

## ANNUAL REPORT SUMMARY FOR TESTING IN 2008

### Prepared by the Relationship Testing Program Unit

### PREFACE

The goal of the survey is to ask relevant questions, gather pertinent data, track trends in testing, and to provide information on the state of the relationship testing community. As a reminder evaluation of these data is anonymous. None of the members of the Relationship Testing Standards Program Unit (RT SPU) is aware of which laboratories submitted data. Many of the laboratories report testing a broad range of cases, including relationship tests for routine paternity testing, immigration, prenatal evaluations, and post-mortem evaluations. Almost all of the laboratories reporting performed immigration testing and reconstruction (family study) cases. Presentation of the most current data occurs every year at the AABB annual meeting.

As in the past, this report provides some commentary for the layman on common misconceptions in paternity testing. Some of the commentary is from a previous year's report, as the commentary remains relevant to issues raised this year.

The RT SPU would also like to remind readers that the *Guidance for Standards for Relationship Testing Laboratories*, discusses the *Standards* in some detail and provides suggestions on how to achieve compliance with the *Standards*. The Guidance also contains explanations on how to properly implement standards, various calculations used, and other general issues in relationship testing. The 9th edition of *Standards* went into effect on January 1, 2010 and for the first time the guidance document appears on a CD packaged with the *Standards*. All accredited laboratories will receive a copy of the *Standards* with the attached guidance CD. The RT SPU encourages all laboratories to read and review the guidance document as they implement the 9th edition.

### ANNUAL VOLUME OF TESTING

The total volume reported for cases tested in 2008 was 414,843, an increase of 1.99% over 2007. It should be noted that several laboratories did not provide data or responses to the survey. A summary of the total cases reported since 1988 is shown in Table 1 and Figure 1.

**Table 1.** The Number of Relationship Cases Reported for 1988-2009.

Year	No. of Cases	Year	No. of Cases
1988	77000	1999	280510
1989	85231	2000	300626
1990	120436	2001	310490
1991	143459	2002	340798
1992	161000	2003	354011
1993	189904	2004	390928
1994	193000	2005	398880
1995	149100	2006	420740
1996	172316	2007	406147
1997	237981	2008	414843

**Figure 1.** Graph of the Case Volume for 1988-2008.

As in the past, laboratories were asked if they tested cases where the chain of custody did not meet the requirements of the *Standards for Relationship Testing*. The tested individuals, without a proper witness (see *Standards*), generally collect these so called “non-legal” tests. AABB has taken the position that it cannot prohibit accredited laboratories from performing these types of tests, but reminds laboratories that they cannot claim or advertise that their “non-legal” testing meets AABB *Standards*, nor may they state the “testing” meets the standards and only the chain of custody is lacking. Laboratories may only conform in all aspects of the *Standards* and cannot pick and choose standards to which they would like to adhere. Of the laboratories reporting, over half (58%) reported that they performed testing of this type. Those laboratories reported 5,707 non-legal cases or 1.38% of the total cases reported. This is down from the 3.35% reported in 2007; however some laboratories did not track the number of non-legal cases they evaluated or declined to provide this information. A liberal estimate would be that no more than 10% of all cases evaluated by the reporting laboratories were of a “non-legal” type. Of the laboratories performing non-legal testing, these tests account for 4.72% of their total volume.

During the revision cycle of the 9th edition, the Department of Homeland Security, United States Citizenship and Immigration Service (USCIS) and the US State Department met with the RT SPU to discuss the “non-legal” testing and potential fraud (with both legal and non-legal collections). Non-legal testing is not acceptable for immigration purposes. In 2008, the US State Department propagated new rules for collections at its overseas posts. These rules include:

1. All collections are performed at the embassy (post)
2. The collections must be witnessed by a “cleared” officer (post arranges this)

3. All kits must be sent directly to the post and must have a prepaid shipping label for shipment back to the laboratory.
4. Posts will not collect any money.
5. Posts will not be able to take pictures, so when arranging collections, the laboratories should tell their potential clients to bring a passport size photograph to the collection. The cleared officer will review the photograph to make sure it matches the person collected.
6. The sample will still be collected by a technician or panel physician (post arranges).
7. Because sibling studies do not meet their standards, they are instructing the post not to request sibling studies, other distant relationships, or "are they related" studies. Future US State Department collection should involve the parents of alleged siblings.
8. After collection, the witnessing officer then takes possession of the samples.
9. The US State Department is developing their own chain of custody form in conjunction with AABB, which will be made available to the laboratories at a later time.
10. Samples from third party administrators (TPA) are acceptable as long as the TPA has a formal (written) agreement with the laboratory that requires the TPA to follow AABB collection standards.

As they become available, other requirements will be transmitted to accredited laboratories. Note that these rules do not necessarily apply to samples collected for USCIS cases.

### **LABORATORIES BY SIZE**

Table 2 indicates the size of the various responding laboratories by volume of cases reported. Not all of the responding laboratories provided total volumes, and only 24 laboratories out of over 40 accredited laboratories responded to the survey. This breakdown is by each laboratory, but be aware that a single corporation may own several laboratories.

**Table 2. Laboratories by the Volume of Cases Reported.**

Case Volumes	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008
1-500	40	26	25	20	19	19	13	17	14	18	16	16	15	15	5
501-1,000	6	4	8	7	6	5	6	6	2	3	2	4	4	6	1
1,001-5,000	7	9	6	10	11	9	11	11	13	11	7	8	11	11	7
5,001-10,000	6	4	3	5	0	3	3	5	1	3	7	7	6	6	2
10,001-50,000	1	2	3	5	5	7	8	6	7	7	6	5	5	4	4
50,001 – 100,000	2	1	1	1	2	1	1	1	0	0	1	1	1	1	3

>100,000	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
<b>Total Laboratories</b>	62	46	46	48	43	44	42	46	38	43	40	42	43	44	23

### **EXCLUSION RATE**

For 2008, some laboratories did not track the number of exclusions. For the laboratories tracking exclusions, there were 398,124 cases completed and 103,098 (25.90%) were reported as exclusions, similar to the 25.39% observed in 2007. The average exclusion rate for the laboratories reporting exclusions is 22.37% with a standard deviation of 8.05. The median exclusion rate is 23.33% with a range of 11.43% to 42.50%. The explanation for the range of exclusion rates is complex but appears related to the laboratories volume and client base. Anecdotal explanations for the various exclusion rates include differences with the type of case (private versus public contracts), and the geographic source of the case (rural versus metropolitan areas). For the non-legal testing laboratories, there were 609 exclusions from laboratories reporting exclusion data (total of 5,707 cases) or an exclusion rate of 28.67%, a higher percentage than the 25.90% seen for legal testing. The range for non-legal laboratories is 23.81 to 41.67% (one laboratory tested a single non legal case that excluded the relationship, which is not included in this range).

### **MISCONCEPTIONS IN PATERNITY TESTING – EXCLUSION RATE**

AABB has seen the exclusion rate misused by those trying to claim that 30% of men are misled into believing they are the biological fathers of children when the mother knows this not to be true. This view is incorrect. The exclusion rate includes a number of factors. One is a woman may allege several men as possible fathers because she was sexually active with these individuals. These are not men who were misled into believing they were fathers and then later discover they are not. The testing merely sorts out which man is the biological father and excludes the others. Another factor is that the unexcluded alleged father, as part of his defense, will allege the mother had multiple sexual partners during the time of conception. These men are subsequently tested. Sometimes testing of a man is required because of a legal presumption, when the mother properly names the correct biological father but because the mother is married to a man who is not the child's father (she is or was married to someone other than the biological father) there is a legal presumption the husband is the father. The husband is tested to rebut the legal presumption even though no one believes he is the biological father of the child. In each of these examples, there is no evidence that a large number of the men excluded in the testing were misled into believing they are the biological father of a given child.

### **COMBINED PATERNITY INDEX (COMBINED LIKELIHOOD RATIO)**

The laboratories were asked to indicate what combined paternity index (CPI) they considered acceptable for cases with a standard trio (mother, child, father), single parent cases (mother or father not tested cases), and reconstruction cases (where the disputed parent is missing and other relatives are used to evaluate parentage). Some laboratories reported using varying CPIs for different classes of clients (private versus public contracts, or for different technologies). For these laboratories, the higher CPI was used for this report.

The results for the laboratories that responded are shown in Table 3. The most common minimum CPI for a standard trio is 100 with 47.83% of laboratories using this value, with a range of 100 to 10,000. For mother not tested cases, the most common minimum CPI is 100 with 52.17% of laboratories using this value, with a range of 100 to 10,000. For the family study or reconstruction cases, 40% indicated that they report "whatever was obtained" and the majority considered a combined likelihood ratio of 101 or less reportable. Almost all laboratories considered a likelihood ratio of 100 or less as acceptable for sibling studies.

A common issue is the significance of the paternity index and the reliability of the AABB standard requiring a CPI of 100 to 1. The RT SPU is concerned about the meaning of the tests and thus the choice of the 100 to 1 for a reasonable level of significance. First and foremost, this level was chosen because it provides reasonable evidence of paternity in a standard case where a trio is tested. Generally, when a laboratory tests a case, if the disputed person is not excluded and does not reach the laboratory's minimum value, additional testing is performed to evaluate this person. This additional testing may result in non-exclusion, exclusion, or inconclusive reports. The view that AABB is only concerned with the performance of the testing, but not the meaning of the test, is incorrect.

Another issue arises with regard to performing other relationship analyses such as reconstruction cases, trios with genetic anomalies, and samples from exhumations, coroners, and postmortem testing. Importantly, a CPI of less than 100 is not an indicator of no relationship, unless 0 (or much less than 1), and may still in fact be a strong indicator of a relationship. Practical difficulties exist with the ability to obtain results from degraded samples, as happens in postmortem testing, and in the mathematical analysis of the relationships in reconstruction cases. Understanding this is particularly important for legislators who establish presumption levels based on paternity calculations, and contract administrators, who need to differentiate between reasonable science and what might be achieved under ideal conditions. The other important concept is that a laboratory's minimum combined paternity index, which may reflect scientific reality, is not necessarily the laboratory's testing goal or median combined paternity index.

### **SIBLING CALCULATIONS**

Human identity laboratories are often called upon to help identify familial relationships in the absence of parental DNA, which is known as sibship testing. Sibship analyses, when submitting only two individuals for analysis, can be more demanding than parentage testing in that there are no obligatory alleles between siblings that make it possible to conclusively include or exclude the tested biological relationship. In addition, full siblings are as likely to share two alleles, identical by descent from common ancestors, as they are to share zero alleles at a given locus due to genetics. Thus a lack of shared alleles at any particular locus does not exclude a sibling relationship between two individuals. Many times additional loci will not necessarily help resolve a case.

The results for sibship analysis are expressed as a likelihood ratio and are often converted to a probability of sibship using an appropriate prior probability. Several small publications address the issues of sibship analysis and provide empirical data on the range of combined sibling-ship indices (likelihood ratios) encountered with individual pairs that are known full siblings, half-siblings, and unrelated individuals.<sup>1,2,3</sup>

<sup>1</sup> Valentin, J. 1983. Positive Evidence of Paternity Calculated According to Essen-Moller: The Bayesian Approach. In *Inclusion Probabilities in Parentage Testing*. Ed. Richard H. Walker, M.D., pp 63-75.

<sup>2</sup> Reid, T.M., Wolf, C.A., Kraemer, C.M., Lee, S.C., Baird, M.L., and Lee, R.F. Specificity of sibship determination using the ABI Identifiler multiplex system. *J. Forensic Science*, 49: 1262-1264, 2004.

In one study, combined likelihood ratios for known full siblings ranged from 4.6 to over 1 billion and for random, unrelated individuals from 0.000000045 to 0.12. There was no overlap between the group of true siblings and the group of unrelated individuals.<sup>2</sup> In a study of known half-siblings, the combined likelihood ratio for known half-siblings ranged from 0.1 to 3763 with a median likelihood ratio of 24. The combined half-sibling indices for the unrelated pairs ranged from 0.0001 to 42 with a median likelihood ratio of 0.13. There is little overlap between the known half-siblings and unrelated pairs.<sup>3</sup> If a prior probability of 0.5 is correct, then a likelihood ratio of 10 to 1 (90% probability of a sibling relationship) may be considered reasonable evidence of either a full or half sibling relationship. There is need for further study.

**Table 3.** The Number of Laboratories Using Various Minimum Combined Likelihood Ratios for Standard Trios, One Parent (Mother (or Father) not Tested (MNT)) and Reconstruction Cases (Note: not all laboratories indicated a CPI for each type of case).

<b>W</b>	<b>Choice of Minimum Likelihood Ratios Used by Type of Case (% Using)</b>

<b>10000</b>	<b>8.70</b>	<b>8.70</b>	<b>0.00</b>	<b>0.00</b>	<b>0.00</b>

### TESTING WITHOUT THE MOTHER

There is still a strong concern about submitting disputed paternity cases without the mother since such testing presents a number of problems. First, the paternity index is, on average, cut in half. This also greatly reduces the ability to detect a falsely accused man, and in some cases, such as incest, can easily produce false inclusions. When an apparent inconsistency (mutation) is present, it may not be possible to render an opinion of paternity without obtaining a sample from the mother. The mother is also an

<sup>3</sup> Fu, J., Allen, R.W., Reid, T.M., and Baird, M. Considerations for the interpretation of STR results in cases of questioned half-sibship. *Transfusion*, 47: 515-519, 2007.

important QC step. If the mother is excluded, it may indicate a problem in the testing. The testing of the mother may also allow for the detection of fraud, such as welfare fraud on the part of the mother or cases where the alleged father brings a child he knows is his, but is not the child of the mother. Thus, the testing of the mother, even if maternity is not disputed, is important in evaluating the questioned relationship, it improves the chance of obtaining clear results and is a quality control check for both the scientific and legal community. Every effort should be made to test the mother. Testing without the mother should only be done when the mother's location is unknown or she is deceased.

## **TECHNOLOGY USE**

The 2008 survey showed a continued trend toward the increased use of polymerase chain reaction (PCR) technology (STR analysis) with a decrease in the use of restriction fragment length polymorphism (RFLP) methods. In fact, at this time, the use of RFLP has dropped below the level of HLA molecular techniques. PCR technology was used in 99.6% and RFLP was used in 0.02% of reported cases. Y Chromosome testing continues to increase in use, albeit Y Chromosome analysis was used in only about 0.32% of cases reported. Note that the 9<sup>th</sup> edition of *Standards*, no longer contains standards for serologically tested red cell antigens, HLA serology, red cell enzymes, serum proteins, allotyping, and RFLP methods. These were dropped because of the current lack of their use in the industry. Proficiency testing may be difficult to obtain and finding any laboratory to do comparison testing may be problematic. However, if a laboratory wishes to use these methods the laboratory may refer to the appropriate testing standards in the 8th edition of *RT Standards*. Proficiency testing would need to meet the 9th edition of *RT Standards*.

Table 4 provides a breakdown of the technology used to resolve the reported paternity cases. The three laboratories using HLA molecular methods were asked to identify the source of the frequencies. Laboratories using HLA molecular methods for Class I HLA methods reported using serologic tables for calculating paternity indices.

**Table 4.** The Technology Used in Cases Reported in 2008

<b>Technology</b>	<b>Number of Cases</b>	<b>Utilization (%)</b>
<b>Red Cell Antigens</b>	<b>0</b>	<b>0</b>
<b>HLA Serology</b>	<b>0</b>	<b>0</b>
<b>HLA Class I Molecular</b>	<b>315</b>	<b>0.08</b>
<b>HLA Class II Molecular</b>	<b>33</b>	<b>0.01</b>
<b>Red Cell Enzymes/Serum Proteins</b>	<b>0</b>	<b>0</b>
<b>Allotyping</b>	<b>0</b>	<b>0</b>
<b>RFLP</b>	<b>282</b>	<b>0.07</b>
<b>STR</b>	<b>412,833</b>	<b>99.59</b>
<b>SNP</b>	<b>0</b>	<b>0</b>
<b>Y Chromosome</b>	<b>1,078</b>	<b>0.26</b>
<b>Total of All Technologies</b>	<b>414,541</b>	<b>100</b>

\*Note that some cases used more than one technology.

Figure 2 shows the use of various technologies since 1990. As indicated above, the most commonly used technologies in 1990 (red cell antigens, HLA, and red cell enzymes and serum proteins) now account for less than 1% of all casework. The change in DNA technologies from RFLP to PCR technology is also obvious. Prior to 1995, the survey only asked about the use of DNA testing but not about which DNA technology was used (PCR versus RFLP). Note that in some instances multiple technologies were used in the same case.

**Figure 2. The Use of Various Technologies Since 1990.**

**SAMPLE SOURCE**

Laboratories reported approximately 966,728 samples used for the casework in 2008. Of these samples, buccal swabs account for 98.5227% of the samples. Whole blood samples accounted for 0.38%. Various other samples were also reported (See Table 5). Not all laboratories reported the samples they used.

Table 5. Sample Source in 2008.

Sample	Number	Percent	Sample	Number	Percent
Buccal Swabs	952,447	98.5227	Hair	139	0.0144
Blood	3,674	0.3800	CVS	223	0.0231
Blood Spot Cards	9,279	0.9598	Products of Conception	23	0.0024
Amniotic Fluid	687	0.0711	Bone	42	0.0043

Misc. Tissues	170	0.0176	Teeth	8	0.0008
Paraffin Blocks	36	0.0037	Total	966,728	100

## AMELOGENIN

A number of laboratories use the amelogenin locus to test for the gender of the sample. A number of males lacking the Y or X amelogenin allele were observed. Laboratories were asked to track the apparent X males observed in their laboratory. Like other DNA loci, amelogenin is subject to mutations. Therefore, occasionally normal males have only an X amelogenin phenotype or only a Y phenotype. There seems to be an interest in the laboratories in the East Asian (Oriental) and Asian Indian population and, as such, the data collected is presented here.

**Table 6.** A Summary of Data on Apparent X and Y Males Seen with ABI Primers

	<b>Race/Ethnicity - 2008 Data - ABI Primers</b>					
	<b>Black</b>	<b>White</b>	<b>Hispanic</b>	<b>American Indian</b>	<b>East Asian (Oriental)</b>	<b>Asian (India)</b>
<b>Number X Males Observed</b>	7	16	15	0	6	3
<b>%</b>	0.0112	0.0345	0.0709	-	1.8293	0.0239
<b>Number Y Males Observed</b>	38	4	6	0	0	0
<b>%</b>	0.0607	0.0086	0.0284	-	-	-
<b>Total Number of Males Tested</b>	62,598	46,366	21,144	1,245	505	12,533

## MUTATION CALCULATION AND FREQUENCIES

Single inconsistencies are routinely seen in the testing of paternity cases. If a laboratory concludes that the inconsistency is a mutation, then the mutation result must be incorporated into the reported results. Laboratories were asked how they calculated the paternity index (PI) for these loci. The laboratories all use one of several calculation methods. Some laboratories are most commonly using the mutation rate divided by the average probability of exclusion (65.22%). Some laboratories use Brenner's method (30.43%) in looking at the repeat length difference between STR alleles and one laboratory claimed to use Fimmer's method (4.35%).

A summary of the mutation frequencies for each STR locus is provided in Appendix 1. Note that these frequencies incorporate the indeterminate findings. The calculations are summarized at the bottom of the table for each paternal allele as shown in Appendix 2. The frequencies for changes from one allele to another are presented in Appendix 3.

A continuing objective of this year's report is to begin to collect data on STR loci to provide laboratories with frequencies to use in the mutation calculation. The guidance document for both the 8th and 9th editions of *RT Standards* contains a discussion of two methods that might be useful. One limitation of this data set is if the laboratory did not see any mutations, the laboratory did not provide data on the maternal and paternal meiosis. Many laboratories did not provide any data, so there is limited data presented.

If one wished to determine the specific mutation frequency at locus D3S1358 for the apparent paternal mutation event of the alleged father's allele 16 changing to an allele 17 in the child. Suppose that are 16 instances where, simply, 16 changed to 17 out of 79247 meioses reported or a frequency of 0.000202. However, there are several other opportunities for this change. If there were five instances where the alleged father's 16 could have changed to either a 15 or 17 (child is a clone of the mother or mother was not tested). To incorporate this data, one approach is to calculate the relative chance that the change was 16 to 17 rather than 16 to 15. Note the clear changes and calculate the relative chance of each change. Multiply the relative chance times the number of changes where the allele is 16 to 15 or 17, which is 5 in this data set, to obtain the relative portion attributable to a 16 to 17 change.

Table 6. Relative Chance of allele 16 changing to 15 or 17.

Change	Observed	Relative Chance	Portion of 5
16 to 17	16	$16/31 = 0.516$	$5 * 0.516 = 2.58$
16 to 15	15	$15/31 = 0.484$	$5 * 0.484 = 2.42$
Total	31	1	5

From this data, add 2.56 to the 16 observed potential changes from 16 to 17 to get the total of 18.56. Similarly, there were seven observations where the alleged father has alleles 16 and 18, either of which could mutate to a 17.

Table 7. Relative Chance of allele 16 or 18 changing 17.

Change	Observed	Relative Chance	Portion of 7
16 to 17	16	$16/26 = 0.615$	$7 * 0.615 = 4.305$
18 to 17	10	$10/26 = 0.385$	$7 * 0.385 = 2.695$
Total	26	1	5

From this data, add 4.305 to the 18.56 potential changes (paragraph above) from 16 to 17 to get the total of 22.865.

Hypothetically, there were instances where the father's alleles 16 and 19 could have changed to a 17 or 18. To incorporate this data, a similar approach is used.

Table 8. Relative Chance of allele 16 or 19 changing to 17 or 18.

Change	Observed	Relative Chance	Portion of 1
16 to 17	16	$16/21 = 0.762$	$1 * 0.762 = 0.762$

16 to 18	0	$0/21 = 0$	$1*0 = 0$
19 to 17	0	$0/21 = 0$	$1*0 = 0$
19 to 18	5	$5/21 = 0.238$	$1* 0.238 = 0.238$
Total	31	1	1

From this data, add 0.762 to the 22.865 above yielding 23.627.

Lastly, data from those cases where the mutation is either maternal or paternal (indeterminate) may be incorporated. Hypothetically, there were 7 instances where the mutation to a 17 could have been from a paternal 16. The approach to incorporate these data is similar to the above. First, look to the data to determine the frequency of the changes.

Table 9. Relative Chance of allele 16 changing to 17.

Change	Observed	Relative Chance	Portion of 7
16 to 17 Maternal	$1 / 67521 = 0.00001481$	$0.00001481/0.0002167 = 0.0683$	$7 * 0.0683 = 0.478$
16 to 17 Paternal	$16 / 79247 = 0.0002019$	$0.0002019/0.0002167 = 0.9317$	$7 * 0.9317 = 6.522$
Total	0.0002167	1	7

Finally, add 6.522 to the 23.627 yielding 30.149. Thus, for this hypothetical population, the frequency of paternal mutation from a 16 to a 17 is  $30.149/ 79247 = 0.00038$  as compared to the 0.000202 without incorporating all possible mutation events. The committee invites comments on alternative methods of determining the mutation frequencies.

**Appendix 1. Summary of Apparent Mutations at various Loci analyzed by PCR in 2008.**

## Appendix 2. Mutation Data

At the bottom of each table is a summary of the total mutations seen, the proportion of indeterminate mutations assigned from appendix 3, the total mutation including the indeterminate mutations, and the overall mutation rate without regard to race. The frequencies shown for the individual changes do not include indeterminate mutations. These can be incorporated following the discussion presented in the "mutation calculations and frequencies" found in the discussion above.

## Appendix 3.

At the bottom of each table are the numbers used to apportion the indeterminate mutations between paternal and maternal origin. The method used is described in the “mutation calculation and frequency” section. The numbers used in the apportionment include the paternal and maternal mutations from Appendix 2, the relative percent of maternal and paternal mutations, and the number of mutations assigned to either paternal or maternal origin.
