Abstract

Amazon Relational Database Service (Amazon RDS) makes it easy to set up, operate, and scale a relational database in the cloud.

If your Amazon Web Services (AWS) account was created before 2013, chances are you may be running Amazon RDS MySQL in an Amazon Elastic Compute Cloud (EC2)-Classic environment, and you are looking to migrate RDS into an EC2-VPC environment. This whitepaper outlines the requirements and detailed steps needed to migrate Amazon RDS MySQL databases from EC2-Classical to Amazon Virtual Private Cloud (VPC) with minimal down-time using RDS MySQL Read Replicas and ClassicLink.

Introduction

Based on when an AWS account was created, Amazon EC2 instances and RDS DB instances can be launched into either an EC2-Classical environment or an EC2-VPC environment. EC2-Classical enables instances to run in a single, flat network while VPC provides logical network isolation to run EC2 instances and RDS DB instances. This logical network isolation closely resembles a traditional network you might operate in your own data center, plus it has the benefits of the AWS scalable infrastructure.

If you're running RDS DB instances in an EC2-Classical environment, you might be considering migrating databases to Amazon VPC to take advantage of Amazon VPC features and capabilities. However, migrating databases across environments can involve complex backup and restore operations with longer down times that you might be able to tolerate in your production environment. By leveraging RDS MySQL Replication with ClassicLink you can migrate databases easily and securely with minimal down time.

Solution Overview

ClassicLink is set up to enable communication between a VPC and RDS DB instances in EC2-Classical. A Read Replica of the RDS DB instance in EC2-Classical is created. Then, a snapshot of the DB instance is used to set up a Read Replica in the VPC. A ClassicLink proxy in the VPC enables communication between the

source (also called the “master”) RDS DB instance in EC2-Classic and the target VPC replica. Once the replica in the VPC has caught up with the master RDS DB instance in EC2-Classic, updates against the master are stopped and the VPC replica is promoted to master. At this point, the connection details in any application that is reading or writing to the database are updated. The source database remains fully operational during the migration, minimizing downtime to applications.

ClassicLink and EC2-Classic

ClassicLink allows linking EC2-Classic instances to a VPC in your account within the same region. This allows you to associate VPC security groups with the EC2-Classic instance, enabling communication between EC2-Classic and instances in a VPC using private IP addresses. The association between VPC security groups and the EC2-Classic instance removes the need to use public IP addresses or Elastic IP addresses to enable communication between these platforms.

ClassicLink is available to all users with accounts that support the EC2-Classic platform and can be used with any classic instance. Using ClassicLink and private IP address space for migration ensures all communication and data migration happens within the Amazon network without requiring a public IP address for your RDS DB instance or an Internet Gateway (IGW) to be set up for the VPC.

RDS Read Replicas

You can create one or more Read Replicas of a given source RDS MySQL instance and serve application read traffic from replicated copies of your data. Amazon RDS uses the MySQL engine’s native asynchronous replication to update the slave whenever there is a change to the master DB instance. The Read Replica operates as a DB instance that allows only read-only connections; applications can connect to a Read Replica just as they would to any DB instance. Amazon RDS replicates all databases in the source DB instance. Read replicas can also be promoted, so that they become standalone DB instances.

RDS Snapshots

This solution relies on Amazon RDS snapshots to initially create the target MySQL DB instance in your VPC. Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just

individual databases. When you create a DB snapshot, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. Creating this DB snapshot on a Single-AZ DB instance results in a brief I/O suspension that typically lasts no more than a few minutes. Multi-AZ DB instances are not affected by this I/O suspension since the backup is taken on the standby instance.

Alternative Approaches

AWS Database Migration Service (DMS)

An alternative approach to migration is to use AWS Database Migration Service (DMS). The AWS Database Migration Service can migrate your data to and from most widely used commercial and open-source databases. The service supports homogenous migrations such as Amazon RDS to RDS, as well as heterogeneous migrations between different database platforms, such as Oracle to Amazon Aurora or Microsoft SQL Server to MySQL. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database.

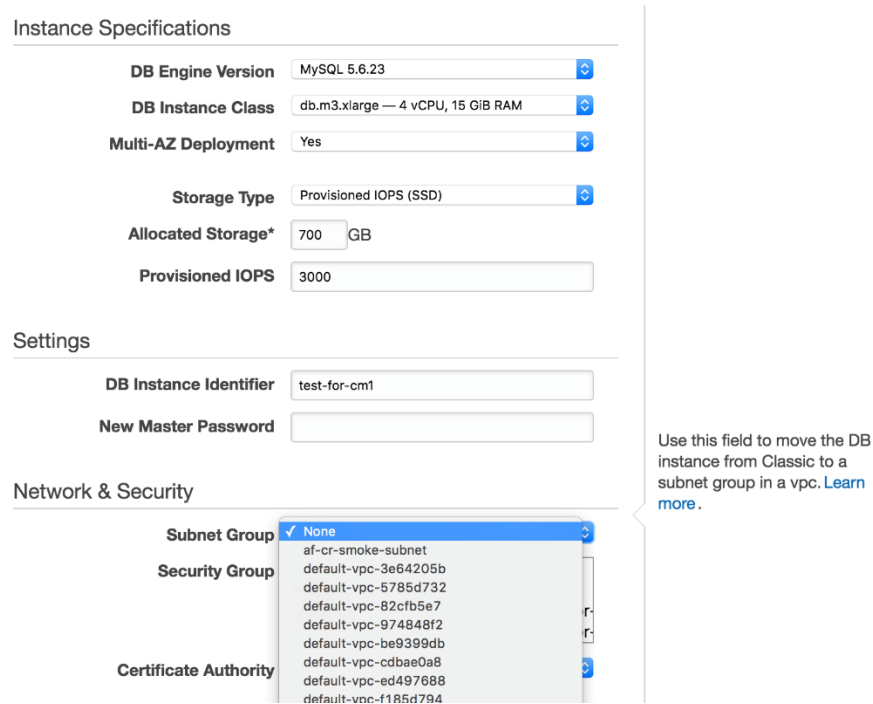

Although AWS DMS can provide comprehensive ongoing replication of data, it replicates only a limited amount of data definition language (DDL). AWS DMS doesn't propagate items such as indexes, users, privileges, stored procedures, and other database changes not directly related to table data. In addition, DMS does not automatically leverage RDS snapshots for the initial instance creation, which can increase migration time.

Changing the VPC Subnet for a DB Instance

Amazon RDS now provides a feature that enables you to specify a new VPC for an existing database instance in the RDS Console, the Amazon RDS API, or the AWS Command Line Tools. This feature also allows you to easily move an RDS DB instance in EC2-Classic to VPC. To specify a new subnet group, under **Network & Security, Subnet Group**, open the drop-down list and select the subnet group that you want from the list. You may choose to apply this change immediately or during the next scheduled maintenance window.

However, there are a few limitations with this approach:

- The database instance will not be available during the move. The move could take between 5 to 10 minutes.
- Moving Multi-AZ instances to a VPC is not currently supported.
- Moving an instance with Read Replicas to a VPC is not currently supported.

Instance Specifications

DB Engine Version: MySQL 5.6.23

DB Instance Class: db.m3.xlarge — 4 vCPU, 15 GiB RAM

Multi-AZ Deployment: Yes

Storage Type: Provisioned IOPS (SSD)

Allocated Storage*: 700 GB

Provisioned IOPS: 3000

Settings

DB Instance Identifier: test-for-cm1

New Master Password: [Empty]

Network & Security

Subnet Group: None

Security Group: af-cr-smoke-subnet, default-vpc-3e64205b, default-vpc-5785d732, default-vpc-82cfb5e7, default-vpc-974848f2, default-vpc-be9399db, default-vpc-cdbae0a8, default-vpc-ed497688, default-vpc-f185d794

Certificate Authority: [Empty]

Use this field to move the DB instance from Classic to a subnet group in a vpc. [Learn more](#).

Figure 1: Specifying a new subnet group (in a VPC) for a database instance

If these limitations are acceptable for your RDS DB instances, we recommend that you try out this feature by restoring a snapshot of your database in EC2-Classic and then moving it to your VPC. If these limitations are not acceptable, then the approach presented in the rest of this paper will enable you to minimize downtime during the migration to your VPC.

Migration Topology

This document focuses on how to use RDS Read Replica and snapshot capabilities to migrate a RDS MySQL DB instance in EC2-Classic to a VPC over ClassicLink. ClassicLink allows you to link your EC2-Classic instance to a VPC in your account within the same region. After you've linked an EC2-Classic instance,

it can communicate with instances in your VPC using their private IP addresses. However, instances in the VPC cannot access the AWS services provisioned by the EC2-Classic platform using ClassicLink. So to migrate an RDS database from EC2-Classic to VPC you must set up a proxy server. The proxy server uses ClassicLink to link to the VPC with the Read Replica instance; port forwarding on the proxy server allows communication between the source RDS database in EC2-Classic and the target VPC RDS DB instance. This topology is illustrated in Figure 2. If you are moving your RDS database to a different account you will need to set up a peering connection between the local VPC and the target VPC in the remote account. This topology is illustrated in Figure 3.

Figure 2: Topology for migration in the same account

Figure 3: Topology for migration to a different account

Figure 4 illustrates how the snapshot of the DB instance is used to set up a Read Replica in the target VPC. A ClassicLink proxy in the VPC enables communication between the source RDS DB instance in EC2-Classic and the target VPC replica, as illustrated in Figure 5.

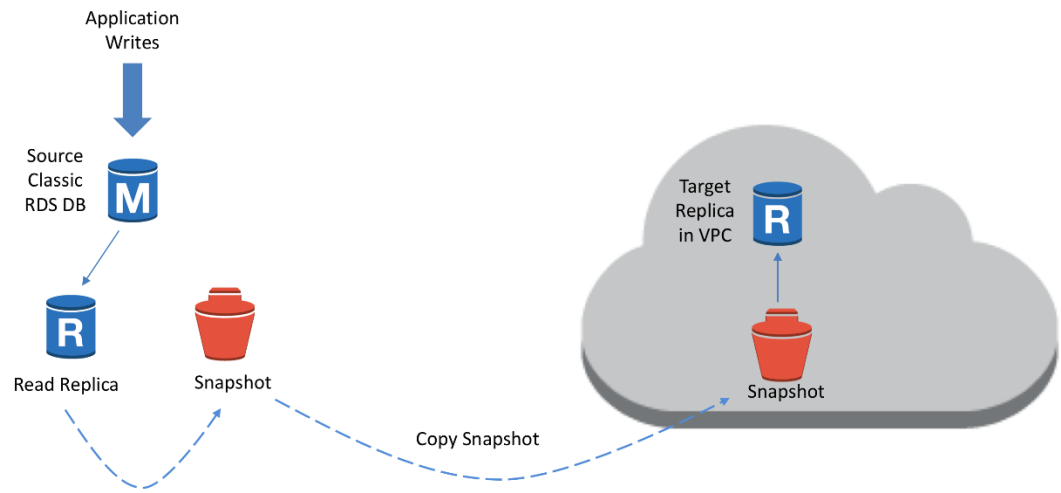

Figure 4: Creating a Read Replica snapshot and restoring in VPC

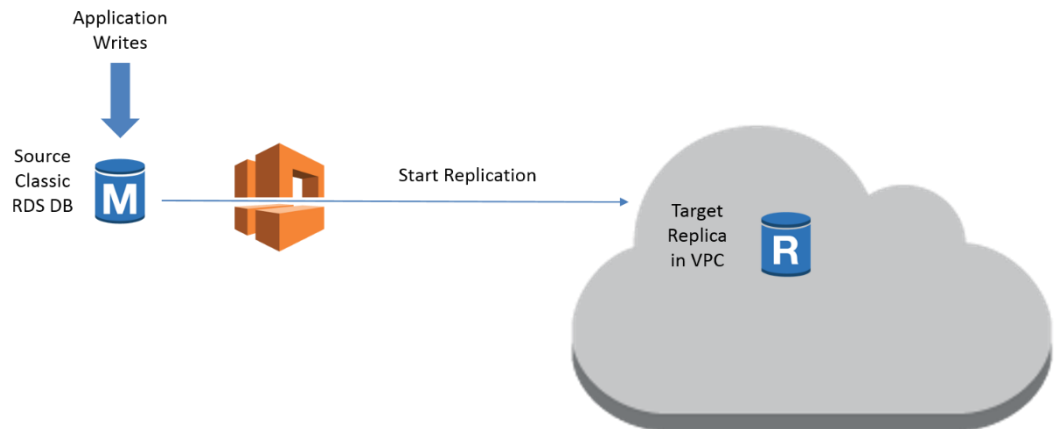

Figure 5: Setting up replication between the Classic and VPC Read Replica

Figure 6 illustrates how updates against the master are stopped and the VPC replica is promoted to master.

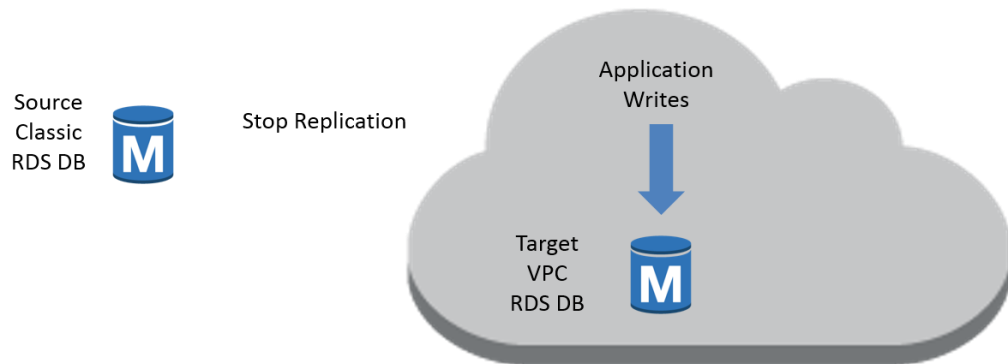

Figure 6: Cutting over application to the VPC RDS DB instance

Migration Steps

The following section lists the steps necessary to perform the migration.

Step 1: Enable ClassicLink for Target VPC

In the Amazon VPC console, on the VPC Dashboard, select the VPC for which you want to enable ClassicLink, select Actions in the drop-down list, and select **Enable ClassicLink** as shown below:

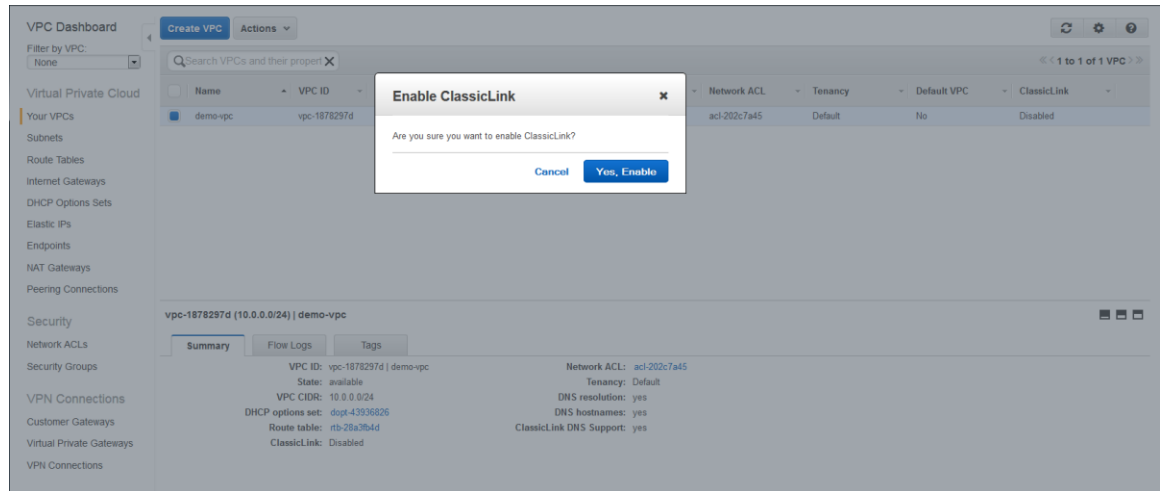

Figure 7: Enabling ClassicLink

Step 2: Set up a Proxy Server on an EC2-Classic Instance

Install a proxy server on an EC2-Classic instance. The proxy server forwards traffic to and from the RDS instance in EC2-Classic. You can use an open-source package such as NGINX for port forwarding. For detailed information on setting up NGINX, see Appendix A.

Set up appropriate security groups so the proxy server can communicate with the RDS instance in EC2-Classic. In the following example, the proxy server and the RDS instance in EC2-Classic are members of the same security group that allows traffic within the security group.

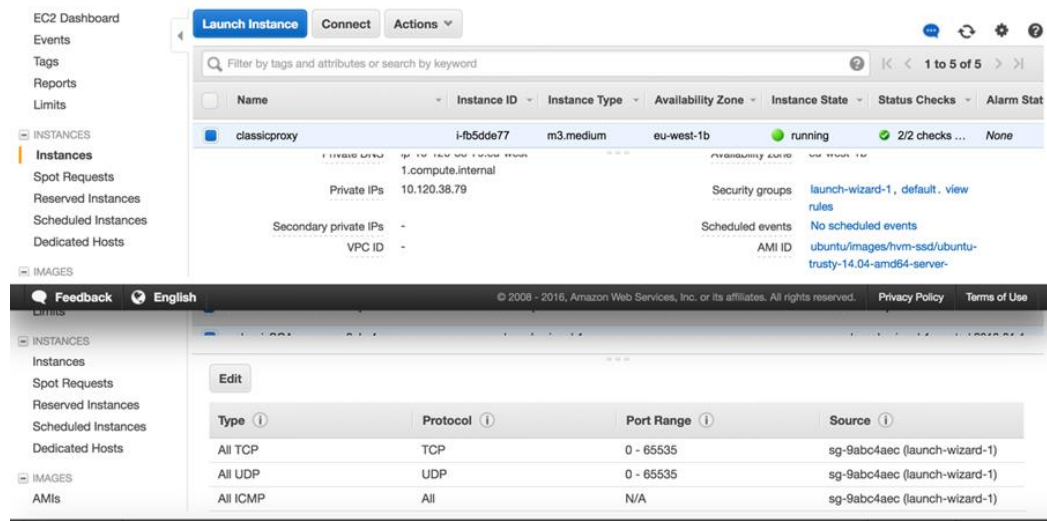

Figure 8: Security group setup

Step 3: Use ClassicLink between Proxy Server and Target VPC

In the Amazon EC2 console EC2 Instances Dashboard, select the EC2-Classic instance running the proxy server and choose **ClassicLink** on the Actions drop-down list to create a ClassicLink connection with the target VPC. Select the appropriate security group so that the proxy server can communicate with the RDS DB instance in your VPC. In the example in Figure 9, SG A1 is selected.

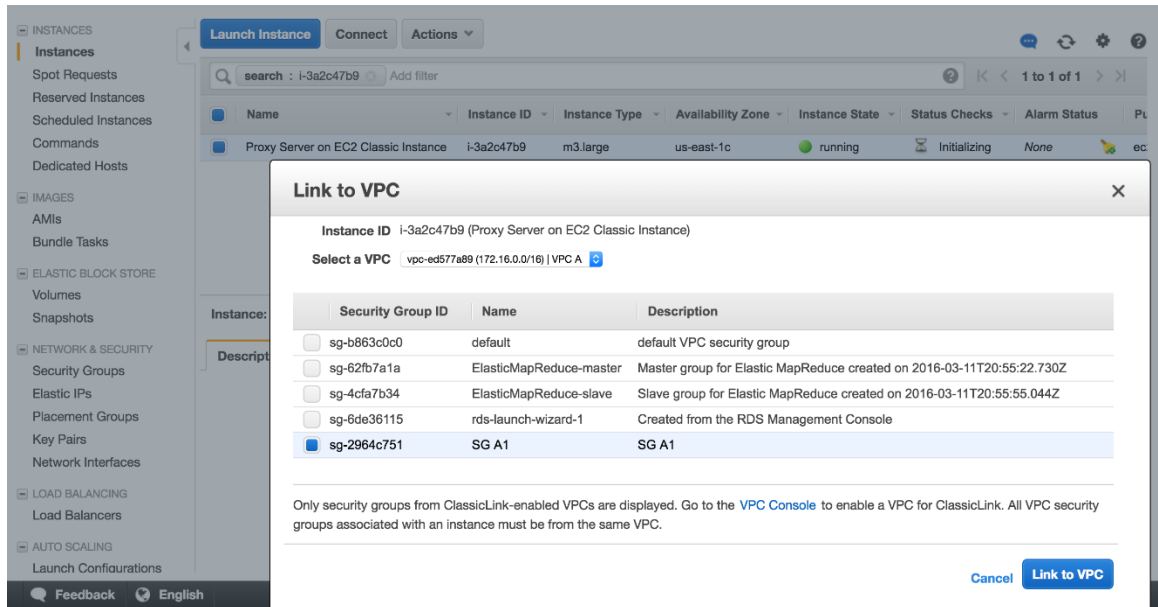

Figure 9: ClassicLink connection to VPC security group

Step 4: Configure the DB Instance (EC2-Classic)

In the Amazon RDS console, on the **Parameter Groups** page, select the parameter group associated with the RDS DB instance and use **Edit Parameters** to ensure the `innodb_flush_log_at_trx_commit` parameter is set to 1 (the default). This ensures ACID compliance; for more information see <http://tinyurl.com/innodb-flush-log-at-trx-commit>. This step is necessary only if the value has been changed from the default of 1.

RDS Dashboard

Parameter Groups > classicrdsparamgroup

Parameters Recent Events Tags

Filter: Cancel Editing Preview Changes Save Changes

Viewing 2 of 2 parameters

Name	Edit Values	Allowed Values	Is Modifiable	Source	Apply Type	Data Type	Description
innodb_flush_log_at_timeout	<input type="text"/>		false	engine-default	dynamic	integer	Write and flush the
innodb_flush_log_at_trx_commit	<input type="text" value="1"/>	0-2	true	engine-default	dynamic	integer	Determines InnoDB

Figure 10: Parameter group values on Classic DB instance

Step 5: Create a User on DB Instance (EC2-Classic)

Connect to the RDS DB instance running in EC2-Classic via `mysql` client to create a user and grant permissions to replicate data.

```
Prompt> mysql -h classicrdsinstance.123456789012.us-east-1.rds.amazonaws.com
-P 3306 -u hhar -p
MySQL [(none)]> create user replicationuser identified by 'classictoVPC123';
Query OK, 0 rows affected (0.01 sec)
MySQL [(none)]> grant replication slave on *.* to replicationuser;
Query OK, 0 rows affected (0.01 sec)
```

Step 6: Create a Temporary Read Replica (EC2-Classic)

Use a temporary Read Replica to create a snapshot and ensure that you have the correct information to set up replication on the new VPC DB instance. In the Amazon RDS console for the EC2-Classic DB Instance, on the **Instances** page select **Create Read Replica DB Instance**, and specify your replication instance information.

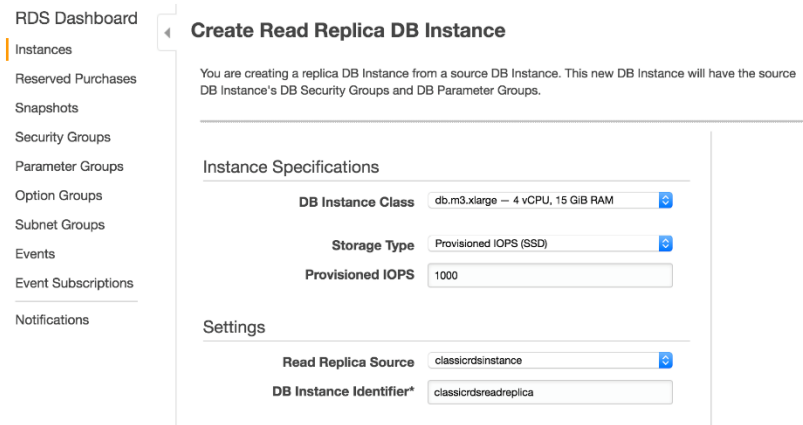

Figure 11: Classic Read Replica instance properties

You will then need to specify the network and security properties for the replica.

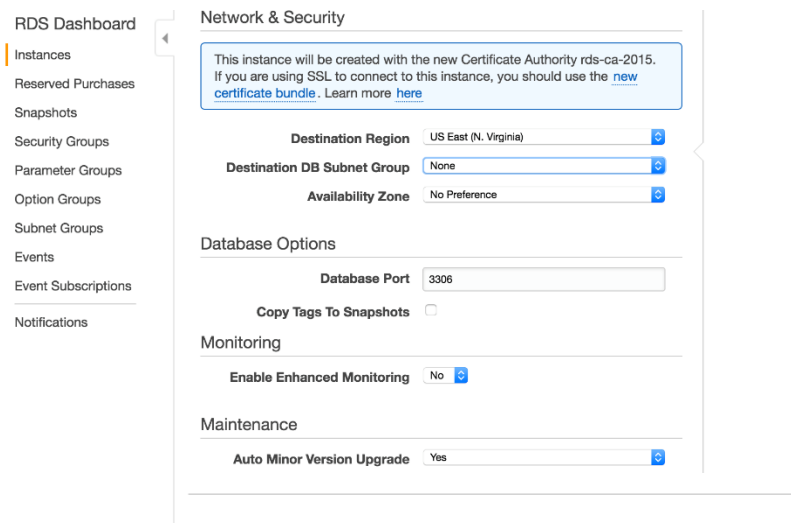

Figure 12: Classic Read Replica network and security properties

Step 7: Enable Backups on the Read Replica (EC2-Classic)

In the Amazon RDS console, on the **Instances** page select the Read Replica in EC2-Classic, and use **Modify DB Instances** to set the **Backup Retention Period** to a non-zero number of days. Setting this parameter to a positive number enables automated backups.

RDS Dashboard

- Instances
- Reserved Purchases
- Snapshots
- Security Groups
- Parameter Groups
- Option Groups

Maintenance

Auto Minor Version Upgrade Yes

Maintenance Window Start Day Friday
Start Time 05 : 06 UTC
Duration 0.5 hours

Apply Immediately

The number of days for which automated backups are retained. Setting this parameter to a positive number enables backups. Setting this parameter to 0 disables automated backups.

Cancel Continue

Figure 13: Enabling backups

Step 8: Stop Replication on Read Replica (EC2-Classical)

When you are ready to switch over, connect to the RDS replica in EC2-Classical via a `mysql` client and issue the `mysql.rds_stop_replication` command.

```
Prompt> mysql -h classicrdsreadreplica1.chd3laahf8xl.us-east-1.rds.amazonaws.com -P 3306 -u hhar -p
MySQL [(none)]> call mysql.rds_stop_replication;
+-----+
| Message |
+-----+
| Slave is down or disabled |
+-----+
1 row in set (1.02 sec)
Query OK, 0 rows affected (1.02 sec)
MySQL [(none)]>
```

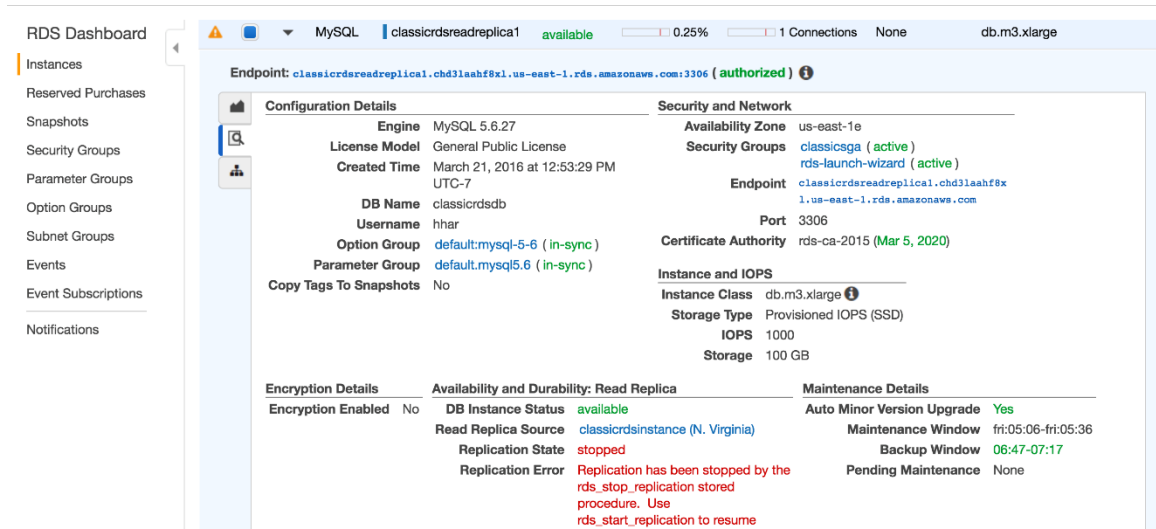

Figure 14: Confirmation of replica status on the console

Using the `show slave status` command, save the replication status data in a local file. You will need it later when setting up replication on the DB instance in VPC.

```
Prompt> mysql -h classicrdsreadreplica1.chd3laahf8xl.us-east-1.rds.amazonaws.com -P 3306 -u hhar -p -e "show slave status \G" > readreplicastatus.txt
```

Step 9: Create Snapshot from the Read Replica (EC2-Classic)

In the Amazon RDS console, on the **Instances** page select the Read Replica that you just stopped, and use **Take Snapshot** to create a DB snapshot.

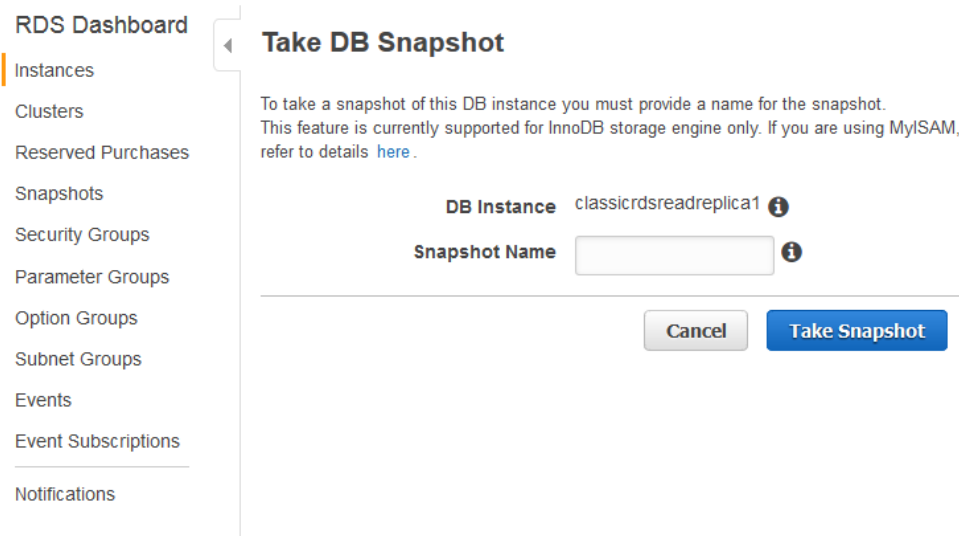

Figure 15: Taking a Snapshot of the Read Replica

Step 10: Share the Snapshot (Optional)

If you are migrating across accounts, you will need to share the snapshot. In the Amazon RDS console, on the **Snapshots** page, select the recently created Read Replica, and use **Share Snapshot** to make the snapshot available across accounts. This step is not required if the target VPC is in same account. After sharing the snapshot, log on to the new account after this step is finished.

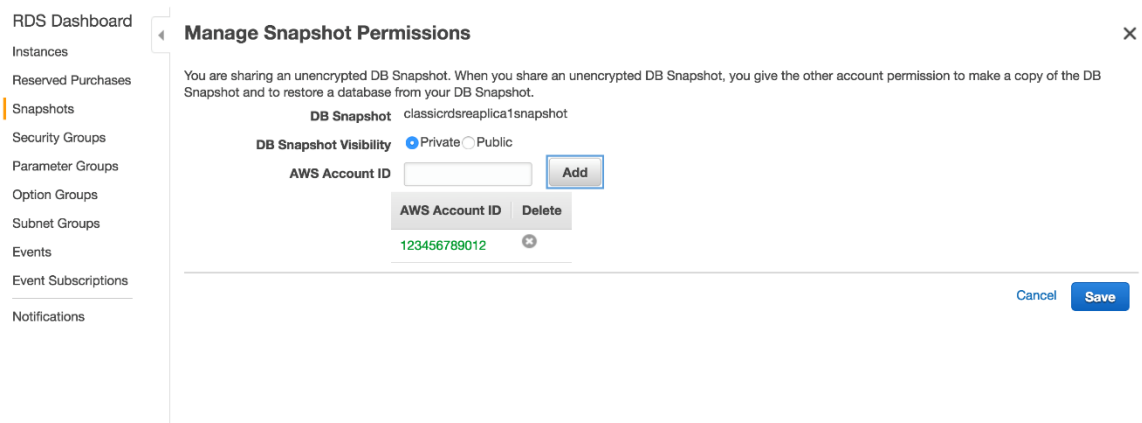

Figure 16: Sharing a snapshot between accounts

If you are migrating to a different account you will also set up a peering connection between the local VPC and target VPC in remote account. Also, you

will have to allow access to the security group that you used when you enabled the ClassicLink between the proxy server and VPC.

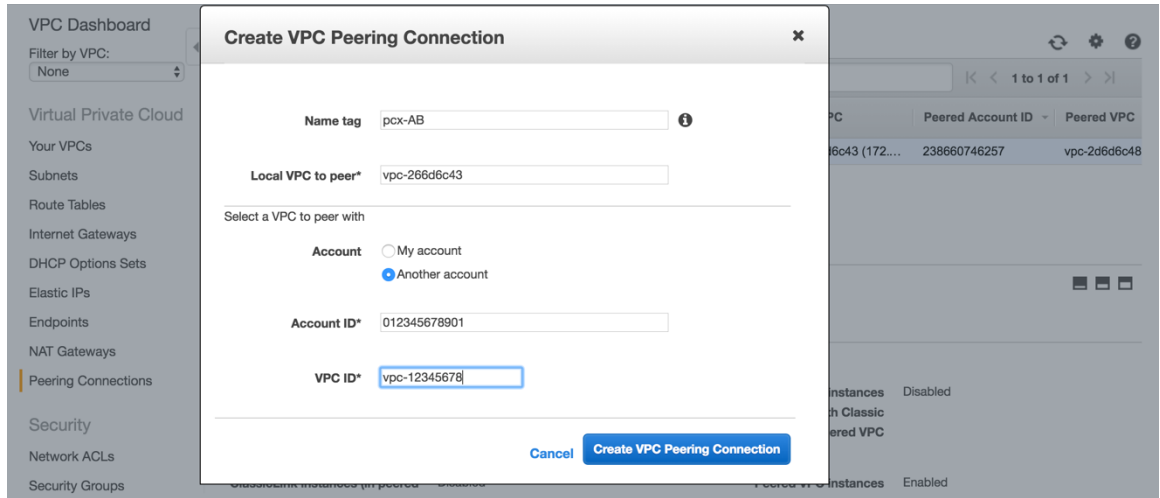

Figure 17: Creating VPC Peering Connection

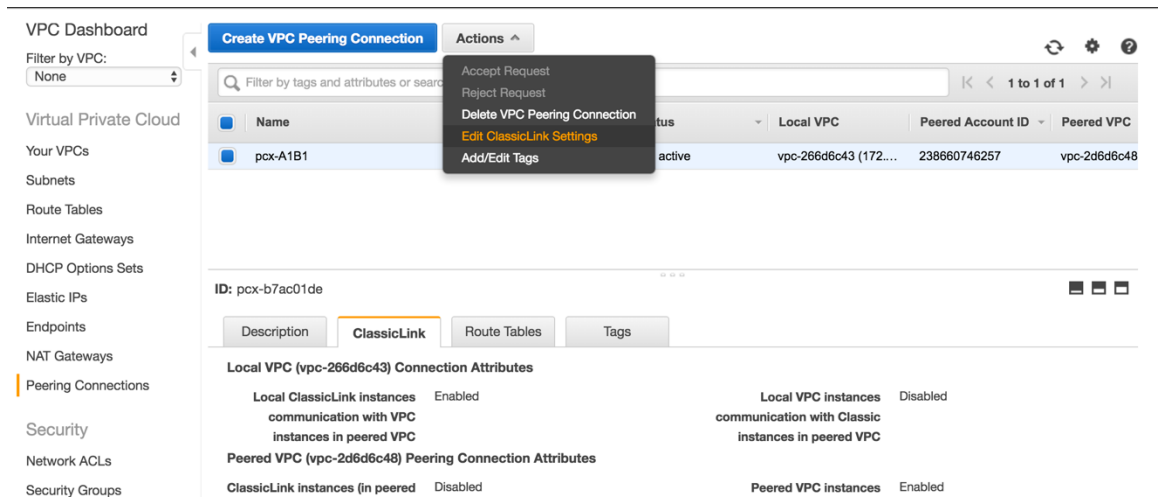

Figure 18: Enabling ClassicLink over a peering connection

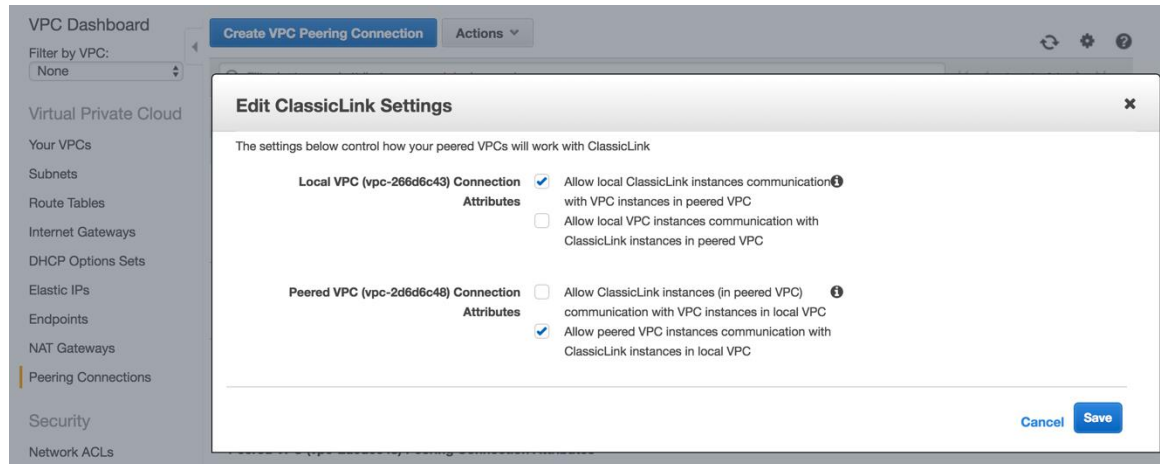

Figure 19: ClassicLink settings for peering

Step 11: Restore the Snapshot in the Target VPC

In the Amazon RDS console, on the **Snapshots** page, select the Classic Read Replica, and use **Restore Snapshot** to restore the Read Replica snapshot. You can also select **Multi-AZ Deployment** at this time.

RDS Dashboard

- Instances
- Clusters
- Reserved Purchases
- Snapshots
- Security Groups
- Parameter Groups
- Option Groups
- Subnet Groups

- Event Subscriptions
- Notifications

Restore DB Instance

You are creating a new DB Instance from a source DB Instance at a specified time. This new DB Instance will have the default DB Security Group and DB Parameter Groups. This feature is currently **supported for InnoDB storage engine only** . If you are using MyISAM, refer to details [here](#) .

Instance Specifications

DB Engine	mysql
License Model	general-public-license
DB Instance Class	db.t2.micro — 1 vCPU, 1 GiB RAM
Multi-AZ Deployment	Yes
Storage Type	
	General Purpose (SSD)

Settings

DB Snapshot ID	rds:mysqldevelopment-2016-06-20-22-52
DB Instance Identifier*	<input type="text"/>

Network & Security

VPC*	Default VPC (vpc-3bd2205f)
Subnet Group	default
Publicly Accessible	Yes
Availability Zone	No Preference

Figure 20: Restoring snapshot in target VPC

Also, in the Networking and Security settings, Set **Publicly Accessible** to Yes and select the target VPC and appropriate subnet groups to ensure connectivity from the VPC RDS DB instance to the Classic Proxy Server.

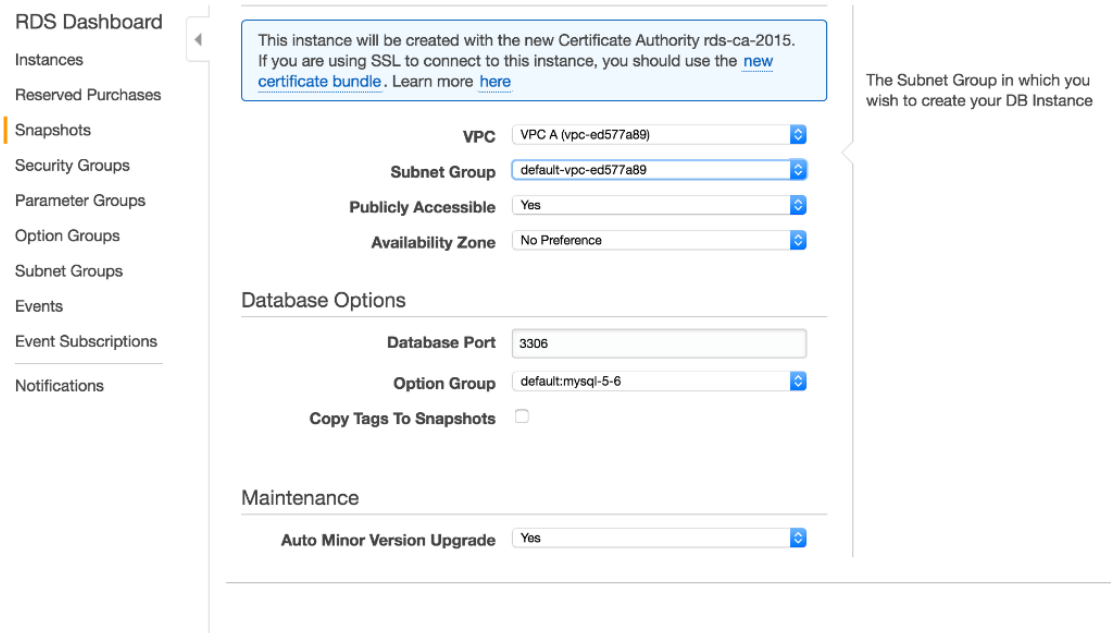

Figure 21: Setting VPC and subnet group on VPC DB instance

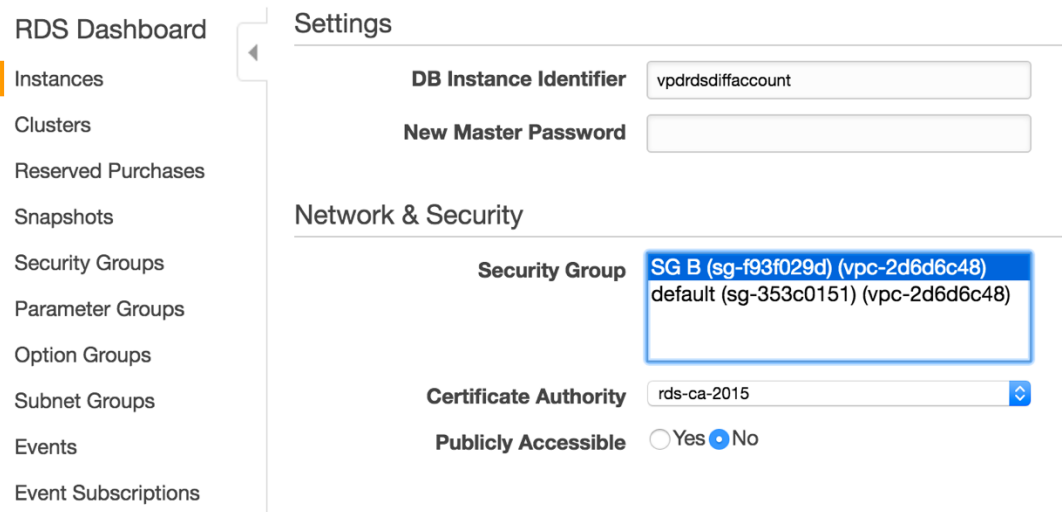

Figure 22: Security group settings for cross-account migration

Step 12: Enable Backups on VPC RDS DB Instance

By default, backups are not enabled on Read Replicas. In the Amazon RDS console, on the **Instances** page select the VPC RDS DB instance and use **Modify DB Instances** to enable backups.

The screenshot shows the AWS RDS console configuration page for a database instance. The left sidebar contains navigation links: RDS Dashboard, Instances, Reserved Purchases, Snapshots, Security Groups, Parameter Groups, Option Groups, Subnet Groups, Events, Event Subscriptions, and Notifications. The main content area is divided into sections: Backup, Monitoring, and Maintenance. In the Backup section, 'Copy Tags To Snapshots' is unchecked, 'Backup Retention Period' is set to 1 days, and 'Backup Window' has a Start Time of 06:47 UTC and a Duration of 0.5 hours. In the Monitoring section, 'Enable Enhanced Monitoring' is set to No. In the Maintenance section, 'Auto Minor Version Upgrade' is set to Yes, and 'Maintenance Window' has a Start Day of Friday, a Start Time of 05:06 UTC, and a Duration of 0.5 hours. At the bottom, there are 'Apply Immediately' (unchecked), 'Cancel', and 'Continue' buttons.

Figure 23: Setting Backup Retention

Step 13: Set up Replication between VPC and EC2-Classic DB Instances

Retrieve the log file name and log position number from information saved in the previous step.

```
Prompt> cat readreplicastatus.txt | grep Master_Log_File
      Master_Log_File: mysql-bin-changelog.001993
Prompt> cat readreplicastatus.txt | grep Exec_Master_Log_Pos
      Exec_Master_Log_Pos: 120
```

Connect to the VPC RDS DB instance via a `mysql` client through the ClassicLink proxy and set the Classic RDS DB instance as the replication master by issuing the `rds_start_replication` command. Use the private IP address of the EC2-Classic proxy server as well as the log position from the output above.

```
MySQL [(none)]> call mysql.rds_set_external_master('<private-ip-address-of-proxy>', 3306, 'replicationuser', 'classictoVPC123', 'mysql-bin-changelog.001993', 120, 0);
Query OK, 0 rows affected (0.12 sec)
```

```
MySQL [(none)]> call mysql.rds_start_replication;
+-----+
| Message          |
+-----+
| Slave running normally. |
+-----+
1 row in set (1.03 sec)
Query OK, 0 rows affected (1.03 sec)
```

Verify the replication status on VPC Read Replica via the `show slave status` command.

```
MySQL [(none)]> show slave status \G;
```

Step 14: Switch to the VPC RDS DB Instance

After ensuring that the data in the VPC Read Replica has caught up to the EC2-Classical master, configure your application to stop writing data to the RDS DB instance in EC2-Classical. Once the replication lag has caught up, connect to the VPC RDS instance via a `mysql` client and issue the `rds_stop_replication` command.

```
MySQL [(none)]> call mysql.rds_stop_replication;
```

At this point, the VPC will no longer be replicating data from the master. You can now promote the replica by connecting to the VPC RDS instance via a `mysql` client and issuing the `mysql.rds_reset_external_master` command.

```
MySQL [(none)]> call mysql.rds_reset_external_master;
```

```
+-----+
| Message          |
+-----+
| Slave is down or disabled |
+-----+
1 row in set (1.04 sec)
+-----+
| message          |
+-----+
| Slave has been reset |
+-----+
1 row in set (3.12 sec)
Query OK, 0 rows affected (3.12 sec)
```

You can now change the endpoint in your application to write to the VPC RDS DB instance.

Step 15: Take a Snapshot of the VPC RDS DB Instance

In the Amazon RDS console, on the **Instances** page select the VPC RDS DB instance and use **Take Snapshot** to capture a user snapshot for recovery purposes.

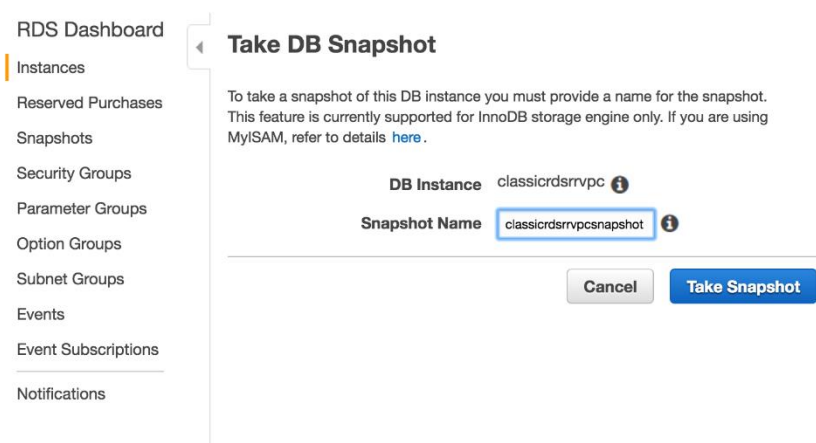

Figure 24: Taking a Snapshot of the DB Instance in VPC

Step 16: Change the VPC DB Instance to be 'Privately' Accessible (Optional)

Once the migration to the new VPC RDS instance is complete, you can change the VPC RDS instance to be privately (not publicly) accessible. In the Amazon RDS console, on the **Instances** page, select the DB instance and click **Modify**. Under **Network and Security**, for **Publicly Accessible**, choose **No**.

The screenshot shows the Amazon RDS console 'Modify' page for a DB instance. The left sidebar contains navigation links: RDS Dashboard, Instances, Reserved Purchases, Snapshots, Security Groups, Parameter Groups, Option Groups, Subnet Groups, Events, Event Subscriptions, and Notifications. The main content area is divided into sections: Settings and Network & Security. The Settings section includes fields for DB Instance Class (db.m3.xlarge), Multi-AZ Deployment (Yes), Storage Type (Provisioned IOPS (SSD)), Allocated Storage* (100 GB), and Provisioned IOPS (1000). The Network & Security section includes fields for DB Instance Identifier (classiordrvpc), New Master Password, Security Group (ElasticMapReduce-slave (sg-4cfa7b34) (SG A1 (sg-2964c751) (vpc-ed577a89) default (sg-b863c0c0) (vpc-ed577a89) rds-launch-wizard-1 (sg-6de36115) (vpc-...)), Certificate Authority (rds-ca-2015), and Publicly Accessible (radio buttons for Yes and No, with No selected).

Figure 25: Setting instance to not be publicly accessible

Step 17: Move the VPC DB Instance into Private Subnets (Optional)

You can edit the **DB Subnet Groups** membership for your VPC RDS DB instance to move the VPC RDS DB instance to a private subnet. In the example below, the subnets 172.16.2.0/24 and 172.16.3.0/24 are private subnets.

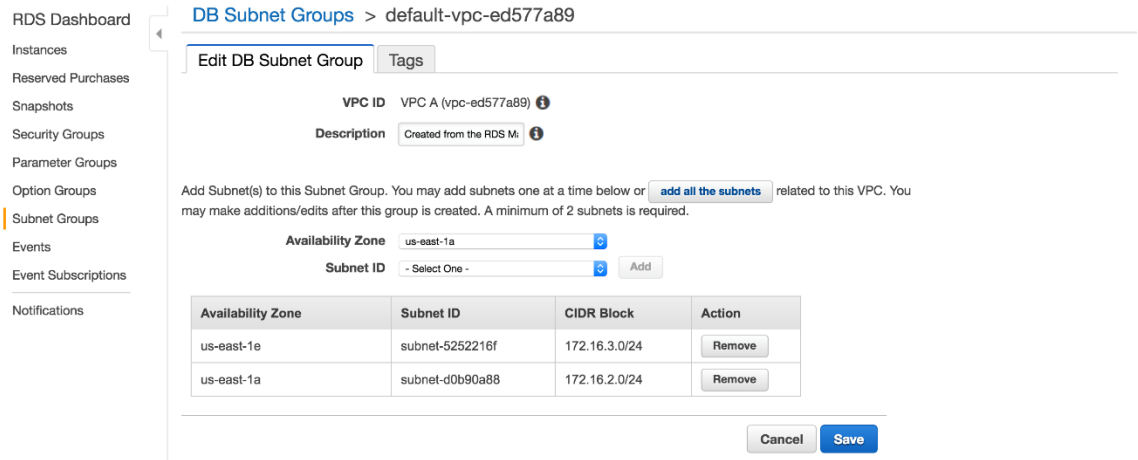

Figure 26: Configuring subnet groups

To change the private IP address of the RDS DB instance in the VPC you will have to perform a scale up or scale down operation. For example, you could choose a larger instance size. Once the IP address changes, you can scale again to the original instance size.

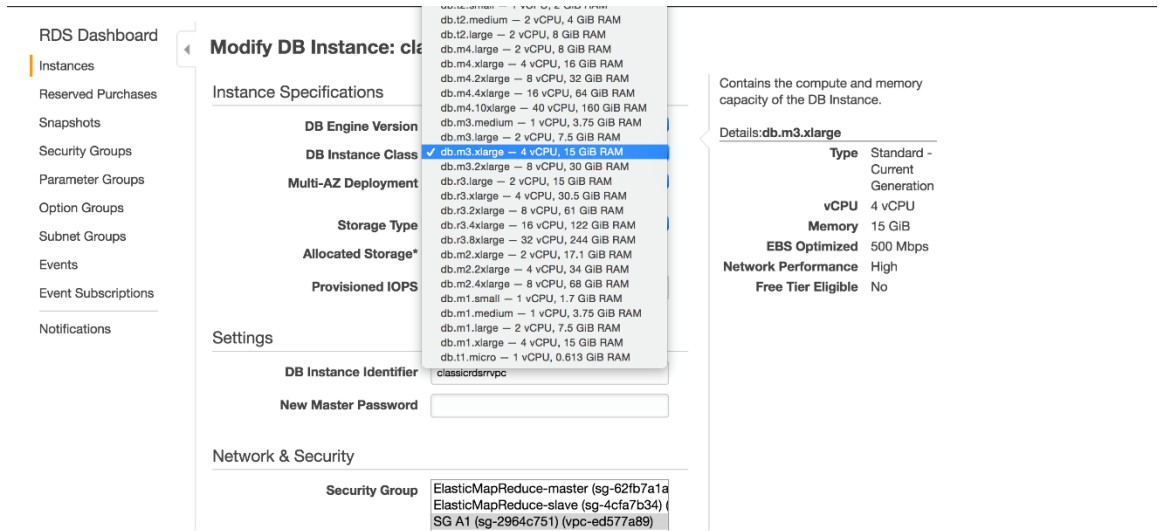

Figure 27: Forcing a scale optimization

Note: Alternatively, you can open an AWS support request (<https://aws.amazon.com/contact-us/>) and the RDS Operations team will move the migrated VPC RDS instance to the private subnet.

Conclusion

This paper highlights the key steps to migrate RDS MySQL instances from EC2-Classic to EC2-VPC environments using ClassicLink and RDS Read Replicas. This approach enables minimal down-time for production environments.

Appendix A: Set Up Proxy Server in Classic

Use an Amazon Machine Image (AMI) of your choice to launch an EC2 Classic instance. The example below is based on the AMI Ubuntu Server 14.04 LTS (HVM).

Connect to the EC2-Classic instance and install NGINX:

```
Prompt> sudo apt-get update
Prompt> sudo wget http://nginx.org/download/nginx-1.9.12.tar.gz
Prompt> sudo tar -xvzf nginx-1.9.12.tar.gz
Prompt> cd nginx-1.9.12
Prompt> sudo apt-get install build-essential
Prompt> sudo apt-get install libpcre3 libpcre3-dev
Prompt> sudo apt-get install zlib1g-dev
Prompt> sudo ./configure --with-stream
Prompt> sudo make
Prompt> sudo make install
```

Edit the NGINX daemon file `/etc/init/nginx.conf`:

```
# /etc/init/nginx.conf - Upstart file

description "nginx http daemon"
author "email"

start on (filesystem and net-device-up IFACE=lo)
stop on runlevel [!2345]

env DAEMON=/usr/local/nginx/sbin/nginx
env PID=/usr/local/nginx/logs/nginx.pid

expect fork
respawn
respawn limit 10 5

pre-start script
    $DAEMON -t
```

```
        if [ $? -ne 0 ]
            then exit $?
        fi
    end script

    exec $DAEMON
```

Edit the NGINX configuration file `/usr/local/nginx/conf/nginx.conf`:

```
# /usr/local/nginx/conf/nginx.conf - NGINX configuration file

worker_processes 1;
events {
    worker_connections 1024;
}

stream {
    server {
        listen 3306;
        proxy_pass classicrdsinstance.123456789012.us-east-1.rds.amazonaws.com:3306;
    }
}
```

From the command line start NGINX:

```
Prompt> sudo initctl reload-configuration
Prompt> sudo initctl list | grep nginx
Prompt> sudo initctl start nginx
```

Configure NGINX port forwarding:

```
# /usr/local/nginx/conf/nginx.conf - NGINX configuration file
worker_processes 1;
```

```
events {
    worker_connections 1024;
}
stream {
    server {
        listen 3306;
        proxy_pass classicrdsinstance.123456789012.us-east-1.rds.amazonaws.com:3306;
    }
}
```
