connection from which socket events come:

- For the Unix domain listener socket (`server_unix_socket`), the port is 0, and the IP is ''.
- For client connections via the Unix domain listener (`client_connection`), the port is 0, and the IP is ''.
- For the TCP/IP server listener socket (`server_tcpip_socket`), the port is always the master port (for example, 3306), and the IP is always 0.0.0.0.
- For client connections via the TCP/IP listener (`client_connection`), the port is whatever the server assigns, but never 0. The IP is the IP of the originating host (127.0.0.1 or ::1 for the local host)

## 21.9.4 Performance Schema Wait Event Tables

These tables store wait events:

- `events_waits_current`: Current wait events
- `events_waits_history`: The most recent wait events for each thread
- `events_waits_history_long`: The most recent wait events overall

The following sections describe those tables. There are also summary tables that aggregate information about wait events; see [Section 21.9.14.1, “Event Wait Summary Tables”](#).

## Wait Event Configuration

To enable collection of wait events, enable the relevant instruments and consumers.

The `setup_instruments` table contains instruments with names that begin with `wait`. For example:

```
mysql> SELECT * FROM setup_instruments
  -> WHERE NAME LIKE 'wait/io/file/innodb%';
```

| NAME                                 | ENABLED | TIMED |
|--------------------------------------|---------|-------|
| wait/io/file/innodb/innodb_data_file | YES     | YES   |
| wait/io/file/innodb/innodb_log_file  | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file | YES     | YES   |

```
mysql> SELECT * FROM setup_instruments WHERE
  -> NAME LIKE 'wait/io/socket/%';
```

| NAME                                   | ENABLED | TIMED |
|----------------------------------------|---------|-------|
| wait/io/socket/sql/server_tcpip_socket | NO      | NO    |
| wait/io/socket/sql/server_unix_socket  | NO      | NO    |
| wait/io/socket/sql/client_connection   | NO      | NO    |

To modify collection of wait events, change the `ENABLED` and `TIMING` columns of the relevant instruments. For example:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
  -> WHERE NAME LIKE 'wait/io/socket/sql/%';
```

The `setup_consumers` table contains consumer values with names corresponding to the current and recent wait event table names. These consumers may be used to filter collection of wait events. The wait consumers are disabled by default:

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%waits%';
```

| NAME                      | ENABLED |
|---------------------------|---------|
| events_waits_current      | NO      |
| events_waits_history      | NO      |
| events_waits_history_long | NO      |

To enable all wait consumers, do this:

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES'
  -> WHERE NAME LIKE '%waits%';
```

The `setup_timers` table contains a row with a `NAME` value of `wait` that indicates the unit for wait event timing. The default unit is `CYCLE`.

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'wait';
```

| NAME | TIMER_NAME |
|------|------------|
| wait | CYCLE      |

To change the timing unit, modify the `TIMER_NAME` value:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'NANOSECOND'
  -> WHERE NAME = 'wait';
```

---

For additional information about configuring event collection, see [Section 21.2, “Performance Schema Configuration”](#).

### 21.9.4.1 The `events_waits_current` Table

The `events_waits_current` table contains current wait events, one row per thread showing the current status of the thread's most recent monitored wait event.

The `events_waits_current` table can be truncated with `TRUNCATE TABLE`.

Of the tables that contain wait event rows, `events_waits_current` is the most fundamental. Other tables that contain wait event rows are logically derived from the current events. For example, the `events_waits_history` and `events_waits_history_long` tables are collections of the most recent wait events, up to a fixed number of rows.

For information about configuration of wait event collection, see [Section 21.9.4, “Performance Schema Wait Event Tables”](#).

The `events_waits_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together form a primary key that uniquely identifies the row. No two rows will have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.7.8. As of 5.7.8, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

- `SPINS`

For a mutex, the number of spin rounds. If the value is `NULL`, the code does not use spin rounds or spinning is not instrumented.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`, `OBJECT_INSTANCE_BEGIN`

These columns identify the object “being acted on.” What that means depends on the object type.

For a synchronization object (`cond`, `mutex`, `rwlock`):

- `OBJECT_SCHEMA`, `OBJECT_NAME`, and `OBJECT_TYPE` are `NULL`.
- `OBJECT_INSTANCE_BEGIN` is the address of the synchronization object in memory.

For a file I/O object:

- `OBJECT_SCHEMA` is `NULL`.
- `OBJECT_NAME` is the file name.
- `OBJECT_TYPE` is `FILE`.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a socket object:

- `OBJECT_NAME` is the `IP:PORT` value for the socket.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a table I/O object:

- `OBJECT_SCHEMA` is the name of the schema that contains the table.
- `OBJECT_NAME` is the table name.
- `OBJECT_TYPE` is `TABLE` for a persistent base table or `TEMPORARY TABLE` for a temporary table.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

An `OBJECT_INSTANCE_BEGIN` value itself has no meaning, except that different values indicate different objects. `OBJECT_INSTANCE_BEGIN` can be used for debugging. For example, it can be used with `GROUP BY OBJECT_INSTANCE_BEGIN` to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.

- `INDEX_NAME`

The name of the index used. `PRIMARY` indicates the table primary index. `NULL` means that no index was used.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

- `OPERATION`

The type of operation performed, such as `lock`, `read`, or `write`.

- [NUMBER\\_OF\\_BYTES](#)

The number of bytes read or written by the operation. For table I/O waits (events for the [wait/io/table/sql/handler](#) instrument), `NUMBER_OF_BYTES` is `NULL` before MySQL 5.7.5. For table I/O events as of 5.7.5, this column indicates the number of rows. If the value is greater than 1, the event is for a batch I/O operation. The following discussion describes the difference between exclusively single-row reporting and reporting that reflects batch I/O.

MySQL executes joins using a nested-loop implementation. The job of the Performance Schema instrumentation is to provide row count and accumulated execution time per table in the join. Assume a join query of the following form that is executed using a table join order of `t1`, `t2`, `t3`:

```
SELECT ... FROM t1 JOIN t2 ON ... JOIN t3 ON ...
```

Table “fanout” is the increase or decrease in number of rows from adding a table during join processing. If the fanout for table `t3` is greater than 1, the majority of row-fetch operations are for that table. Suppose that the join accesses 10 rows from `t1`, 20 rows from `t2` per row from `t1`, and 30 rows from `t3` per row of table `t2`. With single-row reporting, the total number of instrumented operations is:

```
10 + (10 * 20) + (10 * 20 * 30) = 6210
```

A significant reduction in the number of instrumented operations is achievable by aggregating them per scan (that is, per unique combination of rows from `t1` and `t2`). With batch I/O reporting, the Performance Schema produces an event for each scan of the innermost table `t3` rather than for each row, and the number of instrumented row operations reduces to:

```
10 + (10 * 20) + (10 * 20) = 410
```

That is a reduction of 93%, illustrating how the batch-reporting strategy significantly reduces Performance Schema overhead for table I/O by reducing the number of reporting calls. The tradeoff is lesser accuracy for event timing. Rather than time for an individual row operation as in per-row reporting, timing for batch I/O includes time spent for operations such as join buffering, aggregation, and returning rows to the client.

For batch I/O reporting to occur, these conditions must be true:

- Query execution accesses the innermost table of a query block (for a single-table query, that table counts as innermost)
  - Query execution does not request a single row from the table (so, for example, [eq\\_ref](#) access prevents use of batch reporting)
  - Query execution does not evaluate a subquery containing table access for the table
- [FLAGS](#)

Reserved for future use.

#### 21.9.4.2 The `events_waits_history` Table

The `events_waits_history` table contains the most recent `N` wait events per thread. The value of `N` is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_waits_history_size` system variable at server startup. Wait events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_waits_history` table has the same structure as `events_waits_current`. See [Section 21.9.4.1, “The `events\_waits\_current` Table”](#).

The `events_waits_history` table can be truncated with `TRUNCATE TABLE`.

For information about configuration of wait event collection, see [Section 21.9.4, “Performance Schema Wait Event Tables”](#).

### 21.9.4.3 The `events_waits_history_long` Table

The `events_waits_history_long` table contains the most recent *N* wait events. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_waits_history_long_size` system variable at server startup. Wait events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_waits_history_long` table has the same structure as `events_waits_current`. See [Section 21.9.4.1, “The `events\_waits\_current` Table”](#).

The `events_waits_history_long` table can be truncated with `TRUNCATE TABLE`.

For information about configuration of wait event collection, see [Section 21.9.4, “Performance Schema Wait Event Tables”](#).

## 21.9.5 Performance Schema Stage Event Tables

The Performance Schema instruments stages, which are steps during the statement-execution process, such as parsing a statement, opening a table, or performing a `filesort` operation. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table. Stages begin and end when state values change.

Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store stage events:

- `events_stages_current`: Current stage events
- `events_stages_history`: The most recent stage events for each thread
- `events_stages_history_long`: The most recent stage events overall

The following sections describe those tables. There are also summary tables that aggregate information about stage events; see [Section 21.9.14.2, “Stage Summary Tables”](#).

### Stage Event Configuration

To enable collection of stage events, enable the relevant instruments and consumers.

The `setup_instruments` table contains instruments with names that begin with `stage`. Other than those instruments that provide statement progress information, these instruments are disabled by default. For example:

```
mysql> SELECT * FROM setup_instruments WHERE NAME RLIKE 'stage/sql/[a-c]';
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
stage/sql/After create	NO	NO
stage/sql/allocating local table	NO	NO
stage/sql/altering table	NO	NO
stage/sql/committing alter table to storage engine	NO	NO
stage/sql/Changing master	NO	NO
stage/sql/Checking master version	NO	NO
stage/sql/checking permissions	NO	NO
+-----+-----+-----+
```

## Performance Schema Stage Event Tables

|                                               |    |    |
|-----------------------------------------------|----|----|
| stage/sql/checking privileges on cached query | NO | NO |
| stage/sql/checking query cache for query      | NO | NO |
| stage/sql/cleaning up                         | NO | NO |
| stage/sql/closing tables                      | NO | NO |
| stage/sql/Connecting to master                | NO | NO |
| stage/sql/converting HEAP to MyISAM           | NO | NO |
| stage/sql/Copying to group table              | NO | NO |
| stage/sql/Copying to tmp table                | NO | NO |
| stage/sql/copy to tmp table                   | NO | NO |
| stage/sql/Creating sort index                 | NO | NO |
| stage/sql/creating table                      | NO | NO |
| stage/sql/Creating tmp table                  | NO | NO |

As of MySQL 5.7.7, stage event instruments that provide statement progress information now are enabled and timed by default:

```
mysql> SELECT * FROM setup_instruments WHERE
-> ENABLED='YES' AND NAME LIKE "stage/%";
```

| NAME                                                 | ENABLED | TIMED |
|------------------------------------------------------|---------|-------|
| stage/sql/copy to tmp table                          | YES     | YES   |
| stage/innodb/alter table (end)                       | YES     | YES   |
| stage/innodb/alter table (flush)                     | YES     | YES   |
| stage/innodb/alter table (insert)                    | YES     | YES   |
| stage/innodb/alter table (log apply index)           | YES     | YES   |
| stage/innodb/alter table (log apply table)           | YES     | YES   |
| stage/innodb/alter table (merge sort)                | YES     | YES   |
| stage/innodb/alter table (read PK and internal sort) | YES     | YES   |
| stage/innodb/buffer pool load                        | YES     | YES   |

To modify collection of stage events, change the `ENABLED` and `TIMING` columns of the relevant instruments. For example:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
-> WHERE NAME = 'stage/sql/altering table';
```

The `setup_consumers` table contains consumer values with names corresponding to the current and recent stage event table names. These consumers may be used to filter collection of stage events. The stage consumers are disabled by default:

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%stages%';
```

| NAME                       | ENABLED |
|----------------------------|---------|
| events_stages_current      | NO      |
| events_stages_history      | NO      |
| events_stages_history_long | NO      |

To enable all stage consumers, do this:

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES'
-> WHERE NAME LIKE '%stages%';
```

The `setup_timers` table contains a row with a `NAME` value of `stage` that indicates the unit for stage event timing. The default unit is `NANOSECOND`.

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'stage';
```

| NAME  | TIMER_NAME |
|-------|------------|
| stage | NANOSECOND |

```
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
-> WHERE NAME = 'stage';
```

For additional information about configuring event collection, see [Section 21.2, “Performance Schema Configuration”](#).

## Stage Event Progress Information

As of MySQL 5.7.5, the Performance Schema stage event tables contain two columns that, taken together, provide a stage progress indicator for each row:

- `WORK_COMPLETED`: The number of work units completed for the stage
- `WORK_ESTIMATED`: The number of work units expected for the stage

Each column is `NULL` if no progress information is provided for an instrument. Interpretation of the information, if it is available, depends entirely on the instrument implementation. The Performance Schema tables provide a container to store progress data, but make no assumptions about the semantics of the metric itself:

- A “work unit” is an integer metric that increases over time during execution, such as the number of bytes, rows, files, or tables processed. The definition of “work unit” for a particular instrument is left to the instrumentation code providing the data.
- The `WORK_COMPLETED` value can increase one or many units at a time, depending on the instrumented code.
- The `WORK_ESTIMATED` value can change during the stage, depending on the instrumented code.

Instrumentation for a stage event progress indicator can implement any of the following behaviors:

- No progress instrumentation

This is the most typical case, where no progress data is provided. The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both `NULL`.

- Unbounded progress instrumentation

Only the `WORK_COMPLETED` column is meaningful. No data is provided for the `WORK_ESTIMATED` column, which displays 0.

By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, but cannot report whether the stage is near completion. Currently, no stages are instrumented like this.

- Bounded progress instrumentation

The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both meaningful.

This type of progress indicator is appropriate for an operation with a defined completion criterion, such as the table-copy instrument described later. By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, and can report the overall completion percentage for the stage, by computing the `WORK_COMPLETED / WORK_ESTIMATED` ratio.

The `stage/sql/copy to tmp table` instrument illustrates how progress indicators work. During execution of an `ALTER TABLE` statement, the `stage/sql/copy to tmp table` stage is used, and this stage can execute potentially for a long time, depending on the size of the data to copy.

The table-copy task has a defined termination (all rows copied), and the `stage/sql/copy to tmp table` stage is instrumented to provide bounded progress information: The work unit used is number of rows copied, `WORK_COMPLETED` and `WORK_ESTIMATED` are both meaningful, and their ratio indicates task percentage complete.

To enable the instrument and the relevant consumers, execute these statements:

```
mysql> UPDATE setup_instruments SET ENABLED='YES'
-> WHERE NAME='stage/sql/copy to tmp table';
mysql> UPDATE setup_consumers SET ENABLED='YES'
-> WHERE NAME LIKE 'events_stages_%';
```

To see the progress of an ongoing `ALTER TABLE` statement, select from the `events_stages_current` table.

### 21.9.5.1 The `events_stages_current` Table

The `events_stages_current` table contains current stage events, one row per thread showing the current status of the thread's most recent monitored stage event.

The `events_stages_current` table can be truncated with `TRUNCATE TABLE`.

Of the tables that contain stage event rows, `events_stages_current` is the most fundamental. Other tables that contain stage event rows are logically derived from the current events. For example, the `events_stages_history` and `events_stages_history_long` tables are collections of the most recent stage events, up to a fixed number of rows.

For information about configuration of stage event collection, see [Section 21.9.5, “Performance Schema Stage Event Tables”](#).

The `events_stages_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together form a primary key that uniquely identifies the row. No two rows will have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.7.8. As of 5.7.8, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

- `WORK_COMPLETED`, `WORK_ESTIMATED`

These columns provide stage progress information, for instruments that have been implemented to produce such information. `WORK_COMPLETED` indicates how many work units have been completed for the stage, and `WORK_ESTIMATED` indicates how many work units are expected for the stage. For more information, see [Stage Event Progress Information](#).

These columns were added in MySQL 5.7.5.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested. The nesting event for a stage event is usually a statement event.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

### 21.9.5.2 The `events_stages_history` Table

The `events_stages_history` table contains the most recent *N* stage events per thread. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_size` system variable at server startup. Stage events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_stages_history` table has the same structure as `events_stages_current`. See [Section 21.9.5.1, “The `events\_stages\_current` Table”](#).

The `events_stages_history` table can be truncated with `TRUNCATE TABLE`.

For information about configuration of stage event collection, see [Section 21.9.5, “Performance Schema Stage Event Tables”](#).

### 21.9.5.3 The `events_stages_history_long` Table

The `events_stages_history_long` table contains the most recent *N* stage events. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_long_size` system variable at server startup. Stage events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_stages_history_long` table has the same structure as `events_stages_current`. See [Section 21.9.5.1, “The `events\_stages\_current` Table”](#).

The `events_stages_history_long` table can be truncated with `TRUNCATE TABLE`.

For information about configuration of stage event collection, see [Section 21.9.5, “Performance Schema Stage Event Tables”](#).

## 21.9.6 Performance Schema Statement Event Tables

The Performance Schema instruments statement execution. Statement events occur at a high level of the event hierarchy: Wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store statement events:

- `events_statements_current`: Current statement events
- `events_statements_history`: The most recent statement events for each thread
- `events_statements_history_long`: The most recent statement events overall
- `prepared_statements_instances`: Prepared statement instances and statistics (added in MySQL 5.7.4)

The following sections describe those tables. There are also summary tables that aggregate information about statement events; see [Section 21.9.14.3, “Statement Summary Tables”](#).

### Statement Event Configuration

To enable collection of statement events, enable the relevant instruments and consumers.

The `setup_instruments` table contains instruments with names that begin with `statement`. These instruments are enabled by default:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'statement/%';
+-----+-----+-----+
| NAME                                | ENABLED | TIMED |
+-----+-----+-----+
statement/sql/select	YES	YES
statement/sql/create_table	YES	YES
statement/sql/create_index	YES	YES
...		
statement/sp/stmt	YES	YES
statement/sp/set	YES	YES
statement/sp/set_trigger_field	YES	YES
statement/scheduler/event	YES	YES
statement/com/Sleep	YES	YES
statement/com/Quit	YES	YES
statement/com/Init DB	YES	YES
...		
statement/abstract/Query	YES	YES
statement/abstract/new_packet	YES	YES
statement/abstract/relay_log	YES	YES
+-----+-----+-----+
```

To modify collection of statement events, change the `ENABLED` and `TIMING` columns of the relevant instruments. For example:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
-> WHERE NAME LIKE 'statement/com/%';
```

The `setup_consumers` table contains consumer values with names corresponding to the current and recent statement event table names, and the statement digest consumer. These consumers may be used to filter collection of statement events and statement digesting. `events_statements_current`, `events_statements_history`, and `statements_digest` are enabled by default (before MySQL 5.7.5, `events_statements_history` is disabled by default):

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%statements%';
```

| NAME                           | ENABLED |
|--------------------------------|---------|
| events_statements_current      | YES     |
| events_statements_history      | YES     |
| events_statements_history_long | NO      |
| statements_digest              | YES     |

To enable all statement consumers, do this:

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES'
-> WHERE NAME LIKE '%statements%';
```

The `setup_timers` table contains a row with a `NAME` value of `statement` that indicates the unit for statement event timing. The default unit is `NANOSECOND`.

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'statement';
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
| statement | NANOSECOND |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
-> WHERE NAME = 'statement';
```

For additional information about configuring event collection, see [Section 21.2, “Performance Schema Configuration”](#).

## Statement Monitoring

Statement monitoring begins from the moment the server sees that activity is requested on a thread, to the moment when all activity has ceased. Typically, this means from the time the server gets the first packet from the client to the time the server has finished sending the response. Before MySQL 5.7.2, monitoring occurs only for top-level statements. Statements within stored programs and subqueries are not seen separately. As of 5.7.2, statements within stored programs are monitored like other statements.

When the Performance Schema instruments a request (server command or SQL statement), it uses instrument names that proceed in stages from more general (or “abstract”) to more specific until it arrives at a final instrument name.

Final instrument names correspond to server commands and SQL statements:

- Server commands correspond to the `COM_xxx` codes defined in the `mysql_com.h` header file and processed in `sql/sql_parse.cc`. Examples are `COM_PING` and `COM_QUIT`. Instruments for commands have names that begin with `statement/com`, such as `statement/com/Ping` and `statement/com/Quit`.
- SQL statements are expressed as text, such as `DELETE FROM t1` or `SELECT * FROM t2`. Instruments for SQL statements have names that begin with `statement/sql`, such as `statement/sql/delete` and `statement/sql/select`.

Some final instrument names are specific to error handling:

- `statement/com/Error` accounts for messages received by the server that are out of band. It can be used to detect commands sent by clients that the server does not understand. This may be

---

helpful for purposes such as identifying clients that are misconfigured or using a version of MySQL more recent than that of the server, or clients that are attempting to attack the server.

- `statement/sql/error` accounts for SQL statements that fail to parse. It can be used to detect malformed queries sent by clients. A query that fails to parse differs from a query that parses but fails due to an error during execution. For example, `SELECT * FROM` is malformed, and the `statement/sql/error` instrument is used. By contrast, `SELECT *` parses but fails with a `No tables used` error. In this case, `statement/sql/select` is used and the statement event contains information to indicate the nature of the error.

A request can be obtained from any of these sources:

- As a command or statement request from a client, which sends the request as packets
- As a statement string read from the relay log on a replication slave (as of MySQL 5.7.2)
- As an event from the Event Scheduler (as of MySQL 5.7.2)

The details for a request are not initially known and the Performance Schema proceeds from abstract to specific instrument names in a sequence that depends on the source of the request.

For a request received from a client:

1. When the server detects a new packet at the socket level, a new statement is started with an abstract instrument name of `statement/abstract/new_packet`.
2. When the server reads the packet number, it knows more about the type of request received, and the Performance Schema refines the instrument name. For example, if the request is a `COM_PING` packet, the instrument name becomes `statement/com/Ping` and that is the final name. If the request is a `COM_QUERY` packet, it is known to correspond to a SQL statement but not the particular type of statement. In this case, the instrument changes from one abstract name to a more specific but still abstract name, `statement/abstract/Query`, and the request requires further classification.
3. If the request is a statement, the statement text is read and given to the parser. After parsing, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

For a request read as a statement from the relay log on a replication slave:

1. Statements in the relay log are stored as text and are read as such. There is no network protocol, so the `statement/abstract/new_packet` instrument is not used. Instead, the initial instrument is `statement/abstract/relay_log`.
2. When the statement is parsed, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

The preceding description applies only for statement-based replication. For row-based replication, table I/O done on the slave as it processes row changes can be instrumented, but row events in the relay log do not appear as discrete statements.

For a request received from the Event Scheduler:

The event execution is instrumented using the name `statement/scheduler/event`. This is the final name.

Statements executed within the event body are instrumented using `statement/sql/*` names, without use of any preceding abstract instrument. An event is a stored program, and stored programs are precompiled in memory before execution. Consequently, there is no parsing at runtime and the type of each statement is known by the time it executes.

Statements executed within the event body are child statements. For example, if an event executes an `INSERT` statement, execution of the event itself is the parent, instrumented using `statement/scheduler/event`, and the `INSERT` is the child, instrumented using `statement/sql/insert`. The parent/child relationship holds *between* separate instrumented operations. This differs from the sequence of refinement that occurs *within* a single instrumented operation, from abstract to final instrument names.

For statistics to be collected for statements, it is not sufficient to enable only the final `statement/sql/*` instruments used for individual statement types. The abstract `statement/abstract/*` instruments must be enabled as well. This should not normally be an issue because all statement instruments are enabled by default. However, an application that enables or disables statement instruments selectively must take into account that disabling abstract instruments also disables statistics collection for the individual statement instruments. For example, to collect statistics for `INSERT` statements, `statement/sql/insert` must be enabled, but also `statement/abstract/new_packet` and `statement/abstract/Query`. Similarly, for replicated statements to be instrumented, `statement/abstract/relay_log` must be enabled.

No statistics are aggregated for abstract instruments such as `statement/abstract/Query` because no statement is ever classified with an abstract instrument as the final statement name.

The abstract instrument names in the preceding discussion are as of MySQL 5.7.3. In earlier 5.7 versions, there was some renaming before those names were settled on:

- `statement/abstract/new_packet` was `statement/com/` before MySQL 5.7.3.
- `statement/abstract/Query` was `statement/com/Query` before MySQL 5.7.3.
- `statement/abstract/relay_log` was `statement/rpl/relay_log` in MySQL 5.7.2 and did not exist before that.

### 21.9.6.1 The `events_statements_current` Table

The `events_statements_current` table contains current statement events, one row per thread showing the current status of the thread's most recent monitored statement event.

The `events_statements_current` table can be truncated with `TRUNCATE TABLE`.

Of the tables that contain statement event rows, `events_statements_current` is the most fundamental. Other tables that contain statement event rows are logically derived from the current events. For example, the `events_statements_history` and `events_statements_history_long` tables are collections of the most recent statement events, up to a fixed number of rows.

For information about configuration of statement event collection, see [Section 21.9.6, “Performance Schema Statement Event Tables”](#).

The `events_statements_current` table has these columns:

- `THREAD_ID, EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together form a primary key that uniquely identifies the row. No two rows will have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

---

The name of the instrument from which the event was collected. This is a [NAME](#) value from the [setup\\_instruments](#) table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

For SQL statements, the [EVENT\\_NAME](#) value initially is `statement/com/Query` until the statement is parsed, then changes to a more appropriate value, as described in [Section 21.9.6, “Performance Schema Statement Event Tables”](#).

- [SOURCE](#)

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- [TIMER\\_START](#), [TIMER\\_END](#), [TIMER\\_WAIT](#)

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The [TIMER\\_START](#) and [TIMER\\_END](#) values indicate when event timing started and ended. [TIMER\\_WAIT](#) is the event elapsed time (duration).

If an event has not finished, [TIMER\\_END](#) and [TIMER\\_WAIT](#) are `NULL` before MySQL 5.7.8. As of 5.7.8, [TIMER\\_END](#) is the current timer value and [TIMER\\_WAIT](#) is the time elapsed so far ([TIMER\\_END](#) - [TIMER\\_START](#)).

If an event is produced from an instrument that has [TIMED](#) = `NO`, timing information is not collected, and [TIMER\\_START](#), [TIMER\\_END](#), and [TIMER\\_WAIT](#) are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

- [LOCK\\_TIME](#)

The time spent waiting for table locks. This value is computed in microseconds but normalized to picoseconds for easier comparison with other Performance Schema timers.

- [SQL\\_TEXT](#)

The text of the SQL statement. For a command not associated with a SQL statement, the value is `NULL`.

As of MySQL 5.7.6, the maximum number of bytes to display can be changed by changing the [performance\\_schema\\_max\\_sql\\_text\\_length](#) system variable at server startup. Before 5.7.6, the maximum is fixed at 1024.

- [DIGEST](#)

The statement digest MD5 value as a string of 32 hexadecimal characters, or `NULL` if the [statement\\_digest](#) consumer is `no`. For more information about statement digesting, see [Section 21.7, “Performance Schema Statement Digests”](#).

- [DIGEST\\_TEXT](#)

The normalized statement digest text, or `NULL` if the [statement\\_digest](#) consumer is `no`. For more information about statement digesting, see [Section 21.7, “Performance Schema Statement Digests”](#).

The [performance\\_schema\\_max\\_digest\\_length](#) system variable determines the maximum number of bytes available for computing statement digests. However, the display length of statement digests may be longer than the available buffer size due to encoding of statement components such as keywords and literal values in digest buffer. Consequently, values selected from the [DIGEST\\_TEXT](#) column of statement event tables may appear to exceed the [performance\\_schema\\_max\\_digest\\_length](#) value.

This variable was added in MySQL 5.7.8. In MySQL 5.7.6 and 5.7.7, use `max_digest_length` instead. Before 5.7.6, the value cannot be changed.

- `CURRENT_SCHEMA`

The default database for the statement, `NULL` if there is none.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`

For nested statements (stored programs), these columns contain information about the parent statement. Otherwise they are `NULL`.

- `OBJECT_INSTANCE_BEGIN`

This column identifies the statement. The value is the address of an object in memory.

- `MYSQL_ERRNO`

The statement error number, from the statement diagnostics area.

- `RETURNED_SQLSTATE`

The statement SQLSTATE value, from the statement diagnostics area.

- `MESSAGE_TEXT`

The statement error message, from the statement diagnostics area.

- `ERRORS`

Whether an error occurred for the statement. The value is 0 if the SQLSTATE value begins with 00 (completion) or 01 (warning). The value is 1 if the SQLSTATE value is anything else.

- `WARNINGS`

The number of warnings, from the statement diagnostics area.

- `ROWS_AFFECTED`

The number of rows affected by the statement. For a description of the meaning of “affected,” see [Section 23.8.7.1, “mysql\\_affected\\_rows\(\)”](#).

- `ROWS_SENT`

The number of rows returned by the statement.

- `ROWS_EXAMINED`

The number of rows read from storage engines during statement execution.

- `CREATED_TMP_DISK_TABLES`

Like the `Created_tmp_disk_tables` status variable, but specific to the statement.

- `CREATED_TMP_TABLES`

Like the `Created_tmp_tables` status variable, but specific to the statement.

- `SELECT_FULL_JOIN`

Like the `Select_full_join` status variable, but specific to the statement.

- `SELECT_FULL_RANGE_JOIN`

Like the `Select_full_range_join` status variable, but specific to the statement.

- `SELECT_RANGE`

Like the `Select_range` status variable, but specific to the statement.

- `SELECT_RANGE_CHECK`

Like the `Select_range_check` status variable, but specific to the statement.

- `SELECT_SCAN`

Like the `Select_scan` status variable, but specific to the statement.

- `SORT_MERGE_PASSES`

Like the `Sort_merge_passes` status variable, but specific to the statement.

- `SORT_RANGE`

Like the `Sort_range` status variable, but specific to the statement.

- `SORT_ROWS`

Like the `Sort_rows` status variable, but specific to the statement.

- `SORT_SCAN`

Like the `Sort_scan` status variable, but specific to the statement.

- `NO_INDEX_USED`

1 if the statement performed a table scan without using an index, 0 otherwise.

- `NO_GOOD_INDEX_USED`

1 if the server found no good index to use for the statement, 0 otherwise. For additional information, see the description of the `Extra` column from `EXPLAIN` output for the `Range checked for each record` value in [Section 8.8.2, “EXPLAIN Output Format”](#).

- `NESTING_EVENT_ID`, `NESTING_EVENT_TYPE`, `NESTING_EVENT_LEVEL`

Before MySQL 5.7.2, only `NESTING_EVENT_ID` and `NESTING_EVENT_TYPE` exist and are always `NULL`.

As of MySQL 5.7.2, all three columns exist and are used with other columns to provide information as follows for top-level (unnested) statements and nested statements (executed within a stored program).

For top level statements:

```
OBJECT_TYPE = NULL
OBJECT_SCHEMA = NULL
OBJECT_NAME = NULL
NESTING_EVENT_ID = NULL
NESTING_EVENT_TYPE = NULL
NESTING_LEVEL = 0
```

For nested statements:

```
OBJECT_TYPE = the parent statement object type
OBJECT_SCHEMA = the parent statement object schema
```

```

OBJECT_NAME = the parent statement object name
NESTING_EVENT_ID = the parent statement EVENT_ID
NESTING_EVENT_TYPE = 'STATEMENT'
NESTING_LEVEL = the parent statement NESTING_LEVEL plus one

```

### 21.9.6.2 The `events_statements_history` Table

The `events_statements_history` table contains the most recent *N* statement events per thread. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_size` system variable at server startup. Statement events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_statements_history` table has the same structure as `events_statements_current`. See [Section 21.9.6.1, “The `events\_statements\_current` Table”](#).

The `events_statements_history` table can be truncated with `TRUNCATE TABLE`.

For information about configuration of statement event collection, see [Section 21.9.6, “Performance Schema Statement Event Tables”](#).

### 21.9.6.3 The `events_statements_history_long` Table

The `events_statements_history_long` table contains the most recent *N* statement events. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_long_size` system variable at server startup. Statement events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_statements_history_long` table has the same structure as `events_statements_current`. See [Section 21.9.6.1, “The `events\_statements\_current` Table”](#).

The `events_statements_history_long` table can be truncated with `TRUNCATE TABLE`.

For information about configuration of statement event collection, see [Section 21.9.6, “Performance Schema Statement Event Tables”](#).

### 21.9.6.4 The `prepared_statements_instances` Table

As of MySQL 5.7.4, the Performance Schema provides instrumentation for prepared statements, for which there are two protocols:

- The binary protocol. This is accessed through the MySQL C API and maps onto underlying server commands as shown in the following table.

| C API Function                    | Corresponding Server Command  |
|-----------------------------------|-------------------------------|
| <code>mysql_stmt_prepare()</code> | <code>COM_STMT_PREPARE</code> |
| <code>mysql_stmt_execute()</code> | <code>COM_STMT_EXECUTE</code> |
| <code>mysql_stmt_close()</code>   | <code>COM_STMT_CLOSE</code>   |

- The text protocol. This is accessed using SQL statements and maps onto underlying server commands as shown in the following table.

| SQL Statement                                 | Corresponding Server Command           |
|-----------------------------------------------|----------------------------------------|
| <code>PREPARE</code>                          | <code>SQLCOM_PREPARE</code>            |
| <code>EXECUTE</code>                          | <code>SQLCOM_EXECUTE</code>            |
| <code>DEALLOCATE PREPARE, DROP PREPARE</code> | <code>SQLCOM_DEALLOCATE PREPARE</code> |

Performance Schema prepared statement instrumentation covers both protocols. The following discussion refers to the server commands rather than the C API functions or SQL statements.

Information about prepared statements is available in the `prepared_statements_instances` table. This table enables inspection of prepared statements used in the server and provides aggregated statistics about them. To control the size of this table, set the `performance_schema_max_prepared_statements_instances` system variable at server startup.

Collection of prepared statement information depends on the statement instruments shown in the following table. These instruments are enabled by default. To modify them, update the `setup_instruments` table.

| Instrument                             | Server Command                |
|----------------------------------------|-------------------------------|
| <code>statement/com/Prepare</code>     | <code>COM_STMT_PREPARE</code> |
| <code>statement/com/Execute</code>     | <code>COM_STMT_EXECUTE</code> |
| <code>statement/sql/prepare_sql</code> | <code>SQLCOM_PREPARE</code>   |
| <code>statement/sql/execute_sql</code> | <code>SQLCOM_EXECUTE</code>   |

The Performance Schema manages the contents of the `prepared_statements_instances` table as follows:

- Statement preparation

A `COM_STMT_PREPARE` or `SQLCOM_PREPARE` command creates a prepared statement in the server. If the statement is successfully instrumented, a new row is added to the `prepared_statements_instances` table. If the statement cannot be instrumented, `Performance_schema_prepared_statements_lost` status variable is incremented.

- Prepared statement execution

Execution of a `COM_STMT_EXECUTE` or `SQLCOM_EXECUTE` command for an instrumented prepared statement instance updates the corresponding `prepared_statements_instances` table row.

- Prepared statement deallocation

Execution of a `COM_STMT_CLOSE` or `SQLCOM_DEALLOCATE_PREPARE` command for an instrumented prepared statement instance removes the corresponding `prepared_statements_instances` table row. To avoid resource leaks, removal occurs even if the prepared statement instruments described previously are disabled.

The `prepared_statements_instances` table has these columns:

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented prepared statement.

- `STATEMENT_ID`

The internal statement ID assigned by the server. The text and binary protocols both use statement IDs.

- `STATEMENT_NAME`

For the binary protocol, this column is `NULL`. For the text protocol, this column is the external statement name assigned by the user. For example, for the following SQL statement, the name of the prepared statement is `stmt`:

```
PREPARE stmt FROM 'SELECT 1';
```

- `SQL_TEXT`

The prepared statement text, with ? placeholder markers.

- `OWNER_THREAD_ID`, `OWNER_EVENT_ID`

These columns indicate the event that created the prepared statement.

- `OWNER_OBJECT_TYPE`, `OWNER_OBJECT_SCHEMA`, `OWNER_OBJECT_NAME`

For a prepared statement created by a client session, these columns are `NULL`. For a prepared statement created by a stored program, these columns point to the stored program. A typical user error is forgetting to deallocate prepared statements. These columns can be used to find stored programs that leak prepared statements:

```
SELECT OWNER_OBJECT_TYPE, OWNER_OBJECT_SCHEMA, OWNER_OBJECT_NAME,
STATEMENT_NAME, SQL_TEXT
FROM performance_schema.prepared_statements_instances
WHERE OWNER_OBJECT_TYPE IS NOT NULL;
```

- `TIMER_PREPARE`

The time spent executing the statement preparation itself.

- `COUNT_REPREPARE`

The number of times the statement was reprepared internally (see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#)). Timing statistics for reparation are not available because it is counted as part of statement execution, not as a separate operation.

- `COUNT_EXECUTE`, `SUM_TIMER_EXECUTE`, `MIN_TIMER_EXECUTE`, `AVG_TIMER_EXECUTE`, `MAX_TIMER_EXECUTE`

Aggregated statistics for executions of the prepared statement.

- `SUM_xxx`

The remaining `SUM_xxx` columns are the same as for the statement summary tables (see [Section 21.9.14.3, “Statement Summary Tables”](#)).

`TRUNCATE TABLE` resets the statistics columns of the table.

## 21.9.7 Performance Schema Transaction Tables

As of MySQL 5.7.3, the Performance Schema instruments transactions. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store transaction events:

- `events_transactions_current`: Current transaction events
- `events_transactions_history`: The most recent transaction events for each thread
- `events_transactions_history_long`: The most recent transaction events overall

The following sections describe those tables. There are also summary tables that aggregate information about transaction events; see [Section 21.9.14.4, “Transaction Summary Tables”](#).

### Transaction Event Configuration

To enable collection of transaction events, enable the relevant instruments and consumers.

The `setup_instruments` table contains an instrument named `transaction`. This instrument is disabled by default:

```
mysql> SELECT * FROM setup_instruments WHERE NAME = 'transaction';
+-----+-----+-----+
| NAME          | ENABLED | TIMED |
+-----+-----+-----+
| transaction   | NO      | NO    |
+-----+-----+-----+
```

To enable collection of transaction events, including timing information, do this:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
-> WHERE NAME = 'transaction';
```

The `setup_consumers` table contains consumer values with names corresponding to the current and recent transaction event table names. These consumers may be used to filter collection of transaction events:

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%transactions%';
+-----+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+-----+
events_transactions_current	NO
events_transactions_history	NO
events_transactions_history_long	NO
+-----+-----+-----+
```

To enable all transaction consumers, do this:

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES'
-> WHERE NAME LIKE '%transactions%';
```

To enable collection of transaction events only for specific transaction event tables, enable the corresponding transaction consumers.

The `setup_timers` table contains a row with a `NAME` value of `transaction` that indicates the unit for transaction event timing. The default unit is `NANOSECOND`.

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'transaction';
+-----+-----+
| NAME          | TIMER_NAME |
+-----+-----+
| transaction   | NANOSECOND |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
-> WHERE NAME = 'transaction';
```

For additional information about configuring event collection, see [Section 21.2, “Performance Schema Configuration”](#).

## Transaction Boundaries

In MySQL Server, transactions start explicitly with these statements:

```
START TRANSACTION | BEGIN | XA START | XA BEGIN
```

Transactions also start implicitly. For example, when the `autocommit` system variable is enabled, the start of each statement starts a new transaction.

When `autocommit` is disabled, the first statement following a committed transaction marks the start of a new transaction. Subsequent statements are part of the transaction until it is committed.

Transactions explicitly end with these statements:

```
COMMIT | ROLLBACK | XA COMMIT | XA ROLLBACK
```

Transactions also end implicitly, by execution of DDL statements, locking statements, and server administration statements.

In the following discussion, references to `START TRANSACTION` also apply to `BEGIN`, `XA START`, and `XA BEGIN`. Similarly, references to `COMMIT` and `ROLLBACK` apply to `XA COMMIT` and `XA ROLLBACK`, respectively.

The Performance Schema defines transaction boundaries similarly to that of the server. The start and end of a transaction event closely match the corresponding state transitions in the server:

- For an explicitly started transaction, the transaction event starts during processing of the `START TRANSACTION` statement.
- For an implicitly started transaction, the transaction event starts on the first statement that uses a transactional engine after the previous transaction has ended.
- For any transaction, whether explicitly or implicitly ended, the transaction event ends when the server transitions out of the active transaction state during the processing of `COMMIT` or `ROLLBACK`.

There are subtle implications to this approach:

- Transaction events in the Performance Schema do not fully include the statement events associated with the corresponding `START TRANSACTION`, `COMMIT`, or `ROLLBACK` statements. There is a trivial amount of timing overlap between the transaction event and these statements.
- Statements that work with nontransactional engines have no effect on the transaction state of the connection. For implicit transactions, the transaction event begins with the first statement that uses a transactional engine. This means that statements operating exclusively on nontransactional tables are ignored, even following `START TRANSACTION`.

To illustrate, consider the following scenario:

```
1. SET autocommit = OFF;
2. CREATE TABLE t1 (a INT) ENGINE = InnoDB;
3. START TRANSACTION;                -- Transaction 1 START
4. INSERT INTO t1 VALUES (1), (2), (3);
5. CREATE TABLE t2 (a INT) ENGINE = MyISAM; -- Transaction 1 COMMIT
   -- (implicit; DDL forces commit)
6. INSERT INTO t2 VALUES (1), (2), (3); -- Update nontransactional table
7. UPDATE t2 SET a = a + 1;             -- ... and again
8. INSERT INTO t1 VALUES (4), (5), (6); -- Write to transactional table
   -- Transaction 2 START (implicit)
9. COMMIT;                             -- Transaction 2 COMMIT
```

From the perspective of the server, Transaction 1 ends when table `t2` is created. Transaction 2 does not start until a transactional table is accessed, despite the intervening updates to nontransactional tables.

From the perspective of the Performance Schema, Transaction 2 starts when the server transitions into an active transaction state. Statements 6 and 7 are not included within the boundaries of Transaction 2, which is consistent with how the server writes transactions to the binary log.

## Transaction Instrumentation

Three attributes define transactions:

- Access mode (read only, read write)
- Isolation level (`SERIALIZABLE`, `REPEATABLE READ`, and so forth)
- Implicit (`autocommit` enabled) or explicit (`autocommit` disabled)

To reduce complexity of the transaction instrumentation and to ensure that the collected transaction data provides complete, meaningful results, all transactions are instrumented independently of access mode, isolation level, or autocommit mode.

To selectively examine transaction history, use the attribute columns in the transaction event tables: `ACCESS_MODE`, `ISOLATION_LEVEL`, and `AUTOCOMMIT`.

The cost of transaction instrumentation can be reduced various ways, such as enabling or disabling transaction instrumentation according to user, account, host, or thread (client connection).

## Transactions and Nested Events

The parent of a transaction event is the event that initiated the transaction. For an explicitly started transaction, this includes the `START TRANSACTION` and `COMMIT AND CHAIN` statements. For an implicitly started transaction, it is the first statement that uses a transactional engine after the previous transaction ends.

In general, a transaction is the top-level parent to all events initiated during the transaction, including statements that explicitly end the transaction such as `COMMIT` and `ROLLBACK`. Exceptions are statements that implicitly end a transaction, such as DDL statements, in which case the current transaction must be committed before the new statement is executed.

## Transactions and Stored Programs

Transactions and stored program events are related as follows:

- Stored Procedures

Stored procedures operate independently of transactions. A stored procedure can be started within a transaction, and a transaction can be started or ended from within a stored procedure. If called from within a transaction, a stored procedure can execute statements that force a commit of the parent transaction and then start a new transaction.

If a stored procedure is started within a transaction, that transaction is the parent of the stored procedure event.

If a transaction is started by a stored procedure, the stored procedure is the parent of the transaction event.

- Stored Functions

Stored functions are restricted from causing an explicit or implicit commit or rollback. Stored function events can reside within a parent transaction event.

- Triggers

Triggers activate as part of a statement that accesses the table with which it is associated, so the parent of a trigger event is always the statement that activates it.

Triggers cannot issue statements that cause an explicit or implicit commit or rollback of a transaction.

- Scheduled Events

The execution of the statements in the body of a scheduled event takes place in a new connection. Nesting of a scheduled event within a parent transaction is not applicable.

## Transactions and Savepoints

Savepoint statements are recorded as separate statement events. Transaction events include separate counters for [SAVEPOINT](#), [ROLLBACK TO SAVEPOINT](#), and [RELEASE SAVEPOINT](#) statements issued during the transaction.

## Transactions and Errors

Errors and warnings that occur within a transaction are recorded in statement events, but not in the corresponding transaction event. This includes transaction-specific errors and warnings, such as a rollback on a nontransactional table or GTID consistency errors.

### 21.9.7.1 The `events_transactions_current` Table

The `events_transactions_current` table (added in MySQL 5.7.3) contains current transaction events, one row per thread showing the current status of the thread's most recent monitored transaction event. For example:

```
mysql> SELECT * FROM events_transactions_current LIMIT 1\G
***** 1. row *****
      THREAD_ID: 26
      EVENT_ID: 7
      END_EVENT_ID: NULL
      EVENT_NAME: transaction
      STATE: ACTIVE
      TRX_ID: NULL
      GTID: 3E11FA47-71CA-11E1-9E33-C80AA9429562:56
      XID: NULL
      XA_STATE: NULL
      SOURCE: transaction.cc:150
      TIMER_START: 420833537900000
      TIMER_END: NULL
      TIMER_WAIT: NULL
      ACCESS_MODE: READ WRITE
      ISOLATION_LEVEL: REPEATABLE READ
      AUTOCOMMIT: NO
      NUMBER_OF_SAVEPOINTS: 0
      NUMBER_OF_ROLLBACK_TO_SAVEPOINT: 0
      NUMBER_OF_RELEASE_SAVEPOINT: 0
      OBJECT_INSTANCE_BEGIN: NULL
      NESTING_EVENT_ID: 6
      NESTING_EVENT_TYPE: STATEMENT
```

The `events_transactions_current` table can be truncated with [TRUNCATE TABLE](#).

Of the tables that contain transaction event rows, `events_transactions_current` is the most fundamental. Other tables that contain transaction event rows are logically derived from the current events. For example, the `events_transactions_history` and `events_transactions_history_long` tables are collections of the most recent transaction events, up to a fixed number of rows.

For information about configuration of transaction event collection, see [Section 21.9.7, “Performance Schema Transaction Tables”](#).

The `events_transactions_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together form a primary key that uniquely identifies the row. No two rows will have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 21.4, “Performance Schema Instrument Naming Conventions”](#).

- `STATE`

The current transaction state. The value is `ACTIVE` (after `START TRANSACTION` or `BEGIN`), `COMMITTED` (after `COMMIT`), or `ROLLED BACK` (after `ROLLBACK`).

- `TRX_ID`

Unused.

- `GTID`

This column changed in MySQL 5.7.6.

- Versions of MySQL prior to 5.7.6:

If `gtid_mode=OFF`, the value is `NULL`. If `gtid_mode=ON`, this is the value of `gtid_next` when the transaction started. If `gtid_next=AUTOMATIC` the value is `AUTOMATIC`, otherwise the value is a GTID in `UUID:NUMBER` format.

- Versions of MySQL 5.7.6 and later:

The GTID column contains the value of `gtid_next`, which can be one of `ANONYMOUS`, `AUTOMATIC`, or a GTID using the format `UUID:NUMBER`. For transactions that use `gtid_next=AUTOMATIC`, which is all normal client transactions, the GTID column changes when the transaction commits and the actual GTID is assigned. If `gtid_mode` is either `ON` or `ON_PERMISSIVE`, the GTID column changes to the transaction's GTID. If `gtid_mode` is either `OFF` or `OFF_PERMISSIVE`, the GTID column changes to `ANONYMOUS`.

- `XID`

The XA transaction identifier. It has the format described in [Section 13.3.7.1, “XA Transaction SQL Syntax”](#). This column was removed in MySQL 5.7.7 and replaced with the `XID_FORMAT_ID`, `XID_GTRID`, and `XID_BQUAL` columns representing the components of XID values.

- `XID_FORMAT_ID`, `XID_GTRID`, and `XID_BQUAL`

The components of the XA transaction identifier. They have the format described in [Section 13.3.7.1, “XA Transaction SQL Syntax”](#). These columns were added in MySQL 5.7.7 as replacements for the `XID` column.

- `XA_STATE`

The state of the XA transaction. The value is `ACTIVE` (after `XA START`), `IDLE` (after `XA END`), `PREPARED` (after `XA PREPARE`), `ROLLED BACK` (after `XA ROLLBACK`), or `COMMITTED` (after `XA COMMIT`).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.7.8. As of 5.7.8, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 21.2.3.1, “Performance Schema Event Timing”](#).

- `ACCESS_MODE`

The transaction access mode. The value is `READ ONLY` or `READ WRITE`.

- `ISOLATION_LEVEL`

The transaction isolation level. The value is `REPEATABLE READ`, `READ COMMITTED`, `READ UNCOMMITTED`, or `SERIALIZABLE`.

- `AUTOCOMMIT`

Whether autocommit mode was enabled when the transaction started.

- `NUMBER_OF_SAVEPOINTS`, `NUMBER_OF_ROLLBACK_TO_SAVEPOINT`,  
`NUMBER_OF_RELEASE_SAVEPOINT`

The number of `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

- `OBJECT_INSTANCE_BEGIN`

Unused.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`. (`TRANSACTION` will not appear because transactions cannot be nested.)

### 21.9.7.2 The `events_transactions_history` Table

The `events_transactions_history` table (added in MySQL 5.7.3) contains the most recent *N* transaction events per thread. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_transactions_history_size` system variable at server startup. Transaction events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_transactions_history` table has the same structure as `events_transactions_current`. See [Section 21.9.7.1, “The `events\_transactions\_current` Table”](#).

The `events_transactions_history` table can be truncated with `TRUNCATE TABLE`.

For information about configuration of transaction event collection, see [Section 21.9.7, “Performance Schema Transaction Tables”](#).

### 21.9.7.3 The `events_transactions_history_long` Table

The `events_transactions_history_long` table (added in MySQL 5.7.3) contains the most recent  $N$  transaction events. The value of  $N$  is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_transactions_history_long_size` system variable at server startup. Transaction events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_transactions_history_long` table has the same structure as `events_transactions_current`. See [Section 21.9.7.1, “The `events\_transactions\_current` Table”](#).

The `events_transactions_history_long` table can be truncated with `TRUNCATE TABLE`.

For information about configuration of transaction event collection, see [Section 21.9.7, “Performance Schema Transaction Tables”](#).

## 21.9.8 Performance Schema Connection Tables

The Performance Schema provides statistics about connections to the server. When a client connects, it does so under a particular user name and from a particular host. The Performance Schema tracks connections per account (user name plus host name) and separately per user name and per host name, using these tables:

- `accounts`: Connection statistics per client account
- `hosts`: Connection statistics per client host name
- `users`: Connection statistics per client user name

There are also summary tables that aggregate information about connections. See [Section 21.9.14.8, “Connection Summary Tables”](#).

The meaning of “account” in the connection tables is similar to its meaning in the MySQL grant tables in the `mysql` database, in the sense that the term refers to a combination of user and host values. Where they differ is that in grant tables, the host part of an account can be a pattern, whereas in Performance Schema tables, the host value is always a specific nonpattern host name.

The connection tables all have `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns to track the current and total number of connections per “tracking value” on which statistics are based. The tables differ in what they use for the tracking value. The `accounts` table has `USER` and `HOST` columns to track connections per user name plus host name combination. The `users` and `hosts` tables have a `USER` and `HOST` column, respectively, to track connections per user name and per host name.

Suppose that clients named `user1` and `user2` each connect one time from `hosta` and `hostb`. The Performance Schema tracks the connections as follows:

- The `accounts` table will have four rows, for the `user1/hosta`, `user1/hostb`, `user2/hosta`, and `user2/hostb` account values, each row counting one connection per account.
- The `users` table will have two rows, for `user1` and `user2`, each row counting two connections per user name.
- The `hosts` table will have two rows, for `hosta` and `hostb`, each row counting two connections per host name.

When a client connects, the Performance Schema determines which row in each connection table applies to the connection, using the tracking value appropriate to each table. If there is no such row, one is added. Then the Performance Schema increments by one the `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns in that row.

When a client disconnects, the Performance Schema decrements by one the `CURRENT_CONNECTIONS` column in the row and leaves the `TOTAL_CONNECTIONS` column unchanged.

The Performance Schema also counts threads for internal threads and user sessions that failed to authenticate. These are counted in rows with `USER` and `HOST` column values of `NULL`.

Each connection table can be truncated with `TRUNCATE TABLE`, which has this effect:

- Rows with `CURRENT_CONNECTIONS = 0` are deleted.
- For rows with `CURRENT_CONNECTIONS > 0`, `TOTAL_CONNECTIONS` is reset to `CURRENT_CONNECTIONS`.
- Connection summary tables that depend on the connection table are truncated implicitly (summary values are set to 0). For more information about implicit truncation, see [Section 21.9.14.8, “Connection Summary Tables”](#).

### 21.9.8.1 The accounts Table

The `accounts` table contains a row for each account that has connected to the MySQL server. For each account, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_accounts_size` system variable at server startup. To disable account statistics, set this variable to 0.

The `accounts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 21.9.8, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection, or `NULL` for an internal thread or user session that failed to authenticate.

- `HOST`

The host from which the client connected, or `NULL` for an internal thread or user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the account.

- `TOTAL_CONNECTIONS`

The total number of connections for the account.

### 21.9.8.2 The hosts Table

The `hosts` table contains a row for each host from which clients have connected to the MySQL server. For each host name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_hosts_size` system variable at server startup. To disable host statistics, set this variable to 0.

The `hosts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 21.9.8, “Performance Schema Connection Tables”](#).

- `HOST`

The host from which the client connected, or `NULL` for an internal thread or user session that failed to authenticate.

- [CURRENT\\_CONNECTIONS](#)

The current number of connections for the host.

- [TOTAL\\_CONNECTIONS](#)

The total number of connections for the host.

### 21.9.8.3 The users Table

The `users` table contains a row for each user who has connected to the MySQL server. For each user name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_users_size` system variable at server startup. To disable user statistics, set this variable to 0.

The `users` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 21.9.8, “Performance Schema Connection Tables”](#).

- [USER](#)

The client user name for the connection, or `NULL` for an internal thread or user session that failed to authenticate.

- [CURRENT\\_CONNECTIONS](#)

The current number of connections for the user.

- [TOTAL\\_CONNECTIONS](#)

The total number of connections for the user.

## 21.9.9 Performance Schema Connection Attribute Tables

The Performance Schema makes these types of connection attributes available:

- Attributes defined by application programs, which can provide key/value connection attributes to be passed to the server at connect time, using the `mysql_options()` and `mysql_options4()` C API functions. The `session_account_connect_attrs` and `session_connect_attrs` tables expose this information:
  - `session_account_connect_attrs`: Connection attributes for sessions for the current account
  - `session_connect_attrs`: Connection attributes for all sessions
- User-defined variables, in the `user_variables_by_thread` table.

The set of connection attributes visible on a given connection may vary depending on your platform and Connector used to establish the connection.

The `libmysqlclient` client library sets these attributes:

- `_client_name`: The client name (`libmysql` for the client library)
- `_client_version`: The client library version
- `_os`: The operating system (for example, `Linux`, `Win64`)
- `_platform`: The machine platform (for example, `x86_64`)
- `_pid`: The client process ID

- `_thread`: The client thread ID (Windows only)

Other MySQL connectors may define connection attributes:

- `_client_license`: The connector license type (Connector/J).
- `_runtime_version`: The Java runtime environment (JRE) version (Connector/J).
- `_runtime_vendor`: The Java runtime environment (JRE) vendor (Connector/J).

Attribute names that begin with `_` are reserved for MySQL itself and should not be used by client applications. This permits new attributes to be introduced by MySQL without colliding with application attributes.

Many MySQL client programs set a `program_name` attribute with a value equal to the client name. For example, `mysqladmin` and `mysqldump` set `program_name` to `mysqladmin` and `mysqldump`, respectively.

Some MySQL clients define additional attributes:

- `mysqlbinlog` defines the `_client_role` attribute as `binary_log_listener`.
- Replication slave connections define `program_name` as `mysqld`, `_client_role` as `binary_log_listener`, and `_client_replication_channel_name` as the channel name.
- `FEDERATED` storage engine connections define `program_name` as `mysqld` and `_client_role` as `federated_storage`.

### 21.9.9.1 The `session_account_connect_attrs` Table

Application programs can provide key/value connection attributes to be passed to the server at connect time, using the `mysql_options()` and `mysql_options4()` C API functions. For descriptions of common attributes, see [Section 21.9.9, “Performance Schema Connection Attribute Tables”](#).

The `session_account_connect_attrs` table contains connection attributes only for sessions for your own account. To see connection attributes for all sessions, look in the `session_connect_attrs` table.

The `session_account_connect_attrs` table contains these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

### 21.9.9.2 The `session_connect_attrs` Table

Application programs can provide key/value connection attributes to be passed to the server at connect time, using the `mysql_options()` and `mysql_options4()` C API functions. For descriptions of common attributes, see [Section 21.9.9, “Performance Schema Connection Attribute Tables”](#).

The `session_connect_attrs` table contains connection attributes for all sessions. To see connection attributes only for sessions for your own account, look in the `session_account_connect_attrs` table.

The `session_connect_attrs` table contains these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

### 21.9.9.3 The `user_variables_by_thread` Table

As of MySQL 5.7.5, the Performance Schema provides a `user_variables_by_thread` table that exposes user-defined variables. These are variables defined within a specific session and include a `@` character preceding the name; see [Section 9.4, “User-Defined Variables”](#).

The `user_variables_by_thread` table contains these columns:

- `THREAD_ID`

The thread identifier of the session in which the variable is defined.

- `VARIABLE_NAME`

The variable name, without the leading `@` character.

- `VARIABLE_VALUE`

The variable value.

## 21.9.10 Performance Schema Replication Tables

As of MySQL 5.7.2, the Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW SLAVE STATUS` statement, but representation in table form is more accessible and has usability benefits:

- `SHOW SLAVE STATUS` output is useful for visual inspection, but not so much for programmatic use. By contrast, using the Performance Schema tables, information about slave status can be searched using general `SELECT` queries, including complex `WHERE` conditions, joins, and so forth.
- Query results can be saved in tables for further analysis, or assigned to variables and thus used in stored procedures.
- The replication tables provide better diagnostic information. For multi-threaded slave operation, `SHOW SLAVE STATUS` reports all coordinator and worker thread errors using the `Last_SQL_Errno` and `Last_SQL_Error` fields, so only the most recent of those errors is visible and information can be lost. The replication tables store errors on a per-thread basis without loss of information.
- The last seen transaction is visible in the replication tables on a per-worker basis. This is information not available from `SHOW SLAVE STATUS`.

- Developers familiar with the Performance Schema interface can extend the replication tables to provide additional information by adding rows to the tables.

## Replication Table Descriptions

The Performance Schema provides several replication-related tables:

- Tables that contain information about the connection of the slave server to the master server:
  - `replication_connection_configuration`: Configuration parameters for connecting to the master
  - `replication_connection_status`: Current status of the connection to the master
- Tables that contain general (not thread-specific) information about the transaction applier:
  - `replication_applier_configuration`: Configuration parameters for the transaction applier on the slave. Renamed from `replication_execute_configuration` in MySQL 5.7.6.
  - `replication_applier_status`: Current status of the transaction applier on the slave. Renamed from `replication_execute_status` in MySQL 5.7.6.
- Tables that contain information about specific threads responsible for applying transactions received from the master:
  - `replication_applier_status_by_coordinator`: Status of the applier (formerly SQL or coordinator) thread. Renamed from `replication_execute_status_by_coordinator` in MySQL 5.7.6.
  - `replication_applier_status_by_worker`: Worker thread applier status (empty unless slave is multi-threaded). Renamed from `replication_execute_status_by_worker` in MySQL 5.7.6.
- Tables that contain information about replication group members:
  - `replication_group_members`: Provides network and status information for group members.
  - `replication_group_member_stats`: Provides statistical information about group members and transaction in which they participate.

The following sections describe each replication table in more detail, including the correspondence between the columns produced by `SHOW SLAVE STATUS` and the replication table columns in which the same information appears.

The remainder of this introduction to the replication tables describes how the Performance Schema populates them and which fields from `SHOW SLAVE STATUS` are not represented in the tables.

## Replication Table Life Cycle

The Performance Schema populates the replication tables as follows:

- Prior to execution of `CHANGE MASTER TO`, the tables are empty.
- After `CHANGE MASTER TO`, the configuration parameters can be seen in the tables. At this time, there are no active slave threads, so the `THREAD_ID` columns are `NULL` and the `SERVICE_STATE` columns have a value of `OFF`.
- After `START SLAVE`, non-`NULL` `THREAD_ID` values can be seen. Threads that are idle or active have a `SERVICE_STATE` value of `ON`. The thread that connects to the master server has a value of `CONNECTING` while it establishes the connection, and `ON` thereafter as long as the connection lasts.
- After `STOP SLAVE`, the `THREAD_ID` columns become `NULL` and the `SERVICE_STATE` columns for threads that no longer exist have a value of `OFF`.

- The tables are preserved after `STOP SLAVE` or threads dying due to an error.
- The `replication_applier_status_by_worker` table is nonempty only when the slave is operating in multi-threaded mode. That is, if the `slave_parallel_workers` system variable is greater than 0, this table is populated when `START SLAVE` is executed, and the number of rows shows the number of workers.

## SHOW SLAVE STATUS Information Not In the Replication Tables

The information in the Performance Schema replication tables differs somewhat from the information available from `SHOW SLAVE STATUS` because the tables are oriented toward use of global transaction identifiers (GTIDs), not file names and positions, and they represent server UUID values, not server ID values. Due to these differences, several `SHOW SLAVE STATUS` columns are not preserved in the Performance Schema replication tables, or are represented a different way:

- The following fields refer to file names and positions and are not preserved:

```
Master_Log_File
Read_Master_Log_Pos
Relay_Log_File
Relay_Log_Pos
Relay_Master_Log_File
Exec_Master_Log_Pos
Until_Condition
Until_Log_File
Until_Log_Pos
```

- The `Master_Info_File` field is not preserved. It refers to the `master.info` file, which has been superseded by crash-safe slave tables.
- The following fields are based on `server_id`, not `server_uuid` [2426], and are not preserved:

```
Master_Server_Id
Replicate_Ignore_Server_Ids
```

- The `Skip_Counter` field is based on event counts, not GTIDs, and is not preserved.
- These error fields are aliases for `Last_SQL_Errno` and `Last_SQL_Error`, so they are not preserved:

```
Last_Errno
Last_Error
```

In the Performance Schema, this error information is available in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns of the `replication_applier_status_by_coordinator` table (and `replication_applier_status_by_worker` if the slave is multi-threaded). Those tables provide more specific per-thread error information than is available from `Last_Errno` and `Last_Error`.

- Fields that provide information about command-line filtering options is not preserved:

```
Replicate_Do_DB
Replicate_Ignore_DB
Replicate_Do_Table
Replicate_Ignore_Table
Replicate_Wild_Do_Table
Replicate_Wild_Ignore_Table
```

- The `Slave_IO_State` and `Slave_SQL_Running_State` fields are not preserved. If needed, these values can be obtained from the process list by using the `THREAD_ID` column of the appropriate replication table and joining it with the `ID` column in the `INFORMATION_SCHEMA.PROCESSLIST` table to select the `STATE` column of the latter table.

- The `Executed_Gtid_Set` field can show a large set with a great deal of text. Instead, the Performance Schema tables show GTIDs of transactions that are currently being applied by the slave. Alternatively, the set of executed GTIDs can be obtained from the value of the `gtid_executed` system variable.
- The `Seconds_Behind_Master` and `Relay_Log_Space` fields are in to-be-decided status and are not preserved.

## Status Variables Moved to Replication Tables

As of MySQL version 5.7.5, the following status variables (previously monitored using `SHOW STATUS`) were moved to the Performance Schema replication tables:

- `Slave_retried_transactions`
- `Slave_last_heartbeat`
- `Slave_received_heartbeats`
- `Slave_heartbeat_period`
- `Slave_running`

These status variables are now only relevant when a single replication channel is being used because they *only* report the status of the default replication channel. When multiple replication channels exist, use the Performance Schema replication tables described in this section, which report these variables for each existing replication channel.

## Replication Channels

The first column of the replication Performance Schema tables is `CHANNEL_NAME`. This enables the tables to be viewed per replication channel, added in MySQL 5.7.6. When you are using multiple replication channels on a slave, you can filter the tables per replication channel to monitor a specific replication channel. See [Section 17.2.3, “Replication Channels”](#) and [Section 17.1.4.3, “Multi-Source Replication Monitoring”](#) for more information.

### 21.9.10.1 The `replication_connection_configuration` Table

This table shows the configuration parameters used by the slave server for connecting to the master server. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions. This table was added in MySQL 5.7.2.

Compared to the `replication_connection_status` table, `replication_connection_configuration` changes less frequently. It contains values that define how the slave connects to the master and that remain constant during the connection, whereas `replication_connection_status` contains values that change during the connection.

The `replication_connection_configuration` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.3, “Replication Channels”](#) for more information.

- `HOST`

The master host that the slave is connected to. (`CHANGE MASTER TO` option: `MASTER_HOST`)

- `PORT`

The port used to connect to the master. (`CHANGE MASTER TO` option: `MASTER_PORT`)

- `USER`

The user name of the account used to connect to the master. (`CHANGE MASTER TO` option: `MASTER_USER`)

- `NETWORK_INTERFACE`

The network interface that the slave is bound to, if any. (`CHANGE MASTER TO` option: `MASTER_BIND`)

- `AUTO_POSITION`

1 if autopositioning is in use; otherwise 0. (`CHANGE MASTER TO` option: `MASTER_AUTO_POSITION`)

- `SSL_ALLOWED`, `SSL_CA_FILE`, `SSL_CA_PATH`, `SSL_CERTIFICATE`, `SSL_CIPHER`, `SSL_KEY`, `SSL_VERIFY_SERVER_CERTIFICATE`, `SSL_CRL_FILE`, `SSL_CRL_PATH`

These columns show the SSL parameters used by the slave to connect to the master, if any.

`SSL_ALLOWED` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

`CHANGE MASTER TO` options for the other SSL columns: `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`, `MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, `MASTER_SSL_VERIFY_SERVER_CERT`.

Prior to MySQL 5.7.4, the value of `SSL_CRL_PATH` was not displayed correctly. (Bug #18174719)

- `CONNECTION_RETRY_INTERVAL`

The number of seconds between connect retries. (`CHANGE MASTER TO` option: `MASTER_CONNECT_RETRY`)

- `CONNECTION_RETRY_COUNT`

The number of times the slave can attempt to reconnect to the master in the event of a lost connection. (`CHANGE MASTER TO` option: `MASTER_RETRY_COUNT`)

- `HEARTBEAT_INTERVAL`

The replication heartbeat interval on a slave, measured in seconds. Added in MySQL 5.7.5.

The following table shows the correspondence between `replication_connection_configuration` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_connection_configuration</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|----------------------------------------------------------|---------------------------------------|
| <code>HOST</code>                                        | <code>Master_Host</code>              |
| <code>PORT</code>                                        | <code>Master_Port</code>              |
| <code>USER</code>                                        | <code>Master_User</code>              |
| <code>NETWORK_INTERFACE</code>                           | <code>Master_Bind</code>              |
| <code>AUTO_POSITION</code>                               | <code>Auto_Position</code>            |
| <code>SSL_ALLOWED</code>                                 | <code>Master_SSL_Allowed</code>       |
| <code>SSL_CA_FILE</code>                                 | <code>Master_SSL_CA_File</code>       |

| <code>replication_connection_configuration</code> Column | <code>SHOW SLAVE STATUS</code> Column      |
|----------------------------------------------------------|--------------------------------------------|
| <code>SSL_CA_PATH</code>                                 | <code>Master_SSL_CA_Path</code>            |
| <code>SSL_CERTIFICATE</code>                             | <code>Master_SSL_Cert</code>               |
| <code>SSL_CIPHER</code>                                  | <code>Master_SSL_Cipher</code>             |
| <code>SSL_KEY</code>                                     | <code>Master_SSL_Key</code>                |
| <code>SSL_VERIFY_SERVER_CERTIFICATE</code>               | <code>Master_SSL_Verify_Server_Cert</code> |
| <code>SSL_CRL_FILE</code>                                | <code>Master_SSL_Crl</code>                |
| <code>SSL_CRL_PATH</code>                                | <code>Master_SSL_Crlpath</code>            |
| <code>CONNECTION_RETRY_INTERVAL</code>                   | <code>Connect_Retry</code>                 |
| <code>CONNECTION_RETRY_COUNT</code>                      | <code>Master_Retry_Count</code>            |

### 21.9.10.2 The `replication_connection_status` Table

This table shows the current status of the I/O thread that handles the slave server connection to the master server. This table was added in MySQL 5.7.2.

Compared to the `replication_connection_configuration` table, `replication_connection_status` changes more frequently. It contains values that change during the connection, whereas `replication_connection_configuration` contains values which define how the slave connects to the master and that remain constant during the connection.

The `replication_connection_status` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.3, “Replication Channels”](#) for more information.

- `GROUP_NAME`

This column is reserved for future use. Added in MySQL 5.7.6.

- `SOURCE_UUID`

The `server_uuid` [2426] value from the master.

- `THREAD_ID`

The I/O thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle), `OFF` (thread no longer exists), or `CONNECTING` (thread exists and is connecting to the master).

- `RECEIVED_TRANSACTION_SET`

The set of global transaction IDs (GTIDs) corresponding to all transactions received by this slave. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the slave's error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `LAST_ERROR_TIMESTAMP`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent I/O error took place.

- `LAST_HEARTBEAT_TIMESTAMP`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent heartbeat signal was received by a replication slave. Added in MySQL 5.7.5.

- `COUNT_RECEIVED_HEARTBEATS`

The total number of heartbeat signals that a replication slave received since the last time it was restarted or reset, or a `CHANGE MASTER TO` statement was issued. Added in MySQL 5.7.5.

The following table shows the correspondence between `replication_connection_status` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_connection_status</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|---------------------------------------------------|---------------------------------------|
| <code>SOURCE_UUID</code>                          | <code>Master_UUID</code>              |
| <code>THREAD_ID</code>                            | <code>None</code>                     |
| <code>SERVICE_STATE</code>                        | <code>Slave_IO_Running</code>         |
| <code>RECEIVED_TRANSACTION_SET</code>             | <code>Retrieved_Gtid_Set</code>       |
| <code>LAST_ERROR_NUMBER</code>                    | <code>Last_IO_Errno</code>            |
| <code>LAST_ERROR_MESSAGE</code>                   | <code>Last_IO_Error</code>            |
| <code>LAST_ERROR_TIMESTAMP</code>                 | <code>Last_IO_Error_Timestamp</code>  |

### 21.9.10.3 The `replication_applier_configuration` Table

This table shows the configuration parameters that affect transactions applied by the slave server. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions. This table was added in MySQL 5.7.2 with the name `replication_execute_configuration`, and renamed to `replication_applier_configuration` in MySQL 5.7.6.

The `replication_applier_configuration` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.3, “Replication Channels”](#) for more information.

- `DESIRED_DELAY`

The number of seconds that the slave must lag the master. (`CHANGE MASTER TO` option: `MASTER_DELAY`)

The following table shows the correspondence between `replication_applier_configuration` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_configuration</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|-------------------------------------------------------|---------------------------------------|
| <code>DESIRED_DELAY</code>                            | <code>SQL_Delay</code>                |

### 21.9.10.4 The `replication_applier_status` Table

This table shows the current general transaction execution status on the slave server. This table was added in MySQL 5.7.2 with the name `replication_execute_status`, and renamed to `replication_applier_status` in MySQL 5.7.6.

This table provides information about general aspects of transaction applier status that are not specific to any thread involved. Thread-specific status information is available in the [replication\\_applier\\_status\\_by\\_coordinator](#) table (and [replication\\_applier\\_status\\_by\\_worker](#) if the slave is multi-threaded).

The [replication\\_applier\\_status](#) table has these columns:

- [CHANNEL\\_NAME](#)

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.3, “Replication Channels”](#) for more information.

- [SERVICE\\_STATE](#)

Reserved for future use.

- [REMAINING\\_DELAY](#)

If the slave is waiting for [DESIRED\\_DELAY](#) seconds to pass since the master applied an event, this field contains the number of delay seconds remaining. At other times, this field is `NULL`. (The [DESIRED\\_DELAY](#) value is stored in the [replication\\_applier\\_configuration](#) table.)

- [COUNT\\_TRANSACTIONS\\_RETRIES](#)

Added in MySQL 5.7.5, shows the number of retries that were made because the slave SQL thread failed to apply a transaction.

The following table shows the correspondence between [replication\\_applier\\_status](#) columns and `SHOW SLAVE STATUS` columns.

| <a href="#">replication_applier_status</a> Column | <code>SHOW SLAVE STATUS</code> Column |
|---------------------------------------------------|---------------------------------------|
| <a href="#">SERVICE_STATE</a>                     | None                                  |
| <a href="#">REMAINING_DELAY</a>                   | <code>SQL_Remaining_Delay</code>      |

### 21.9.10.5 The [replication\\_applier\\_status\\_by\\_coordinator](#) Table

For a multi-threaded slave, the slave uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the coordinator thread. In MySQL 5.7.9 and later, for a single-threaded slave, this table is empty. (Previously, this table showed the applier thread status for a single-threaded slave; this information can now be found in the [replication\\_applier\\_status\\_by\\_worker](#) table in such cases. See [Bug #74765](#), [Bug #20001173](#).) This table was added in MySQL 5.7.2 as [replication\\_execute\\_status\\_by\\_coordinator](#), and renamed [replication\\_applier\\_status\\_by\\_coordinator](#) in MySQL 5.7.6. For a multi-threaded slave, the [replication\\_applier\\_status\\_by\\_worker](#) table shows the status of the worker threads.

The [replication\\_applier\\_status\\_by\\_coordinator](#) table has these columns:

- [CHANNEL\\_NAME](#)

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.3, “Replication Channels”](#) for more information.

- [THREAD\\_ID](#)

The SQL/coordinator thread ID.

- [SERVICE\\_STATE](#)

`ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the SQL/coordinator thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the slave's error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in [Section B.3, “Server Error Codes and Messages”](#).

- `LAST_ERROR_TIMESTAMP`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent SQL/coordinator error occurred.

The following table shows the correspondence between `replication_applier_status_by_coordinator` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_status_by_coordinator</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|---------------------------------------------------------------|---------------------------------------|
| <code>THREAD_ID</code>                                        | None                                  |
| <code>SERVICE_STATE</code>                                    | <code>Slave_SQL_Running</code>        |
| <code>LAST_ERROR_NUMBER</code>                                | <code>Last_SQL_Errno</code>           |
| <code>LAST_ERROR_MESSAGE</code>                               | <code>Last_SQL_Error</code>           |
| <code>LAST_ERROR_TIMESTAMP</code>                             | <code>Last_SQL_Error_Timestamp</code> |

### 21.9.10.6 The `replication_applier_status_by_worker` Table

In MySQL 5.7.9 and later, if the slave is not multi-threaded, this table shows the status of the applier thread. (Previously, this table was empty in such cases, and this information was reported in the `replication_applier_status_by_coordinator` table; see Bug #74765, Bug #20001173.) Otherwise, the slave uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the worker threads. This table was added in MySQL 5.7.2 as `replication_execute_status_by_worker`, and renamed `replication_applier_status_by_worker` in MySQL 5.7.6. For a multi-threaded slave, the `replication_applier_status_by_coordinator` table shows the status of the coordinator thread.

The `replication_applier_status_by_worker` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 17.2.3, “Replication Channels”](#) for more information.

- `WORKER_ID`

The worker identifier (same value as the `id` column in the `mysql.slave_worker_info` table). After `STOP SLAVE`, the `THREAD_ID` column becomes `NULL`, but the `WORKER_ID` value is preserved.

- `THREAD_ID`

The worker thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

- `LAST_SEEN_TRANSACTION`

The transaction that the worker has last seen. The worker has not necessarily applied this transaction because it could still be in the process of doing so.

If the `gtid_mode` system variable value is `OFF`, this column is `ANONYMOUS`, indicating that transactions do not have global transaction identifiers (GTIDs) and are identified by file and position only.

If `gtid_mode` is `ON`, the column value is defined as follows:

- If no transaction has executed, the column is empty.
- When a transaction has executed, the column is set from `gtid_next` as soon as `gtid_next` is set. From this moment, the column always shows a GTID.
- The GTID is preserved until the next transaction is executed. If an error occurs, the column value is the GTID of the transaction being executed by the worker when the error occurred.
- When the next GTID log event is picked up by this worker thread, this column is updated from `gtid_next` soon after `gtid_next` is set.

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the worker thread to stop. An error number of 0 and message of the empty string mean “no error”. If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the slave's error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in [Section B.3, “Server Error Codes and Messages”](#).

- `LAST_ERROR_TIMESTAMP`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent worker error occurred.

The following table shows the correspondence between `replication_applier_status_by_worker` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_status_by_worker</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|----------------------------------------------------------|---------------------------------------|
| <code>WORKER_ID</code>                                   | None                                  |
| <code>THREAD_ID</code>                                   | None                                  |
| <code>SERVICE_STATE</code>                               | None                                  |
| <code>LAST_SEEN_TRANSACTION</code>                       | None                                  |
| <code>LAST_ERROR_NUMBER</code>                           | <code>Last_SQL_Errno</code>           |
| <code>LAST_ERROR_MESSAGE</code>                          | <code>Last_SQL_Error</code>           |
| <code>LAST_ERROR_TIMESTAMP</code>                        | <code>Last_SQL_Error_Timestamp</code> |

### 21.9.10.7 The `replication_group_members` Table

This table shows network and status information for replication group members. It was added in MySQL 5.7.6 and is reserved for future use.

The `replication_group_members` table has the following columns:

- [CHANNEL\\_NAME](#)  
Name of the group replication channel.
- [MEMBER\\_ID](#)  
Identifier for this member; same as the server UUID.
- [MEMBER\\_HOST](#)  
Network address of this member (host name or IP address).
- [MEMBER\\_PORT](#)  
Port on which the server is listening.
- [MEMBER\\_STATE](#)  
Current state of this member; can be any one of the following:
  - [OFFLINE](#): The group replication plugin is installed but has not been started.
  - [RECOVERING](#): The server has joined a group from which it is retrieving data.
  - [ONLINE](#): The member is in a fully functioning state.

#### 21.9.10.8 The `replication_group_member_stats` Table

This table shows statistical information for replication group members. It was added in MySQL 5.7.6 and is reserved for future use.

The `replication_group_member_stats` table has the following columns:

- [CHANNEL\\_NAME](#)  
Name of the group replication channel
- [VIEW\\_ID](#)  
Current view identifier for this group.
- [MEMBER\\_ID](#)  
Identifier for this member; same as the server UUID.
- [COUNT\\_TRANSACTIONS\\_IN\\_QUEUE](#)  
Number of transactions pending certification
- [COUNT\\_TRANSACTIONS\\_CHECKED](#)  
Number of transactions already certified by this member.
- [COUNT\\_CONFLICTS\\_DETECTED](#)  
Number of transactions that were negatively certified.
- [COUNT\\_TRANSACTIONS\\_VALIDATING](#)  
Number of transactions with which one can execute certification with them, but have not been garbage collected.
- [TRANSACTIONS\\_COMMITTED\\_ALL\\_MEMBERS](#)

Set of stable group transactions.

- [LAST\\_CONFLICT\\_FREE\\_TRANSACTION](#)

Latest transaction certified without conflicts.

## 21.9.11 Performance Schema Lock Tables

The Performance Schema exposes lock information through these tables:

- [metadata\\_locks](#): Metadata locks held and requested
- [table\\_handles](#): Table locks held and requested

The following sections describe these tables in more detail.

### 21.9.11.1 The [metadata\\_locks](#) Table

As of MySQL 5.7.3, the Performance Schema exposes metadata lock information through the [metadata\\_locks](#) table:

- Locks that have been granted (shows which sessions own which current metadata locks)
- Locks that have been requested but not yet granted (shows which sessions are waiting for which metadata locks).
- Lock requests that have been killed by the deadlock detector or timed out and are waiting for the requesting session's lock request to be discarded

This information enables you to understand metadata lock dependencies between sessions. You can see not only which lock a session is waiting for, but which session currently holds that lock.

The [metadata\\_locks](#) table is read only and cannot be updated. It is autosized by default; to configure the table size, set the [performance\\_schema\\_max\\_metadata\\_locks](#) system variable at server startup.

Metadata lock instrumentation is disabled by default. To enable it, enable the [wait/lock/metadata/sql/mdl](#) instrument in the [setup\\_instruments](#) table.

The Performance Schema maintains [metadata\\_locks](#) table content as follows, using the [LOCK\\_STATUS](#) column to indicate the status of each lock:

- When a metadata lock is requested and obtained immediately, a row with a status of [GRANTED](#) is inserted.
- When a metadata lock is requested and not obtained immediately, a row with a status of [PENDING](#) is inserted.
- When a metadata lock previously requested is granted, its row status is updated to [GRANTED](#).
- When a metadata lock is released, its row is deleted.
- When a pending lock request is canceled by the deadlock detector to break a deadlock ([ER\\_LOCK\\_DEADLOCK](#)), its row status is updated from [PENDING](#) to [VICTIM](#).
- When a pending lock request times out ([ER\\_LOCK\\_WAIT\\_TIMEOUT](#)), its row status is updated from [PENDING](#) to [TIMEOUT](#).
- When granted lock or pending lock request is killed, its row status is updated from [GRANTED](#) or [PENDING](#) to [KILLED](#).
- The [VICTIM](#), [TIMEOUT](#), and [KILLED](#) status values are brief and signify that the lock row is about to be deleted.

- The `PRE_ACQUIRE_NOTIFY` and `POST_RELEASE_NOTIFY` status values are brief and signify that the metadata locking subsystem is entering a lock acquisition or leaving a lock release operation. These status values were added in MySQL 5.7.11.

The `metadata_locks` table has these columns:

- `OBJECT_TYPE`

The type of lock used in the metadata lock subsystem: The value is one of `GLOBAL`, `SCHEMA`, `TABLE`, `FUNCTION`, `PROCEDURE`, `TRIGGER` (currently unused), `EVENT`, `COMMIT`, `USER LEVEL LOCK` (a lock acquired with `GET_LOCK()`), or `TABLESPACE`.

For locks acquired using the locking service described in [Section 24.3.1, “The Locking Service”](#), the `OBJECT_TYPE` is `LOCKING SERVICE`.

- `OBJECT_SCHEMA`

The schema that contains the object.

- `OBJECT_NAME`

The name of the instrumented object.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented object.

- `LOCK_TYPE`

The lock type from the metadata lock subsystem. The value is one of `INTENTION_EXCLUSIVE`, `SHARED`, `SHARED_HIGH_PRIO`, `SHARED_READ`, `SHARED_WRITE`, `SHARED_UPGRADABLE`, `SHARED_NO_WRITE`, `SHARED_NO_READ_WRITE`, or `EXCLUSIVE`.

- `LOCK_DURATION`

The lock duration from the metadata lock subsystem. The value is one of `STATEMENT`, `TRANSACTION`, or `EXPLICIT`. The `STATEMENT` and `TRANSACTION` values are for locks that are released at statement or transaction end, respectively. The `EXPLICIT` value is for locks that survive statement or transaction end and are released explicitly, such as global locks acquired with `FLUSH TABLES WITH READ LOCK`.

- `LOCK_STATUS`

The lock status from the metadata lock subsystem. The value is one of `PENDING`, `GRANTED`, `VICTIM`, `TIMEOUT`, `KILLED`, `PRE_ACQUIRE_NOTIFY`, or `POST_RELEASE_NOTIFY`. The Performance Schema assigns these values as described earlier in this section.

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `OWNER_THREAD_ID`

The thread requesting a metadata lock.

- `OWNER_EVENT_ID`

The event requesting a metadata lock.

### 21.9.11.2 The `table_handles` Table

As of MySQL 5.7.3, the Performance Schema exposes table lock information through the `table_handles` table to show the table locks currently in effect for each opened table handle. `table_handles` reports what is recorded by the table lock instrumentation. This information shows which table handles the server has open, how they are locked, and by which sessions.

The `table_handles` table is read only and cannot be updated. It is autosized by default; to configure the table size, set the `performance_schema_max_table_handles` system variable at server startup.

The `table_handles` table has these columns:

- `OBJECT_TYPE`  
The table opened by a table handle.
- `OBJECT_SCHEMA`  
The schema that contains the object.
- `OBJECT_NAME`  
The name of the instrumented object.
- `OBJECT_INSTANCE_BEGIN`  
The table handle address in memory.
- `OWNER_THREAD_ID`  
The thread owning the table handle.
- `OWNER_EVENT_ID`  
The event which caused the table handle to be opened.
- `INTERNAL_LOCK`  
The table lock used at the SQL level. The value is one of `READ`, `READ WITH SHARED LOCKS`, `READ HIGH PRIORITY`, `READ NO INSERT`, `WRITE ALLOW WRITE`, `WRITE CONCURRENT INSERT`, `WRITE LOW PRIORITY`, or `WRITE`. For information about these lock types, see the `include/thr_lock.h` source file.
- `EXTERNAL_LOCK`  
The table lock used at the storage engine level. The value is one of `READ EXTERNAL` or `WRITE EXTERNAL`.

## 21.9.12 Performance Schema System Variable Tables

### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 5.1.4, “Server System Variables”](#).

The MySQL server maintains many system variables that indicate how it is configured (see [Section 5.1.4, “Server System Variables”](#)). As of MySQL 5.7.6, system variable information is available in these Performance Schema tables:

- `global_variables`: Global system variables. An application that wants only global values should use this table.

- `session_variables`: System variables for the current session. An application that wants all system variable values for its own session should use this table. It includes the session variables for its session, as well as the values of global variables that have no session counterpart. (In MySQL 5.7.6 and 5.7.7, the table does not fully reflect all system variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)
- `variables_by_thread`: Session system variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.

The session variable tables (`session_variables`, `variables_by_thread`) contain information only for active sessions, not terminated sessions.

`TRUNCATE TABLE` is not supported for Performance Schema system variable tables.

The `global_variables` and `session_variables` tables have these columns:

- `VARIABLE_NAME`

The system variable name.

- `VARIABLE_VALUE`

The system variable value. For `global_variables`, this column contains the global value. For `session_variables`, this column contains the variable value in effect for the current session.

The `variables_by_thread` table has these columns:

- `THREAD_ID`

The thread identifier of the session in which the system variable is defined.

- `VARIABLE_NAME`

The system variable name.

- `VARIABLE_VALUE`

The session variable value for the session named by the `THREAD_ID` column.

The `variables_by_thread` table contains system variable information only about foreground threads. If not all threads are instrumented by the Performance Schema, this table will miss some rows. In this case, the `Performance_schema_thread_instances_lost` status variable will be greater than zero.

## 21.9.13 Performance Schema Status Variable Tables

### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 5.1.4, “Server System Variables”](#).

The MySQL server maintains many status variables that provide information about its operation (see [Section 5.1.6, “Server Status Variables”](#)). As of MySQL 5.7.6, status variable information is available in these Performance Schema tables:

- `global_status`: Global status variables. An application that wants only global values should use this table.
- `session_status`: Status variables for the current session. An application that wants all status variable values for its own session should use this table. It includes the session variables for its

session, as well as the values of global variables that have no session counterpart. (In MySQL 5.7.6 and 5.7.7, the table does not fully reflect all status variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)

- `status_by_thread`: Session status variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.

There are also summary tables that provide status variable information aggregated by account, host name, and user name. See [Section 21.9.14.11, “Performance Schema Status Variable Summary Tables”](#).

The session variable tables (`session_status`, `status_by_thread`) contain information only for active sessions, not terminated sessions.

The Performance Schema collects statistics for global status variables only for threads for which the `INSTRUMENTED` value is `YES` in the `threads` table. Statistics for session status variables are always collected, regardless of the `INSTRUMENTED` value.

The Performance Schema does not collect statistics for `Com_xxx` status variables in the status variable tables. To obtain global and per-session statement execution counts, use the `events_statements_summary_global_by_event_name` and `events_statements_summary_by_thread_by_event_name` tables, respectively. For example:

```
SELECT EVENT_NAME, COUNT_STAR
FROM events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%';
```

The `global_status` and `session_status` tables have these columns:

- `VARIABLE_NAME`

The status variable name.

- `VARIABLE_VALUE`

The status variable value. For `global_status`, this column contains the global value. For `session_status`, this column contains the variable value for the current session.

The `status_by_thread` table contains the status of each active thread. It has these columns:

- `THREAD_ID`

The thread identifier of the session in which the status variable is defined.

- `VARIABLE_NAME`

The status variable name.

- `VARIABLE_VALUE`

The session variable value for the session named by the `THREAD_ID` column.

The `status_by_thread` table contains status variable information only about foreground threads. If the `performance_schema_max_thread_instances` system variable is not autoscaled (set to `-1`) and the maximum permitted number of instrumented thread objects is not greater than the number of background threads, the table will be empty.

The Performance Schema supports `TRUNCATE TABLE` for status variable tables as follows:

- `global_status`: Resets thread, account, host, and user status. Resets global status variables except those that the server never resets.

- `session_status`: Not supported.
- `status_by_thread`: Aggregates status for all threads to the global status and account status, then resets thread status. If account statistics are not collected, the session status is added to host and user status, if host and user status are collected.

Account, host, and user statistics are not collected if the `performance_schema_accounts_size`, `performance_schema_hosts_size`, and `performance_schema_users_size` system variables, respectively, are set to 0.

`FLUSH STATUS` adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

## 21.9.14 Performance Schema Summary Tables

Summary tables provide aggregated information for terminated events over time. The tables in this group summarize event data in different ways.

### Event Wait Summaries:

- `events_waits_summary_global_by_event_name`: Wait events summarized per event name
- `events_waits_summary_by_instance`: Wait events summarized per instance
- `events_waits_summary_by_thread_by_event_name`: Wait events summarized per thread and event name

### Stage Summaries:

- `events_stages_summary_by_thread_by_event_name`: Stage waits summarized per thread and event name
- `events_stages_summary_global_by_event_name`: Stage waits summarized per event name

### Statement Summaries:

- `events_statements_summary_by_digest`: Statement events summarized per schema and digest value
- `events_statements_summary_by_thread_by_event_name`: Statement events summarized per thread and event name
- `events_statements_summary_global_by_event_name`: Statement events summarized per event name
- `events_statements_summary_by_program`: Statement events summarized per stored program (stored procedures and functions, triggers, and events) (added in MySQL 5.7.2)
- `prepared_statements_instances`: Prepared statement instances and statistics (added in MySQL 5.7.4)

### Transaction Summaries:

- `events_transactions_summary_by_account_by_event_name`: Transaction events per account and event name (added in MySQL 5.7.3)
- `events_transactions_summary_by_host_by_event_name`: Transaction events per host name and event name (added in MySQL 5.7.3)
- `events_transactions_summary_by_thread_by_event_name`: Transaction events per thread and event name (added in MySQL 5.7.3)

- [events\\_transactions\\_summary\\_by\\_user\\_by\\_event\\_name](#): Transaction events per user name and event name (added in MySQL 5.7.3)
- [events\\_transactions\\_summary\\_global\\_by\\_event\\_name](#): Transaction events per event name (added in MySQL 5.7.3)

**Object Wait Summaries:**

- [objects\\_summary\\_global\\_by\\_type](#): Object summaries

**File I/O Summaries:**

- [file\\_summary\\_by\\_event\\_name](#): File events summarized per event name
- [file\\_summary\\_by\\_instance](#): File events summarized per file instance

**Table I/O and Lock Wait Summaries:**

- [table\\_io\\_waits\\_summary\\_by\\_index\\_usage](#): Table I/O waits per index
- [table\\_io\\_waits\\_summary\\_by\\_table](#): Table I/O waits per table
- [table\\_lock\\_waits\\_summary\\_by\\_table](#): Table lock waits per table

**Connection Summaries:**

- [events\\_waits\\_summary\\_by\\_account\\_by\\_event\\_name](#): Wait events summarized per account and event name
- [events\\_waits\\_summary\\_by\\_user\\_by\\_event\\_name](#): Wait events summarized per user name and event name
- [events\\_waits\\_summary\\_by\\_host\\_by\\_event\\_name](#): Wait events summarized per host name and event name
- [events\\_stages\\_summary\\_by\\_account\\_by\\_event\\_name](#): Stage events summarized per account and event name
- [events\\_stages\\_summary\\_by\\_user\\_by\\_event\\_name](#): Stage events summarized per user name and event name
- [events\\_stages\\_summary\\_by\\_host\\_by\\_event\\_name](#): Stage events summarized per host name and event name
- [events\\_statements\\_summary\\_by\\_digest](#): Statement events summarized per schema and digest value
- [events\\_statements\\_summary\\_by\\_account\\_by\\_event\\_name](#): Statement events summarized per account and event name
- [events\\_statements\\_summary\\_by\\_user\\_by\\_event\\_name](#): Statement events summarized per user name and event name
- [events\\_statements\\_summary\\_by\\_host\\_by\\_event\\_name](#): Statement events summarized per host name and event name

**Socket Summaries:**

- [socket\\_summary\\_by\\_instance](#): Socket waits and I/O summarized per instance
- [socket\\_summary\\_by\\_event\\_name](#): Socket waits and I/O summarized per event name

**Memory Summaries:**

- [memory\\_summary\\_global\\_by\\_event\\_name](#): Memory operations summarized globally per event name (added in MySQL 5.7.2)
- [memory\\_summary\\_by\\_thread\\_by\\_event\\_name](#): Memory operations summarized per thread and event name (added in MySQL 5.7.2)
- [memory\\_summary\\_by\\_account\\_by\\_event\\_name](#): Memory operations summarized per account and event name (added in MySQL 5.7.2)
- [memory\\_summary\\_by\\_user\\_by\\_event\\_name](#): Memory operations summarized per user and event name (added in MySQL 5.7.2)
- [memory\\_summary\\_by\\_host\\_by\\_event\\_name](#): Memory operations summarized per host and event name (added in MySQL 5.7.2)

**Status Variable Summaries:**

- [status\\_by\\_account](#): Status variables summarized by account (added in MySQL 5.7.6)
- [status\\_by\\_host](#): Status variables summarized by host name (added in MySQL 5.7.6)
- [status\\_by\\_user](#): Status variables summarized by user name (added in MySQL 5.7.6)

Each summary table has grouping columns that determine how to group the data to be aggregated, and summary columns that contain the aggregated values. Tables that summarize events in similar ways often have similar sets of summary columns and differ only in the grouping columns used to determine how events are aggregated.

Summary tables can be truncated with `TRUNCATE TABLE`. Except for [events\\_statements\\_summary\\_by\\_digest](#) and the memory summary tables, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change.

### 21.9.14.1 Event Wait Summary Tables

The Performance Schema maintains tables for collecting current and recent wait events, and aggregates that information in summary tables. [Section 21.9.4, “Performance Schema Wait Event Tables”](#) describes the events on which wait summaries are based. See that discussion for information about the content of wait events, the current and recent wait event tables, and how to control wait event collection.

Each event waits summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the [setup\\_instruments](#) table.

- [events\\_waits\\_summary\\_global\\_by\\_event\\_name](#) has an `EVENT_NAME` column. Each row summarizes events for a given event name. An instrument might be used to create multiple instances of the instrumented object. For example, if there is an instrument for a mutex that is created for each connection, there are as many instances as there are connections. The summary row for the instrument summarizes over all these instances.
- [events\\_waits\\_summary\\_by\\_instance](#) has `EVENT_NAME` and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given event name and object. If an instrument is used to create multiple instances, each instance has a unique `OBJECT_INSTANCE_BEGIN` value, so these instances are summarized separately in this table.
- [events\\_waits\\_summary\\_by\\_thread\\_by\\_event\\_name](#) has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.

All event waits summary tables have these summary columns containing aggregated values:

- [COUNT\\_STAR](#)

The number of summarized events. This value includes all events, whether timed or nontimed.

- [SUM\\_TIMER\\_WAIT](#)

The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of [NULL](#). The same is true for the other [xxx\\_TIMER\\_WAIT](#) values.

- [MIN\\_TIMER\\_WAIT](#)

The minimum wait time of the summarized timed events.

- [AVG\\_TIMER\\_WAIT](#)

The average wait time of the summarized timed events.

- [MAX\\_TIMER\\_WAIT](#)

The maximum wait time of the summarized timed events.

Example wait event summary information:

```
mysql> SELECT * FROM events_waits_summary_global_by_event_name\G
...
***** 6. row *****
EVENT_NAME: wait/synch/mutex/sql/BINARY_LOG::LOCK_index
COUNT_STAR: 8
SUM_TIMER_WAIT: 2119302
MIN_TIMER_WAIT: 196092
AVG_TIMER_WAIT: 264912
MAX_TIMER_WAIT: 569421
...
***** 9. row *****
EVENT_NAME: wait/synch/mutex/sql/hash_filo::lock
COUNT_STAR: 69
SUM_TIMER_WAIT: 16848828
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 244185
MAX_TIMER_WAIT: 735345
...
```

[TRUNCATE TABLE](#) is permitted for wait summary tables. It resets the summary columns to zero rather than removing rows.

### 21.9.14.2 Stage Summary Tables
