Founded in 1988, the Herbal Healer Academy Inc. (H.H.A.) is nonaccredited. It has a letterbox in Mountain View, Arizona. I learned of the academy from a composite alternativist mailing (Health Pak™) I received in October 1995. H.H.A.’s Health Pak card quoted its founder and director, Marijah McCain, N.D., M.H. (“Master Herbalist”), “DIHom” (evidently a homeopathic “credential”): “OUR MEMBERS SAVE THOUSANDS IN DOCTOR BILLS! SOME MEMBERS SAVE THEIR LIVES!!!” H.H.A.’s “Special” offer was “Private” lifetime membership for \$5. The mailing I received the following month for five bucks included a laminated membership card, a copy of H.H.A.’s Fall ’95 newsletter (whose “front-page headline” was “...AND GOD GAVE THE HERBS FOR THE HEALING OF MANKIND”); an interview with a nonpracticing chiropractor, titled “Essiac: Nature’s Cure for Cancer” [see NF 11:54–55, 1994; and NF 12:54, 1995]; a catalog of such supplements as Pycnogenol® [see NF 11:54, 1994], shark cartilage [see NF 12:58–59, 1995], and *Super Energy* (which reportedly contains ma huang [see NF 12:33–34, 1995]); a “Natural Medicine Supply Catalog”; and order forms. The latter catalog offered correspondence courses leading to certificates in acupuncture, Bach flower therapy, footreflexology [see NF 12:61–64, 1995], “herbology,” and hypnotherapy. The acupuncture course covered “electrical acupuncture,” “electrical acupressure,” “five element theory,” “meridians,” “Oriental diagnosis,” and “Yin/Yang science”; the “herbology” course, reflexology; and the hypnotherapy course, neuro-linguistic programming (NLP [see NF 12:8, 1995]). The “Natural Medicine Supply Catalog” also stated that McCain had diplomas in aromatherapy [see NF 12:31, 1995], homeopathy [see NF 11:58–59, 1994], and Touch for Health (an offshoot of applied kinesiology [see NF 12:26, 1995]), and that she had trained with “an outstanding Brazilian psychic surgeon.” There were no prerequisites for admission to any of the courses. At least two of them did not have a time limit for completion.

The main question here is not whether H.H.A.’s manner of “credentialing” by correspondence is technically sound, nor whether its certificates represent proficiency. The nuts and bolts of an academic program are immaterial if its teachings are unfounded. The main question is: Do the certificates represent science-oriented learning, or indoctrination in unscientific methods? In other words, are they credentials or pseudocredentials? Are students learning facts about methods, absorbing propaganda, or simply learning little? To all appearances, H.H.A. wants to attract would-be practitioners of the methods that are the courses’ subjects. Certainly Bach flower therapy, foot reflexology, and traditional Chinese acupuncture lack scientific support (“Yin/Yang science” is an oxymoron). Thus I conclude that the academy is in the business of indoctrination, not education (which, ideally, is nonpartisan).

California College for Health Sciences

The main question regarding California College for Health Sciences (CCHS), in National City, California, is different: It is whether the school's manner of credentialing by correspondence is sound. In other words, do its degrees represent proficiency?

CCHS is accredited by the Accrediting Commission of the Distance Education and Training Council, which is recognized by CORPA and the U.S. Secretary of Education. Last summer I applied to the school's M.S. correspondence program in Community Health Administration and Wellness Promotion. (It also offers health-related correspondence programs leading to a B.S. degree or an Associate.) The application procedure was a breeze. There were only two entrance requirements: (1) a baccalaureate from an accredited school and (2) completion of an introductory psychology course. Graduation requires completion of 36 semester credits, 27 of which the enrollee must complete at CCHS. The school admitted me to the program within a month of my applying.

In October, I enrolled in the first course in the core curriculum: "Ethical Considerations in Healthcare Delivery." Designed for the course and published by CCHS, the colloquial, 380-page textbook *What Is a Life Worth?* (1993) is interesting despite grammatical imperfections, stylistic flaws, and typographical errors. But it's not especially user-friendly. Earning the self-contained course's three credits requires only that the student pass: (1) five "open-book" exams, which consist of multiple-choice and "true-false" items; and (2) a "closed-book" final exam, consisting of 100 items (most multiple-choice, some "true-false"), that must be supervised by a "responsible individual" who does not have a personal or professional "direct involvement" with the examinee. This is, in effect, an honor system. Students may take the final exam three times during the enrollment period (two months per semester credit).

In November, I phoned the college and inquired whether my primary candidate for proctorship was eligible. I described her as a medical librarian who (1) worked at my former place of employment and (2) was a member of the editorial board of the newsletter I coedit. An official at CCHS told me that the librarian could be my proctor.

The five "open-book" exams are half the basis of the final grade. To pass them, one need only search the textbook sections titled "Study Questions and Answers."

"Believing Is Magic"

Later in November, I enrolled in another course, titled "Health Psychology." Unlike the ethics course, this psych course has a final project requirement, which involves interviewing five patients in a clinic or hospital regarding their pain. Supervision is not mandatory. The

project is half the basis of the final grade. The course materials, which I received in December, included a 114-page booklet titled *Developing Self-Esteem: A Guide for Positive Success* (1994). My first assignment, in effect, was to "attempt" to do all the exercises in the booklet and mail the "completed" booklet to the school. The exercises, which are self-inventories, have no bearing on the final grade. On page 44, the author declares: "Believing is magic."

Because it has an easygoing exam system, requires only one internship (a 3-credit course), and does not have a thesis requirement, CCHS's M.S. degree may be more acceptable as an adjunctive credential than as a "stand-alone" master's degree. Nevertheless, I like the school's organized, uncomplicated, low-cost, continuing-education approach. For credentialed health professionals employed in a healthcare facility, the M.S. program may be worth a try.

Suspicious Characteristics

Most providers of dubious credentials make good first impressions, and many have a streamlined (and therefore inviting) application procedure and minimal entrance requirements. These are not signs of pseudocredentialing but may put consumers off guard. To evaluate a "credentialing" organization, consumers often must penetrate a veneer of friendliness and/or respectability. Below is a list of characteristics that are, in my opinion, grounds for caution.

- *The organization does not possess accreditation by an entity recognized by the U.S. Secretary of Education or CORPA. Although the institution of academic accreditation does not protect consumers against health-related rubbish and disinformation [see NF 12: 14, 1995], accreditation by an entity recognized by either of the aforementioned agencies at least weeds out fly-by-night and financially shaky organizations.*
- *The organization claims accreditation, but neither the U.S. Secretary of Education nor CORPA recognizes the accrediting entity.*
- *Potential enrollees must pay to receive a course catalog.*
- *Consumer telephone requests for printed information elicit requests for prerequisite autobiographical letters.*
- *Literature from the organization does not specify the location of its headquarters.*
- *The organization has changed its address more than twice within ten years.*
- *Letters, postcards, or phone calls from the organization foretell a fee increase. During my 1994-1995 study, one program director, a naturopath who evidently thought I was a potential enrollee, spoke of such a deadline in three messages on my answering machine.*

- *The organization makes offers of substantial tuition discounts with short time limits.* An introductory mailing from the University of Metaphysics [see NF 12:60,1995] postmarked July 12, 1995, included a "Half-Price Tuition offer" expiration-dated July 31, 1995. In a follow-up mailing, postmarked July 20, 1995, the university added to this offer a free meditation course and a "Beautiful Doctoral Graduate Lapel Pin To Wear Proudly." (See below.)
- *The organization mails unsolicited partial-scholarship applications to potential enrollees who have not requested a scholarship application.* A mailing from the University of Metaphysics (see above) postmarked September 8, 1995, included an unsolicited scholarship application whose deadline was September 30, 1995. Persons who were unemployed, disabled, or retired, or who had a financial reason for not enrolling, qualified—with prepayment by September 30, 1995—for a tuition discount of approximately 90 percent. A "LAST MINUTE SCHOLARSHIP REMINDER" followed.
- *The organization offers a degree with a nonstandard wording.* Examples are "Doctor of Holistic Health" (H.H.D.) and "Doctor of Naturology" (D.N.).
- *The person who answers the phone for the organization does not immediately state its name.*
- *Prerequisites for admission are trivial, very flexible, or nonexistent.*

The Bottom Line

Few providers of alternative health education deserve the personal consideration of health professionals who desire *additional* credentials; i.e., few deserve candidacy as sources of credentials for credentialed people. Even fewer deserve the personal consideration of *would-be* health professionals.

I think credentialing by correspondence is a viable, even promising, movement. Alas, it is a movement dominated by fast-buck artists, charlatans, and propagators of mysticism, pseudoscience, and supernaturalism.

*By "nonaccredited," I mean: "without institutional, departmental, or programmatic accreditation whose source is recognized by the U.S. Secretary of Education or the Commission on Recognition of Postsecondary Accreditation (CORPA)." The U.S. Secretary of Education and CORPA autonomously decide whether (1) to grant recognition to any functioning or would-be "accreditor" that expressly wants it, or (2) to withhold or withdraw it from such an entity. In practical terms, recognition constitutes publicizing acceptance of such an entity as an accreditor.

Healthcare Esoterica

Between *Alternative Healthcare: A Comprehensive Guide* (1994) and issues of NUTRITION FORUM published since September 1994, I have described well over 750 health-related methods that I consider mystical or supernaturalistic. All the members of this vast smorgasbord share two characteristics: (1) each has a mystical or supernaturalistic application, theory, significance, or pedigree; and (2) each has a name that proponents or uncritical writers have used to denote a method, a group of methods, a system, or a general "approach."

Aboukra: Purported ancient Egyptian "healing art" that allegedly strengthens and balances the body's "natural energy fields" and "meridians."¹

Angel Chiropractic Care: "A wholistic approach to healing and wellness" promoted by Dr. Steven B. Angel. It encompasses applied kinesiology [see NF 12:26, 1995], Bach flower therapy [see NF 12:26, 1995], biomagnetic therapy [see NF 12:27, 1995], chiropractic techniques, craniosacral therapy,* nutritional counseling, reflexology [see NF 12:61-64, 1995], and vibrational medicine [see NF 12:31, 1995].²

Aston Movement: Mode of bodywork expounded and promoted by Judith Aston, the founder of Aston-

That is, each name denotes a procedure or a group of procedures, not merely a concept (e.g., "pyramid energy" or "pyramid power"), a brand or proprietary product, a type of object or product (e.g., Chinese health balls and "crystal cards"), or a company (e.g., Imaginetics). My list does not include countless dubious "health" practices that are nameless or naturalistic, as well as inconveniently identifiable methods.

Below are descriptions of more than sixty mystical/supernaturalistic methods.—J.R.

Patterning@.* One of its premises is that bodily "patterns"—ways of moving, areas of ease, and areas of discomfort—reveal everyone's history of attitude, injury, and physical activity.³

Astrology: Alleged means of obtaining information that can provide "individualized insights" regarding emotional, professional, and health matters.⁴ (Related methods include astrological counseling [see NF 12:26, 1995], astrologic medicine,* and psychological astrology.*)

Bhuta shuddhi: Technique of kundalini yoga (see below) whose purported design is to purify the "physical and subtle body."⁵

Bi-Digital O-Ring Test Molecular Identification Method (Bi-Digital O-Ring Test, O-Ring technique): Means of determining internal-organ "representation areas" on the human tongue. Theoretically, this enhances tongue acupuncture and the "tongue diagnosis" of traditional Chinese medicine.*⁶ Yoshiaki Omura, M.D., Sc.D., developed the method in New York City.⁷ It includes the Direct Bi-Digital O-Ring Test Method and the Indirect "Bi-Digital O-Ring Test" (see below for both). Omura has promoted the method worldwide, and there are "O-ring societies" in Europe and Japan.⁷

Bio-Magnetic Healing™ (Bio-Magnetic Healing Methodology™, Bio-Magnetic Methodology™, Bio-Magnetic Touch™): Manual "technique" that allegedly helps to heal "recipients" and increases their quality of life. Practitioners, who supposedly are tools of a "greater Force," lightly touch specific points on recipients, purportedly to allow this "Force" to "reawaken" the healing process.⁸

Body Centered Therapy: Method whose components apparently include: (1) "Conscious Communication Skills," which involve learning the "language of Microscopic Truth"; (2) "Movement Therapy"; (3) "Pre- and Perinatal Psychology," which posits "cellular imprints" created at conception and between conception and birth; and (4) radiance breathwork.*⁹

Bön shamanic practices: A number of traditional methods—rituals and modes of visualization—purportedly used to generate "vital forces" and "heal" internal and external obstacles to growth. The Tibetan word "bön" literally means "invocation, recitation." "Bön" or "Pön" refers to various religious customs in Tibet that preceded the introduction of Buddhism. Bön involved worship of spirits and protectional deities (e.g., the Lord of the Soil). It reportedly survives in modified form in Nepal.¹⁰⁻¹³

Breema Bodywork: Purportedly, an ancient health-improvement method whose design is: (1) to "release" tension; (2) to promote health, vitality, and "inner harmony"; and (3) to create emotional, physiological, structural, and "energetic" balance in the practitioner and "recipient."¹⁴

Direct Bi-Digital O-Ring Test Method: Form of the Bi-Digital O-Ring Test Molecular Identification Method (see above). The subject holds in one hand: (1) a slide with a specimen of an internal organ or tumor, and (2) a rod (e.g., of bamboo). Supposedly, when the subject places the tip of the rod on (1) the skin above "identical" tissue or (2) the tissue's "organ representation area" on the tongue, the subject's other hand (apparently, the muscle tone of the forefinger and thumb) reveals the match.⁶

Emotional Energetic Healing (E.E.H., E.E.H. Healing methodology): "Holistic healing" method founded by Mari Angelique Raphael that includes "hands-on energy work" and "spiritual counseling." Supposedly, it utilizes "the divine healing energy of the Angelic Realm," activates the client's "Lightbody," and "clears" past, present, and future "lifetimes."¹⁵

Energy Integration: Group of "techniques" that posit a "human energy field," "meridians," and a system of chakras. One of its premises is that one's body is the icon of one's character.¹⁶

EnLighten™ Systems of stress management (EnLighten Systems, EnLighten™): Variation of Bach flower therapy [see NF 12:26, 1995]. Purportedly, EnLighten is a "natural" homeopathic system of liquid Traditional Flower Remedies® that bypasses physical causes and targets emotions affected by "stressful situations." It comprises: (1) the EnLighten Habit Modification System(s); (2) the EnLighten System for Animals (also called the EnLighten for Animals™ healing system and the EnLighten for Animals™ system), which supposedly improves the disposition of pets; (3) the EnLighten System for Children with Learning Difficulties; (4) the EnLighten System for Teenagers, purported help for overcoming turmoil and peer pressure; and (5) the EnLighten Weight Management System, which allegedly moderates emotions that lead to overeating.¹⁷

Er Mei Qi Gong (Er Mei, Er Mei Qi Gong Therapy, Er Mei Chi Gong Therapy, Er Mei Qi Gong Therapy External Energy Diagnosis and Treatment system, Er Mei system): Form of Qigong therapy* founded in 1227 by a Buddhist who had been a Taoist priest. Its purported focus is development of the (alleged) ability to transmit Qi ("vital energy," a "unique substance") to others with the intention of furthering their healing and/or "spiritual empowerment." In practitioners, it supposedly develops clairvoyance and precognitive and telepathic abilities. Er Mei posits "spiritual channels" and a "third eye." It includes "acu-meridian energy transmission bodywork." ("Er Mei" is also the name of a mountain visited by the system's founder.)^{18, 19} (See "Quan Chi Chi Gong," below.)

Essene way of self-healing: Purported means of tapping alleged psychic and healing powers of the universe. It reportedly involves affirmations, "color therapies," exercise, songs, visualizations, and communion with the angels of the "Earthly Mother" and "Heavenly Spirit."²⁰ (The Essenes, also called Physicians, were a Jewish sect that preceded Christianity. Their specialty was faith healing.²¹)

Healing Heart Meditation: Alleged "Healing tool" that purportedly "re-connects" people with their "spiritual roots." It includes "guided meditation." Apparently, one of its postulates is that people are unconditional love.²²

Holistic psychiatry: Form of "psychiatry" that may include "energy healing" and homeopathy.²³

Indirect "Bi-Digital O-Ring Test": Form of the Bi-Digital O-Ring Test Molecular Identification Method (see above) that involves three individuals: (1) an examiner, the practitioner who examines the empty hand of (2) an "intermediary," a surrogate who has placed the tip of a metal rod on (3) a patient (adult, child, or animal). Either the "intermediary" or the patient holds a slide with a tissue specimen. Allegedly, the metal rod transmits the patient's "electro-magnetic field" to the "intermediary."⁶

Inner bonding: Stepwise "psychospiritual process" that allegedly creates "a powerful spiritually connected Inner Adult" capable of healing addictive behavior and bringing "Love" and "Truth" from a "Higher Power."²⁴

Integrative Manual Therapy: Combination of allegedly efficient "therapies" that draws on cranio-sacral therapy* and other "modalities." Sharon Weiselfish, Ph.D., developed the method.²⁵

Intuitive Aura Reading: Component of Psychic Magic (see below) that allegedly enables users to read "subtle energy fields" surrounding people and places, and to intuit the "real" emotional, mental, physical, and spiritual states of anyone they meet.²⁶

Karga puja (karga healing ritual): One of the shamanic "healing" ceremonies of the Tamangs, a group of Tibetan Buddhists in Nepal. "Karga" is the Tamang word for a constellation of planets, and "puja" is a Nepalese word for "ritual." Karga puja is a purported remedy for simultaneous "soul loss" and "spirit possession," the Tamangs' major categories of mental illness. The ritual posits evil spirits, "healing spirits," and "planet divinities."²⁷

Kinetic Trance-Meditation (KTM): Technique that supposedly allows one to tap into the unconscious to access information and "energy" (e.g., for "self-healing*"). Teodoro (Teo) Cordova, a hypnotherapist, developed the method.²⁸

Kundalini yoga (Shakti Yoga, tantra yoga): Purported means of activating kundalini (also called *ahamkara* and *kundalini shakti*). This, allegedly, is a "dormant infinite force," "potential cosmic power," or "spiritual power" that, in most people, is asleep, without self-awareness, in a chakra at the coccyx. Supposedly, when kundalini is awake, it enriches

people's lives "spiritually, intellectually, emotionally, and physically." Moreover, its arousal purportedly contributes to the cure of many intractable diseases. Kundalini yoga includes *bhuta shuddhi* (see above).^{12, 29-34}

Lok Hop Ba Fa: Set of movements purportedly usable for self-defense and for massaging organs with *chi*. Chen Bok, a Taoist priest, invented the system in China over a thousand years ago.³⁵

Lomi work (Lomi approach): System of bodywork cofounded by "Aikidoist" Richard Strozzi Heckler, Ph.D. It purportedly is a "unique blend of contemplative disciplines and the embodiment of right action." Lomi work involves meditation and, supposedly, the use of "energy" in the context of healing.³⁶

Lung Ta: Purportedly ancient shamanic tradition of the Nam Chuks, a Tibetan tribe. It apparently involves using the "basic archetypes" of "healing deities" to augment the process of healing.³⁷

Multidimensional Cellular Healing™: Apparently, a group of "down to earth" techniques that enables "conscious connection to other realities" and involves "Achieving a State of Holographic Beingness." Author and "transformational healer" Ken Page created the method.³⁸

Nichiren Buddhism (Nichiren Shoshu, NS, Nichiren Shoshu Buddhism, Nichirenism, Nichiren): Mystical Japanese religion named after Nichiren Daishonin (1222-1282), founder of *nichiren-shu* ("School of the Lotus of the Sun"). Daishonin was a militant Japanese patriot and, supposedly, an incarnation of an early disciple of the Buddha. Chanting the Japanese expression "*Namu myoho renge-kyo*" (which literally means "Veneration to the sutra [scriptural discourse] of the lotus of the good law [i.e., the *Lotus Sutra*]) is the core of NS worship. NS chanting allegedly is a means of gaining anything one wants, notably health, influence, and material assets.³⁹⁻⁴³

Pleiadian lightwork: Subject of *The Pleiadian Workbook: Awakening Your Divine Ka*. This, allegedly, is not merely a paperback, but a transmission of the "Pleiadian Emissaries of Light" (by inference, "light beings" from the Pleiades, a cluster of stars in Taurus)—through "natural healer" and "psychic" Amorah Quan Yin—to earth. Pleiadian lightwork purportedly is a means of opening "ka channels," which supposedly pull "energy" from an individual's "multidimensional holographic selves" into the "physical body." According to Pleiadian theory, alignment of one's "divine self" and "physical body" increases one's "vibratory rate," restores youthfulness, quickens "spiritual evolution," and stimulates emotional healing.⁴⁴

Psychic Magic: Program of ten audiocassettes that allegedly fosters clairvoyance, precognitive and telepathic abilities, and the capacity for out-of-body experiences. It also purportedly increases one's "natural" ability to heal oneself, others, pets, and plants. It includes Intuitive Aura Reading (see above).²⁶

Quan Chi Chi Gong: Form of Qigong therapy (external Qi healing). Quan Chi Chi Gong purportedly involves a variant of psychokinesis or telekinesis. Supposedly, practitioners transfer *chi* (Qi, "energy") stored in their "energy body" into the patient. The method allegedly is instrumental in accelerating healing, effectively treating drug addiction, and causing weight reduction.⁴⁵ (There are more than a dozen terms for Qigong therapy.)

Quantum ReleaseWork™: "Process" that supposedly uses the "Higher Self" to perform "vibrational, multi-dimensional" healing. Its originators are two former university professors: medical anthropologist Beatrix Pfeleiderer, "DR PHIL," and "consciousness researcher" Andrew Terker, Ph.D. According to Quantum ReleaseWork theory: (1) culture and "frozen" emotions suppress one's "true core"; (2) bodily cells hold emotional and psychological "woundings"; (3) "woundings" compress information in cells; (4) such compression prevents people from fulfilling their "true" potential; and (5) as people decompress the information in their cells, they slow the aging process and access their hidden potential for bliss, "energy," and creativity.^{46, 47}

Radiant breathing (radiant breathwork): Apparently, a method for the "release" of unconscious beliefs that "block" aliveness and for becoming aware of "Deep Body Memories."⁴⁸

Santeria: Subject of the 1987 occult thriller "The Believers." Like vodou [see NF 12:22, 1995], Santeria is a combination of Catholicism and ancient African magic. The word "Santeria" literally means "the worship of saints." Believers visit Santerian "spiritual healers" for "medical help" (e.g., to cure cancer). All Santerian priests and priestesses are herbalists. Most of the plants they use supposedly serve as remedies and as magical ingredients.^{49, 50, 51}

Scientific palmistry: Variation of medical palmistry* practiced by Nathaniel Altman, author of *Medical Palmistry*, *Palmistry for Lovers*, and *The Palmistry Workbook*. Supposedly, it involves "analysis" of the consistency and flexibility of the client's hands and reveals "detailed" information about health and spirituality.⁵²

Seitai control technique (seitai technique): Alleged aid to the restoration of a "true" state of perfect physical and mental health. It is related to Yoshida

taido (see below). The Japanese word "seitai" means "true physical and spiritual state."⁵³

Shamanic midwifery: Apparently Native American form of midwifery that frames childbearing as a spiritual quest and potential sacred "initiation" into a "mystery tradition."⁵⁴

SoulWork: A "holistic counseling and educational process" that includes guided imagery* and "other" shamanic "processes," purportedly for "soul access and retrieval."²²

Spiritual surgery: Form of spirit healing* and variation of spirit surgery* promoted by Lorna Green. Green is a medium for the "Spiritual Surgeons," supposed Christian spirits who work through God.⁵⁵

Starlink: Supposedly, an "interdimensional set" of "healing" movements derived from the work of the American Taoist Healing Center* with English "crop circle energies."⁵⁶

TaeUIJu healing meditation (TaeUIJu, TaeUIJu meditation, TaeUIJu healing): Mode of meditation promoted by JeungSanDo, an organization founded in 1871 by "Supreme Lord" JeungSan SangJeNim, in Korea. Supposedly, it is a process of returning to the magnanimous "bosom" of the original "Mother," and the first step to eternal life. The practice of TaeUIJu amounts to (1) sitting comfortably and (2) repeatedly, patiently chanting a "mantra" whose meaning is that one wants to return to the "Origin of the Universe." JeungSanDo defines "mantra" as "a set of words that contain concentrated energy of the universe." The aforementioned "Origin" purportedly can cure all mental and physical illnesses. Allegedly, the "original healing mantra," called TaeUIJu, protects one from sudden accidents and helps to fight disease and to resolve conflicts.⁵⁷

T'ai Chi Dao Yin: System of exercises that resembles hatha yoga and borrows from Taoist Chi Kung* and Chen style T'ai Chi Chuan (the prototype of tai chi³⁵). It supposedly increases "internal chi cultivation."⁵⁸

Taiji Wuxigong: Form of Qigong.* It is a set of exercises whose purported focus is the opening of the body's (alleged) "middle [energy] channel." Supposedly, steady practice of these exercises "can" conduce to an improvement of health, an increase in mental stability, restoration of vitality, and "possible" activation of "certain" latent abilities.⁵⁹

Tamang shamanism: Type of shamanism* practiced by the Tamangs, a group of Tibetan Buddhists in Nepal. It borrows from Buddhism and Hinduism and includes karga puja (see above). Tamang shamans always impute the disorders they treat to evil spirits.^{27, 60}

Tao healing energy chant: Adjunct to TaeUIJu healing meditation (see above) that supposedly structures "TaeUIJu Healing Energy." Up-and-down vibration of both hands purportedly concentrates the "Healing Energy" of chanters.⁵⁷

Taoist energy touch: A "traditional healing art" taught by Nan Lu (see Chapter 4 of *"Alternative" Healthcare: A Comprehensive Guide*). It purportedly involves summoning and directing "internal energy" to alleviate common minor ailments.⁶¹

Tattva shuddhi (tattva shuddhi meditation): Tantric form of meditation that posits chakras and five elements: air, earth, ether, fire, and water. It purportedly is adaptable to "self-healing."* "Tattva shuddhi" means "purification of the elements."⁶²

Ten Jin Do: "Transformational" mode of "energy work" that includes a meditative form of absent healing* (also called distance healing and distant healing).⁶³ The "Touch" of Ten Jin Do supposedly is available anywhere on earth through distance healing.^{64, 65}

Thai-style bodywork: Variety of bodywork "therapies" whose origin is Thailand. Their purported design is to create "energetic" balance and "wholeness" of body, mind, and spirit in practitioners and their clients.⁶⁶

Thought Therapy: "Self-study process" that posits a "spiritual-self" and purportedly enables use of twelve ("not just five") senses.¹

Transformational Breath™: "Powerful catalyst" and "gift of joy" that borrows from yogic doctrines. One of its premises is that suppressed emotions limit the ability "to feel and to be in the present" and tend to keep the body "under-oxygenated" and "under-energized."⁶⁷

Uighur medicine: Medical tradition of the Uighurs, the Turkic inhabitants of Xinjiang (Xinjiang Uygur), an autonomous region of westernmost China. It is a combination of ayurveda [see NF 11:36-38, 1994], traditional Chinese medicine,* and Unani medicine* (Unani *tibb*), an Islamic development.⁶⁸

Vedic astrology (Jyotish): Ancient system that allegedly helps to resolve doubts concerning children, health, "spiritual growth," and other subjects. Suggestions regarding donations, gemstones, herbs, mantras, *yantras* (mystic "diagrams"), and rituals are integral to the system.⁶⁹

VEGAtest method (Vega in vitro test method): Variant of applied kinesiology [see NF 12:26, 1995] developed by Helmet (sic) Schimmel, M.D., D.D.S., a German. Purportedly, it is a "bioenergetic evaluation system" for revealing "disturbance patterns" in a patient's "electro-magnetic acupuncture system." The method posits Qi ("inherent human bioenergy") and features an alleged multipurpose "kinesiologic muscle test" whereby practitioners can learn the "key toxin" causing bodily problems and select "proper" homeopathic "remedies."⁷⁰ Apparently, practitioners use portable instruments that reportedly measure skin conductivity and allegedly can help in the location of areas of "energetic imbalance or weakness."⁷¹

Vietnamese traditional medicine (Vietnamese medicine): Syncretic medical tradition of Vietnam. It includes acupuncture, cupping,* moxibustion,* and scarification.⁶⁸

Waitankung: Ancient Chinese exercise system of Taoist origin. Supposedly, the Waitankung exercises allow *chi* ("inner energy") to fill the body like an electric current.⁷²

Weigh Down Workshop: Christian weight loss program founded by nutritionist Gwen Shamblin, who apparently ascribes it to divine inspiration. According to a 1995 edition of the television newsmagazine "A Current Affair," Shamblin's "gospel" is: "Eat what you want, whenever you want, and ask the lord to help you to stop when you've had enough, so you leave room for a hefty helping of the holy spirit." The program includes audiocassettes, videos, books (e.g., *Feasting on the Will of the Father*), and "revival-like religious rallies."⁷³

WooJangJu power meditation (WooJangJu power chant): Variant of TaeUIJu healing meditation (see above) whose purported design is to protect meditators, while they are healing, from vengeful spirits.⁵⁷

Yoshida taido (Yoshida taido technique): "A kind of keep-fit technique" apparently developed by Toshiro Yoshida. Its apparent main premises are that (1) all diseases stem from leg disorders, and (2) maintaining "a good physical balance" and enabling adequate intake of "natural energy" are the keys to preserving soundness of body and mind. "Taido" means "body guidance." Yoshida *taido* and the *seitai* control technique (see above) are related.⁵³

*See *"Alternative" Healthcare: A Comprehensive Guide* (Prometheus Books, 1994).

Love Is Like Oxygen

Oxygen, the most abundant element on earth, is like love: Buying it is riskier than getting it free. And while some people receive it inattentively, others, it seems, can't get enough.

Something in the Air

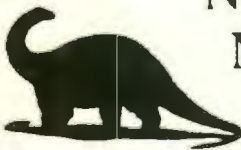

About fifteen years ago, I was a supplement buff reading *Rejuvenation*, a book in which "nutrition reporter" Linda Clark (then one of my favorite authors) recommended a liquid supplement called *Zell Oxygen*. ("Zell" is a German prefix that means "cell" (*Zelle*.) I eagerly bought at least one bottle of the refrigerated yeast preparation in a health-food store. It was unpalatable. An ad in an early 1992 issue of *Health World* magazine described *Genesis 1000*, a liquid mineral preparation, as "the oxygen supplement." It quoted a previous issue, which had designated this product "the vital nutrient." The March 1992 issue of *Let's Live* magazine carried the display for *Genesis 1000* substantially reproduced on page 15.

So-called oxygen supplements are still around. They're just obscure. Last year, I heard a vender at a health-food trade show describe oxygen as "vitamin O," the "most

vital nutrient" (see NF 12:12, 1995). *One Sickness—One Disease—One Treatment* (1995) recommends "formulas" such as *Liquid Lightning Oxygen-O₃* for "oxygen deprivation." (See the entry for Daniel's Diet in this issue's installment of "Healthcare Esoterica.") The December 1995/January 1996 issue of *To Your Health!* ("The Magazine of Healing and Hope!") included the ad below.

Where Do We Draw the Line?

Vitamins are by definition organic compounds (they contain carbon). Oxygen is not a compound and therefore not a vitamin. But is it a nutrient? Trying to define "nutrient" (or "food") is an exercise in tautology. Broadly, a nutrient is any substance that promotes development of the body, is necessary for life, or contains something necessary for life. According to *The Nutrition and Health Encyclopedia* (1989), "nutrient" is "a general term for any substance which can be used in the metabolic processes of the body." *Realities of Nutrition* (1993) states: "Nutrient is a general term that refers to any dietary substance that nourishes the body in some way."

**No Oxygen!
No Minerals!
No Wonder!**

Heritage Health Products offers:

Oxy-Aloe: a Super OXYGEN supplement using 20 drops of 35% Food Grade Hydrogen Peroxide (H₂O₂) in a base of Aloe Vera Juice and 5% Plant Source Colloidal Minerals.

Jurassic Minerals: 60-72 plant source trace colloidal minerals. No longer available through our food!

**Why Degenerate?
Mineralize and Oxygenate**

Jurassic Complete: You can get energized with this state-of-the-art ALL-IN-ONE liquid mineral, vitamin, antioxidant, amino acid supplement.

However, according to *The Dictionary of Nutrition and Food Technology* (1990), nutrients are "essential dietary factors such as vitamins, minerals, amino acids and fats"—substances that: are indispensable, we ingest, and have significance as part of a diet.

The meanings of words depend on general usage; and, in particular fields, the definitions of some words differ from their popular meanings. Apparently, most dietitians, qualified nutritionists, and food scientists do not designate oxygen a nutrient. Although oxygen is essential for metabolism in animals and plants, there are reasons for not considering it a nutrient:

- Oxygen is dietarily ubiquitous: It is a percentage component of air (as in ice cream) and a molecular component of carbon dioxide (as in soda pop), water, and many other food constituents (e.g., the essential nutrients lysine, tryptophan, and vitamins A, B₁, B₂, B₆, B₁₂, C, D, and K). However, oxygen is not in itself a dietary factor, because: (1) oxygen in the alimentary canal does not discretely contribute to digestion or absorption (that is, nascent (atomic) oxygen (O), ordinary (diatomic) oxygen (O₂), and triatomic oxygen (O₃), as such, do not contribute); and (2) oxygen does not contribute to metabolism as a discrete dietary component.

In short, oxygen is dietarily ubiquitous, yet oxygen whose source is food or dietary water does not discretely contribute to digestion, absorption, or metabolism. (In a related vein, the metallic element cobalt apparently is essential to humans solely because it is part of cobalamin—vitamin B₁₂. However, cobalt is not dietarily ubiquitous.)

- Hypoxia (definable as a deficiency of oxygen in body tissues) and anoxia (which includes severe hypoxia and histotoxic anoxia (a condition due to the inability of tissues to utilize oxygen)) are not related to the amount of oxygen that enters the gastrointestinal tract.
- Although O₂, like other small molecules, is absorbable from the gastrointestinal tract (particularly the small intestine), we expel most of the air we swallow. The proportion of oxygen in swallowed air that we absorb from the gastrointestinal tract appears unknown, but it is probably very small.
- It is not useful for science-oriented health professionals to consider oxygen a nutrient: Dietary supplements cannot beneficially change oxygen intake. Diet affects oxygen intake only rarely, as in cases of asthma and/or hypersensitivity to sulfites. The effect in such cases is due to the inclusion or exclusion of particular foods, not to the amount of oxygen in the diet.

Carbon, which is dietarily ubiquitous, and nitrogen, a constituent of all amino acids, are also essential to life, but I've never heard or read a description of either as a nutrient for humans. Perhaps this is because there is no financial reason to describe them as such.

The "O" Zone

Oxymania has increased considerably since I bought *Zell Oxygen* circa 1980. Self-"oxygenators" don't necessarily take supplements, though. Some introduce an allotrope of oxygen—ozone (O₃)—into their colons via the anus. (Ozone yields O₂ and atomic oxygen (O), which is more active chemically than O₂.) Some drink hydrogen peroxide solutions and/or "therapeutically" ozonized water.

Alternative Medicine: The Definitive Guide (1993) (see NF 11:57, 1994) states that *oxygen therapy* refers to "a wide range of therapies utilizing oxygen in various forms to promote healing and destroy pathogens (disease-producing microorganisms and toxins) in the body." According to the *Guide*, the two main categories of oxygen therapy (also called *oxygen therapies*) are: (1) *oxygenation therapy*, which comprises methods that purportedly add oxygen to blood or tissues (e.g., hyperbaric oxygen therapy (HBOT)); and (2) *oxidation therapy*, which includes hydrogen peroxide therapy. (Use of a "pressure chamber" that fits one person or several people distinguishes HBOT, which has utility in treating burns, carbon monoxide poisoning, smoke inhalation, and other conditions.) The *Guide* suggests that ozone therapy spans both categories. Expressions related to oxygen therapy include: *oxygen healing therapies*, *hyperoxygenation therapy* (or *hyperoxygenation therapies*) (see NF 12:55, 1995), *oxidative therapy* (or *oxidative therapies*), *bio-oxidative therapy*, and "bio-oxidative medicine." However, all of the oxygen therapy-related expressions in italics in this paragraph are elusive; there is no consensus on their meanings.

The expression "bio-oxidative medicine" is part of the name of the International Bio-oxidative Medicine Foundation, in Oklahoma City, Oklahoma. On January 17, a telephone operator told me that Southwestern Bell did not have a listing for the foundation. Later that day, I called the foundation using the phone number provided by *Alternative Medicine: The*

Definitive Guide and the *Alternative Medicine Yellow Pages*. The call led to my hearing a "message-only recording" on what the voice referred to as voice mail.

In a two-part article, Dr. Saul Green vaporizes the mystique of "oxygenation therapy." Part I,

below, deals with hydrogen peroxide therapy and "glyoxylide," an alleged oxidizer of purported value in curing cancer. Part II, which will head the next issue of *NF*, flattens the "champagne" of oxygen therapies—ozone therapy.—*J.R.*

Oxygenation Therapy: *Healing or Hot Air?*

Part I: "Glyoxylide" and Hydrogen Peroxide

Saul Green

The universal fear of life-threatening illnesses such as cancer and AIDS smoothes the way for entrepreneurs to swindle the unsuspecting and the desperate with the promise of a safe and effective treatment. The crescendo of the rhetoric extolling oxygenation therapy is such that it must seem a medical miracle to the scientifically illiterate.

The cornerstone of oxygenation therapy is the dogma that all human diseases are caused by the absence of oxygen in body tissues. This anoxia allegedly results in: the production of "inferior" energy through anaerobic fermentation, incapacity for oxidative detoxification of metabolic poisons, and inability of the immune system to destroy pathogenic bacteria and viruses. Purportedly to correct these alleged results,

oxygenation therapists promote the use of chemicals that, supposedly, release oxygen into tissue fluids or kill germs in vivo. Their claims trace to two medical doctors: William F. Koch¹ (1885–1962) and Otto Warburg² (1883–1970).

Roots

After he noticed that removal of the parathyroid gland caused blood clotting, Detroit physician William F. Koch concluded that the cause of cancer was a metabolic defect due to a single toxin generated by an injury or irritation. In 1919, he proposed that the burning of toxins produced as metabolic byproducts, and by bacteria, normally accompanied carbo-

hydrate metabolism, but that when these toxins persisted in the blood, they damaged the toxin-burning system and converted a normally present "harmless germ" into a virulent carcinogen. Koch claimed to have invented an "antitoxin to cancer"—a supposed mixture of parabenzoquinone (which contains oxygen) and an alleged oxidant he called glyoxylide ($O=C=C=O$). He reportedly injected a millionfold dilution of this mixture into patients every six months, to "stimulate all the body's oxidation reactions to cure the cancer and a host of other diseases."³ Koch never revealed how to manufacture glyoxylide.

Otto Warburg affirmed that the solution to cancer lay in identifying a biochemical difference between the energy-producing systems of normal cells and those of cancer cells. In 1931, he won the Nobel Prize for his discovery of the oxygen-transferring enzymes in cellular respiration. In 1944 he

NEW!

GENESIS 1000™

THE OXYGEN SUPPLEMENT™

Imported from New Zealand

Genesis 1000 is a liquid concentrate formulated to ensure the greatest amounts of bio-available electrolytes of oxygen.

It's easy to use—just put 10-15 drops in a glass, add water and drink!

VITAMIN "O" — OXYGEN!

Health professionals now recognize that a shortage of oxygen can lead to a wide variety of health problems, especially those involving bacteria, fungi and viruses.

Your checklist for better health

- ✓ Fights stress & pollution
- ✓ Is recommended where there is fatigue, depression, low energy, and poor resistance
- ✓ Will not harm friendly intestinal flora
- ✓ Is a powerful free radical scavenger
- ✓ Has unique anti-viral, anti-bacterial and anti-fungal properties
- ✓ Increases endurance, stamina and aerobic capacity

GAIN & MAINTAIN OPTIMUM HEALTH & FITNESS

Safe • Proven • Effective GENESIS 1000—ASK FOR IT!

Available at better Health Food Stores

won another, for identifying the enzymes that transfer hydrogen in metabolism. But his research never showed that normal cells and cancer cells use oxygen differently. He did find, however, that whereas normal cells produced lactic acid only under conditions such as oxygen depletion or deprivation, cancer cells produced lactic acid even when plenty of oxygen was present. From this observation he concluded that energy metabolism in cancer cells was defective.⁴ Moreover, he professed, erroneously, that cancer cells produced lactic acid because they could not use oxygen.

Over the next three decades, cancer researchers identified nearly all of the energy-producing metabolic pathways in normal cells and in cancer cells and learned that the energy-producing systems in both were the same.⁵ Nevertheless, Warburg insisted until his death in 1970 that "inferior" energy produced by anaerobic metabolism was the cause of cancer.⁴

Misguided by the conclusions of Koch and Warburg, proponents of oxygenation therapy claim: (a) that "toxins" in the environment, in processed foods, and in modern medicines harm normal mammalian cells; (b) that an oxygen deficiency results; (c) that this deficiency damages the oxidative metabolism of normal cells; (d) that normal cells consequently fall back on anaerobic metabolism; (e) that anaerobic metabolism produces "inferior" energy; and (f) that the final stage of this chain of (alleged) events is cancer. To restore the effective use of oxygen for proper digestion and excretion and for efficient immune function, they say, treatment should include: pure, "all-natural," poison-free nutrients; vitamin and mineral supplements; and substances that replenish tissues with oxygen and thus restore processes that burn off toxins.

Hydrogen Peroxide: "God's Given Immune System"?

Among the earliest proponents of the use of hydrogen peroxide (H_2O_2) as a treatment for "degenerative diseases" like cancer was Father Richard Willhelm, a Catholic priest.⁶ Willhelm said that, working with a microbiologist at the Mayo Clinic in the 1940s, he "learned that bacteria can gnaw at the joints, cause inflammatory arthritis, give off calcium waste that cements bones together, lodge in the liver and kidney and form stones, leave hard deposits on walls of arteries, short-circuit the energy in the brain, cut off the blood supply to cells, and cause a loss of oxidative metabolism." From Koch's and Warburg's work he gathered that "cancer doesn't like oxygen," and because hydrogen peroxide gives off oxygen when it decomposes, he concluded that it should be used to treat diseases caused by "inadequate oxygen metabolism." Willhelm has referred to hydrogen peroxide as "God's given immune system."⁶

In 1982, Willhelm met Walter Grotz, a retired employee of the United States Postal Service. When Grotz complained about his arthritic pain, Willhelm suggested that, for several weeks, the retiree drink daily between 1 and 7 glasses of pure water to which a few drops of a "food grade"

35% hydrogen peroxide solution had been added. Grotz said that doing this had freed him from pain, and he became Willhelm's disciple. As they traveled around the United States spreading their gospel, people began to use hydrogen peroxide solutions to bathe pets, disinfect aquariums, mist flowers, oxygenate garden soil, treat livestock, and wash crops. Usually, however, hydrogen peroxide was promoted as a treatment for human illness; Willhelm maintained in the 1980s that hydrogen peroxide "joyfully relieves" amebiasis, angina, arthritis, asthma, cancer, candidiasis, the common cold, emphysema, gingivitis, hemorrhoids, herpes, lupus, malaria, moles, multiple sclerosis, psoriasis, tumors, and warts.

Home Is Where the H_2O_2 Is?

A French chemist discovered hydrogen peroxide in 1818. It is present in nature in trace amounts. At solutions of 30 to 35 percent, so-called food grade hydrogen peroxide is so caustic it can burn skin severely; if one allows it to dry on a combustible surface, it can start a fire. Hydrogen peroxide decomposes violently when it is in contact with rough surfaces or with traces of organic matter. Heat, light, agitation, and substances such as carbonates, charcoal, chlorides, iron, and proteins accelerate decomposition of hydrogen peroxide in solution. Decomposition of the hydrogen peroxide in one volume of a 30% hydrogen peroxide solution generates 100 volumes of oxygen gas.

Some proponents of hydrogen peroxide therapy (e.g., in books such as *Hydrogen Peroxide Therapy: New Hope for Incurable Disease*) have suggested that patients treat themselves at home by drinking a hydrogen peroxide solution, taking homemade hydrogen peroxide pills,⁷ brushing their teeth with hydrogen peroxide preparations, massaging a hydrogen peroxide solution (e.g., a gel) into their skin, soaking in bathwater containing it, or administering it in enemas or douches. In a 1986 issue of the newsletter *Nutrition in Action*, for example, Kurt Donsbach [see NF 4:65-68, 1987; and NF 11:19, 1994] gave instructions on preparing "food grade" hydrogen peroxide for drinking. Donsbach said it took a week to "clean out" gastric flora, "good" and "bad." Although the stomach does not harbor any microbes, he stated:

When hydrogen peroxide comes in contact with virus and streptococcus in your stomach, it liberates free oxygen. If your stomach feels queasy after you drink the [hydrogen peroxide] solution, the peroxide is seeking out and destroying virus and streptococci. The normal flora, the good ones, can then be replaced by eating plain yogurt and health food supplements that contain acidophilus, bifidus and bulgaricus.

Charles H. Farr M.D., Ph.D., promotes intravenous

"Every dogma must have its day."

—H.G. Wells

infusion of hydrogen peroxide as "oxidative therapy."⁸ He has provided a detailed recipe for injectable hydrogen peroxide⁹ and declared:

There is no distinct class of patients that are best suited for intravenous hydrogen peroxide therapy because of the wide variety of pathological conditions that improve from oxidative detoxification, the oxygenation of hypoxic tissues and the stimulation of the immune system that an intravenous infusion of hydrogen peroxide induces. Specific benefits are seen in patients with peripheral-vascular, cerebrovascular and cardiovascular diseases, arrhythmias, emphysema, asthma, cancer, M.S., rheumatoid arthritis, Parkinson's, migraine, cluster and vascular headaches, allergies and pain. There may even be a reversal of atherosclerosis due to the action of the peroxide on the lipid material in blood vessel walls.⁸

Q & A: Missing Ingredients and "Farr-Out" Claims

Below are some questions whose answers shed a skeptical light on the claims for oxygenation therapy already conveyed.

• Ghostlike Glyoxylide

Does the alleged molecule Koch termed glyoxylide exist? "Glyoxylide" has been a subject of investigation or evaluation by some of the world's most distinguished organic chemists, from H. Staudinger in 1913 to J.A. Berson in 1986. In 1993, the *International Journal of Mass Spectroscopy and Ion Processes* presented a review of the literature on "glyoxylide." Therein, D. Sulzle and associates found that all efforts to prepare, isolate, or chemically characterize this alleged compound had failed. Moreover, Sulzle's inspection of the theoretical chemistry of "glyoxylide" had shown that the substance described by Koch cannot exist in nature (it's too unstable). The combination of the aforementioned finding and W.F. Jenssen's finding that Koch's "medicine" did not contain any component identifiable as glyoxylide or parabenzoquinone³ leads one to conclude that "glyoxylide" was a mere figment of Koch's imagination.

• The "Primary Cause of Cancer"?

Does anaerobic metabolism cause cancer? In a 1961 monograph,⁵ Aisenberg minutely reviewed published studies on energy metabolism in normal and tumor tissues. He came to the following conclusions.

- Most carcinogens are not respiratory poisons.
- Most respiratory poisons are not carcinogens.
- Oxygen neither prevents nor inhibits cancer growth.
- Tumor cells grow optimally in tissue-culture dishes in air.
- Tumors grow rapidly in tissues that are well supplied with oxygenated blood.

- The absence of oxygen does not stimulate tumor growth in vitro or in vivo.
- Agents effective against cancer interfere with DNA synthesis, not with fermentative metabolism.
- Tumors do not get a significant amount of their energy from fermentation.
- Tumors produce energy through oxygen-driven metabolism of carbohydrates and fats.

Since the mid 1960s, scientists have identified the processes of cancer initiation, promotion, and progression. Their findings show that cancer arises from the disruption of genetic regulation, DNA damage, and the activation of oncogenes. (Oncogenes are defective genes capable of transforming normal cells into cells that proliferate abnormally. Without a trigger, they don't do any harm.) Evidence of "poisoning" in the respiratory enzyme systems of tumors does not exist.

Although Warburg did discover scientifically significant differences in the metabolism of normal and cancer cells, these differences did not identify the replacement of respiration by fermentation as the "primary cause of cancer."⁵

• A Drop in the Bucket

Can the oxidative therapy of Charles H. Farr oxygenate hypoxic tissues?

At sea level, we normally inhale about 500 milliliters of air, about 21 percent of which is oxygen. The pressure of this oxygen is about 160 mm Hg (millimeters of mercury). When inhaled air reaches the surface of the alveoli (air sacs) of the lungs, it contacts the air already there, which has a pressure of 100 mm Hg. The difference in pressure drives the inhaled oxygen across the alveolar membrane, into the air sac. There, the difference between the pressure of the newly arrived oxygen and that of the oxygen in the venous blood that bathes the alveolar membrane—40 mm Hg—makes the additional oxygen diffuse into the venous blood. The hemoglobin in red blood cells (RBCs) takes up the oxygen, and the blood, now oxygen-rich, returns to the heart, which pumps it into arteries. When this arterial blood reaches the tissues, the oxygen carried by the hemoglobin moves into the tissue cells.

The delivery of oxygen to tissues depends on the capacity of RBC hemoglobin to carry oxygen. Normally, the hemoglobin leaving the lungs is 98% saturated with oxygen. Complete saturation is achievable only if: (a) the amount of oxygen in the inhaled air is about threefold the amount in normal air, or (b) the subject inhales oxygen exclusively for at least several hours. The hemoglobin in one liter of blood can carry about 200 milliliters of oxygen. Tissues take up about 50 milliliters of this. The tissues of a normal, 60-kilogram adult require delivery of 200 to 250 milliliters of oxygen per minute.¹⁰ Hydrogen peroxide in the amount infused into a patient during one oxidative-therapy session yields 100 milliliters of oxygen per day—an insignificant contribution.¹¹

• A Double-Edged Sword

Is hydrogen peroxide a germicide? Phagocytosis is the

principal natural mechanism for the removal of bacteria, fungi, and viruses from the body. Activated phagocytes (e.g., white blood cells) attach to pathogenic organisms and parasites and ingest (phagocytize) them. The killing of such pathogens occurs inside the phagocytes. There, an enzyme generates superoxide free radicals. Another enzyme, superoxide dismutase (SOD), fuses these free radicals into hydrogen peroxide, which turns intracellular chloride ions into free radicals that kill germs.

Proponents of oxidative therapy say that oxygen and hydrogen peroxide kill anaerobic bacteria, and that they do so because anaerobic bacteria lack: (a) SOD, which protects cells against oxidative damage; and (b) the peroxide-destroying enzymes catalase and peroxidase, without which hydrogen peroxide accumulates to toxic levels. But evidence of an oxygen intolerance in anaerobic organisms does not exist. And, though Farr has alluded to a variety of antibacterial, antiviral, and antiparasitic actions of hydrogen peroxide,⁸ he has admitted that there hasn't been any observation of a connection between peroxide-related germicidal activity and the infusion of hydrogen peroxide in patients infected with a variety of organisms.⁹ Independent investigators have confirmed this, explaining that the lack of a bactericidal effect of high concentrations of hydrogen peroxide was directly related to the presence in the blood of catalase.¹² The large amounts of catalase and peroxidase normally present in the blood precludes the existence of hydrogen peroxide there for more than a few seconds. One must conclude that hydrogen peroxide introduced into the human bloodstream does not act as a germicide.

Hydrogen peroxide does participate in bactericidal processes within activated phagocytes, but when it escapes from these cells into adjacent extracellular spaces during inflammatory processes, it becomes a major contributor to tissue damage in cases of lung disease, malignant tumors, and hemolytic disorders.

Hydrogen peroxide in pharmacologic concentrations in the blood can easily cause as much harm as good.¹³

• Viva In Vivo Peroxide?

Can infused hydrogen peroxide increase the level of oxygen in the blood? The hemoglobin of RBCs in arterial blood gives up about 25 percent of its oxygen when it passes through the tissues. Thus, the hemoglobin of venous blood (the blood leaving the tissues) is oxygen-poor. When a solution of hydrogen peroxide is injected into venous blood, the hemoglobin takes up the oxygen released by catalase. Therefore, when this venous blood reaches the lungs its hemoglobin contains more oxygen than it otherwise would have contained and requires less airborne oxygen for saturation.

Since arterial blood leaving the lungs is almost fully saturated with oxygen, it is likewise impossible for the arterial infusion of hydrogen peroxide to increase the amount of oxygen carried to the tissues. Johnson and associates¹⁴ created a theoretical model to predict the effects of such an infusion. Johnson recognized that arterial hemoglobin,

since it was saturated with oxygen, could not take up the oxygen released from hydrogen peroxide. Only the plasma could accommodate the released oxygen. But there's a hitch: Because gaseous oxygen dissolves slowly in plasma, bubbles of oxygen gas would linger in the blood for as long as half an hour. Johnson predicted that, under certain circumstances, these bubbles would cause a gas embolism. He found that, when the arterial blood of rabbits contained 0.01 volumes percent of hydrogen peroxide, bubbles of oxygen gas caused embolisms that resulted in complete shutdown of capillary blood flow.

• O₂, O₂ Everywhere, But...

Can oxygen dissolved in plasma relieve anoxia? With little or no unsaturated hemoglobin, 100 cc of plasma at 100 millimeters of ambient pressure can hold 0.3 of a milliliter of oxygen in simple solution. This means that the total amount of oxygen dissolvable in all the plasma of a 60-kilogram adult is about 20 milliliters.¹⁰ Since there is no physiological mechanism whereby tissues can extract oxygen dissolved in plasma, and since tissues require 200 to 250 milliliters of oxygen per minute,¹¹ 20 milliliters of oxygen dissolved in plasma is a triviality.

• Possible Adverse Reactions

Is ingestion or infusion of hydrogen peroxide safe? At the end of his paper on how to infuse a solution of hydrogen peroxide, Farr stated that, since the ability of the lungs to filter out microbubbles is limited, a continuous infusion of hydrogen peroxide that results in a volume of 0.01 per 100 milliliters of blood can cause an arterial gas embolism and irreversible lung damage.⁹ That such adverse reactions have occurred is clear from reports in the conventional medical literature. These incidents include: emphysema following use of a hydrogen peroxide solution as a mouthwash or gargle; gas embolism and emphysema following deep wound irrigation; gas embolism in the portal circulation; hemolytic crisis following ingestion of a hydrogen peroxide solution; necrosis and gangrene following enemas or colonic lavage with a hydrogen peroxide solution; respiratory arrest; seizures; shock; stroke and multiple cerebral infarcts; ulcerative colitis; and venous embolism following irrigation of an anal fistula and irrigation of surgical wounds.

Reports of adverse clinical incidents are absent from the literature disseminated by proponents of oxygenation therapy.

Conclusions

(1) "Glyoxylide," an alleged ingredient of William F. Koch's "antitoxin to cancer," cannot exist. (2) Neither anoxia nor anaerobic metabolism cause cancer. (3) Ingesting, infusing, or injecting hydrogen peroxide solutions cannot oxygenate body tissues, is risky, and lacks proof of therapeutic or preventive utility.

NF contributing editor Saul Green, Ph.D., is a biochemist who conducted cancer research at Memorial Sloan-Kettering Cancer Center for 23 years. He is president of ZOL Consultants, Inc., in New York City, and a board member of the National Council Against Health Fraud.

Healthcare Esoterica

Presenting the 10th installment of descriptions of mystical and/or supernaturalistic
alternativist methods. Wonders never cease.—J.R.

Celtic shamanism: Apparent distillation of an ancient tribal tradition, promoted by Geo Cameron, M.A. It purportedly involves: meditating to cleanse "energy centers"; chanting to receive a "healing song" and enter a "web of light that connects all things"; and awakening spirits, including an arborescent warrior, "Fairy Folk," and the "transformative power of the sacred fire."¹

Chi Healing (Fa Chi): Component of Chi Lei (see below) in which "teachers" (apparently "doctors") allegedly bring "healing energy from the universe" to individuals to facilitate healing.²

Chi Lei: Variation of Qigong* and Qigong therapy* developed by Pang Ming, a physician and "chigong grandmaster," and practiced at the Wahzhan Zhineng Chigong Clinic and Training Center, a "medicineless hospital" in Qinhuangdao, China. This "healing art" has four components: (1) generation of a strong belief (*shan shin*)—e.g., by listening to testimonials—that *chi* ("life energy") can heal all ailments; (2) Chu Chong (see below); (3) Chi Healing, also called Fa Chi (see above); and (4) Lan Gong ("practice"), which includes methods from Zhineng Chigong (see below).²

Chu Chong (Group Healing): Component of Chi Lei (see above) wherein a "teacher" (apparently a "doctor") allegedly: (1) synchronizes the thinking of a group of "students" (patients) to obtain *chi* ("life energy") from the "universe," and (2) brings it into a "healing energy field."²

Daniel's Diet: Alleged medical panacea and "higher way of eating" promoted by microbiologist Robert O. Young, Ph.D., author of *Colloids of Light & Life*, *Profiles of Microscopy*, and *Sick & Tired*. In *One Sickness—One*

Disease—One Treatment (1995), Young holds that mycosis, or fungal infection, or over-acidification of the body (or blood), is the only disease.³ He further holds that an "inverted" way of living and eating, especially excessive consumption of sugars and animal protein, causes such over-acidification. Daniel's Diet excludes all foods except avocados, lemons, limes, tomatoes, vegetables (e.g., buckwheat and soybeans), dark-green vegetable juice, tofu (bean curd), millet, "sprouted" or soaked seeds and nuts, oils, sea salt, herbal teas (e.g., "Essiac Tea" [see NF 11:54-55, 1994]), specific dietary supplements (e.g., Pycnogenol [see NF 11:54, 1994]), and *LiquidLightning Oxygen-O₃* (a "formula" purportedly beneficial for "oxygen deprivation"). The diet is the namesake of a Jewish "prophet" and fortuneteller of the sixth century B.C.E. According to the Book of Daniel, in the Old Testament, Daniel refused to consume meat and wine assigned to him by a Babylonian king, requested vegetables and water, and, after eating only vegetables for ten days, appeared healthier and stronger.⁴ In the aforementioned 1995 book, Young, evidently a theist, states: "In all of Gods' [sic] creations there is order and purpose."

Dreambody Work: Mode of bodywork* [see NF 11:51-52, 1994] developed by American psychotherapist Arnold Mindell, Ph.D., at the Jung Institute in Zurich, Switzerland. It includes dreamwork.* The purported design of Dreambody Work is to heal the source of illness "as it manifests in the unconscious."⁵

Feldenkrais method: Mode of bodywork* [see NF 11:51-52, 1994] originated in Israel by physicist and engineer Moshe Feldenkrais, D.Sc. (1904-1984). It is a form of "movement reeducation" whose alleged results include "increased levels of vital energy"⁵ ("renewed inner

vitality"⁶). The method encompasses: (1) private, one-on-one instruction, called Functional Integration®, and (2) group instruction, called Awareness through Movement®.

Intuitive diagnosis: Alleged diagnosis by "accurate intuition," such as that practiced by Edgar Cayce.* Its apparent main premise is that the conscious ignores "signals" that surround humans, but that such "information" is obtainable if one's mind functions as a "super-receiver."⁷

Kali Yoga: Purported means of opening all of one's chakras and realizing one's "greatest potential."⁸

Multi incarnational recall and emotional body balancing: Form of "energetic healing" developed by author Chris Griscom, founder of the Light Institute of Galisteo, in New Mexico. It purportedly uses techniques from "Windows [or "Window"] to the Sky acupressure" to remove "blockages" and to facilitate recall of "multi incarnations."⁵

Nine Star Ki: System of "directionology"⁹ and futuristic astrology based on "Oriental five element theory,"¹⁰ Supposedly, it is a "profound science" and the most comprehensive astrological system. Members of the macrobiotic* community reportedly use Nine Star Ki to determine the best directions in which to travel and which directions to avoid.

Oriental 7-Day Quick Weight-Off Diet: "Unique" plan originated by the late "mystical philosopher" Norvell, author of *Mind Cosmology*, *Norvell's Dynamic Mental Laws for Successful Living*, and *Universal Secrets of Telecosmic Power*. It includes a "Vitalic Sustaining Diet" and techniques for using the "power of 'negative energizer foods.'"¹¹

Reiki meditation: Meditation system that purportedly involves the "healing power" of reiki.* It allegedly can bring on clairvoyance and release or transmute "negative energy."¹²

**"If everything on earth were rational,
nothing would happen."**

—Feodor Dostoyevsky

SkyDancing Tantra: Westernized form of tantra* developed by Margo Anand,* author of the bestseller *The Art of Sexual Magic*. An "approach to sexual ecstasy," it borrows from bioenergetics,* neuro-linguistic programming,* shamanism,* and transpersonal psychology* [see NF 12:60, 1995]. SkyDancing Tantra supposedly "awakens" vitality and "hidden powers of the brain."^{13, 14}

Soul reading: Variation of psychic healing* practiced by Irishman Niall Gerrard, a former student of "metamorphic techniques"¹⁵ (probably the metamorphic technique*).

Spirit releasement: Form of exorcism that purportedly removes "negative energy" from persons and property. Alleged causes of symptoms supposedly clearable with spirit releasement include curses, ghosts, and Ouija.¹⁶

Structural Alignment: Form of bodywork* whose purported design is to restore "Balance" physically, emotionally, and "energetically."¹⁷ Apparently, Structural Alignment supposedly: makes a "new way of being" available to clients and precipitates a feeling of being supported by gravity ("the earth's energy field").

Whole System Healthscan: "Healing system" that includes cranial work.* Related to contact reflex analysisSM (CRA) [see NF 11:47, 1994], it purportedly enables doctors to assess nutritional needs and "biochemical deficiencies" accurately through analysis of "electrical pathways" and "reflex points."¹⁸

Zhineng Chigong: Form of Qigong* practiced at the Wahzhan Zhineng Chigong Clinic and Training Center, a "medicineless hospital" in Qinhuagdao, China. It includes the "Lift Chi Up and Pour Down Method" and the "Three Centers Merge Standing Method."²

Readers' Forum

Vegephilia, or Anticarnivorism?

Dear Jack:

“The Skinny on Low-Fat Dieting” [NF 12:65–70, 1995] states in error that “all SDAs are vegetarians.” Only half of Seventh-day Adventists are vegetarians. Unlike smoking tobacco or ingesting alcohol or pork, which can get one disfellowshipped (kicked out of the church), vegetarianism is optional. I am a nonvegetarian SDA. Only about one percent of SDAs are vegans.

John Morgan, Ph.D., an epidemiologist with the Adventist Health Study who is a board member of the National Council Against Health Fraud, tells me that the low incidence of colorectal cancer reported (retrospectively) for SDAs has not held up to prospective study. Meta-analysis of research has revealed a null effect when the study was well designed; so it is with the more reliable data on SDAs. This has not been published yet. Morgan reported some difficulty getting it published. I believe there is a lot of wishful thinking

(a form of pathological science) driving the diet-disease literature. I agree wholeheartedly with the three factors in your editor's note [“The beneficialness or harmfulness of ingesting a particular food depends on: (1) the amount consumed, (2) the frequency of consumption, and (3) the eater's health status, genetics, and long-term pattern of food consumption and physical activity.”].

Vegetarianism is wrongly named. Vegetarians are defined not by a love of vegetables, as the term suggests, but by their hatred of meat: They are anticarnivorists. I am a vegetable enthusiast because I believe that vegetables have highly desirable nutritional features, but these can be obtained without excluding meat or other animal foods. Rational, pragmatic vegetarianism and ideological vegetarianism are very different.

BOOK REVIEWS

Title: *The Complete Book of Dental Remedies: A Guide to Nutritional and Conventional Dental Care* (1996)

Author: Flora Parsa Stay

Publisher: Avery Publishing Group, Garden City Park, New York

Price: \$15.95 softcover

Reviewed by: John E. Dodes

The publisher of this paperback calls it a “reliable source of information that can help you learn your options and give you plenty of reasons to smile.” I’m not smiling. The author, Flora Parsa Stay, does not help consumers distinguish methods of proven safety and efficacy from discredited or experimental ones. Stay is a dentist who

received her D.D.S. degree some twenty years ago from the University of California at San Francisco and has attended a nonaccredited acupuncture college.

Cleaning Blood at Herbal Teatime

The book has three main sections. Part One, “Exploring the Essentials,” describes: the structures of the mouth; basics of dental hygiene and ingredients of mouthwashes and toothpastes; diet and nutrition; homeopathy; herbal therapy; and how to choose a dentist. Much of the basic information is accurate, but Stay’s descriptions of nonconventional dental “therapies” do not suggest any doubt that untested and scientifically

discredited methods work. In her discussion of mouth structures, she states: "According to Chinese medical science, the tongue is divided into certain sections, with each part pertaining to an organ....Color, texture, size, and shape of the tongue are taken into consideration as a diagnostic tool to help determine the organ to be treated." However, she doesn't say whether this "science" and "approach to the diagnosis and treatment of disease" is useful to patients.

Describing homeopathy, Stay states: "Each agent is prepared by successive dilutions of the ingredients...alternating with...vigorous shaking...which is continued until the resulting medicine contains no molecules of the original substance." Yet she doesn't explain how a "medicine" or "therapeutic agent" without an active ingredient could work; and, with just a few weak caveats, she recommends homeopathic self-"treatment." [See NF 11:58-59, 1994.]

Describing "herbal therapy," she uses imprecise expressions such as "cleanse the blood" and "warm and stimulate the body." Again, her warnings are few and mild. Stay fails to note that most herbal "remedies" are untested, unregulated, and nonstandardized. Further, she recommends drinking a tea made from lobelia and other herbs to relieve jaw pain. In *The Honest Herbal* (1993), the eminent pharmacognosist Dr. Varro Tyler states that crude lobelia "has been thoroughly discredited, and any use of it...is definitely not recommended."

The "Price" is Wrong

Stay implicitly approves the discredited notions of Weston Price, the dentist who wrote *Nutrition and Physical Degeneration* (first published in 1939). Price wrongly concluded that tooth decay was a tragic consequence of our "modern degeneration," which he called "race decay." He blamed soil depletion, pasteurized milk, sugar, and white flour. The sections on vitamins and minerals are fairly accurate. Stay tacitly endorses the Recommended Dietary Allowances (RDAs), and she even mentions adverse effects of excessive intakes. However, she sometimes misrepresents the RDAs as average

suggested intakes, daily minimal requirements, daily requirements, doses, and recommended daily doses. For example, she states that the "daily requirement" for folate for adults is 400 micrograms, which is the RDA for pregnant females, not all adults.

Part Two, "Common Dental Disorders," features an alphabetical list of dental problems. Stay's "conventional," herbal, homeopathic, and dietary-supplement recommendations follow each problem's definition. This gives the dangerous impression that the herbal, homeopathic, and nutritional treatments are as effective and safe as scientifically tried and true treatments. For example,

Stay's discussion of "mercury toxicity" is loaded with innuendo and approval of discredited practices such as hair analysis and "mercury toxicity" testing with vapor-detecting machines. She cites one such device, the Jerome analyzer, which is designed for industrial use but misused by many anti-amalgam dentists. It measures the amount of mercury in a small sample of air and then multiplies that number by a factor of 8,000 to give the amount in a cubic meter of air. This volume is much larger than that of the human mouth and leads to inaccurate and, often, frightening readings. That Dr. Stay does not exhibit a firm position on the proven safety of silver amalgam fillings suggests a lack of scientific understanding.

Part Three, "Dental Techniques," deals with widely accepted methods, such as bonding, root canal therapy, orthodontics, and periodontal therapy, and—promotionally—with acupuncture, chelation therapy, and herbal treatments. Again, much of the basic dental information is accurate and useful, but there is also too much that is false and misleading,

This could have been a valuable book if the author had been much more discriminating. Carl Sagan has said that one should not keep one's mind so open that one's brain falls out. I fear that Dr. Stay checked her brain at Avery Publishing Group before she wrote this book.

John E. Dodes, D.D.S., is president of the New York Chapter of the National Council Against Health Fraud and coauthor of an upcoming book (tentatively titled *Toothache*) from St. Martin's Press.

"Tales from the 'O' Zone"

A Professional Natural Hygienist's Review of
Chiropractic:
The Victim's Perspective

Title: *Chiropractic: The Victim's Perspective* (1995)

Author: George Magner (edited by Stephen Barrett)

Publisher: Prometheus Books, Amherst, New York

Price: \$24.95 hardcover

Reviewed by: Donald E. Paulin

In 1991, George Magner founded Victims of Chiropractic, which provides information and support to chiropractic casualties. His book is a terrific gift of the heart for all who want to separate reliable, scientific health information from health hype, propaganda, and politics. Magner tells us exactly why chiropractic's infamous subluxation theory is a fraud. We learn that its "preventive maintenance" pitch is just so much offensive twaddle. Ultimately we conclude that magical, wishful, delusional thinking in many chiropractors and their patients is the engine of chiropractic's very existence. In my observation, chiropractors think they're all things to all people. Their profession smacks of messianism.

**An Act Perhaps
...but Not a Class Act**

My own research into chiropractic began in 1986 after some disturbing experiences with two Orange County, California, chiropractors. Both were self-proclaimed fervent Christians. Myself a Christian, and then unemployed, I responded to the following classified ad in the *Orange County Register*.

Sales

Motivated and experienced salesperson needed for dynamic, growing Health Care Facility. To educate the public on health care, emphasize prevention and wellness. Must be enthusiastic, positive, prof'l and REALLY care about people. Potential for BIG BUCKS. Call....

Of course, the uppercase "big bucks" didn't suggest to me a "class" organization, but I sent a résumé out of curiosity. I had been both a teacher and a salesman and felt I had a good general knowledge of

health. The position turned out to be that of pitchman for a chiropractor. The hiring was to set up a table in shopping malls and at health fairs and offer "health passes" (allegedly a hundred-dollar value!) to those who signed up for a free exam. The doc said I would make \$1,000 to \$1,300 a week, working only on weekends! He asked me to undergo the exam, apparently so that I would learn about what I'd be pitching. I agreed.

Fishy Chiropractors

A series of six interview/pre-employment propaganda sessions followed. It was a mind-boggling, almost mesmeric hustle. I stuck it out but suspected strongly that the chiropractor wanted me to become his patient, not his employee. Finally I called him a fraud to his face.

Through a large ad in the Yellow Pages, I contacted another "pious" chiropractor. I went to his office and requested advice on how to report the classified advertiser to the proper authorities. All this guy had to do was give me the address of the State Board of Chiropractic Examiners, but he hesitated and said he'd think about it and get back to me. Although his ad in the Yellow Pages featured a large Christian fish symbol, I was taken aback when he said he wanted to lead me in prayer! After we prayed, he told me he was a multilevel-marketing distributor and invited me to an "opportunity" meeting. He said he was forsaking chiropractic

because of experiences like the one I'd had with the classified advertiser. Yet he stated that the next time I had a cold, I could come by and he'd treat me without charge! Nine days later, I phoned him to ask again to whom should I complain about his "predecessor." He (the distributor) hadn't called me. And he has never answered my question. I told him (in a very "un-Christianlike" manner) that he was full of a certain waste product. He hung up.

High incomes and the title "doctor" lend too much credibility to both the medical and nonmedical pronouncements of physicians—the professionals to whom many chiropractors misrepresent themselves as

equivalent or superior. Chiropractors have lower incomes, but because all chiropractors are "doctors," and because most practicing chiropractors conduct themselves as providers of primary care, chiropractors in general have way too much popular credibility. Their pronouncements, as Magner makes clear, are

too often pseudomedical, too often ridiculous, and too often dangerous.

Mr. Paulin, an English teacher, lives in Huntington Beach, California, and hopes to start a Victims of Chiropractic group in Orange County this year.

Nutrition

Oxygenation Therapy: *Healing or Hot Air?*

Part II: Tales from the "O" Zone

Saul Green

One of the lesser come-ons on the cover of the January 1996 issue of *Penthouse*—"Ozone Therapy: Why Is Its Vast Healing Potential Being Kept Secret?"—approaches the height of presupposition. Nutritionist and "medical reporter" Gary Null, Ph.D., wrote the corresponding article, titled "Ozone: A Wide-Spectrum Healer." He states therein:

[W]hile ozone can be used to treat a wide spectrum of conditions [including AIDS, allergies, arthritis, cancer, candida infection, bladder infections, gastrointestinal disorders, hepatitis, herpes, multiple sclerosis, parasitic conditions, respiratory conditions, other sexually transmitted diseases, and "wound problems"], it can also be used prophylactically to combat harmful viruses, bacteria, and free radicals before degeneration and disease occur. Additionally, healthy people can use ozone to rejuvenate cells to stay younger longer.

Have conventional health professionals been ignoring—or, worse, suppressing—a miracle cure right under (or above) their noses?

Whither the Ozone?

Discovered in 1839, triatomic oxygen (O_3), better known as ozone, is formed when oxygen atoms from a diatomic oxygen molecule (O_2) split by an electric spark or ultraviolet light combine with O_2 . Because of the highly reactive free radicals it generates on decomposition, ozone is among the most powerful natural oxidants. These free radicals can destroy very many natural substances. The discovery of inert plastics enabled medical applications of ozone, and in the late 1930s German doctors began to use it in experiments on patients who had a variety of infections and wounds. Experimenters bubbled ozone gas directly into the bloodstream; withdrew, ozonated, and then replaced blood; applied ozone in enemas and douches; and pumped ozone into the rectum.

Except in cases of topical treatment, evaluation of the effects of ozone administration rested entirely on statements from patients.

When ozone reacts with the water in red blood cells, hydrogen peroxide is generated. This aqueous decomposition of ozone also produces germ-killing free radicals. Researchers who studied this germicidal activity in vitro found that killing microorganisms on open surfaces and in water requires a 2-hour exposure to 1200 ppm (parts per million) ozone.¹ Medical (pure, concentrated) ozone must be prepared on-site because, at room temperature, it has a "half-life" of only 45 minutes under optimal conditions.

Ozone and HIV

Human immunodeficiency virus (HIV, formerly called HTLV-III) is the retrovirus that causes AIDS. Retroviruses are viruses that contain RNA and produce an enzyme wherewith viral DNA originates from the RNA. Many produce tumors. There are two strains of HIV: HIV-1 and HIV-2, which is rare in the United States. M.T.F. Carpendale, M.D., has stated that medical ozone can inactivate extracellular HIV-1 in certain tissue-culture fluids and can inhibit the virus without detriment to tissue-culture cells. He has cited published allegations that ozone benefits AIDS patients but has added: "Further experimentation and development of methods for use of ozone as a treatment of ARC/AIDS patients are still needed."

Another proponent of ozone therapy against AIDS is writer Ed McCabe,² In testimony before Senator Tom Harkin's Subcommittee of the U.S. Senate Appropriations Committee in 1993,³ he stated that 644 German ozone therapists had "successfully" treated 384,775 patients with 5,579,238 doses of ozone "with no ill effects," and that thousands of published medical papers contained proof of ozone's effectiveness in vivo. McCabe further asserted: "Numerous U.S. physicians have converted hundreds of AIDS patients from HIV seropositive to HIV seronegative status using ozone." And he's

said that the "medical establishment" is ignoring this "help...available to AIDS patients right now."

Is ozone an effective anti-HIV medicine? In 1991, Wells and associates¹ reported that gaseous ozone inactivated HIV-1 in a culture medium from which all cells had been removed. Using increasing concentrations, they showed that a 1200-ppm dose delivered into the solution for two hours reduced the number of infectious viruses by about 10¹¹ and detectable virions (complete virus particles) by about 85 percent. However, the authors also reported a significant reduction in infectivity after exposure of the virus to a flow of nitrogen alone. The protein and plasma in the culture medium also affected the rate and degree of inactivation of HIV-1 by ozone. The researchers concluded that, while ozone had utility in decontaminating commercial blood products, far more extensive analysis of HIV-1's life cycle was necessary to define ozone's usefulness as an *in vivo* anti-retroviral agent. One of the researchers, Poiesz, wrote in August 1995: "No further *in vitro* work has been done and to my knowledge no *in vivo* work has been done."⁴

When Carpendale and Freeberg⁵ studied the effect of ozone at 4 ppm on HIV-1 suspensions *in vitro*, they found that the serous components of the culture medium degraded the ozone rapidly. They theorized that "unknown" ozone reaction products caused the (alleged) inactivation of viruses. The cellular effects of some ozonides (reaction products of ozone and fatty acids) mimic those of ozone. But Carpendale has never reported on the effects of ozonides on HIV in suspension.

Autohemotherapy

Autohemotherapy involves drawing blood from a patient, ozonating it, and returning it to the patient. Ozone has been used to treat infections for nearly fifty years. Mostly, treatments were based on impressions from clinical anecdotes conveyed by German periodicals: newspapers, popular magazines, and proponent newsletters.

When AIDS became pandemic in the 1980s, the number of patients aware of autohemotherapy rocketed. Organizations sprang up and promoted the medical use of ozone at international meetings. Most papers presented at these meetings referred to the *in vitro* germicidal activity of ozone at high concentrations. No convincing evidence was presented that autohemotherapy (with ozone concentrations ranging from 0.1 to 5.0 ppm) had an anti-HIV effect in AIDS patients.

In 1991, Garber and associates⁶ carried out the first well-controlled clinical study of autohemotherapy for AIDS. They first tested for safety and found no toxicity after 12 weeks of treatment. In the trial that followed, AIDS patients were entered into a randomized, placebo-controlled, double-blind program designed to enable comparison and evaluation of the effects of unprocessed and ozonated blood infused over eight weeks. All the subjects had CD4 (T4) cell counts of 200 to 400 per microliter of blood. (A microliter of blood normally contains 1,000 to 1,300 CD4 cells,

the primary "targets" of HIV. Also called helper cells, CD4 cells are a type of T [thymus-derived] lymphocyte.)

This trial showed that the infusion of patients' ozonated blood had no significant hematologic, biochemical, or clinical toxicologic effects in comparison with the controls. Furthermore, the investigators found that autohemotherapy had not altered CD4 cell counts or the levels of beta-2 macroglobulin, gamma interferon, interleukin-2, neopterin, and the HIV antigen p-24 (the "p" stands for "protein"). They concluded that autohemotherapy does not enhance immune response or reduce the p-24 antigen (an HIV marker) in HIV-infected patients. Independent investigators⁷ have replicated these results.

In May 1995, the twelfth World Congress of the International Ozone Association convened in Lille, France. Of the 42 papers presented, none was presented by an American and none addressed the treatment of AIDS with autohemotherapy. In a letter to me dated August 30, 1995, one of the organizers of the meeting, Prof. V. Bocci, wrote:

My position is based on theoretical grounds that ozone autohemotherapy may be useful only because there is no valid alternative. From a practical point of view I have great difficulty organizing clinical trials. I have frequently expressed my deep concern over the irresponsible, uncontrolled and unscrupulous information that is being spread around. You must understand that I am not responsible for what is being done or said by people in the U.S. Personally, my interest is in investigating whether properly performed autohemotherapy can be useful for the treatment of chronic viral diseases and other pathologies. As of this time there is no evidence of its validity.

Do CD4 cell counts have prognostic significance in determining whether autohemotherapy is effective? Upon HIV-1 infection, CD4 cells migrate to and infect lymphoid organs. This infection depletes CD4 cells, decreases their functionality, and, eventually, causes dysfunction of the immune system. The consequence is a high risk of opportunistic infections. The utility of CD4 cell counts for evaluating medicines administered to HIV-positive persons is questionable, because of the lack of standardization in: the frequency of the count, the timing thereof, and the intervals between counts. Moreover, the relationship between the numbers of CD4 cells in peripheral blood and their immune activity appears weak. This raises the possibility that immune system dysfunction precedes detection of changes in levels of CD4 cells.

Nutrition Forum (ISSN 0748-8165) is published bimonthly for \$35.00 (individuals in U.S. and Canada) or \$50 (institutional, overseas) per year by Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197. Second-class postage paid at Buffalo, NY. POSTMASTER: Send address changes to Prometheus Books at address above. Manuscripts and all editorial correspondence should be directed to: Jack Raso, 71-11 60th Avenue, Maspeth, NY 11378-2908.

In a 1991 review of clinical histories of AIDS patients treated with ozone, H.S. Füessl, a leading German AIDS specialist, stated:⁸

After observing ozone-treated AIDS patients for long periods of time, we noted that patients who had just started on the ozone therapy showed some increases in CD4 cell counts. But a few weeks later their CD4 cell counts not only returned to their original low levels but in many cases went lower as the clinical picture clearly worsened. Two patients died before our eyes from opportunistic infections soon after beginning the ozone therapy. Those of us who treat HIV-infected patients on a daily basis recognize that monitoring the changes of the CD4 cell counts over a short period of time does not accurately reflect the effect of the treatment or the prognosis of the patient. After following a number of AIDS patients that were receiving ozone therapy, I recognized that increases in the CD4 cell counts could occur in any patient, at any time. But it did not mean that human immunodeficiency viruses were being killed or that the infection was being arrested. In spite of this knowledge, CD4 cell counts are still the primary diagnostic and prognostic tools used by ozone therapists. [my translation from the German]

Autohemotherapy proponents continually refer to the widespread use of this treatment in Germany, implying that it is sanctioned by the German medical establishment. Dr. Barbara Burkhard of the Medical Office of Patients' Insurance-Bavaria (Munich, Germany) wrote:⁹

Ozone therapy is not approved by the medical establishment in our country. The National Health Insurance (Gesetzliche Krankenversicherung) is not allowed to pay for it. In the book of laws on this subject (Sozial Gesetzbuch V), the obligations for insurance institutions are fixed. They are only required to pay for methods which are in accordance with generally accepted medical knowledge and which have made proven contributions in medicine. Doctors who have contracts with health insurance companies only get reimbursement for treatments that are approved by the "Bundesausschuss der Arzt und Krankenkassen." This committee is governed by social insurance regulations and issues the rules for

diagnostic and therapeutic medical methods. In an Appendix to their book of rules, methods not approved are listed. Ozone therapy is number 3 on that list.

Where's the Beef?

A mid-August 1995 search of the Medline, Health, AIDSline and Cancerlit databases back to 1966 generated references to more than a hundred papers citing adverse effects of ozone or ozone reaction products on humans or experimental animals. The search did not generate any references to papers in peer-reviewed medical journals that reported beneficial effects of ozone as a treatment for viral infections.

The claim that autohemotherapy can cure AIDS is being disseminated by people with more skill in advertising than in science or medicine. For example, Ed McCabe (see above), in testimony before Senator Harkin's Subcommittee in 1993, did not: (a) define "successfully treated"; (b) identify any of the "thousands of medical papers" he said provided evidence of autohemotherapy's effectiveness; (c) name the U.S. physicians he said had accomplished seroconversion in hundreds of AIDS patients; (d) state how, when or where he had interviewed the 644 German ozone therapists who had "successfully treated" the 384,775 patients with 5,579,238 ozone treatments; or (e) say when and from whom he had obtained the patients' medical records, or what evidence he'd seen in those charts that autohemotherapy was clinically effective and safe.

The Bottom Line

Not letting facts interfere with marketing, promoters of oxygenation therapy follow the line that putting oxygen-generating substances into the body will cure disease. But alternativist claims for oxygenation therapy are on shaky or nonexistent ground. Scientific evidence that autohemotherapy benefits HIV-infected persons does not exist.

BOOK REVIEW

Title: *Chiropractic: The Victim's Perspective* (1995)

Author: George Magner (edited by Stephen Barrett)

Publisher: Prometheus Books, Amherst, New York

Price: \$24.95 hardcover

Reviewed by: Ralph C. Cinque

This is an important and timely book that especially should be read by anyone who is either receiving or contemplating receiving chiropractic treatment. Magner is a retired agricultural researcher who, in the late '80s, visited an "upper cervical" chiropractor because of lower-back pain. After his sixth cervical "adjustment," he experienced new pains in his neck and right shoulder and ringing in his ears (tinnitus). Over the next five months, Magner received treatment from three other chiropractors, his tinnitus worsened, and he developed numbness and tingling in his left foot. Apparently, he still had these problems when this book was completed in 1995. Magner is also the founder of Victims of Chiropractic, a support and information network concerned with chiropractic's hazards.

Things that Go Bump in the Night?

After relating the nightmare of his own experience as a chiropractic patient, Magner summarizes the stories of 20 other chiropractic victims. For most of them, the consequences of chiropractic treatment—including stroke, paralysis, coma, and death—were graver than Magner's problems. Reading that section reminded me of something more frightening: a study published by the Australian Chiropractic Association in the late 1980s. It detailed over 100 cases of stroke, paralysis, coma, and other serious problems that had resulted from chiropractic "adjustments."

Magner provides a rather lively history of the founding of chiropractic at the turn of the century by D.D. Palmer, an itinerant "magnetic healer" in Iowa. Chiropractic has been mired in conflict and melodrama

from its very beginnings. As every first-semester chiropractic student knows, the first chiropractic patient was Harvey Lillard. Supposedly, Lillard was "deaf" but recovered his ability to "hear as before" by receiving the premier chiropractic adjustment from D.D. Palmer. Although it often takes weeks and months for chiropractors to resolve common back complaints in their patients, "The Founder" allegedly cured deafness in one treatment—by adjusting the fourth thoracic segment. This segment has absolutely nothing to do with hearing, but learned-sounding chiropractors have expounded how sympathetic nerve reflexes could have traveled up the cervical chain ganglia affecting the circulation to the ear and thereby restored hearing. I call this *chirobabble*. In the last hundred years, many thousands of chiropractic patients must have had some degree of hearing impairment. The number of incontrovertible cures should have famed chiropractic as a treatment for auditory problems. Another question leaps from the Lillard case: How could a single "adjustment" have quickly and safely corrected a joint displacement that had persisted for 17 years? Magner quotes Samuel Homola, D.C.:

A displacement in the spine severe enough to cause a "bump" on the back [as described by Palmer] would, of necessity, have to be a rather severe dislocation and, consequently, a quite crippling injury. In addition, adhesions usually form around displaced joints after a matter of weeks, and, over a period of time, muscles, ligaments, and other tissues shorten to accommodate changes in the joints. Yet, Palmer was supposed to have made the correction in one treatment!

I cite this because it reminds me of how often chiropractors have told me that what they really do is "break adhesions." Adhesions are made of tough, fibrous connective tissue, and I dread to think of how much force would be necessary to "break" them.

“Subluxated” Thinking

Chapter 3 deals with the elusive chiropractic “subluxation.” Magner quotes many definitions of “subluxation” from various chiropractic sources. The more definitions one reads, the funnier they sound. Here’s my favorite, which I believe the American Chiropractic Association (ACA) issued in the 1980s:

Subluxation is an aberrant relationship between two adjacent articular [joint] structures that may have functional or pathological sequelae [consequences], causing an alteration in the bio-mechanical and/or neurophysiological reflections of those articular structures, their proximal structures, and/or other body systems that may be directly or indirectly affected by them.

I don’t know if it’s possible to cram more gobbledegook into one sentence.

Magner cites Yale anatomist Edmund S. Crelin’s study of spinal movement in the 1970s, which showed that nerve impingement does not occur in the spine without major dislocation or fracture. I was then a student at Western States Chiropractic College, and I remember the furor that Crelin’s study caused within the chiropractic community. The ACA president said that the study was meaningless because it was done on cadavers. Magner quotes Crelin’s response:

In a living person there is a reflex response by the powerful spinal muscles to fight or resist any forces that would subluxe a vertebra to the degree that it and/or spinal nerves could be damaged....Thus, if the impingement on the nerves could not happen in a dead body, it definitely could not happen in a living one.

This response, which makes perfect sense, did not reach me at chiropractic college.

Love Is Blind?

Reading Chapter 5, “Questionable Marketing Tactics,” reminded me of an experience I had several years ago during a continuing-education seminar for license renewal. Ostensibly, the subject was “Chiropractic Pediatrics,” but the seminar actually dealt with how to steer parents into subjecting their children to “adjustments.” The instructor presented a “patient education” video he had made, in which he initiates his young son into chiropractic. He shows the boy a chart of the nervous system, lays him on a table, and gently performs several perfunctory-looking spinal “adjustments.” Then he stands the boy on the table and asks him: “Do you know why I gave you those chiropractic adjustments, Son?”

“Why, Dad?” the boy inquires.

“Because I love you.”

“I love you, too, Dad.”

Then the chiropractor picks his son up, hugs him, and, eyes closed, starts dancing around the room with him. In the soundtrack, Michael Jackson sings about saving children.

At this point, I was queasy, but the roomful of chiropractors burst into applause. Then the instructor stepped up to the mike and said: “Are parents going to eat this up, or what?” Copies of his video were for sale at the end of the program and, believe me, sales were brisk.

Chapter 6 deals with chiropractic “preventive maintenance”—treating well, nonsymptomatic persons on a regular basis. I receive two chiropractic newspapers (only because they are sent to me free), and I can tell you that “maintenance care” is very big. Chiropractic is less about solving particular spinal problems with manipulation than about conditioning people to the “adjustment” experience and routinizing them to interconnect “adjustments” and how they feel. In my observation, people who submit to frequent spinal “adjustments” eventually start waking up every morning with the thought, “Is my neck in or out?”

Once when I was a practicing chiropractor, a young man visited me who said he’d gone to 28 chiropractors in the previous month, searching for the perfect adjustment. I asked him: “Did any of the chiropractors, upon finding out how many others you had seen previously in such a short time, suggest that what you really needed was not another adjustment, but rather, psychological help to deal with your obsession?” He answered no. Every single one of them had stepped up to the plate and taken another crack at this kid’s neck. I assure you he did not receive an “adjustment” from me.

A Fool’s Paradise

The chapter titled “Dubious Diagnostic and Therapeutic Techniques” only scratches the surface of chiropractic’s methodological madness. There are so many different chiropractic techniques—many more than Magner lists—all allegedly comprehensive—that I honestly don’t know how chiropractors decide which ones to learn and use. I have often thought that the best way to reveal chiropractic for what it is would be to send someone undercover to at least a dozen chiropractors and record all of their responses. This has been done several times, and Magner relates three undercover investigations in which the patients were children. The chiropractic “diagnoses” were akin to what one would expect from “psychic” advisors. Magner quotes Prof. Craig Nelson, D.C. of Northwestern College of Chiropractic:

[C]hiropractic supports dozens of different techniques....The various chiropractic techniques....[have] different theoretical bases.... [M]any...are truly distinct and incompatible with each other....There is no comparable circumstance in any other health care profession.

Magner should have added that in no other healthcare profession do we find so much personality cultism. Barge, Dejarnette, Epstein, Fefferi, Fuhr, Gonstead, Goodheart, Merick, Morter, Nimmo, Pettibone, Pierce, Stillwagon, Thompson, Toftness, Van Rump—these names, and many others, are familiar to every chiropractor in America. They are the names of chiropractic gurus with devoted followings. The word “chiropractic” has become nothing more than a convenient slogan used by competing factions of a manual-therapy subculture with different and conflicting theoretical bases.

This brings me to a very important point about chiropractic research. Magner does a good job picking apart the Meade study, the RAND study, and the Manga report, all of which, according to most chiropractors, proved the effectiveness and superiority of chiropractic treatment. However, Magner did not make the following point clearly enough. Considering what a theoretic mess chiropractic is, and how much chiropractors contradict each other in what they say and do, what good is there in trying to measure chiropractic effects? Here’s an analogy: Imagine a study in which physicians prescribe whatever medicines they deem appropriate without identifying their prescriptions. Because of the plethora of medicines available and the lack of medicine identification, all this study could possibly demonstrate is the subjective effect of the belief that one is taking medicine—the placebo effect. Unless one precisely identifies and limits the object of evaluation, a study has no meaning. But this is exactly the case with chiropractic research. In most instances, no attempt is made to define or limit the “adjustive” and ancillary techniques to be evaluated. No one looks into what the chiropractors actually did, so long as they did something that was called chiropractic. The results, therefore, are absolutely meaningless, yet chiropractors shout and jump for joy at their “vindication.” It’s a fool’s paradise.

The chapter titled “Nutrition-Related Nonsense” brought to mind another experience I had at chiropractic college. An instructor who loved “muscle testing” à la applied kinesiology [see NF 11:47, 1994] claimed not only that he could determine thereby whether a person needed a particular vitamin, but also that he could find out exactly how much the person needed and which brand would be best. A friend of mine and I played a trick on him one day. We emptied a vitamin capsule and filled it with plain sucrose. We produced it during class and told the professor it was vitamin C. Through “muscle testing,” he seemingly determined that a particular student was deficient in table sugar. The “muscle tester” wasn’t happy when he learned of the prank but of course had an explanation. Chiropractors always do. **Editor’s note:** With tongue in cheek, I’ll offer a “spirited” alternativist explanation: The capsule contained an infinitesimal quantity of vitamin C or just the “energy” of vitamin C. This increased muscle strength, indicating need of a homeopathic “dose” of vitamin C to treat hypervitaminosis C.—J.R.]

Just What Chiropractors Need—Another Fixation?

I think the book’s only major shortcoming is that it does not adequately address the shift underway within chiropractic toward motion palpation and the fixation concept. Many chiropractors, realizing the bankruptcy of the “bone-out-of-place,” “kink-in-the-nerve” dogma, have abandoned the classical subluxation theory in favor of the “motion paradigm.” According to this up-and-coming chiropractic theory, the bone is not “out of place” but, rather, stuck in place, unable to move throughout its normal range of motion and thus in need of mobilization. Although some chiropractors are fighting it kicking and screaming, this theory is being hailed as the profession’s ticket into the realm of science. Also, the belief that this is the right direction for chiropractic to take seems to be a growing within medicine.

I, however, think that this transition is fraught with danger—to patients. It’s a piece of cake for chiropractors to come up with misalignments, but conjuring fixations is a snap. Usually, fixations are relative. If I palpate a segment and turn the patient to the right and to the left, one side may move significantly less than the other, and I can pronounce the less mobile side “fixated.” But the body is not structurally symmetrical, and there is no reason to expect it to be functionally symmetrical. Another way to find “fixations” is to “motion palpate” several successive vertebral segments. One could declare that the segment with the shortest range of motion is fixated. But one of them had to have the least mobility.

Finding chiropractic “fixations” is even more arbitrary than finding chiropractic “subluxations.” Typically, it hinges on the intuitions, the feelings, of the chiropractor, and it might surprise you to know just how different those feelings can be. Magner did point out that “most studies have demonstrated marginal-to-poor interexaminer reliability” for motion palpation, but I would like to give a specific example. Several years ago, the *Journal of Manipulative and Physiological Therapeutics (JMPT)*, a chiropractic publication out of National College, reported on a study of the reliability of cervical motion palpation. The report stated: “The palpatory task consisted of determining whether end-range joint resistance on lateral flexion was greater on one side of a given cervical segment when compared to that of the contralateral joint.” In other words, the test involved just one segment and the principal question was unambiguous: Did it bend better to the right or to the left? The main finding of the study was that “interexaminer agreement rates with respect to the side of greatest fixation were not found to be significantly different from that expected by chance alone.” In other words, fixation-finding is a crap shoot. The chiropractors could not agree on whether one segment moved better to the right or to the left. In light of this, what chance is there of concordance if the field of observation is expanded to include the whole spine or the entire body? Other studies

reported in *JMPT* and the *American Journal of Chiropractic Medicine* have demonstrated the interexaminer unreliability of motion palpation. Yet, "life is motion" is chiropractic's new battle cry.

There is another problem with the fixation concept: It is difficult to drum up dire consequences from it. After all, how harmful can a fixation be? As far as I know, no one has ever died from one. Restricted motion may be the only significant consequence of a joint fixation. What is the real correlation between joint fixations and symptoms? In other words, do people with joint fixations tend to have more symptoms (such as pain) than those whose joints are more mobile? To my knowledge, no one has ever tried to answer that question scientifically. Until such a study is done, it is only an assumption that joint fixations are the cause of anyone's pain. Inadequacy of joint mobility can be troublesome, but whether high-velocity thrusting is the best way to rectify it is highly questionable.

Rotten Apple

The last chapter of the book deals with how to reform chiropractic. Wagner advocates the establishment of chiropractic training programs within universities that

teach medicine and dentistry. He proposes a new kind of degree, "Doctor of Chiropractic Medicine," to represent the science-oriented chiropractors. He states: (a) that standards should be established for the upgrading of D.C. degrees to D.C.M. degrees; (b) that D.C.M.s "should be permitted to utilize prescription drugs appropriate to the scope of their practices"; and (c) that the plan of Western States Chiropractic College (my alma mater) to start a D.C.M. program "appears to be a step in the right direction." I think that Wagner is being a Pollyanna here. I don't think there is any way to divorce chiropractic from its historical and philosophical roots. You can't remove subluxation theory and inanities such as "Innate Intelligence" from chiropractic and still call it chiropractic. Spinal manipulation has limited therapeutic utility in healthcare and can be taught and administered in nonchiropractic settings.

The chiropractic apple is rotten to the core with dogmatism and cultism. I say chuck it.

Dr. Cinque, a nonpracticing chiropractor, directs Dr. Cinque's Health Retreat ("A Residential Facility for Fasting and Hygienic [Natural Hygiene] Care"), in Buda, Texas. He is the author of *Quit For Good: How to Break a Bad Habit* (Monarch Books of Canada, 1994) and a founding member and past president of the International Association of Hygienic Physicians.

Healthcare Esoterica

Preesenting... the 11th installment of descriptions of mystical and/or supernaturalistic alternativist methods.—*J.R.*

Biodynamic psychology (Biodynamic therapy): "Therapeutic approach" developed by Gerda Boyesen, a clinical psychologist and physiotherapist of Norwegian birth.¹ It is related to bioenergetics.^{*} One of its premises is that, when bodily fluids do not circulate efficiently or tissues are not "properly cleansed," "emotional tensions or blockages" show up and prevent "bioenergy" from vitalizing the body.

Bowen technique (Bowen therapeutic technique, Bowen therapy): Form of bodywork^{*} and vibrational healing² [see NF 12: 31, 1995] originated by Australian engineer Tom Bowen (deceased) in the early 1950s,^{3, 4, 5} developed by Oswald Rentsch (an osteopath²) and Elaine Rentsch (who holds a diploma in Bach flower therapy² [see NF 12:26, 1995]) in Australia, and introduced in the United States in 1990.² Its theory affirms the concepts of *chi* ("universal life energy")⁷ and human "energy vortexes."²

Dō-In (Dao In, Tao-in, Taoist yoga, Taoist hatha yoga): Ancient system of stretching, bodily postures, and movements, comparable to hatha yoga.⁸ Michio Kushi⁸ introduced Do-In in the United States in 1968.⁹ Its theory posits "Chi energy flow"⁸ and the "energy meridians" of acupuncture⁸ and shiatsu.⁹ Although Do-In is a discipline of "self-healing,"⁸ its "ultimate goal" is "spiritual harmony with the universe."⁹

Gnosis: "The enduring philosophy of the universe....as old as the world itself," according to the Gnostic Association of Anthropology and Scientific Studies (AGEACAC), a bilingual (Spanish/English) organization whose National Center is in Elmhurst, New York.¹⁰ AGEACAC holds that humans cannot develop their faculties if they lose "sexual energy" in any way (e.g., masturbation), that religious principles are eternal and universal truths, that there are no false religions, and that "Cosmic Religion" vibrates in every atom. Gnosis supposedly permits the "harmonious" development of "infinite human possibilities."

Inner Peace Facilitation (inner peace counseling): Philosophy of spiritual counseling marked by the goal of increasing clients' awareness of "inner spaciousness."¹¹ An "inner peace facilitator" is anyone committed to discovering and "melting" obstacles to "the natural radiance and transforming power of the spirit dwelling within."

Nwoti (Cherokee herbal medicine): Native American form of botanical "healing" that purportedly treats all human components: emotional, physical, societal, and spiritual.¹²

Oriental medicine: In general, the use of acupuncture,⁸ "Chinese herbal combinations," diet, and "emotional changes" with the purported aim of eliminating problems with meridians ("invisible energy pathways").¹³

Psychography: Purportedly, a unique, nonhypnotic, "altered-state" technique, a form of "regression therapy" developed by Rev. Dr. Franklin Loehr (deceased).¹⁴ Psychography supposedly "allows" one to "look back" between one's lives and over one's past, present, and future lives. One of its premises is that each human has an omniscient inner "part" that can help to bring healing to souls.

Rolfing Movement Integration (RMI): Spinoff of Rolfing®¹⁵ whose groundwork was laid in the 1960s and 1970s by rolfer Dorothy Nolte and Judith Aston, the dancer who developed Aston-Patterning®¹⁵ and Aston Movement

[see NF 13:6, 1996].¹⁵ RMI somewhat resembles the Alexander Technique®¹⁵ [see NF 11:57, 1994]; both involve a "teacher" who gives tactile and oral guidance to a "student" (in the Alexander Technique, also called a pupil). An alleged effect of RMI is the experience of a "transformation of energy"—the release (very possibly "chaotic") of "energy" the body stored.

Spiritual Counseling: As taught by the National Interfaith Seminary, in St. Paul, Minnesota, a ministerial approach that apparently embraces chakra therapy,¹⁶ inner child work,¹⁶ and "Totem Psychology."¹⁶

Tai Chi-Chi Kung (taiji qigong): Alleged "path to self mastery" that consists mainly of *chi kung*¹⁷ exercises and tai chi.¹⁷ Its purported key is dynamic balance of "the mind and body energy." Tai Chi-Chi Kung includes "Chi Kung Meridian exercises," "Chi meditation," and "Five Element Energy Balancing exercises." The *chi kung* exercises supposedly release very potent "healing energy" in the body for dramatic health benefits.

Thai Massage-Reflex Yoga with Metta Touch: Purported powerful synthesis of acupressure massage, reflexology [see NF 12: 61-64, 1995], and yoga¹⁸ (see below).¹⁸ Allegedly, it stimulates

meridians ("energy lines"), vitalizes bodies, and clears "energy blocks" that cause fatigue and illness. The Thai word "metta" means "loving kindness."

Transformation-oriented bodywork (transformational bodywork):

Philosophy of bodywork* involved in many forms of "energetic balancing," psychotherapy, spiritual counseling, and touch therapy [see NF 11:51, 1994].¹¹ Transformation-oriented bodywork descends from Bioenergetic Analysis (also called bioenergetics¹⁹), massage, the personal/spiritual growth movement, and Reichian therapy.* Apparently, the fundamental postulates of transformation-oriented bodywork include the following. (1) Constricted muscles block "energy" in the body. (2) Constriction shows up as pettiness. (3) The "Highest Ideal" lies in "the realm of Divinity—the Source from which we and our planet derive our life and meaning."

Windows to the Sky acupressure (Window to the Sky acupressure):

Apparently, a form of acupressure²⁰ whose focus is the neck. The term "windows to the sky" refers to most of the "acupressure points" thereon.²¹

Yoga: Hodgepodge of dozens of religious and quasi-religious systems and methods, many of which are health-related. The word "yoga" comes from a Sanskrit term that literally means "yoke" and, in Hinduism [see NF 11:34–37, 1994], implies harnessing oneself to God.²² However, contextually or with a qualifier (e.g., *chakra*, *Chinese*, *polarity*, *Taoist*, or *Tibetan*), the word "yoga" often seems to mean simply "religious or quasi-religious practice or group of practices." For instance, according to yoga teacher Mary Mickelson of Long Island City, New York, yoga is a relaxation method that: increases vitality by oxygenating and energizing nervous plexuses, brings in "cosmic energy," improves sexual response by amplifying "erotic energy," and causes the control of "sexual energy" for "psychomental" and spiritual purposes.²³

Editor's note: Testimonials are the lifeblood of alternative healthcare. The word "testimonial" commonly refers to an individual's commendatory statement of facts and/or opinions. Antitestimonials, or reverse testimonials, differ from testimonials only in that their design is not to foster confidence in a person or thing but to provoke caution. An example is the "Supplement Junkie" section in Chapter 1 of my 1993 book *Mystical Diets*. Testimonials and antitestimonials share a fatal flaw: Despite appearances, they cannot establish causation. Indeed, they tend to blur causation. Nevertheless, often a single testimonial or antitestimonial, upbeat or lurid, can outperform a thousand icily scientific papers in changing behavior.

I present the following antitestimonial as a human-interest story and food for thought, not as a blanket condemnation of veganism.—J.R.

Quicksand

Dear Mr. Raso:

I've been a subscriber to NUTRITION FORUM for many years and applaud all you are doing to throw light on today's problems. I am particularly pleased that you are exposing pseudocredentials [e.g., in the March/April 1995, July/August 1995, and January/February 1996 issues of *NF*].

Not long ago in *NF*, you requested written accounts of personal experiences that might be of interest to your readers. Hence I submit the following.

Fifty-four years ago, struggling to shake off poor health, I turned to veganism—a diet of plant foods only, with the promise of excellent health. Little did I know that horrors would result.

How could I have credited dietary advice inconsistent with what I had learned studying biochemistry as a chemistry major at Cornell University? My trust arose from desperation: Two years after the birth of my second son, I suffered from constant fatigue and an endless cold, but my family physician couldn't get to the bottom of my problems. Physical exercise only exhausted me, and practicing relaxation improved my condition only temporarily.

I called a friend, a cellist with the Cincinnati Symphony, who seemed somewhat knowledgeable about food. My husband and I didn't approve of his vegetarian philosophy, but I hadn't tried diet and was ready for a change. He referred me to a chiropractor. Following the chiropractor's instructions, I enthusiastically ate lots of fresh and dried fruits, vegetables, and nuts. I also ate whole wheat bread, but not much, for in 1942 it was hard to find.

The change in diet worked wonderfully well at first. I had needed to lose weight, and did. Friends and acquaintances raved about how much better I looked. What was I to think—except that I'd made an important discovery? I devoured vegetarian newspapers and numerous books like Arnold Ehret's *Mucusless Diet Healing System* [see *NF* 12:28, 1995]. Many such books are still in print.

However, even after a couple of years, I hadn't attained good health. The chiropractor told me he knew of women in poor health who

had improved after becoming pregnant. "They lost a lot of blood, and that cleansed their systems," he said.

That was all I needed to hear. Having had two boys, I wanted a girl.

In a year on a vegan diet, my children had not grown; so I began serving them and my husband eggs, milk, and cheese. I continued to consume mostly fruits (fresh and dried) and vegetables (raw and steamed). Occasionally, and sparingly, I also ate homemade desserts: bread pudding, cookies, gingerbread, ice cream, and sponge cake. Otherwise, I avoided consuming foods of animal origin. About five months after I became pregnant, I resolved to follow an "all raw" diet. For more than six weeks, I consumed only fresh fruits, juices, raw vegetables, and nuts. Then I included cooked vegetables and whole grains in my diet, but I often abstained from eating them (whenever I felt I had a cold). Frequently, I ate only at night. I thought that fasting could cure anything. I gained only 15 pounds during my pregnancy. I was gaunt, always tired and cross, and often faint; my skin was flaky and my throat always sore.

I gave birth to our daughter at home, without anesthesia. I used my knowledge of relaxation techniques to sail through labor. The infant weighed 5 $\frac{3}{4}$ lbs and seemed fine. The doctor remarked that she was "clean."

I maintained records and kept a diary. On the day of the birth, I consumed only grapefruit juice. The next day, I ate 7 oranges, 4 grapefruits, 2 peaches, a cantaloupe, bananas, and many almonds. Later, I ate in addition raw and steamed vegetables, other nuts, other fruits, and, occasionally, dark rye bread, not whole-grain, but the best we could find.

Six days after the birth of my daughter, my head hurt and I was woozy. Ten days later, I developed hives, which I'd never had. The itch was maddening, and I couldn't fall asleep until 4 o'clock the next morning. A body temperature of 100° F and breast pain shortly followed. Meanwhile I was trying to nurse the baby.

Poor health with flu-like symptoms persisted. Worse was to come. I was on a bus, taking my seven-year-old to a magic show, when I suddenly became frightened. This was the first of many crippling panic attacks over several years. They would happen without warning, even when I was lying on a couch.

I insisted on nursing the baby. Whenever I fell acutely ill, the chiropractor would tell me to give the baby fruit juices "If you give her milk, she'll have colds and sinus trouble all her life," he would say. He vehemently discouraged consumption of dairy products.

When my daughter was about ten months old, she developed a facial rash. She became steadily weaker and weighed only 11 pounds at 11 months. My health was so poor, I couldn't understand what was happening. Alarmed, I called a pediatrician, who

immediately put our child in the hospital. After five weeks, the baby hadn't gained much weight on an amino acid formula and drugs like phenobarbital. Over the phone, the doctor said she was dying. We decided that, if she was going to die, we wanted her home. It had been frustrating to see her only through glass walls. We could never touch her.

Our 13-month-old daughter returned from the hospital with a tremor over her entire body. With another pediatrician's help, we administered a formula of condensed milk plus vegetable broth. Improvement was slow, but eventually the tremor left every part of her body except her mouth. Later, it disappeared.

The child relearned all that a baby does. She turned over, sat up, and walked at 18 months. But she was five years old before she talked, and she never learned how to read or write.

Epileptic seizures began when she was two. She was an emotional wreck with vast fear. When something frightened her, she would bite her arm, breaking the skin; or her hands would fly to the neck of her dress and, no matter how tough the material, she would tear it to shreds. Whenever I picked her up from her slow-learner class, safety pins were keeping her dress on. If we picnicked in a park, she would bury her head and cry: "He's looking at me."

Finally, we knew we could not manage her at home. When she was 10, she left Cincinnati for an institute for retardates, in a black car apparently designed to hold criminals. She died at the institute during a seizure when she was 21.

After five years of veganism, I found a chiropractor with an M.D. degree. On my second visit, he came in waving a paper and said: "I don't know why you are alive. According to your tests, you should be dead. It must be your maternal instinct keeping you alive."

I didn't have to be told how poor my health was. On the trolley I took to his office, I had had an agonizing loss of breath and forced myself to count telephone poles to keep from crying out.

This doctor helped me get over my devotion to vegetarian ethics. He said many animals wouldn't have any life at all if they hadn't been raised for food.

I recovered on an unrestricted diet that included fresh fruits, vegetables, nuts, whole grains, meat, fish, chicken, eggs, dairy products, and organ meats such as liver, heart, and kidney. The vitamin B₁₂ in the organ meats undoubtedly helped banish my aberrations. Now, at the age of 82, I travel around the world and climb mountains 4,000 feet high.

A poor diet during pregnancy can cause many defects, including epilepsy and mental disturbances. Our daughter had severe malocclusion and a deficient chin, both due to a prenatal lack of calcium and protein.

Appropriate dietary supplementation and careful selection of foods for nutritional adequacy can make veganism safe and even helpful for many adults. But extremely little is said about its effects in pregnancy. I've spent the years since our tragedy trying to find out what went wrong. After age 40, I returned to college for another four years to study nutrition, and I became keenly aware of the influence of "never-say-die" nutritional folklores.

- **Protein.** In 1942 I heard that a handful of almonds contains all the protein one needs. Hardly. It would take at least 115 almonds to match the amount of protein in one "Whopper" hamburger. Potatoes, too, were supposed to furnish ample protein. But it would take ten 4-oz potatoes (providing about twice as many calories as the Whopper) to match the amount of protein in one Whopper.
- **Human history.** We were nomadic hunter-gatherers for tens of thousands of years. Our physiology hasn't had time to change.
- **Anatomy.** We are omnivorous. The length of our intestines is midway that of carnivores and that of herbivores. Twenty of our teeth are carnivorous, twelve herbivorous.
- **Vitamin B₁₂.** Recently I heard, as I had years ago, that to be strong, we should eat grass like a cow. This shows disregard for the ability of a cow to make its own B₁₂ in one of its stomachs. I have also heard claims that there is B₁₂ in algae and

fermented soy products. We know now that there are only analogs of B₁₂ in those foods [see NF 12:44, 1995]. Moreover, they can cause a B₁₂ deficiency.

- **Teeth.** I couldn't understand why I was losing teeth on a vegan diet. A disturbance of acid-base balance can destroy teeth. Excessive consumption of fruits and vegetables with an alkaline reaction can cause as much damage as overconsumption of acid-forming foods (e.g., fish, meat, and poultry).
- **Zinc.** This trace element is difficult to absorb from plant foods because of their phytate content. Time after time, animal experiments have shown that even a small deficiency of zinc in the diet of pregnant animals will produce birth defects such as clubfoot and cleft palate.

How many tragedies have silently resulted from vegetarian irrationalism?

Ruth F. Rosevear, L.D.
Cincinnati, Ohio

I spoke with *NF* scientific consultant John Dodes, D.D.S., regarding the dental effects of veganism. It is unlikely that a vegan diet would significantly change the pH of saliva. However, excessive consumption of acidic fruits, particularly those with high concentrations of acetic acid (e.g., oranges and grapefruits) can, under certain circumstances, cause dissolution of tooth enamel. Moreover, periodontal bone loss can result from adherence to very restricted diets deficient in protein.—J.R.

ARE YOU A GAME?

I had the pleasure of reading the prepublication version of *Chiropractic: The Victim's Perspective*, as a consultant. It is a powerful, comprehensive, amply illustrated indictment of a "healing" system I consider an abomination. Last January, I asked four very different professionals to review the book for *NF*: Dr. Cinque, an eminent Natural Hygienist who has described himself as a "chiropractic heretic" and nonreligionist; Don Paulin, a self-described chiropractic victim and an avowed Christian (see the previous issue of *NF* for his review); and two practicing chiropractors, one a prospective Catholic priest, the other a "nutritional consultant" and bodybuilder. Dr. Cinque and Mr. Paulin submitted their reviews in short

order. The practicing chiropractors acknowledged their review copies when I ran into them within a month of my request. The "nutritional consultant" said he didn't have time to write the review, but he implied that he would do so in two months. The priest-to-be said the book was interesting. On February 6, he asked to see an issue of *NF*, and I mailed two issues to him. The next day, he said he feared writing a review that might bring on violence against him, and he requested a sit-down, face-to-face collaboration with me.

I have not received reviews from the practicing chiropractors. Any chiropractor game for reviewing the book is welcome to contact me.—J.R.

RASO'S LIST

Index to Mystical and Supernaturalistic Health-Related Methods

Below are references to descriptions published in NUTRITION FORUM, *"Alternative" Healthcare: A Comprehensive Guide* (AH), and *Mystical Diets: Paranormal, Spiritual, and Occult Nutrition Practices*. An asterisk follows the name of every method that is the subject of a chapter in each book. *Mystical Diets* is cited as "MD" only when the method is the subject of a chapter in that book only or not described in AH or NF. *"Alternative" Healthcare, Mystical Diets*, and all back issues of NF (\$6 per copy) are available from Prometheus Books (1-800-853-7545). Only photocopies are available from Prometheus for the first four issues of Volume 11 (pages 1-42). Readers may mail requests for original copies of these issues to Jack Raso.

Healthcare Esoterica

Acupressure massage: Acupressure* [see NF 11:47, 1994] in the form of a massage (*An Mo*). Apparently, it is the equivalent of amma.* Acupressure massage purportedly is usable to promote the flow of *Qi* (*chi*) through the “meridian system.” Yet, supposedly, everything in the universe is composed of *Qi*.¹

Body acupuncture: Apparently, “ordinary” acupuncture: any form of acupuncture whose “channel theory” is that of traditional Chinese medicine* and whose scope is the entire human body (e.g., not just the ears).²

Cayce diet: Diet that stems from the “readings” of Edgar Cayce.* One of its “concepts” is that emphasizing in one’s diet fruits and vegetables that are “locally-grown” promotes acclimation and helps to align bodily “energies” with environmental “energies.”³

Celestial Training: Program that includes Awareness Release Technique® [see NF 12:26, 1995].⁴

Chakral pranic healing: Component of advanced pranic healing [see NF 12:59, 1995].⁵

Chinese herbal medicine: A “major pillar” of Chinese medicine (see below). Its theory holds that herbs can influence the “Yin and Yang energy patterns” of the body.¹

Chinese medicine: “Holistic” system of “medical analysis, interpretation and treatment” whose “basic foundation” consists of acupuncture meridian theory, “Five Phase Theory,”* “herbology,” nutrition, and yin/yang theory.*⁶

Chinese Qigong massage (An Mo, Chinese massage, Qigong massage): Component of traditional Chinese medicine that emphasizes the “proper level,” quality of “circulation,” and alleged preventive uses of *Qi*, “the energy circulating in human or animal bodies.” The categories of Chinese Qigong massage are: (1) Pu Tong An Mo* (General Massage), (2) Tui Na An Mo* (Push Grab Massage), (3) Dian Xue An Mo* (Cavity Press Massage), and (4) Qi An Mo* (Qi Massage).⁷

Chi Weight Lifting: Component of Bone Marrow Nei Kung* that purportedly can rejuvenate bone marrow by supplying the body with abundant “Ching Chi,” an alleged combination of sex hormones and “sexual energy.” It involves genitally lifting weights attached to the penis and scrotum or to the vagina.⁸

Co-Centering: Component of Bodywork Tantra.* It supposedly “connects” one’s alleged three “basic centers”: body, heart, and mind. Co-Centering includes Basic Co-Centering and Expanded Co-centering.⁹

Color pranic healing (pranic color healing): Component of advanced pranic healing [see NF 12:59, 1995]. Its theory posits “color pranas.” In the “visualization approach,” the “pranic healer” visualizes *prana* (*ki*, “vital energy”) of an appropriate color emanating from his or her “hand chakra.”⁵

Direct moxabustion: Form of moxabustion* that requires placing small cones of “moxa” (a dried herb) on

specific acupuncture points and burning them almost to the skin.¹

Distant pranic healing: Form of distant healing (absent healing*) propounded by Choa Kok Sui.*⁵

FITONICS™: Purportedly revolutionary “natural health and weight-loss program” promoted by Marilyn Diamond* (coauthor of the bestseller *Fit for Life* [see NF 3:57–59, 1986]) and clinical hypnotherapist Donald Burton Schnell, M.S., coauthors of *Fitonics for Life* (Avon Books, 1996).¹⁰ It apparently encompasses “enzyme nutrition” [see NF 12:3–4, 1995], “*khanda* (sweetness of life) meditation,” Mindtonic training, and the “spine-based Bodytonic routine for toning and flexibility.” Mindtonic training supposedly allows union of one’s conscious mind and one’s “subconscious spiritual core.”

HaelanWork™: “Complementary healing therapy” that purportedly blends “centering prayer,” “healing dialogue,” Holotropic Breathwork,* meditation, and Therapeutic Touch.*¹¹

Indirect moxabustion: Form of moxabustion* that requires burning “moxa” (a dried herb) not in contact with skin. Forms of indirect moxabustion include: burning moxa cones on a slice of garlic or ginger, or on a layer of salt; manipulating burning moxa sticks over the “affected” area; burning pieces of moxa sticks on needles inserted into acupuncture points; and burning moxa on a grill in a box over the “affected” area.¹

Invocative pranic healing (Invocative healing): Form of pranic healing* in which “mighty invisible spiritual beings” or “healing angels” supposedly control the “healing energy” and the “bioplasmic body” of patients.⁵

Jin shinn (jin shin): Form of bodywork* whose modes are jin shin do* and jin shin jitsu.*¹²

Motional Processing®: Form of bodywork* developed by Alice Rutkowski, Ph.D., R.M.T. (“registered movement therapist”). Its purported design is “to get us out of our heads and into the memories housed in the body.” Motional Processing supposedly is appropriate for “those seeking to unlock their bodies to access more life energy.”¹³

Non-Contact Therapeutic Touch (NCTT): Variation of Therapeutic Touch* (TT) that does not involve touching.

In the early 1980s, NCTT replaced TT in the TT community. Apparently, “Therapeutic Touch” and “TT” now refer primarily to NCTT.¹⁴

Oriental body and facial diagnosis: “Ancient art of health evaluation” taught by author Steven Acuff. One of its principles is that “life energy” is balance or imbalance of “the polarity between” yin and yang.¹⁵

Oriental massage (amma massage): Form of massage that emphasizes alleged acupuncture meridians whereby the body’s “vital energy force” is channeled.¹⁶

Paneurhythmy: Purportedly sacred “circle dance” created by Beinsa Douno, a Bulgarian mystic of the early 20th century.¹⁷ It supposedly has “individual and universal healing properties” and nourishes the “auric field.”*

Physio-Spiritual Etheric Body healingSM (PSEBSM):

One of several Reiki Plus* “healing modalities” allegedly co-created by God and Reverend David G. Jarrell. It purportedly “balances” the “biomagnetic energy” surrounding the “physical body.”¹⁸

Primordial Sound Meditation:

Ancient form of “mantra (or sound) meditation” revived by Deepak Chopra, M.D.* [see NF 11:40–41, 1994]. It purportedly involves selection of a mantra (“primordial sounds”) based on the date, time, and place of the prospective meditator’s birth.¹⁹

Psycho-Therapeutic ReikiSM (Psycho-therapeutic ReikiSM healing):

One of several Reiki Plus* “healing modalities” allegedly co-created by God and Reverend David G. Jarrell. Its purported design is to release “the memories retained in the bodies and conscious and soul memory.”¹⁸

Radiant Healing Massage Method®: Combination of massage techniques that allegedly

was developed because all massage methods are not equally able to “unlock” one’s “healing potential.”²⁰

Regression therapy (hypnotic regression therapy): Method that allegedly evokes memories of, symbols of, and/or fantasies about adolescent, childhood, in utero, and “past-life” events.²¹

Sexual Energy Massage: The “primary practice” of Bone Marrow Nei Kung.* It involves simultaneous digital massage of one’s genitals and “meditative breathing.” The

purported purpose of Sexual Energy Massage is to release "Ching Chi" from the genitals for dissemination in the body and absorption by the bones.⁸ "Ching Chi" is an alleged combination of sex hormones and "sexual energy" that can regenerate bone marrow.

Shaman stone healing: "Therapy" practiced by Anju T. Myodo, an "empathic healing channel."²² It integrates hand reflexology, "psychic palmistry," and "spiritual healing" [see NF 11:50–51, 1994].

Spinal AttunementSM Technique (SATSM): One of several Reiki Plus* "healing modalities" allegedly co-created by God and Reverend David G. Jarrell.¹⁸

Tongue diagnosis: Form of pseudodiagnosis whose theory posits *Qi* (pronounced "chee") [see NF 12:46, 1995].²³ Allegedly, *Qi*—often called "energy," "life-force," and "vitality"—is that which defines life.

Traditional acupuncture: Form of acupuncture* usually practiced in the context of traditional Chinese medicine.²⁴

Zazen: Ancient form of meditation that purportedly enables touching the "source of life." Apparently, Zazen supposedly also helps to "awaken" *jariki*, "the spiritual energy necessary to be of true service."²⁵

Addendum

Fit for Life program: Variation of the pseudo-dietetics of Natural Hygiene developed by Harvey and Marilyn Diamond. [H. Diamond and M. Diamond. *Fit for Life*. New York: Warner Books, Inc., 1985.]

Fountain of Youth Qigong (Fountain of Youth): Purported ancient secret to increasing "original Qi Energy" ("the Primordial Qi"). It allegedly restores youth. [Display, *Newlife* (special expo edition), Vol. 10, No. 48, April 1996, p. 34.]

Living Health life-style: Apparently, a long-term variation of the Living Health program (see below).

Living Health program: Apparently, the two-week program expounded and recommended by Harvey and Marilyn Diamond in *Fit for Life II: Living Health* (Warner Books, 1987). Its philosophy posits an "inner voice" in everyone that knows what is right.

Rhythmical Massage: "Approach to massage" developed by physician and anthroposophist Ita Wegman. According to its theory, *effleurage* (light manual rubbing) in the form of the figure "8" strengthens the "etheric (life) body." [E. Bristol, "Rhythmical Massage: A New Approach," *LILIPOH*, Vol. 1, No. 4, Winter/Spring 1996, p. 6.]

SHADOW, SUBSTANCE, and *THE ZONE*

A REVIEW

James J. Kenney

In his bestseller, *The Zone: A Revolutionary Life Plan to Put Your Body in Total Balance for Permanent Weight Loss*, published last year by HarperCollins, Barry Sears, Ph.D., says he is “firmly convinced” that certain low-fat, low-protein, high-carbohydrate diets (by implication, all such diets) “can actually be dangerous,” that they “can actually help bring on the diseases they’re supposed to prevent...[b]ecause they violate the basic biochemical laws required to enter the Zone” (p. xvi).

Twilight Zone?

The book’s dust cover gives the appearance that its title is “Enter the Zone” and describes the work as a “dietary road map.” Yet “the Zone” is not a place; at least, it’s not a “place” in the usual sense of the word. Is it a distinct physiological or psychological state? According to the book’s index, “Zone” is defined on pages 1–3 and on page 7. The word is not defined on page 7, however. I gleaned the following phrases from pages xvi and 1–3.

- “...that state of optimal good health, physical performance, and mental alertness...” (p. xvi)
- “...that mysterious but very real state in which your body and mind work together at their ultimate best... In the Zone, the mind is relaxed, yet alert and exquisitely focused. Meanwhile, the body is fluid, strong, and apparently indefatigable. It’s almost euphoric. There are no distractions, and time seems to slow down to a graceful waltz.” (p. 1)
- “[T]here’s nothing mystical about the Zone. *The Zone is a real metabolic state that can be reached by everyone, and maintained indefinitely on a lifelong basis.*” (p. 2)
- “Simply put, [the Zone is] the metabolic state in which the body works at peak efficiency... In the Zone, problems don’t go away, but their solutions become more obvious... In the Zone [weight loss] is painless, almost automatic.” (p. 2)

- “The Zone is beyond wellness. The Zone is about *optimal health.*” (p. 2)
- “The truth is that *every time you open your mouth to eat, you’re applying for a passport to the Zone.*” (p. 3)

Is this “the truth,” or is it an attempt at euphemizing mysticism? Another author, Phil Scott, defines “the Zone” as “the level of peak performance at which an athlete feels capable of doing anything, effortlessly and efficiently.”¹ Scott equates the Zone and “runner’s high.”² Whereas Sears claims that the “only...route to reach the Zone at will” is dietary (p. 3), Scott states that the “secret” to “get[ting] to the Zone with consistency” is respiratory³ (specifically, a routine characterized by “Ayurvedic breathing” and a series of yoga postures).

The concept of “the Zone” is comparable to that of “flow,” the subject of a much more scholarly work, Prof. Mihaly Csikszentmihaly’s *Flow: The Psychology of Optimal Experience*. Therein, Dr. Csikszentmihaly defines “flow” as “the way people describe their state of mind when consciousness is harmoniously ordered, and they want to pursue whatever they are doing for its own sake.”⁴ He suggests that an “almost infinite range” of activities “produce flow,” and he states that some—including art, games, hobbies, and sports—do so consistently.⁵

My point is that “the Zone” is, at best, ill-defined, and, at worst, a fantasy with a host of roadmaps and gurus showing the “path” from which we have “strayed” (p. 104).

Danger Zone?

The Zone is a confusing blend of science and nonsense. As its popularity has soared, its claims about the dangers of high-carbohydrate diets have become a source of consternation for people following the Pritikin Eating Plan, which emphasizes a diet composed primarily of high-carbohydrate foods. The chief potential danger of Sears’ book is the suggestion, based on little more than anecdotes,

that the “Zone-favorable diet” (herein referred to as “the Zone diet”) has powerful effects on many major diseases. However, there is no credible research to support the use of the Zone diet to treat *any* disease. Furthermore, Sears contends that other diets—diets of proven efficacy—are dangerous! If people abandon such diets, and medical treatments with good track records, to adopt Sears’ untested and highly speculative approach, the likely result will be needless deaths and suffering.

Using a variation of bait and switch, HarperCollins repeats on the back of the dust cover a claim made by Sears on page 11: “Eating fat doesn’t make you fat.” But, on page 87, Sears states: “[R]emember, a Zone-favorable diet is a low-fat diet.” Indeed—despite statements such as “[Y]ou may have trouble eating all the food required to reach the Zone” (p. 97)—the Zone diet is simply a thinly disguised calorie-restricted, tightly portion-controlled diet.

Although Sears states that when one has reached one’s ideal weight or percentage of body fat, one must consume more calories, he claims that all these extra calories must come from fat in order for one to stay in “the Zone.” For most people, that prescription translates into a diet with 45–60 percent of calories from fat. This means that unless one is actively losing weight, one will be on a very high-fat diet for the rest of one’s life. The appeal of this book stems in part from the marketing of the Zone diet as a scientific breakthrough that enables eating fatty foods without gaining weight. In fact, high-fat diets have been shown to *promote* weight gain. For example, a high-fat diet (in which fat provided 59 percent of the calories) was shown to increase ad-lib caloric intake by 40 percent over a two-week period, relative to a diet in which fat provided only 20 percent of the calories.⁶

There *is* reason to believe that diets very low in carbohydrate (less than 40–50 grams per day) may reduce caloric intake because of the metabolic effects of the ketosis they produce. However, even at Sears’ most restrictive carbohydrate level, his diet is not deficient enough to trigger ketosis. It should not be confused with ketogenic diets, such as Atkins’, Stillman’s, and the ketogenic diet recommended more recently, by the Eades, in *Protein Power* (Bantam Books, 1996).

It may be hard to believe that someone with a doctorate in biochemistry from Indiana University could come up with the unlikely thesis that diets high in carbohydrates, rather than fat, are the main cause of heart disease and obesity. Of course, as Ted Kaczynski, the suspected “Unabomber,” has demonstrated, some very bright people with doctorates from excellent schools can concoct some pretty lame theories. This is particularly true when one ventures too far from one’s area of expertise. Despite Kaczynski’s brilliance in mathematics, his ideas about psychology, sociology, and ecology are rather naive. Likewise, Sears’ extensive training in biochemistry has not prevented him from making some rather naive statements about clinical nutrition and sports nutrition.

But let’s give Sears credit for having a much better

strategy for promoting, and profiting from, his flawed thesis than Kaczynski apparently had. Clearly, writing books with wacky ideas about nutrition is about as American as apple pie. Mailing bombs to maim and kill people is not nearly as acceptable. The alleged Unabomber appears to have a grudge against nearly all of modern society, whereas Sears’ grudge appears aimed primarily at Pritikinesque “low-fat radicals” (p. 11). According to Sears, anyone who supports a high-carbohydrate diet for Americans cannot be trusted. This includes *Consumer Reports* magazine and the National Research Council’s Committee on Diet and Health (p. 10).

Number Munching?

Let’s take a closer look at Sears’ central thesis: He claims that a diet with a caloric makeup of 40 percent carbohydrate, 30 percent protein, and 30 percent fat (or simply 40/30/30) is the secret to good health, optimal athletic performance, and longevity. One who wants to maintain one’s current weight may change this makeup to 25/19/56.

In Chapter 9, Sears correctly points out that grains were not part of our ancestral diet. He then implies that human beings are not genetically adapted to eating grains. This is naive. Grains are rich in starch, a form of carbohydrate that was certainly a major part of our ancestral diet. Starchy vegetables like beets, cassava root, potatoes, squashes, and yams have long been part of human and prehuman primate diets. Our pancreas and salivary glands produce the starch-digesting enzyme amylase. Amylase works quite well on starch from grains, beans, and starchy vegetables alike, even though only starchy vegetables were a major part of our ancient ancestral diet. Tuna was not part of our ancestral diet either, but that doesn’t mean we aren’t genetically designed to eat it. Furthermore, it’s extremely implausible that our ancestors ate three small meals and two snacks daily, and that each meal and snack had a 40/30/30 makeup. Indeed, it’s hard to think of a single food item likely to have constituted a meal for our ancestors that approaches this caloric makeup. It’s even harder to believe that Sears’ diet is the “*evolutionary diet*,” the “genetically correct” diet for all humankind (p. 104).

Yet Sears doesn’t stop there: He contends that his 40/30/30 diet is the key to “living in the nearly euphoric metabolic state called the Zone” ((p. 8). Forget for the moment that “the Zone” is ill-defined. Has anyone done any scientific research that supports the notion of an evolutionary adaptation to a caloric makeup of 40/30/30? Nope! I gather from the book that

Nutrition and Health Forum (ISSN 0748-8165) is published bimonthly for \$35.00 (individuals in U.S. and Canada) or \$50 (institutional, overseas) per year by Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197. Second-class postage paid at Buffalo, NY. POSTMASTER: Send address changes to Prometheus Books at address above. Manuscripts and all editorial correspondence should be directed to: Jack Raso, 71-11 60th Avenue, Maspeth, NY 11378-2908.

the only support for this claim consists of fossil evidence and anthropological studies suggesting that Paleolithic humans consumed about 3000 calories a day in a 45/34/22 ratio.⁷ However, the report of these findings also included an estimate of the sodium content of this Paleolithic diet: 690 mg—much less than a Zone dieter would consume if he or she followed the recipes in Sears' book.

In the Preface (p. xv), Sears states that cancer drugs function in "a Zone...known as the therapeutic zone." In a sense, this is true: Too low a concentration results in insufficient destruction of cancer cells, and too high a concentration in the destruction of too many normal cells. However, no scientific evidence suggests that this pharmacologic range or "zone" has any relationship to the "flow"-like "Zone" posited by Sears.

Nevertheless, he speculates: (a) that an "eicosanoid Zone" combines "properties" of the "Zone" of cancer drugs and that of optimum athletic performance (p. xv), and (b) that the ratio of caloric nutrients in the diet determines whether one gets into this supposed "eicosanoid Zone." There are a few holes in this theory. For example, no scientific evidence, or rationale, connects the "flow"-like "Zone" and the "therapeutic zone" of drugs.

Then there is a problem with Sears' claim that a specific proportion of macronutrients (carbohydrate, protein, and fat) can put one in the "eicosanoid Zone." Eicosanoids are hormonelike substances derived from polyunsaturated fatty acids such as arachidonic acid. While diet does affect eicosanoid levels, the effect depends primarily on which types of fat one consumes. So why does Sears stress the ratio of macronutrients? Hard to say. A cynic might contend that the 40/30/30 ratio he pedestals is just a marketing ploy for *BioZone* "nutrition bars," which Sears developed. Was *The Zone* designed as a marketing tool for this product? One can get 14 little *BioZone* bars for \$35, plus \$5 for shipping and handling, by calling the toll-free number in the book (p. 213). That's a week's supply if one follows the "Spartacus Quick Start Plan" from Envion International. This company is part of Surfactant Technologies, Inc., of which Sears is an owner.

(Reportedly, before he left Balance Foods, Inc., Sears helped to develop that company's "nutritional food bar," *Balance*. A June press release claimed: "Balance combines nutrients in the clinically proven 40-30-30 ratio of carbohydrates, protein, and dietary fat; a nutritional concept that helps the body access body fat for energy, and maintain steady blood sugar levels.")

Has Sears done any research to see if his 40/30/30 diet really does alter eicosanoid levels? Nope. On August 22,

1995, on a KSRO radio show with Dr. John McDougall, he admitted that he'd never even looked at eicosanoid levels in people following his dietary advice. Have any studies demonstrated that changes in macronutrient ratios affect eicosanoid levels? Limited research suggests some effects, but their relationship to health is unclear. Furthermore, there is absolutely no credible support for the claim that changing the proportion of carbohydrate, protein, and fat in one's diet affects athletic performance by altering eicosanoid levels.

Despite the holes in his thesis, and the complete lack of data from controlled scientific studies to substantiate the macronutrient/eicosanoid relationship he posits, Sears claims that his Zone diet is the ticket to feeling great, preventing or eliminating many diseases, and optimizing athletic performance. That's good marketing, but bad science.

Trimming the Fat

Okay, so the Zone diet's theoretical basis is shaky. Perhaps Sears and the rest of us don't understand yet how the diet works. After all, if the diet could do just ten percent of what Sears says it can, it would be a breakthrough even if its theory posited the tooth fairy. Sears claims or suggests (p. xvi) that his diet: can help prevent, or even help reverse, heart disease; prevents cancer; has a "positive impact" on a "host of other diseases"; helps one to live a longer and more satisfying life; keeps one performing at one's "absolute best"; and can help one lose weight permanently. The dust cover suggests that one can use it to reset one's genetic code and fight cancer, depression, diabetes, PMS, and symptoms of HIV infection and multiple sclerosis. The trouble is, no one has done any credible research to determine whether any of these claims and hints deserve even a whit of confidence.

The claim, on the back of the book's cover, that apple juice, orange juice, bananas, raisins, carrots, lima beans, rice, bagels, bread, dry cereal, pasta, popcorn, and ketchup "could be dangerous to your health" is meaningless except as a come-on. The real danger is his "guess" (p. 153) that people who follow very low-fat, high-carbohydrate diets, such as those advocated by Dean Ornish and Pritikin Longevity Centers, "will ultimately have more heart attacks, strokes, and a higher cardiovascular death rate" than those who do not. This seems absurd, since Ornish showed that most people following his program experienced regression or reversal of their atherosclerosis.⁸ Atherosclerotic lesions (which clog arteries) are the underlying cause of most cardiovascular deaths, yet Sears is suggesting that a diet

with the proven ability to counteract such lesions increases cardiovascular mortality.

Of course, Sears is correct in pointing out that we don't know how Ornish's patients will fare in the end. However, many years ago, Lester Morrison, M.D., conducted a study of diet and heart disease that involved 100 people. Their average age at the start of the study (in the late 1940s) was 62, and all of them had had at least one heart attack before that time. Morrison put half of them on a very low-fat, low-cholesterol diet similar to diets later formulated by Ornish, Nathan Pritikin, and others. The other fifty subjects continued eating as usual. After twelve years, 31 of the 50 low-fat dieters had died. Even though the study took place before the introduction of bypass surgery and effective cholesterol-lowering drugs, and before the American Heart Association's advocacy of fat-and-cholesterol restriction, a 38-percent survival rate is not great.

Do the fates of the other fifty subjects bear out Sears' "guess" that low-fat, high-carbohydrate dieters "will ultimately have more heart attacks, strokes, and a higher cardiovascular death rate"? Their diets were much higher in fat and cholesterol, and much lower in carbohydrate, than the experimental diet. After twelve years, all of them had died, most from cardiovascular disease.⁹

Lose Weight Now. Ask Me How.

Morrison's study is also instructive regarding the effect of a high-carbohydrate diet on weight. The subjects on the low-fat, high-carbohydrate diet lost an average of about 25 lbs and remained lighter for 12 years. This makes me wonder why Sears claims that "eating fat doesn't make you fat" (p. 11). Most scientific researchers have found that increasing dietary fat increases caloric intake and promotes weight gain. That's why most people in China are slim, and so many Americans are overweight. Americans derive about a third of their calories from fat—which is awfully close to the percentage that Sears recommends. Lauren Lissner, Ph.D., found that adding fat to foods caused both a spontaneous increase in caloric intake and weight gain in human subjects who lost weight when they consumed the same foods prepared so as to make them much lower in fat.¹⁰

Sears makes much of the modest decrease in the percentage of calories Americans derive from fat and the increasing incidence of obesity in America. In fact, the reason Americans are getting fatter relates more to a decrease in activity and smoking than to dietary changes. It's true that Americans are deriving a smaller percentage of calories from fat today than they were five or ten years ago. However, this is more attributable to an increase in refined-carbohydrate intake than to a decrease in fat consumption. In 1995, the average daily intake of fat by Americans was 74.2 grams in 1995—up slightly from 71.8 grams in 1990.

Consider that adding three tablespoons of "fat free" chocolate syrup to a glass of whole milk decreases the percent-

age of fat-derived calories from 50 percent to 30 percent, but it doesn't decrease the amount of fat in the drink or make the drink less "fattening." To imply that Americans are getting fatter because they are ingesting less fat demonstrates a lack of understanding of nutrition and weight control. Sears also claims (p. 59): "[Y]ou can burn body fat...by watching TV...." A statement on the back of the dust cover is stronger: "You can burn more fat watching TV than by exercising." Let's face it: If watching television and eating high-fat foods were the key to permanent weight loss, Americans would be thin and the Chinese would be fat.

Rest assured that you'll lose weight if you follow the dictates in Chapter 8 of *The Zone*. How could someone who apparently lacks understanding of nutrition and weight control devise a diet that can effect weight loss? It's easy! The reason you would lose weight on the Zone diet has nothing to do with insulin levels or eicosanoid levels, as Sears suggests, and everything to do with caloric restriction. Most women who calculate how much protein, carbohydrate, and fat they may consume daily according to the diet would wind up with a daily caloric value between 800 and 1400. Of course, calorie-restricted diets whose daily caloric value is significantly lower than that of the dieter's ad-lib intake—slow one's metabolism and leave one hungry and craving high-fat and/or high-sugar foods. They also can impair athletic performance by decreasing glycogen synthesis in muscles.

Whence Carbophobia?

Sears bases much of his criticism of high-carbohydrate diets on research that demonstrated some adverse metabolic effects of a diet higher in carbohydrate compared to one higher in monounsaturated fat. Most of this research was conducted by Gerald Reaven, M.D., Ph.D., at Stanford University. These adverse effects include hyperinsulinemia, hypertriglyceridemia, and a decrease in HDL-cholesterol. However, as we shall see, the protocols of Reaven's studies make their findings largely irrelevant to free-living subjects (who rarely can adhere for long to a prescribed caloric level). Perhaps we should not be too hard on Sears for failing to see the design flaws in Reaven's research. Other researchers, plus a disturbing number of health professionals, have also failed to perceive the clinical irrelevance of Reaven's short-term studies.

All the studies that have shown adverse effects of a diet higher in carbohydrate relative to a diet higher in monounsaturated fat have had similar design flaws. The most important flaw has been inappropriate control of caloric intake and/or body weight. Although the findings of these studies have scientific value, they have been misinterpreted or overinterpreted in terms of clinical application.

Studies of human populations have linked the development of obesity and/or NIDDM (non-insulin dependent diabetes mellitus) with diets high in fat and refined carbohydrates,^{11,12,13,14} particularly when a low level of physical activity

accompanies such a diet. There seems to be little doubt that adopting a Western lifestyle with its rich diet and sedentariness has a tendency to result in obesity and/or NIDDM in genetically predisposed members of the population. The unanswered question is: Are processed, particularly refined, carbohydrates more conducive than fat to obesity? Most studies suggest that fat is worse, but few researchers would propose that “fat free” products like *SnackWells* and *Entenmann’s* are key to quick and permanent weight loss.

In 1988, Antonio Garg, M.D., and associates concluded that partial replacement of complex digestible carbohydrates with monounsaturated fatty acids may, in non-insulin dependent diabetics, improve both glycemic (blood sugar level) control and levels of triglycerides and HDL-cholesterol.¹⁵ In a letter to the editor,¹⁶ my associates and I pointed out that Garg’s findings were largely the result of a faulty experimental design: The high-fat diet and the high-carbohydrate diet were isocaloric (at the same caloric level). We cited studies clearly demonstrating that most people reduce caloric intake and lose weight when carbohydrate replaces fat in their diets.

Although they have never successfully refuted this criticism, Reaven, Scott Grundy, M.D., and their associates have continued to publish research with protocols that are similarly flawed and limit the clinical relevance of the research. Yet this research is fueling a growing anti-carbohydrate backlash.

Most recently, the Reaven and Garg groups collaborated on a study published in the *Journal of the American Medical Association*. The researchers concluded that, “in NIDDM patients, high-carbohydrate diets compared with high monounsaturated-fat diets caused persistent deterioration of glycemic control and exaggeration of hyperinsulinemia, as well as increased plasma triglyceride and [VLDL-cholesterol] levels.”¹⁷ This is what Sears claims. I sent a letter to the editor that challenged the clinical relevance of the study (in sum, the diets were isocaloric), but the editor decided not to publish it. My letter reportedly was forwarded to Garg, from whom I have not received a response.

Stay Hungry?

The findings of researchers at the Pritikin Longevity Center in Santa Monica, California, contrast markedly with those of Garg and associates. The Pritikin researchers found both improvement in glycemic control and a decrease in insulin and triglyceride levels in patients on a diet very low in fat and high in fiber.^{18,19} However, in the two Pritikin studies, the caloric intake of the subjects was ad-lib, they were discouraged from going hungry, and they began an exercise program. What does Sears say in his book about published research that refutes one of the main tenets of the Zone diet? Nothing.

The vast majority of people—perhaps because of a body-weight “set point” (a hypothetical physiological predisposition to “settling” at a particular weight)—cannot spontaneously control their caloric intake over the long term.²⁰

However, it has been shown repeatedly that both a decrease in caloric intake and weight loss result when people follow calorically unrestricted, high-carbohydrate diets relative to diets higher in fat.^{21,22,23,24} Moreover, when the same amount of weight was lost on a calorically unrestricted, high-carbohydrate diet, relative to a calorie-restricted diet higher in fat, the high-carbohydrate dieters reported less hunger, more gustatory enjoyment, and a higher quality of life.²⁵

A recent study conducted by Alice Lichtenstein, Ph.D., and associates compared the metabolic effects of: (a) a moderate-fat diet (29% of calories from fat), (b) a low-fat diet (15% of calories from fat) isocaloric with the moderate-fat diet, and (c) the same low-fat diet consumed ad lib. The moderate-fat diet was advantageous only when the caloric intake was the same as that occurring with the low-fat diet.²⁶ In this study, the more favorable blood-lipid changes due to the low-fat diet, relative to a diet higher in monounsaturated fat, occurred when caloric intake was ad-lib, even though the ratio of polyunsaturated to saturated fats (P/S ratio) was significantly lower with the low-fat diet (0.51) than with the moderate-fat diet (.62). Presumably, if the P/S ratios had been similar, the low-fat diet would have been yet more advantageous than the moderate-fat diet.²⁷

The most striking finding of Lichtenstein’s study was the significantly lower postprandial level of serum triglycerides with the ad-lib low-fat diet, relative to the moderate-fat diet. Triglyceride levels, both fasting and postprandial, were much higher in subjects who followed the low-fat diet that was isocaloric with the moderate-fat diet. This study and a follow-up study from the same group²⁸ clearly refute the claim that high-carbohydrate diets elevate serum triglycerides relative to diets higher in fat. High-carbohydrate diets do so only when caloric intake is not ad-lib. Since Sears bases his thesis that high-carbohydrate diets cause an increase in insulin levels primarily on Reaven’s work, these studies likewise refute the theoretical basis of the Zone diet. Unfortunately, the media paid little attention to them.

Perhaps the main advantage of a diet very high in complex carbohydrates (relative to one higher in unsaturated fatty acids) is that, under most circumstances, calorie for calorie, dietary carbohydrates cause more satiety than dietary fat. Since few people can lose weight and then maintain their lower body weight by spontaneous caloric restriction, a diet higher in complex carbohydrates, compared to one higher in monounsaturated fatty acids, is useful in that it generally leads to a decrease in caloric intake and a loss of excess body fat, especially in people with central adiposity (a high waist-to-hip ratio) and hyperinsulinemia.

The Right Stuff

But let’s give credit where credit is due. There is some reality in Sears’ claim that different high-carbohydrate foods have different metabolic effects. Work by Reaven and other researchers does indicate that a focus on the percentage of

calories derived from fat is too narrow. Apparently, the metabolic effects of individual high-carbohydrate foods differ just as the blood-lipid effects of some types of fat are worse than those of other types. For example, there is reason to believe that different high-carbohydrate foods (or even different foods high in complex carbohydrates) have different satiety values and different effects on the levels of sugar and insulin in the blood. A recent study suggested that obesity is maintained not only by a diet high in fat but also by one high in refined sugar and low in fiber.²⁹ In general, it appears that those high-carbohydrate foods that cause the greatest insulin response are less likely to conduce to satiety and more likely to increase caloric intake.^{30,31,32} A plausible explanation for these apparent effects is that insulin promotes fat storage and decreases fat oxidation.³³ So there is a point to minding the types of carbohydrate one ingests, and Sears' thesis is not 100% wrong.

That doesn't mean his thesis is sound. After all, even Kaczynski's published anti-technology "manifesto" was not completely off base. If Sears had limited himself to pointing out that "fat free" bakery products aren't great diet aids, his book may have been socially beneficial. But, in Kaczynski style, he started off with some legitimate concerns about too much of the wrong type of high-carbohydrate foods and—with his coauthor, professional writer Bill Lawren—wove those concerns into a self-styled manifesto³⁴ that is sometimes self-contradictory and irrational.

If the main advantages of a high-carbohydrate diet over a high-monounsaturated fat diet are a decrease in caloric intake and a loss of body fat, it seems wise to encourage the consumption of high-carbohydrate foods with a high satiety value. A recent study clearly demonstrated that less-processed starchy foods caused lower glycemic and insulin responses than more-processed starchy foods.³⁵ Even if those high-carbohydrate foods that caused a lower insulin response did not have a higher satiety value and did not conduce more to weight loss, they would be preferable for persons with insulin resistance (Reaven's Syndrome X), because higher insulin levels appear to figure independently in the etiology of atherosclerosis.^{36,37,38}

Another potential advantage of high-carbohydrate diets over the diet higher in monounsaturated fat advocated by Sears is a decrease in clotting factor VII. Diets higher in monounsaturated fatty acids and lower in carbohydrate are likely to conduce to an increase in clotting factor VII, which has been associated with an increased risk of thrombosis.³⁹ Often, persons with extensive atherosclerosis are at high risk of forming blood clots (thrombi) in diseased parts of their arteries. Even a single high-fat meal can cause an increase in clotting factor VII and in the tendency to form blood clots, which can block an artery and trigger a heart attack or stroke. Researchers have also shown that increasing dietary protein tends to increase clotting factor VII.⁴⁰ Sears does not mention this potential problem in his book.

High-carbohydrate diets have other advantages over diets higher in monounsaturated fat. However, to some extent,

these advantages depend on the types of high-carbohydrate foods consumed. Unfortunately, we do not know enough about the particular metabolic effects of different high-carbohydrate foods to prioritize them comprehensively.

Probably one important characteristic of starchy foods is how they affect insulin levels. In general, the more rapidly insulin is released in response to ingestion of a high-carbohydrate food, or the greater the amount released, the less desirable that food would be for one who wants to lose weight, improve blood-lipid conditions, and/or improve blood-sugar regulation in NIDDM.⁴¹

Clinically it appears that foods capable of triggering hyper-insulinemia are likely to be more of a problem for Type II diabetics (who cannot produce enough insulin to prevent abnormal blood-sugar elevations) and/or persons trying to lose body fat (perhaps because insulin promotes oxidation of carbohydrate rather than of fat). High-carbohydrate foods that cause a greater insulin response would seem to be most detrimental to persons with insulin resistance, partly because hyperinsulinemia is very probably an independent factor for the progression of atherosclerosis.⁴²

Refined Tastes

However, Sears overemphasizes avoidance of high-carbohydrate foods that cause the greatest rise in blood-sugar and insulin levels. Other factors are important as well. Many foods rich in complex carbohydrates—such as beans, brown rice, corn, hot whole-grain cereals, potatoes, and whole-wheat pasta—furnish about 500 to 650 kcal per pound. But the most calorie-dense grain products—such as breads, crackers, and dry cereals—furnish about 1250 to 1750 kcal per pound. In many people, consumption of those high-carbohydrate foods that are more calorie-dense apparently leads to greater caloric intake and/or insulin output than consumption of those that are less calorie-dense. The human stomach can hold about 2–3 lbs of food; and increasing the amount of carbohydrate one consumes at one sitting increases the overall insulin response. Therefore, it is easier to overeat calorie-dense foods than it is to overeat foods of low caloric density. Breads, dry cereals, and crackers (even whole-grain crackers) are more likely to exaggerate an insulin response than hot cereals, pasta, potatoes, and rice.

"Fat free" chips and pretzels have a very high caloric density, about 1600–1700 kcal/lb. "Fat free" cakes, cookies, pastries, and muffins furnish 1400–1800 kcal/lb and presumably trigger marked hyperinsulinemia and/or excessive caloric intake in many people. Persons with insulin resistance (Syndrome X) who consume such high-carbohydrate foods ad lib may incur particularly adverse metabolic effects. So here, again, Sears' reasoning (apparently inspired by some of Reaven's studies) is fairly close to reality.

Generally it appears that foods of high caloric density are more conducive to an increase in caloric intake and/or a

decrease in meal frequency than foods of low caloric density. This effect seems at least partially independent of that of dietary fat.⁴³ When the ratio of fat to carbohydrate is changed covertly but the caloric density of diets is maintained, much of the apparent benefit of decreasing the proportion of fat-derived calories disappears.^{44,45} Both an increase in caloric intake and a decrease in meal frequency are likely to increase overall insulin secretion. And the injection of extra insulin both into animals and into humans is associated with weight gain.

The protective effects of consuming starchy foods of relatively low caloric density may be partly due to the tendency to consume fewer calories per sitting when the caloric density of the meal is lower. Consuming meals of lower caloric density may lead to consuming a greater number of meals or to grazing (eating only snacks throughout the day). Grazing, even without a change in the types or quantity of carbohydrate consumed, has been shown to decrease insulin production and insulin resistance and to affect blood-lipid conditions favorably.⁴⁶ As Sears stresses eating small meals, I again give him credit for being reasonable some of the time.

Altering starch structure, or altering or disrupting the cell walls that surround starch granules, increases the caloric density of starchy foods. It also may increase the rate of digestion and absorption. Generally, this results in a higher glycemic index (the blood-sugar response value of a food relative to that of glucose) and a higher insulin index (the relative insulin response value of a food). Such elevations would likely be disadvantageous, particularly for persons with NIDDM and/or Syndrome X and central adiposity. In contrast, there is reason to believe that less processed forms of the same foods (which have a lower glycemic index and/or insulin index) may help to moderate the adverse effects of high-carbohydrate diets on blood-lipid conditions.^{47,48} (For example, whole-wheat berries have a lower glycemic index and/or insulin index than whole-wheat crackers.) Processing that disrupts the botanical structure of the food usually increases the rate at which the carbohydrate is digested and absorbed.^{49,50} Generally, the more rapid the absorption of a food high in complex carbohydrates, the greater the glycemic and insulin response.⁵¹ Insulin elevations have been shown not only to promote fat storage and decrease fat oxidation, but also to decrease the satiety effect of dietary fat.³³

Refining wheat and other flours entails the removal of dietary fibers. The consumption of soluble fibers with starch and/or sugar generally lowers the glycemic and/or insulin index.⁵² Soluble fiber has been shown to decrease ad-lib caloric intake.^{53,54} There is also evidence that soluble fibers may both reduce ad-lib caloric intake and conduce to weight loss (and/or inhibit weight gain).⁵⁵ The evidence that insoluble fibers reduce insulin response and/or facilitate weight loss is inconsistent. A

finding of one study was that intact wheat berries had a much lower insulin index than whole wheat bread, but it is not clear whether the greater insulin response to the bread was due to the effect of processing on its fiber or to the type of starch.

Refining high-carbohydrate foods not only removes most of the dietary fiber but also can increase caloric density. It should come as no surprise that the diets of obese persons have been found to be both higher in fat and refined sugar and lower in fiber than the diets of thin people.⁵⁶

Compared to processed, particularly refined, high-carbohydrate foods, most whole grains and starchy vegetables are rich in nutrients. This is another reason to emphasize relatively unprocessed high-carbohydrate foods. It is especially important for persons attempting to lose weight to consume high-carbohydrate foods that have both a high nutrient density and a low caloric density.

End Zone

This review of *The Zone* provides much more useful information than the book itself. Yet my criticisms herein are just the tip of the iceberg. Some of the recipes in *The Zone* violate its dietary dogma. For example, a computer analysis of the recipe for "Breakfast Burritos" (p. 92) revealed that 46.5 percent, rather than 30 percent, of the dish's calories come from fat. It is also high in saturated fat and cholesterol. Furthermore, many of the recipes are high in salt.

You may ask about all those people with serious diseases that, according to the book, improved on Sears' diet. This is merely anecdotal. And, in *The Zone*, Sears contradicts himself, garbles facts, and often exaggerates.

What about those Zone-dieting athletes winning gold medals? Please, these athletes were world-class before they ever heard of Sears and his *BioZone* bars. I don't doubt that some athletes can perform better on a diet higher in fat and protein. For example, heavyweight Olympic weightlifters, professional football lineman, and sumo wrestlers stand to gain from such a diet. Their average life expectancy is nearly 20 years lower than the overall average.

Athletes and couch potatoes alike usually have good days and bad days whose goodness and badness are unrelated to the particular day's food intake. And it seems reasonable to assume that it takes more than dieting à la Sears to experience a "flow" state or to "Enter the Zone."

I suggest a detour.

NF contributing editor James J. Kenney, Ph.D., R.D., is a nutritionist at the Pritikin Longevity Center in Santa Monica, California, and vice-president of The National Council Against Health Fraud.

Editor's Note

NUTRITION FORUM has been renamed NUTRITION AND HEALTH FORUM. The new name represents the somewhat different direction the newsletter has taken since I became coeditor in early 1994.

For years, I have had a "bee in my bonnet": unnaturalistic healthcare, the subject of *NF*'s now-defunct "Healthcare Esoterica" series. Producing the related index in the previous issue of *NF* enabled me to complete *The Dictionary of Metaphysical Healthcare*, a compilation of about 1,100 descriptions of mystical and supernaturalistic methods related to health. This book, edited by *NHF*'s Dr. Kroger and published by The National Council Against Health Fraud, is available—in printed form and in an expanded diskette version—through LVCAHF, Inc.: (610) 437-1795.

Update: *BioZone* bars, to which Dr. Kenney refers in this issue, are passé. On September 11, I received a mailing from Barry Sears that included a leaflet from Eicotech Foods and Nutrition Products (whose address matches that which *The Zone* gives for Surfactant Technologies). The leaflet portrays the "EicoZone Meal Replacement Bar" as "the easiest, most convenient and delicious way to enter the Zone." Later that day, I phoned the toll-free number in the book. In a prerecorded message, Sears described the EicoZone Bar as "similar to the prototype bar mentioned in my book, but now far more technically advanced." *Mastering the Zone*, a sequel, will become available early next year—*J.R.*

In the Next Issue:

"Why I Am Not a Vegetarian"

WHY I AM NOT A VEGETARIAN

William T. Jarvis

Vegetarianism has taken on a “political correctness” comparable to the respectability it had in the last century, when many social and scientific progressives advocated it. Today, crusaders extol meatless eating not only as healthful but also as a solution to world hunger and as a safeguard of “Mother Earth.” The Physicians Committee for Responsible Medicine (PCRM) aggressively attacks the use of animal foods and has proposed its own food-groups model, which excludes all animal products. Several scientific conferences have focused on vegetarian health. And nutrition policymakers have urgently recommended that people eat more fruits and vegetables.

I disclaimed vegetarianism after many years of observance. Although the arguments in favor of it appear compelling, I have learned to be suspicious, and to search for hidden agendas, when I evaluate claims of the benefits of vegetarianism. Vegetarianism is riddled with delusional thinking from which even scientists and medical professionals are not immune.

Don’t get me wrong: I know that meatless diets can be healthful, even desirable, for some people. For example: (a) Men with an iron-loading gene are better off without red meat, because it contains *heme iron*, which is highly absorbable and can increase their risk of heart disease. (b) Because vegetarian diets are likely to contain less saturated fat than nonvegetarian diets, they may be preferable for persons with familial hypercholesterolemia. (c) Vegetables contain phytochemicals that appear protective against colorectal cancer. (d) Homocysteinemia (elevated plasma homocysteine) approximately doubles the risk of coronary artery disease. Several congenital and nutritional disorders, including deficiencies of vitamins B₆ and B₁₂ and folic acid, can cause this condition. Since folic acid occurs mostly in vegetables, low intakes of the vitamin are less likely among vegetarians than among nonvegetarians. (e) Some people find that being a vegetarian helps to control their weight. Vegetarianism tends to facilitate weight control because it is a form of food restriction; and in our overfed society, food restriction is a plus unless it entails a deficit of some essential nutrient.

However, one need not eliminate meat from one’s diet for any of the foregoing reasons. Apparently, it is ample consumption of fruits and vegetables, not the exclusion of meat, that makes vegetarianism healthful.

Dog Day Afternoon?

The term “vegetarian” is misleading, for it is not a name for people who favor vegetable consumption, but a code

word for those who *disfavor* or protest the consumption of animal foods. The neologism *anticarnivorist* better characterizes the majority of those who call themselves vegetarians. I call myself a “vegetable enthusiast,” because I strongly encourage eating lots of vegetables, including legumes, whole grains, and fruits. I believe that these foods are desirable not only because of their high nutrient density and low caloric density, but also because of aesthetic and gustatory factors. Being a vegetable enthusiast doesn’t entail rejecting the use of meat or animal products.

Most people who categorize vegetarians identify at least five different kinds, based on which types of animal food they consume: *Semivegetarians* consume dairy products, eggs, fish, and chicken; *pesco-vegetarians* consume dairy products, eggs, and fish; *lacto-ovo-vegetarians*, dairy products and eggs; *ovo-vegetarians*, eggs; and *vegans*, no animal foods except honey. From a behavioral standpoint, I categorize vegetarians as either *pragmatic* or *ideologic*. A *pragmatic vegetarian* is one whose dietary behavior stems from objective health considerations (e.g., hypercholesterolemia or obesity). Pragmatic vegetarians are rational, rather than emotional, in their approach to making lifestyle decisions. In contrast, vegetarianism is a “matter of principle” for *ideologic vegetarians*; its appropriateness is a given.

One can spot ideologic vegetarians by their exaggerations of the benefits of vegetarianism, their lack of skepticism, and their failure to recognize (or their glossing over of) the potential risks even of extreme vegetarian diets. Ideologic vegetarians make a pretense of being scientific, but they approach the subject of vegetarianism more like lawyers than scientists. Promoters of vegetarianism gather data selectively and gear their arguments toward discrediting information that is contrary to their dogma. This approach to defending a position is suitable for a debate, but it cannot engender scientific understanding.

Because of the influence of my Seventh-day Adventist (SDA) environment, I practiced vegetarianism for many years. My wife and I even tried to give up consuming all animal products, but this didn’t work. We sometimes muse aloud about the morning we put soymilk on our breakfast cereal. We ended up eating the cereal with a fork because we found the mixture repulsive. We had another unforgettable experience when we ate with a group of vegetarian hippies in the Oregon woods. We were there at their request to advise them on vegetarian eating. They had already prepared the worst-looking vegetarian stew I have ever seen or tasted. It consisted of raw peanuts and a

variety of half-cooked vegetables. After eating it, I had heartburn for hours.

Digestive distress is legendary among SDAs. The heroic attempts by the faithful to chow down on experimental meat substitutes were, to me, a major tip-off that health was not the thrust of their vegetarianism.

Reasons for adopting vegetarianism can be very personal. Some years ago I shared a podium for several days with a vegetarian. It became clear from our informal conversations that he was not religious; so I asked him why he had opted for vegetarianism. He told me a touching story about having been a lonely boy whose closest companion was his pet dog. He said that, one day, as he peered into the dog's eyes, he had come to see the animal as a fellow being. Soon he had applied this view to all animals, and since he could not bear the thought of eating his dog, he could no longer eat other animals.

North by Northwest

Darla Erhardt, R.D., M.P.H., listed five vegetarian postulates: (1) All forms of life are sacred, and all creatures have a right to live out their natural lives. (2) It is anatomically clear that God did not design humans to eat meat. (3) Slaughter is repugnant and degrading. (4) Raising animals for meat is inefficient and misuses available land. (5) Animal flesh is unhealthy because it contains toxins, virulent bacteria, uric acid, impure fluids, and the wrong kinds of nutrients.¹

I find all of these axioms flawed:

(1) The belief that all life is sacred can lead to absurdities such as allowing mosquitoes to spread malaria, or vipers to run loose on one's premises. Inherent in the idea that all life is sacred is the supposition that all forms of life have equal value. The natural world reveals hierarchies in the food chain, the dominance of certain species over others. And most creatures in the wild die (usually the victim of a predator) long before they have reached the genetic limit on their longevity.

(2) The multifarious dietary practices of human populations belie the notion that humans are designed to be vegetarians rather than omnivores. For example, Australian aborigines consume insect larvae and reptiles, Eskimos eat raw meat, and traditional Hindus are vegetarians.

The first SDA physician, John Harvey Kellogg (1852–1943), was a vegetarian zealot. Alonzo Baker, Ph.D., his former private secretary, told me of an incident that occurred circa 1939: Kellogg awakened him in the middle of the night and ordered him to board the morning train for Cleveland. There, Weston Price, D.D.S. [see NF 13:22, 1996], who had just returned from the mysterious high north, was to give a report on Eskimo dietary habits. When Baker returned, he informed Kellogg of Price's finding that Eskimos ate raw meat almost exclusively (*eskimo* literally means "raw meat eater"). Kellogg accused Price of lying.

Perhaps Kellogg disbelieved Price partly because it was widely known that the 1898 Yukon gold rushers had suffered extensively from scurvy. People generally believed that Eskimos derived their vitamin C from berries the snow had preserved. In fact, Eskimos derive vitamin C from the raw meat of animals who synthesize ascorbic acid. If they had cooked their meat, they would have developed scurvy like the gold rushers. (When I visited Northwest Territories, Canada, in 1973, a Franciscan monk who raised beautiful vegetables in a greenhouse in Pelly Bay told me that the Inuits [North American Eskimos] didn't like their taste and wouldn't eat them.)

(3) Whether something is repugnant is highly individual. Hindus who will not eat animal foods readily drink their own urine for the sake of health. And what is repugnant—for example, chores such as changing a baby's diaper or caring for sick people—is not necessarily wrong. Whether such activities are degrading is a matter of opinion. That most prey are eaten while they are still alive testifies to the heartlessness of nature compared to slaughterhouses, where death is generally quick and painless.

(4) The idea that animal-raising is an inefficient way to produce food is half-baked. Animals pull their weight when it comes to land-use and food-production efficiency: They graze on lands unsuitable for crop-growing, eat those portions of plants that are considered inedible (e.g., corn stalks and husks), and provide byproducts and services that ease human burdens.² Many nomadic populations survive on lands that lack farming potential by feeding on animals whose nourishment is coarse vegetation humans can't digest.

(5) The postulate that toxins render meat unfit as food also lacks merit. Plants also contain naturally occurring toxicants, many of which are far more deadly than those of animal flesh.³ Vegetarian evangelists who revel in portraying animal foods as unhealthy disregard the fact that those societies that consume the most animal products enjoy record longevity. They also overlook the reality that the animals they brand as diseased are herbivores whose diet consists entirely of raw vegetation. These animals develop many diseases "despite" becoming vegans after weaning.

Ideologic Vegetarianism

Much of my professional life has been spent studying health fraud, quackery, and related misinformation, and their impact on people's lives. Aware that one's personal philosophy can be a powerful determinant of health, I have tried to

Nutrition and Health Forum (ISSN 1091-2428), © 1996 Prometheus Books, is published bimonthly for \$35.00 (individuals in U.S. and Canada) or \$50 (institutional, overseas) per year by Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197. understand the psychosocial dynamics of the suffering and death that people impose on themselves and their children. I have been struck by how often vegetarianism has been a part of such situations, and I have discerned a recurrent sequence of behaviors: First, the concerned person eliminates reportedly unhealthy foods from his or her diet, beginning with foods that society considers “bad for you” (e.g., sugar, coffee, and white bread). Next, if concerns about food safety grow to neurotic proportions, the person scrutinizes labels and worries about ingredients indicated by terms he doesn’t understand. Then he may patronize health food stores, where clerks and publications can feed his phobias. He may treat modern foods as poisonous. Finally, if he deems vegetarianism not restrictive enough, the “health foodist” may turn to veganism [see NF 13:34–36, 1996]. In my opinion, it is at this point that vegetarianism becomes hazardous, especially for children.

The case of Sonja and Khachadour Atikian illustrates what can happen to those seduced by ideologic vegetarianism. The Atikians were émigrés from Lebanon who—because of unrelenting media barrages focusing on environmental pollution, diet, and health—became overly concerned about the safety and healthfulness of modern foods. Sonja Atikian began shopping at health food stores instead of supermarkets. Gerhard Hanswille, a self-styled herbalist from Germany, taught classes in the rear of a health food store she patronized. Although Hanswille was not licensed to practice medicine, he saw 40 to 45 “patients” day. He treated Ms. Atikian for a sore knee, and she took some of his courses. Hanswille taught that: (a) people should not kill animals, nor consume animal products; (b) God intended cow’s milk to be food for calves, not human babies; (c) eating eggs deprives hens of fulfilling their divinely intended role as mothers; (d) people should not poison themselves or the earth with the unnatural products of modern living; (e) using herbs both as food and as medicine is God’s way; and (f) the medicines of doctors are poisons. “Choose whom you will believe,” said Hanswille, “me or the doctors. You can’t have it both ways.”

Ms. Atikian chose poorly. Except for eating fish occasionally, she followed the herbalist’s advice during pregnancy. She delivered a healthy 8.2-lb girl named Loreie. Hanswille convinced the Atikians that the newborn would become a superbaby if they gave her a vegetarian diet of raw, organic foods. He dissuaded them from having the infant immunized and from continuing to see a pediatrician. And he induced them to rely on him for healthcare advice.

Four and a half months after her birth, Loreie’s weight

was still at the 75th percentile, but when she was 11 months old, breast-feeding—her sole source of animal food—discontinued. Fed only fruits, vegetables, and rice, she eventually stopped growing, slept more and more, and had more and more infections. As the baby’s health spiraled downward, Hanswille assured the parents that her decline was merely “the poisons coming out of her body” and that she would eventually become the superbaby they desired. In 1987, 17-month-old Loreie died of bronchial pneumonia complicated by severe malnutrition. She weighed 11¼ lbs. The Atikians were charged with failing to provide their daughter with the “necessaries of life.” Their defense was that they had truly believed they had been providing the “necessaries of life” when they followed Hanswille’s advice. The judge acquitted them after the discovery that the prosecution had failed to provide important information supporting the couple’s story.

Let’s run through some other examples of ideologic vegetarian extremism:

- It caused mental and growth retardation in two boys underfed from birth to ages 3 and 5. Their mother had become a vegetarian, later eliminated sugar and dairy products from her diet, and eventually adopted a macrobiotic diet.⁴
- Ten cases of nutritional rickets were reported among infants (most of whom were breast-fed) of strict-vegetarian mothers who had not sought medical counsel during pregnancy but had obtained advice from health food stores.⁵
- Scurvy and rickets occurred in two boys, 1½ and 2½ years old, whose parents were adherents of the Zen Macrobiotic diet [see NF 7:17–21, 1990].⁶
- A 36-year-old former college professor who was a follower of the Temple Beautiful diet died of malnutrition attempting to become a “breatharian”—one who supposedly feeds on air alone. First he became a vegetarian, then a fruitarian, then a “liquidarian” (consuming juices only), and finally, a would-be breatharian.⁷
- A 2-month-old boy died because his mother, following the invalid recommendation for colic in Adelle Davis’s *Let’s Have Healthy Children*, overdosed him with potassium.⁸ In a television interview, the mother said that, as she became increasingly estranged toward conventional medicine, she had adopted vegetarianism and then veganism.
- A 24-year-old woman who was head of San Jose State University’s student art program died after taking an extract

of pennyroyal to induce an abortion. She was described as “a strict vegetarian who was involved in holistic medicine.”⁹

A review of the literature includes reports of cases in which vegetarian zealotry played a role in harm to a child.¹⁰

For the ideologist, vegetarianism is a hygienic religion. It enables believers to practice self-denial. As a religion, vegetarianism attracts the guilt-ridden. It attracts masochists because it gives guilt a boost. And it seduces the unskeptical by causing guilt and/or by instilling false guilt. Guilt leads to self-denial, even asceticism. The belief that salvation is attainable by eschewing worldly pleasures marked the asceticism of early Christian zealots. Similarly, health neurotics with medical problems seem to believe that the more they restrict their alimentary pleasures, the more their health will improve. Fasting, austere diets, enemas, and the ingestion of bitter herbs are consistent with the psychological needs of health neurotics, many of whom shun those voices of conventional medicine and public health that might disenchant them.

Of course, I don't blame ideologic vegetarianism *per se entirely* for tragedies such as those outlined above. Mental or emotional disorders apparently figure in many instances. In such cases, extremism is more to blame. However, this doesn't take ideologic vegetarianism off the hook, for it is a potential fuel for, and a potential igniter of, psychological problems.

Eating by the Book?

SDA vegetarianism is rooted in the Bible, according to which for food God gave humans “all plants that bear seed everywhere on earth, and every tree bearing fruit that yields seed” (Genesis 1:29). Meat is said to have become a part of the human diet after the Flood, when all plant life had been destroyed: “Every creature that lives and moves shall be food for you” (Genesis 9:3). Adventists are taught that the introduction of meat into the human diet at that time decreased the human life span from the more than 900 years of the first humans to today's “three-score and ten.”

However, the Bible warns against confusing dietary practices with moral behavior:

For the kingdom of God is not food and drink but righteousness and peace. (Romans 14:17)

Let no one pass judgment on you in questions of food and drink. (Colossians 2:16)

One believes he may eat anything, while the weak man eats only vegetables, let not him who eats despise him who abstains, and let not him who abstains pass judgment on him who eats. (Romans 14:2-4)

It also seems to condemn vegetarianism:

The Holy Spirit tells us clearly that in the last times some in the church will turn away from Christ and

become eager followers of teachers with devil inspired ideas. These teachers will tell lies with straight faces and do it so often that their consciences won't even bother them. They will say that it is wrong to be married and wrong to eat meat, even though God gave these things to well-taught Christians to enjoy and be thankful for. For everything God made is good, and we may eat it gladly if we are thankful for it. (1 Timothy 4:1-4, *Living Bible*)

SDA Church pioneer Ellen G. White (1827–1915) was a proponent of vegetarianism even though she did not practice it herself. Like the Grahamites of her time, she taught that gradually the earth would become more corrupted, diseases and calamities worse, and the food—particularly animal foods—unsafe. In 1902 she wrote that the time might come when the use of milk should be discontinued. Although White was an advocate of science and chiefly responsible for making SDA healthcare a science-based enterprise, clearly she did not anticipate twentieth-century advances in public health and medical science. Despite the record longevity now enjoyed by people in the developed nations, vegetarian zealots within the church caught up in the doomsday hysteria of the 1990s have decided that the time has come to give up all animal foods and are fervidly preaching veganism.

East of Eden

It is now widely recognized that it is possible to provide all essential nutrients except vitamin B₁₂ without using animal foods. It is noteworthy, however, that it is possible to provide all essential nutrients with a diet composed only of meat. Personal dietary appropriateness—including the value of a diet as a source of essential nutrients and its value as a preventative—for oneself and one's significant others is the foremost dietary consideration of pragmatic vegetarians. In contrast, the overriding dietary consideration of ideologic vegetarians varies with the particular ideology. Typically, their motivation is a blend of physical, psychosocial, societal, and moral, often religious, concerns.

A continual problem for SDAs who espouse the “back to Eden” ideology is the absence of a non-animal food source of vitamin B₁₂. A Registered Dietitian, a vegetarian who wrote a column for a church periodical, asked me if I thought vegans could derive vitamin B₁₂ from organic vegetables that were unwashed before ingestion. I opined that it would be better to eat animal foods than fecal residues. She agreed.

A perennial assumption among vegetarians is that vegetarianism increases longevity. In the last century, Grahamites—devotees of the Christian “hygienic” philosophy of Sylvester Graham (1794-1851)—taught that adherence to the Garden of Eden lifestyle would eventuate in humankind's reclamation of the potential for superlongevity, such as that

ascribed to Adam (930 years) or Methuselah (969 years). I discussed this matter 25 years ago with an SDA physician who was dean of the Loma Linda University (LLU) School of Health. Although he admitted that lifelong SDA vegetarians had not exhibited spectacular longevity, he professed that longevity of the antediluvian sort might become possible over several generations of vegetarianism. SDA periodicals publicize centenarians and often attribute their longevity to the SDA lifestyle. However, of 1200 people who reached the century mark between 1932 and 1952, only four were vegetarians.¹¹ I continue to ask: Where on Earth is there an exceptionally longevous population of vegetarians? Hindus have practiced vegetarianism for many generations but have not set longevity records.

At best, the whole of scientific data from nutrition-related research supports vegetarianism only tentatively. The incidence of colorectal cancer among nonvegetarian Mormons is lower than that of SDAs.¹² A review of populations at low risk for cancer showed that World War I veterans who never smoked had the lowest risk of all.¹³ As data accumulate, optimism that diet is a significant factor in cancer appears to be diminishing. An analysis of 13 case-control studies of colorectal cancer and dietary fiber showed that, for the studies with the best research methods, risk estimates for dietary fiber and colorectal cancer were closer to zero.¹⁴ A pooled analysis of studies of fat intake and the risk of breast cancer that included SDA data showed no association.¹⁵

A meatless diet can facilitate weight control because it is a form of food restriction. But one need not eliminate meat to maintain a healthy weight, and there are many overweight vegetarians. Surely prudence and selectivity overshadow mere abstinence from animal products.

In an interview on the school's Christian radio station in the mid-1970s, an LLU nutrition graduate student (who was not an SDA) claimed that vegetarianism produced superior intellects. To make her case, she stated:

Linus Pauling says that vitamin C improves intelligence. Vegetarians get more vitamin C in their diets than meat-eaters. The probable reason why George Bernard Shaw and Leo Tolstoy were brilliant was because they were vegetarians.

The interviewer agreed, extolling the health and intellect of vegetarians. That Adolf Hitler was a vegetarian went unmentioned during the interview. Also unmentioned was that Jesus Christ, Mohammed, and other eminent moralists were not vegetarians. Animal behavioral scientists have noted that, to survive, meat-eating predators must outsmart their vegetarian prey. However, I believe that all such theories break down because of the difficulty of defining intelligence.

Among the claims of vegetarian superiority that SDAs have made again and again is that most beasts of burden are herbivorous. They note that meat-eating predators such as

wolves and lions have tremendous speed but lack endurance. However, Arctic sled dogs that run the 1200-mile Iditarod cover more than a hundred miles per day—a feat no horse, mule or ox can accomplish.

The idea that vegetarians have superior physical endurance was reinforced in 1974 when a group of male vegetarian runners called “the vegetarian seven” set a 24-hour distance record. This inspired an undergraduate dietetics major to seek me out as a coach for a group of seven female vegetarian long-distance runners. I asked her what their motivations were—something every coach needs to know. She said they wanted to demonstrate the superiority of a vegetarian diet. I asked who would be representing the meat-eaters. She said that, because the event would not be a standard competition, no one would represent the meat-eaters. I revealed to her that three of the male runners had not been vegetarians until training for the record-setting event but merely had pledged to become so. I also told her: that genetic factors, principally the capacity for oxygen uptake, determine distance-running ability; that whether a diet is vegetarian is inconsequential to distance-running ability; and that a 24-hour run is a perilous way to try proving vegetarian superiority. “What will you do,” I inquired, “if seven meat-eating, beer-drinking atheists who are world-class runners decide to beat your record?” She got the point. And although she became an accomplished amateur runner, she didn't use her success to propagandize for vegetarianism.

John Harvey Kellogg sought to prove that vegetarians were physically superior by fielding a Battle Creek College football team, which he personally coached. According to a former player, “Brother” Wright, whenever Kellogg's players lost, he railed at them for cheating on their diets and held them captive until one would say he had broken training rules and eaten meat. Wright stated that sometimes a player would eventually lie that he had eaten meat just to get the team released. He described Kellogg's efforts as “a crusade to prove the superiority of vegetarianism.” Ellen G. White's condemnation of this approach to proving SDA superiority led to a policy restricting interscholastic sports by Adventist schools.

Odorless Doo-doo?

The John Harvey Kellogg character in the film *Road to Wellville* stated that his feces had no more odor than that of “freshly baked biscuits.” One evening I offered a ride home from the university to an elderly colleague, an avid vegetarian. Upon entering my car, he declared: “When I drink carrot juice, my bowel movements have no odor.” Before I could respond, he said: “Rabbits eat lots of carrots, and their feces have no odor.” The thought of someone running around sniffing little piles of rabbit doo-doo almost made me laugh, but I didn't want to be disrespectful. His idea that rabbits eat many carrots intrigued me. I had raised them in my boyhood and discovered that, despite the passion for carrots shown by Bugs Bunny, real

bunnies are not particularly fond of carrots. Furthermore, wild rabbits seldom would have an opportunity to eat carrots. Luckily the ride was short.

The late Pulitzer Prize-winning anthropologist Ernest Becker argued that defecation is most closely associated with humankind's animality and mortality.¹⁶ During a Bible class at an SDA school, I was taught that people did not defecate in the Garden of Eden but utilized the food they ingested in its entirety. Apparently, foul odors did not befit Paradise. (Perhaps the persistence of the miasmatic theory of disease—the theory that diseases are due to foul-smelling emanations from the earth—well into the nineteenth century, when SDA beliefs were developed, reinforced the idea of a poopless Paradise.) I was also taught that roughage became part of the human diet after the Fall. Allegedly, this broadening of the diet to include “the herb of the field” (Genesis 3:18, King James version) occurred because humans were now under the “death sentence” caused by original sin. Whether this reportedly was a voluntary dietary change or part of the curse of being ousted from Paradise is debatable. Some versions of the Bible imply that “the herb of the field” merely meant “wild foods” (New English Version), not a new source of food.

Heavy “PETAing”

In the last century, the pacifist movement was vegetarian because of the belief that meat-eating animals were fierce and vegetarian animals were docile. The British poet Percy Bysshe Shelley claimed that the French revolution had been bloody and the English revolution bloodless because the French ate more meat than the English.¹⁷ Such invalid notions have been discredited, but not abandoned. Some boxers still eat raw meat or drink blood before a fight to increase their aggressiveness.

People who fancy themselves morally superior often have a mission to convert humanity to their worldview. The most violent ideological vegetarians are the animal-rights activists, who have destroyed animal research facilities and threatened researchers' lives. Animal-rights groups such as People for the Ethical Treatment of Animals (PETA) consider animals on par with humans. On April 24, 1996, PETA's Ingrid Newkirk appeared on the television newsmagazine *Day & Date* opposing sport fishing. She began her argument by seeking commiseration for suffocating fish. Then she said that fish were unhealthful food because they contained mercury and other environmental contaminants. The solution, according to Newkirk, was vegetarianism. Her opponent, a TV talk-show host, pressed her into acknowledging the PETA creed. The talk-show host described an on-air encounter she had had with another PETA representative. A scenario had been presented in which the representative's daughter needed a vital organ from a beloved household pet in order to survive. The ethical question had been whether the child's life was

worth more than the pet's. The PETA representative had held that the child had no more value than the pet. Newkirk did not contest the assertion that PETA considers the life of a child no more valuable than that of a pet.

When an LLU medical team transplanted a baboon's heart into an infant whose pseudonym was “Baby Fae,” animal-rights activists picketed the medical center. They seemed disillusioned with SDAs, who have no qualms about prioritizing humans over animals. In October 1992, after a pig's liver had been transplanted into a 30-year-old woman to enable her to survive until a human liver was secured, a representative of PCRM engaged in a televised debate with one of the physicians who had performed the transplant. The representative lamented that the pig's consent had not been obtained.

PCRM appears to be largely a personal forum for its leader, Neal Barnard, M.D., and is said to be substantially funded by PETA. (In fiscal year 1994, donations and grants to PCRM reportedly totaled more than a million dollars.¹⁸) Barnard extols the longevity value of vegetarianism. He has claimed: “It's not genetics or fate that gives people long, healthy lives and cuts other people short; for those who want to take care of themselves, it all comes down to diet.” The surgeon argued that pigs were killed daily for meat, including their livers. The PCRM doctor retorted that the consumption of animal fat (which is highly saturated) was responsible for most deaths in modern society. He cited a study conducted by Colin Campbell in China. Campbell had focused on the relative morbidity for certain diseases without pointing out that life expectancy in China (66 years) is lower than that in the United States (75 years).¹⁹

Because they consider themselves morally superior, many vegetarians exhibit no reservations against using mind-control techniques or terrorism to actualize their agenda. Mind control includes using information selectively to “educate” people about the alleged superiority of vegetarianism. It may also include traumatizing people emotionally to condition them against the use of animal foods. Early in my teaching experience, I attended a meeting of SDA secondary school health teachers where many said that they converted students to vegetarianism by taking them on field trips to slaughterhouses to witness the bloodshed. This strategy offended me even though I was a practicing vegetarian at the time. Having studied for years how people have been manipulated by cults and quacks, it is now clear to me that the slaughterhouse tactic is a form of mind control—that it is as unethical as discouraging little girls from having sex by inducing them to watch a difficult childbirth.

Terrorism involves trying to coerce people to behave in ways the perpetrators desire. In December 1994, to keep people from having turkey for Christmas dinner, self-described animal-rights terrorists claimed they had injected rat poison into supermarket turkeys in Vancouver, British Columbia. The scare caused the destruction of more than \$1 million in turkeys. Apparently, the activists had not foreseen the ensuing slaughter of turkeys as replacements.

Disclosure

Research into vegetarianism by vegetarians always involves at least unconscious bias. All humans have entrenched beliefs—beliefs whose rootedness makes doing related scientific research unwise. Kenneth J. Rothman, Dr.P.H., referred to SDAs in a recent discussion of conflicts of interest in research:

We might expect conflict of interest concerns to be raised, for example, about Seventh Day Adventists who are studying the health effects of the comparatively abstemious lifestyle of their fellow Adventists. Whereas policies at [the *Journal of the American Medical Association*] and *The New England Journal of Medicine* emphasize financial conflicts, *Science* asks authors to divulge “any relationships that they believe could be construed as causing a conflict of interest, whether or not the individual believes that is actually so.” In other words, to comply with disclosure policies at *Science*, authors might need to disclose to editors their religion and sexual orientation along with their financial portfolio.²⁰

Although Rothman argues for letting work stand on its own merit rather than judging cynically any possible connection to a funding source, his example makes the point that motivations more powerful than money can distort data. Science fraud can be extremely difficult to detect, because the perpetrators control the information. Mark Twain observed: “Figures don’t lie, but liars figure!”

I don’t believe that *all* research done by vegetarians is untrustworthy. My experience with the ongoing Seventh-day Adventist Health Study (SDAHS), a series of studies conducted from LLU School of Public Health, has been largely positive. Its chief researcher, the late Roland Phillips, M.D., Dr.P.H., was an outstanding scientist in whose objectivity I had the utmost confidence. He recognized the problem of the influence of social expectations on SDAs responding to questions about their lifestyle. Adventist groupthink makes it likely that SDAs will underreport activities disfavored by the church community (e.g., meat-eating, coffee drinking, and imbibing) and overreport those that are approved (e.g., dining meatlessly and exercising). Phillips seemed to feel that the benefits of vegetarianism per se were limited, and that one must take account of heredity, socioeconomic status, and the total SDA lifestyle. Abstinence from tobacco, access to state-of-the-art healthcare, and strong social support probably are responsible for most of the health benefits SDAs enjoy. The main problem with SDA vegetarian science is how the scientific information is used. To paraphrase

an old Pennsylvania Dutch saying: Among SDAs, when the news about vegetarianism and health is good, “we hear it ever”; when the news is not good, “we hear it never.”

I have received numerous reports from SDA health professionals, and have personal knowledge of other cases, in which church members’ overconfidence in vegetarianism prevented them from obtaining effective medical care. Some reports have involved true believers in vegetarianism who were members of physicians’ families. Some denied symptoms, and their denial kept them from seeking effective intervention in time. Others rejected medical care for “natural remedies” that emphasized diet. The attitudes evidenced are consistent with those identified in cancer patients who had turned to quackery because they believed they had brought the disease upon themselves and could cure it by “natural” practices.²¹ The SDA Church has bent over backward to document the benefits of the SDA lifestyle and to persuade members to adopt vegetarian diets. I would like to see the church seek earnestly to expose the harm that its vegetarian teachings have caused its members. Alas, there’s the rub with ideologic vegetarianism: Objectivity always takes a back seat to proselytism.

The data suggest that most SDAs are reasonable in their approach to vegetarianism. In the 1970s, the SDAHS revealed that only one percent were vegans.²² This may change as vegetarianism becomes more popular in the general population. SDAs tend to be overachievers. If we regard something as “good,” we strive to adopt it completely. If we consider something “bad,” we avoid it completely. SDA vegetarian evangelists have become more aggressive in recent years because of the widespread belief in the SDA community that doomsday is nigh.

I recall an SDA church leader’s reply to the question of whether he ate meat: “I eat just enough to keep me from becoming a fanatic!” This impresses me as good advice for body, mind, and society.

One Less “Ism”

I gave up vegetarianism because I found that commitment thereto meant surrendering the objectivity that is essential to the personal and professional integrity of a scientist. As a health educator, I feel I have an obligation to endeavor to stick to whatever unvarnished facts scientific research uncovers. I can support pragmatic vegetarianism, but I believe that crusading vegetarian ideologues are a danger to themselves and to society.

William T. Jarvis, Ph.D., is a professor of public health and preventive medicine at Loma Linda University and founder and president of The National Council Against Health Fraud.

Readers' Forum

Dear Mr. Raso,

I would like to comment on the letter from Ruth Rosevear that appeared in the May/June 1996 issue of *NF*. I am very sorry about the tragedy of her daughter's lifelong impairment and untimely death, and I have no doubt that it resulted from Ms. Rosevear's inadequate vegan diet during pregnancy. I believe that it takes careful planning to make an all-plant diet adequate during pregnancy, and there would certainly be a need to supplement with vitamin B₁₂, and perhaps also with vitamin D, calcium, iron, and zinc. It seems that virtually all obstetricians today require their pregnant patients to take a prenatal vitamin/mineral supplement (whether or not they are vegetarian). I don't know what the practice was in 1942, but consider that vitamin B₁₂ was not even discovered until 1951. Therefore, in 1942, it was impossible to make any vegan diet adequate during pregnancy.

There certainly are vegan women today who have given birth to normal, healthy babies. Much documentation exists pertaining to a vegan community in Tennessee called "The Farm." Medical records have demonstrated not only normal births, but also normal, healthy development for these vegan children, and normal percentiles for height and weight and other variables. At The Farm, they make ample use of highly digestible soy protein products, whole grains, and vegetables, and they supplement with vitamin B₁₂. However, I am still of the opinion that if a woman is not fully adapted to a vegan diet, it is unwise for her to switch to it radically at the time of pregnancy.

But the most important thing I have to say is that there is ample evidence that low-fat vegan diets have benefited nonpregnant adults who have suffered from hypertension, cardiovascular disease, rheumatoid arthritis, gout, adult-onset diabetes, and a host of other chronic diseases. It would be a shame, as you suggested, if Ms. Rosevear's letter fostered "a blanket condemnation of veganism."

Ralph C. Cinque, D.C.
Buda, Texas

While I do not regard voluntary veganism as condemnable across the board, I do consider it an unnecessary extreme. The Farm, by the way, gave us spiritual midwifery [sec NF 12:30, 1995].—J.R.

SHARK CARTILAGE THERAPY AGAINST CANCER

Saul Green

Shark cartilage has displaced laetrile [see NF 12:56, 1995] as the cancer pseudocure of choice. Reportedly, more than 25,000 people a year buy shark-cartilage pills and powders at health food stores.¹ The most influential proponent of so-called shark cartilage therapy is entrepreneur I. William Lane, Ph.D., the coauthor of two books: *Sharks Don't Get Cancer* (1992) and *Sharks Still Don't Get Cancer: The Continuing Story of Shark Cartilage Therapy* (1996). Lane claims or suggests that shark cartilage therapy is effective against osteoarthritis, rheumatoid arthritis, psoriasis, enteritis (inflammation of the intestinal tract), certain eye diseases (e.g., diabetic retinopathy), Kaposi's sarcoma, and cancer of the breast, cervix, uterus, ovary, prostate, kidney, liver, and central nervous system.

Proponents allege that shark cartilage works by inhibiting the formation of blood vessels.

Angiogenesis

The continual emergence of cells in a tumor—cells that are different from their parent cells and that therefore may be resistant to conventional cancer therapy—is the main impediment to successful treatment of advanced cancer. A potential effective approach to cancer is to alter the microenvironmental processes on which tumor growth depends.

Research conducted by Judah Folkman, M.D., in the early 1960s showed that the growth of some solid tumors depends on the formation of blood vessels around the tumor.^{2,3} The term for this complex process is *angiogenesis*. Folkman's work revealed that tumors produce substances that trigger angiogenesis in adjacent tissues and cause the new blood vessels to converge on and enter the tumor.⁴ Folkman hypothesized that inhibition of any step in angiogenesis could be the basis for a mode of cancer

therapy.⁵ Researchers recognized early that angiogenesis occurs only infrequently in normal tissues and that, because normal tissues contain natural inhibitors of angiogenesis, the process concludes after a bed of capillaries has formed. (Angiogenesis normally takes place, for example, during chronic inflammation, wound healing, ovulation, and replacement of intestinal and retinal cells.) In contrast, tumor angiogenesis is not self-limiting; it continues until the tumor is removed or the host dies.⁶

Numerous agents trigger angiogenesis. Besides tumor cells, biological sources of such substances include activated phagocytes (cells that can engulf bacteria and foreign particles), white blood cells, endothelial cells (cells that line particular bodily cavities), and immune system cells in tissue that adjoins a wound or tumor.⁷

Solid tumors require angiogenesis for growth because of their high density (10^8 – 10^9 cells per cubic centimeter); tumor cells that grow separately from one another (as in leukemia) do not.⁸

Since angiogenesis is not unique to tumors, each of its steps represents an opportunity to stop tumor growth by interrupting the process. An inhibitor might:

- prevent the formation, release, or transmission of the angiogenic signal;
- arrest the process by which the signal triggers angiogenesis;
- restrain synthesis of proteins that are structurally essential to blood vessels;
- prevent attachment of new blood vessels to normal tissues; or
- prevent entry of new blood vessels into cancerous tissues.

By *in vitro* experiments, researchers have identified a number of substances that inhibit one or more of these steps. Most of these substances have been isolated, purified, and chemically characterized (vitamin D₃ analogs and sulfated chitin derivatives, for example).^{9,10,11} Three are being tested clinically as treatments for AIDS-related Kaposi's sarcoma.¹²

Angiogenesis Inhibitors in Cartilage

Scientists recognized in 1945 that tumors induce angiogenesis,¹³ but three decades passed before they identified the mechanisms. In 1973 Robert Eisenstein and associates presented the first experimental evidence that cartilage contains inhibitors of angiogenesis.¹⁴ Eisenstein found that, after extraction with the metabolite guanidine, cartilage—which normally does not contain blood vessels—lost its ability to prevent invasion by blood vessels. Eventually researchers learned that cartilage contained certain bioactive enzyme inhibitors.^{15,16} In 1975 Folkman and a colleague found evidence for the presence of an inhibitor of tumor-induced angiogenesis in cartilage from newborn calves.¹⁷ Subsequently, Robert Langer and associates isolated and partially purified an inhibitor from calf cartilage¹⁸ and showed that, after injection into the area around tumors in mice or rabbits, it stopped tumor growth.¹⁹

The scarcity of available cartilage from bony mammals, however, limited the scope of scientific study; thus many researchers considered using shark cartilage instead. Consequently, Langer and a colleague discovered that shark cartilage contains an antiangiogenic agent.²⁰ Despite numerous confirmations of their finding, however, the identity of the inhibitor, the site of inhibition, and clinical proof of its efficacy against cancer in humans have not been reported in the scientific literature.

Shark-Infested Waters?

Alas, sharks rush in where scientists fear to tread. The titles of Lane's two books are misnomers: Sharks do get cancer. Lane himself admits this, but soft-pedals it, in both books. Various forms of cancer in sharks have been reported.^{21,22,23} Indeed, researchers have observed that chondrosarcoma—cancer of the cartilage—is common to all species of shark.

Lane's conclusion that shark cartilage powder can stop tumor growth in humans did not arise from his own research but from the scientific work of others. With a professional background in poultry nutrition and the production of fish meal, Lane spent three years developing a process for powdering shark cartilage. He persuaded Belgian researcher Dr. Ghanem Atassi to feed it to mice with melanomas (malignant tumors).¹ Atassi found that, while some tumors briefly shrunk, their growth resumed and the host mice consequently died. His attempt to repeat these results failed, and Atassi decided not to publish his work.

This, however, did not daunt Lane, who sought human experimentation. He found two controversial alternative-medicine clinics in Tijuana, Mexico, willing to test his shark-cartilage powder on their cancer patients. The first was the Ernesto Contreras Hospital, which treats cancer with laetrile, coffee enemas, and injections of live embryonic sheep cells; the second was the Hoxsey Clinic, where patients are fed herbal potions and rubbed with herbal salves.²⁴ Enemas of a suspension of Lane's shark-cartilage powder were given daily to cancer patients at the clinics; and after some weeks Lane proclaimed the treatment greatly successful. There has been no independent confirmation of this claim.

In 1992 Lane took his shark-cartilage powder to a Cuban hospital, where doctors agreed to treat 29 allegedly terminal cancer patients in a 16-week clinical trial. This time, the "spectacular successes" Lane ascribed to shark cartilage therapy caught the attention of Mike Wallace and the "scientists" at CBS's "60 Minutes."¹ The broadcast newsmagazine dramatized the testimonials of patients who had undergone shark cartilage therapy at the Cuban clinic and thus ignited the shark cartilage craze.

Where's the Evidence?

Medical scientists have determined that the cartilage of calves, cows, and sharks contains an inhibitor of angiogenesis. What evidence is there that ingestion or rectal application of shark cartilage benefits cancer patients?

Nutrition and Health Forum (ISSN 1091-2428), © 1997 Prometheus Books, is published bimonthly for \$35.00 (individuals in U.S. and Canada) or \$50 (institutional, overseas) per year by Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197. There is none!

Catherine Dold¹ interviewed researchers whose work Lane cites. Each refuted Lane's claims. Langer said he has never seen evidence that Lane's shark-cartilage powder acts against cancer in humans. Folkman stated that, because the Mexican and Cuban trials were neither controlled nor peer-supervised, they were not trustworthy. He also noted that gastric acid destroys the antiangiogenic proteins in cartilage; that they are too large to pass through the intestinal wall into the bloodstream; and that their concentrations in cartilage are so low, a patient would have to consume many pounds of it daily to affect the tumor.

The "60 Minutes" public-health fiasco prompted a number of independent reviews of the medical records of the patients treated in Cuba. Investigators for the National Cancer Institute found that the records were incomplete and the results unimpressive. Consequently, the institute decided not to initiate clinical trials of shark cartilage.²⁴ The Office of Alternative Medicine of the National Institutes of

Health was also unimpressed. Its then director, Joseph J. Jacobs, M.D., M.B.A., stated: "It is our view that Lane's claims are unproven, and since there is no demonstrated merit to the use of shark cartilage in the treatment of cancer we do not recommend it."²⁵

Finally, the chief of oncology at the Costa Rican National Children's Hospital stated: "The use of shark cartilage for treatment of cancer is a farce that spells disaster for the shark population in the sea off Costa Rica."²⁶

If the trials of shark cartilage indeed yielded "spectacular" results, why aren't conventional hospitals in Belgium, Costa Rica, Cuba, and Mexico routinely using Lane's powder?

SHARK CARTILAGE
A MIRACLE BREAKTHROUGH FROM THE SEA

**Exciting Good News:
Sharks Don't Get Cancer**

For centuries the Chinese have been aware of the benefits of shark cartilage, and have been consuming it as shark fin soup.

The shark is certainly one of the most remarkable creatures on the face of our planet. The shark appears to be the only animal with a natural immunity to cancer and practically every disease known to man. When wounded it heals quickly; it even has five sets of teeth and can form new ones if needed. The shark is also the only animal with a skeleton composed entirely of cartilage: a tough, bone-like tissue that accounts for eight percent of its total weight. **Scientists now believe it is the shark's cartilage skeleton which is responsible for this super immunity.**

Researchers worldwide are investigating the shark's natural resistance to disease. There has been an explosion of medical research on shark cartilage's amazing ability.

What makes shark cartilage so special is that it contains this miracle nutrient at a concentration one thousand times greater than any other natural type of cartilage.

More studies over the past decade exploring the health

benefits of shark cartilage. It's the subject of several new books as well as popular TV news programs.

Now **Alive & Alert** introduces an exciting new product to satisfy consumers rapidly growing appetite for shark cartilage: New Advanced Shark Cartilage capsules.

Alive & Alert Advanced Shark Cartilage is the purest, highest quality source of cartilage available; **Alive & Alert ADVANCED SHARK CARTILAGE** capsules provide 800 mg of 100% pure shark cartilage.

Clinical Uses:

The current medical literature contains much scientific evidence that shark cartilage is a tremendously effective treatment in many degenerative and inflammatory conditions. Amazingly, we look to one of earth's oldest creatures to provide the means to treat many of our devastating and enigmatic diseases.

Kenney, Ph.D., R.D.; Marilynn Larkin; William M. London, Ed.D., M.P.H.; James A. Lowell, Ph.D.; Wallace Sampson, M.D.; Varro E. Tyler, Ph.D., Sc.D. **SCIENTIFIC CONSULTANTS:** John E. Dodes, D.D.S.; Victor Herbert, M.D., J.D.; Gabe Mirkin, M.D. **INFORMATION CONSULTANT:** Inna Lipnitskaya, M.S.L.I.S.

normally are broken down into amino acids and small peptides. Undigested protein does not pass through the intestinal wall into the bloodstream. But what would happen if it did? Since all the protein in our food comes from other species (shark species, for example), the presence of undigested protein in the bloodstream would immediately cause an immune response. Our immune system would identify the protein as foreign and react as if it signified an infection; antibodies would be produced, killer cells would be activated, and the eater would thenceforth be "allergic" to that protein. A later exposure could trigger anaphylactic shock, a sometimes fatal reaction.

A scientifically critical reading of many of Lane's writings—two books, a patent, numerous letters published in various magazines, articles in newspapers and alternative-medicine periodicals, promotional mailings, etc.—raises more questions than answers. For example, despite his claim that he has done extensive research since 1983, the list of references he offers does not indicate publication of his work in any peer-reviewed scientific journal. Surely Lane recognizes the importance of peer review, since he'd "had the good fortune to be exposed to the thinking of two Nobel Laureates."²⁷

If Lane's work were published in a peer-reviewed scientific journal, we might learn, just for example: (a) when, where, and how he identified the antiangiogenic proteins in shark cartilage; (b) how he determined that shark cartilage contains four such proteins; (c) how he obtained proof of their absorbability; (d) how he established effective doses for patients with different types of cancer; and (e) how he discovered that absorbed shark proteins do more good than harm.

Is It Safe to Go Back into the Health Food Store?

How can desperate cancer patients and other consumers determine which brands of shark cartilage are uncontaminated? They can't! The Food and Drug Administration regulates dietary supplements only minimally. Evidence of (a) high-quality raw material; (b) product purity, sterility, potency; and (c) lack of side effects is not required.

The expression "all natural" is used to promote the shark cartilage sold in health food stores. It implies "non-

As featured on 60 Minutes

Finally, What The World Has Been Waiting For... A Major Cancer Breakthrough

SHARKS DON'T GET CANCER

In 1983, two researchers at MIT published a study showing that shark cartilage contains a substance that significantly inhibits the development of blood vessels that nourish solid tumors, thereby limiting tumor growth. Working independently, researchers at Harvard found that if one could inhibit the development of a new blood network, one could prevent the development of tumor-based cancers and metastasis.

Tying together these two important findings, author Dr. I. William Lane traces further the pioneer work performed in this area and recounts his own involvement in the search for a truly effective treatment of tumor-based cancers. As events and research continue to unfold, shark cartilage may prove to be the first momentous step toward preventing and conquering cancer.

Sharks Don't Get Cancer is the story of this amazing breakthrough.

Ad that appeared in *Natural Foods Merchandiser* shortly after the "60 Minutes" broadcast

toxic." However, many natural substances are poisonous. In any case, the shark-cartilage products in health food stores are anything but "all natural." Their manufacture involves using chemicals for extraction, purification, and concentration. And supplement manufacturers need not test for contaminants. They need not even test for shark cartilage!

The "recommended" daily intake of shark cartilage is about 60 grams. A patient following this recommendation by taking pills must take 80 per day, at a cost of about \$40!

The Bottom Line

If sound evidence exists that shark cartilage can arrest the growth of malignant tumors in humans, it has not come to light. Shark cartilage therapy can cost as much as \$1,200 a month. Whether ingesting shark cartilage can have adverse effects has not been determined. Even desperate consumers can't afford *not* to ask: "Why should I believe the claims of promoters?"

NHF contributing editor Saul Green, Ph.D., is a biochemist who conducted cancer research at Memorial Sloan-Kettering Cancer Center for 23 years. He is president of ZOL Consultants, Inc., in New York City.

FOLIC ACID AND HOMOCYSTEINE

Stephen Barrett

Risk factors for heart attacks and strokes include hereditary predisposition, maleness, advanced age, cigarette smoking, high blood pressure, obesity (especially excess abdominal fat), lack of physical activity, and abnormal blood cholesterol levels. The more risk factors a person has, the greater the likelihood that person will develop heart disease. Modifying controllable risk factors—giving up smoking, for example—can decrease the probability of a heart attack.

During the past few years, researchers have linked high blood levels of the amino acid homocysteine to an increased risk of premature coronary artery disease and stroke, even among people with normal cholesterol levels. Apparently, abnormal homocysteine levels contribute to atherosclerosis in at least three ways: (a) direct damage by homocysteine to the lining of arteries, (b) interference with clotting factors, and (c) oxidation of low-density lipoproteins (LDL).

Suspicious about the connection between homocysteine and cardiovascular disease arose some 25 years ago with the observation that people with homocystinuria, a rare inherited disease, were prone to develop severe cardiovascular disease during their teens and twenties. In homocystinuria, absence of the enzyme essential to the metabolism of another amino acid, *homocystine*, causes the accumulation of homocysteine in the bloodstream and its excretion in the urine.

Recent studies suggest that high blood homocysteine levels are as important as high blood cholesterol levels and can affect health independently. About 10 to 20 percent of cases of coronary heart disease have been linked to high homocysteine levels. Both hereditary and dietary factors may be involved.

Homocystinuria is transmitted by a recessive gene that approximately one person in a hundred carries. Those who have inherited the defective gene from both parents have very high plasma homocysteine levels. Those who have inherited it from only one parent do not develop homocystinuria but often have moderately high plasma levels of homocysteine. Abnormal concentrations also occur among people whose diets provide inadequate amounts of folic acid, vitamin B₆, or vitamin B₁₂. But whatever the cause of abnormal levels, supplementation with one or more of these vitamins can lower plasma homocysteine.

Folic acid supplementation alone can lower elevated homocysteine in most people. The usual dose of folic acid is 1 mg per day. If this is not effective, additional supplementation with vitamin B₆ and/or B₁₂ is advisable. The regimen should be lifelong.

Lowering serum homocysteine has been proven to decrease the risk of adverse cardiovascular events among people with homocystinuria.

Researchers have not yet determined whether lowering moderately elevated blood homocysteine decreases the incidence of heart attacks or strokes, but most experts believe that scientific studies will prove it does so. Screening for elevated homocysteine is advisable for people with coronary artery disease that is disproportionate to their risk factors and for people with a family history of premature atherosclerosis. (Some physicians recommend such screening for all patients with atherosclerosis.) Levels above 10 $\mu\text{mol/liter}$ warrant treatment. The effect of supplementation usually becomes apparent within a month. The lab test costs about \$40.

Since folic acid is nontoxic, using it to treat elevated homocysteine seems prudent. Treatment should be supervised by a well-informed physician.

Stephen Barrett, M.D., a retired psychiatrist, coauthored the college textbook *Consumer Health: A Guide to Intelligent Decisions* (Brown & Benchmark, 1997). His website URL is: <http://www.quackwatch.com>.

BRIEFS

BST labeling law overturned. A federal appeals court has invalidated a 1994 Vermont law that required special labeling of dairy products made from milk produced by cows treated with the hormone BST (bovine somatotropin). The court ruled that the law—the only one of its kind in the United States—was unjustified because it implied, incorrectly, that such dairy products were less safe.

Calcium label claim nixed. The FDA has declined to authorize the proposed food label claim that calcium intake can decrease the risk of high blood pressure. The agency concluded that the available evidence lacks consistency.

CANnot. On October 30, 1996, an attorney affiliated with the Church of Scientology bought the name, logo, and

telephone number of the Cult Awareness Network (CAN) from a bankruptcy trustee for \$20,000. CAN's phone number is operational under this attorney's management. For two decades the lawsuit-plagued original CAN, a nonprofit organization, had been this country's largest secular group focusing on providing the public with information on cults. What CAN does now is debatable. In February 1997 David J. Bardin (of the Arent, Fox law firm, in Washington, D.C.), representing the original CAN, filed an appeal on the bankruptcy sale with the U.S. District Court in Chicago.

Chromium and chromosomes. *Tufts University Diet & Nutrition Letter* has presented a comprehensive report on chromium picolinate. [*Tufts University Diet & Nutrition Letter* 14(8):4–6, 1996.] According to the report: (a) claims

that chromium picolinate supplements can help build muscles are unsubstantiated; (b) chromium supplements may prove useful for people with diabetes who have insufficient chromium in their diet, but no long-range tests have been done to determine whether taking them is safe; and (c) researchers who mixed chromium concoctions with hamster cells found that chromium picolinate was more detrimental to chromosomes than chromium alone, picolinate alone, or another chromium compound.

Dial an R.D. The National Center for Nutrition and Dietetics now offers an R.D.-staffed telephone service (1-900-225-5267) for consumers seeking individualized answers to questions about food and nutrition. Once connected to a dietitian, callers are charged \$1.95 for the first minute and 95 cents for each subsequent minute. Calls are expected to average about four minutes. The center's toll-free number (1-800-366-1655) continues to provide recorded information and referrals to dietitians nationwide.

Dictionary expanded. The second (1997) edition of Jack Raso's *Dictionary of Metaphysical Healthcare: Alternative Healthcare, Paranormal Healing, and Related Methods* (The Georgia Council Against Health Fraud), edited by Manfred Kroger, Ph.D., is an oversize, 166-page catalog of medical weirdness. It features succinct, largely nonjudgmental descriptions of more than 1,150 unnaturalistic (mystical and/or supernaturalistic) health-related methods plus an extensive glossary and bibliography. Author Marvin J. Schissel, D.D.S., vice president of the New York Chapter of The National Council Against Health Fraud, described the first edition as "a relentless account of superstitious 'unreason' that is so far removed from scientific knowledge, it is closer to vaudeville than to science." And, in *Skeptical Briefs*, Gary P. Posner, M.D., wrote: "Should you ever develop an inexplicable desire to undergo a round of 'marma therapy' (or perhaps 'Marma Chikitsa' for the more adventurous), this is an excellent reference to turn to, not simply for its concise yet authoritative definitions, but also for its topic-by-topic bibliography." Copies of the 1997 edition are available for \$21.50 each postpaid from LVCAHF, Inc., P.O. Box 1747, Allentown, PA 18105.

Ensure ads curbed. Abbott Laboratories has agreed to settle FTC charges that it made false and unsubstantiated claims in an extensive national advertising campaign that promoted the supplemental beverage Ensure to healthy,

active adults. Several of Abbott's advertisements featured people who looked active and healthy, some of whom also appeared thirty- or forty-something. The ads include statements such as "Ensure is recommended number one by doctors as a source of complete balanced nutrition." The FTC alleged that Abbott had represented without adequate substantiation that many doctors recommend Ensure as a meal supplement and replacement for healthy adults, including those in their thirties and forties. An FTC official stated that beverage products like Ensure may benefit people with a medical condition that makes eating difficult, or people who consume them occasionally in lieu of a meal. But the ads' implication that physicians recommend Ensure to healthy, active people so that they can stay that way is indefensible.

"Flight path" examined. Several speakers at a 1995 New York Academy of Sciences symposium warned that the alternative-medicine movement is part of a ubiquitous backtracking from science and rationalism. One speaker criticized the stance that scientific modes of testing are inadequate for evaluating alternativist methods. Another lamented that money is wasted on investigating useless methods while many worthy projects lack funds. The proceedings of this symposium, *The Flight from Science and Reason* (1996), are available for \$95 plus a shipping charge from the Academy (1-800-843-6927).

Health claims on restaurant menus. The FDA has published a final rule concerning nutrition claims on restaurant menus. Unlike food manufacturers, who must base their nutrient-content figures on laboratory analyses, restaurateurs may base them on information from nutrient databases, cookbooks, recipe analyses, or any other "reasonable" source. They may also highlight foods that conform to recognized dietary guidelines.

Homeopathy against warts. The difference between placebos and some homeopathic preparations is academic. Supposedly high-potency homeopathic preparations contain little or none of the so-called basic remedy. The conclusion of a double-blind, randomized trial reported in the British journal *Dermatology* was that homeopathic preparations and placebos were about equally useful (or useless) against warts. The trial involved sixty subjects, all children.

Law enforcement on the “web.” The Federal Communications Commission (FCC), the Federal Trade Commission (FTC), the Securities and Exchange Commission, and 70 state and local law enforcement officials from 24 states have notified operators of over 500 websites (“visited” during a single day!) that they may be promoting illegal pyramid schemes in violation of state and federal laws. Many were promoting financial schemes such as simple chain letters, but some were multi-level companies selling “miracle products.” The FTC now posts news releases to its website (<http://www.ftc.gov>) at 10 A.M. every day. Meanwhile, a Minnesota court has ruled that state authorities can regulate out-of-state advertisers who seek business with Minnesotans through the Internet.

New nutrition anthology. Dushkin/McGraw-Hill has published *Nutrition 97/98*, its ninth annual compendium of nutrition articles. Edited by Charlotte Cooke-Fuller, Ph.D., of Towson State University, with help from Stephen Barrett, M.D., the book features 59 significant articles from newspapers, magazines, newsletters, and scientific journals. Copies are available for \$15 each, plus \$2.50 per order for postage from LVCAHF, Inc., P.O. Box 1747, Allentown, PA 18105.

Oxymoron? The only nonmedical services for which Medicare and Medicaid lawfully pay are those that are related to medical care—except in facilities operated or certified by The First Church of Christ, Scientist. Mary (Morse) Baker Eddy (1821–1910) founded Christian Science in 1879. The church’s basic principle is: mind is the only reality; illness, pain, and death are illusory. Christian Science “practitioners” engage in so-called absent healing—specifically, alleged treatment by prayer of patients not in the practitioners’ vicinity. Christian Scientists generally choose “Christianly scientific prayer” over medical treatment. Although Christian Science caregivers do not provide any medical treatment, they have received millions of dollars in Medicare and Medicaid reimbursements. In a letter to the U.S. Senate’s legal counsel released on January 25, 1997, Attorney General Janet Reno stated that this unique coverage violates the Constitutional principle of separation of church and state.

Priorities. Jack Raso has become Director of Publications for the American Council on Science and Health and editor-in-chief of its quarterly magazine, *Priorities*. His e-mail address is: raso@acsh.org.

Textbook updated. The sixth (1997) edition of *Consumer Health: A Guide to Intelligent Decisions* (Brown & Benchmark)

is a detailed 624-page, well-illustrated, exhaustively referenced college text that covers all manner of health-related strategies for consumers. Its 26 chapters include: “Frauds and Quackery”; “Advertising and Other Marketing Practices”; “Mental Health Care”; “Dental Care”; “Alternative Methods”; “Nutrition Fads, Fallacies, and Scams”; “Exercise Concepts, Products, and Services”; “Skin care and Beauty Aids”; and “Health Devices.” All of the authors (Stephen Barrett, M.D., William T. Jarvis, Ph.D., Manfred Kroger, Ph.D., and William M. London, Ed.D., M.P.H.) and one of the three associate editors (Jack Raso) are members of *NHF*’s editorial board. Copies are

available for \$50 each postpaid from LVCAHF, Inc., P.O. Box 1747, Allentown, PA 18105.

Zinc against colds. A study published last year has sharply boosted sales of zinc gluconate lozenges for treating colds. The study compared 50 patients who used the lozenges with 50 who took a placebo. The zinc dose was 13.3 mg every two hours with an average of six per day. “Blinding” was deficient, however, as the zinc lozenges tasted more astringent than the placebos. The zinc-treated patients had fewer cold symptoms but a higher incidence of bad taste, mouth irritation, and nausea. Complete symptom resolution (as reported by the patients) took 4.4 days for the zinc group and 7.6 days for the control group. [Archives of Internal Medicine 125:81, 1996.] *The Medical Letter* reviewed seven other studies and found that only three had shown positive results. It stated: “Treatment with large doses of zinc might decrease the symptoms and shorten the duration of the common cold, but properly blinded confirmatory studies are needed. The long-term safety of taking zinc in doses higher than the Recommended Dietary Allowances has not been established.” [Medical Letter 39:9–10, 1997.] The zinc RDAs for adults are 15 mg (men) and 12 mg (women).

BILL TO LEGALIZE QUACKERY

The Access to Treatment Act (H.R. 746), reintroduced by Rep. Peter DeFazio (D-Ore.), is claimed to permit health-care practitioners to provide "any medical treatment that the individual desires" that does not violate licensing laws. Practitioners may provide the treatment if: (a) it is not known to be directly harmful, (b) the patient is given written notice that the treatment is not government approved, and (c) written information is provided about the nature, anticipated benefits, and foreseeable side effects of the treatment. The act would also require that dangerous outcomes be reported to the Secretary of Health and Human Services and that beneficial outcomes be reported to the NIH Office of Alternative Medicine. Although couched as an effort to preserve patient freedom, the bill's real purpose is to prevent government interference with unscientific practitioners. The alleged safeguards fail to protect patients from practitioners who misrepresent worthless methods as beneficial (as most "alternative" practitioners do). By March 20, H.R. 746 had 43 cosponsors. Many of its proponents spearheaded passage of the 1993 Dietary Supplement Health and Education Act, which has greatly weakened the FDA's ability to regulate false claims made for dietary supplements and herbs. In many states vigorous efforts are also being made to obtain laws that would prevent licensing boards from disciplining "alternative" practitioners.

QUACKERY PROMOTION

The Herb Research Foundation (HRF), whose stated mission is to "disseminate accurate, responsible scientific information on herbs and herbal research," includes several unreliable books in its otherwise valuable catalog. Dr. Stephen Barrett has asked HRF executive director Mark Blumenthal to "purge the catalog of books that contain highly irresponsible or quack advice," including one to which Blumenthal himself wrote the foreword. So far, there is no indication that he will do so.

[continued on page 14]

Exposing Multiple Chemical Sensitivity

*Why this diagnosis is spurious—
and why it persists*

by Stephen Barrett, MD

The expression "multiple chemical sensitivity" ("MCS") is used to describe people with numerous troubling symptoms attributed to environmental factors. Many such people are seeking special accommodations, applying for disability benefits, and filing lawsuits claiming that exposure to common foods and chemicals has made them ill. Their efforts are supported by a small cadre of physicians who use questionable diagnostic and treatment methods. Critics charge that these approaches are bogus and that MCS is not a valid diagnosis.

What Is MCS?

The concepts underlying MCS were developed by allergist Theron G. Randolph, MD (1906–1995), who asserted that patients had become ill from exposure to substances at doses far below the levels normally considered safe. In the 1940s, he declared that allergies cause fatigue, irritability, behavior problems, depression, confusion, and nervous tension in children.

In the 1950s, Randolph suggested that human failure to adapt to modern-day synthetic chemicals had resulted in a new form of sensitivity to these substances. His concern with foods then

expanded to encompass a wide range of environmental chemicals. Over the ensuing years, the condition he postulated has been called allergic toxemia, cerebral allergy, chemical sensitivity, ecologic illness, environmental illness (EI), immune system dysregulation, multiple chemical sensitivity, total allergy syndrome, total environmental allergy, total immune disorder syndrome, toxic response syndrome, 20th century disease, universal allergy, and many other names that suggest a variety of causative factors. These labels are also intertwined with Gulf War syndrome, sick building syndrome, toxic carpet syndrome, and other politically controversial diagnoses.

The complaints associated with these labels include depression; irritability; mood swings; inability to concentrate or think clearly; poor memory; fatigue; drowsiness; diarrhea; constipation; dizziness; mental exhaustion (also called "brain fog" or "brain fog"); lightheadedness; sneezing, runny, or stuffy nose; wheezing; itching eyes and nose; skin rashes; headache; chest pain; muscle and joint pain; urinary frequency; pounding heart; muscle incoordination; swelling of various parts of the body; upset stomach;

William J. Rea, MD, who says he has treated more than 20,000 environmentally ill patients, states that they "may manifest any symptom in the textbook of medicine."

tingling of the fingers and toes; and psychotic experiences associated with schizophrenia. William J. Rea, MD, who says he has treated more than 20,000 environmentally ill patients, states that they "may manifest any symptom in the textbook of medicine."

MCS proponents suggest that the immune system is like a barrel that continually fills with chemicals until it overflows and symptoms appear. Some also say that a single serious episode of infection, stress, or chemical exposure can trigger "immune system dysregulation." Potential stressors include practically everything that modern humans encounter, such as urban air, diesel exhaust, tobacco smoke, fresh paint or tar, organic solvents and pesticides, certain plastics, newsprint, perfumes and colognes, medications, gas used for cooking and heating, building materials, permanent press and synthetic fabrics, household cleaning products, rubbing alcohol, felt-tip pens, cedar closets, tap water, and even electromagnetic forces.

There is no known mechanism whereby low levels of chemicals or chemicals of widely varied structure can interact adversely with numerous organ systems. Moreover, if the "total body load" concept were valid, the "sum" of small amounts of many unrelated chemicals (as well as infections and psychological stresses) would have the same effects as massive doses of single chemicals—which is not true. Like drugs, chemicals have specific effects whose development and severity depend on the amounts to which individuals are exposed.

Most physicians who diagnose and treat MCS identify themselves as "clinical ecologists" or "specialists in environmental medicine." About 400 of them belong to the American Academy of Environmental Medicine (AAEM, which Randolph founded in 1965 as the Society for Clinical Ecology, is composed mainly

of medical and osteopathic physicians. Clinical ecologists also play a significant role in the American Academy of Otolaryngic Allergy [AAOA], which Randolph helped found in 1941).

MCS has never been clearly defined, no scientifically plausible mechanism has been proposed for it, no diagnostic tests have been substantiated, and not a single case has been scientifically validated.

Clinical ecology is not a recognized medical specialty. Environmental medicine is a component of the specialty of preventive medicine (public health), but the theories and practices of clinical ecology are not. Critics of clinical ecology charge that: (1) MCS has never been clearly defined, (2) no scientifically plausible mechanism has been proposed for it, (3) no diagnostic tests have been substantiated, and (4) not a single case has been scientifically validated.

Many prominent scientific panels have concluded that clinical ecology and its associated concepts are—at best—speculative and unproven.

Dubious Diagnosis and Treatment

Ronald E. Gots, MD, PhD, who has reviewed the medical records of more than a hundred MCS patients, describes MCS as "a label given to people who do not feel well for a variety of reasons and who share the common belief that chemical sensitivities are to blame." He further states: "It defies classification as a disease. It has no consistent characteristics, no uniform cause, no objective or measurable features. It exists because a patient believes it does and a doctor validates that belief."

The fact that MCS has not been meaningfully defined does not deter clinical ecologists from diagnosing it—typically in all or nearly all of their patients. Their diagnostic evaluation usually includes an "ecological oriented history," a physical examination, and laboratory tests. The history-taking procedure may include a lengthy

questionnaire that emphasizes dietary habits and exposure to environmental chemicals. The nature and purpose of the physical examination is unclear because no combination of physical findings can establish the diagnosis. Standard allergy test results are often normal.

The test clinical ecologists consider most important is called "provocation-neutralization." During this procedure, the patient is asked to report any symptoms that develop after various concentrations of suspected substances are administered under the tongue or injected into the skin. If symptoms occur, the test is considered positive and various concentrations are given until a dose is found that "neutralizes" the symptoms. Various chemical, hormones, food extracts, and other natural substances may be prescribed as "neutralizing" agents.

"Neutralization" superficially resembles the desensitization process used by allergists. However, allergists test and treat with substances that produce measurable allergic responses, whereas clinical ecologists base their judgments on subjective responses.

Elimination and rotation diets may be used with the hope of identifying problematic foods. Single-food challenges may also be used. In severe cases, Rea's patients may spend several weeks in an environmental care unit (ECU) intended to remove them from exposure to airborne pollutants and synthetic substances. After fasting for several days, these patients are given "organically grown" foods and gradually exposed to environmental substances to see which ones cause symptoms to recur.

Many clinical ecologists use tests related to immune function or exposure to specific chemicals. Samples of blood, urine, fat, and hair may be examined for various environmental chemicals. Other blood tests may assess immunoglobulins, other

immune complexes, lymphocyte counts, and "antipollutant enzyme" levels. Some of these tests lack an accepted protocol and have not been standardized, and none has been demonstrated to have a consistent pattern of alteration in MCS patients.

Some treatments are based on blood tests that can detect chemicals in concentrations of parts per billion. This enables levels too low to be clinically significant to be misinterpreted as evidence of unusual and harmful chemical exposure. If any "toxin" level is interpreted as abnormal, the patient will be advised that "detoxification" or "purification" can wash the undesirable chemicals from the body. The regimens may include exercise, sauna treatments, showers, massage, herbal wraps, megavitamin therapy (usually including several grams of niacin per day), self-administered "desensitization" injections, and the use of water and air purifiers.

The provocation-neutralization test has been conclusively debunked by a study performed in the early 1980s by researchers at the University of California. The tests took place in the offices of clinical ecologists who had been treating the patients.

During three-hour sessions, the patients received three injections of suspected food extracts and nine of normal saline. Sixteen patients were tested once, and two were tested twice. In non-blinded tests, these patients had consistently reported symptoms when exposed to food extracts and no symptoms when given saline injections. Under double-blind conditions, however, they developed symptoms with 16 of 60 food-extract injections (27%) and 44 of the 180 (24%) salt-water injections. The symptoms elicited by both types of injections were identical and included itching of the nose, watery or burning eyes, plugged ears, a feeling of fullness in the ears,

One woman wore a protective mask while shopping and another woman hung her mail on a clothesline for weeks before reading it, to allow the "toxins" in the ink to dissipate.

WEB WATCH

When it comes to nutrition and health information, the World Wide Web is a combination minefield and library. Is that a solid piece of nutrition reporting—or a pseudo-fact ready to explode on contact? This column helps you figure out which is which. Following is a list of some of the best (most reliable, useful) sites and some of the worst (most unreliable, deceptive, weird, and worthless). Ratings and commentary are by Internet-savvy John H. Renner, MD, president of the Consumer Health Information Research Institute.

BEST

<http://www.mayo.ivi.com/> The Mayo site will amaze and please you with a great variety of nutrition and health information. Check out the "Diet & Nutrition Resource Center."

<http://www.blonz.com.blonz/> A site by nutritionist Ed Blonz, PhD, a syndicated writer and a computer wizard. Be careful—at this site, nutrition info could be fun.

<http://www.reutershealth.com/> This is Reuters Health Information Services—one of the most reliable and up-to-date of all the online sources of health information. For both professionals and consumers.

WORST

<http://www.divafarm.com/noni/> This site gives you music and testimonials and disclaimers stating that this is not medical advice. It also has good lawyers, good graphics, and good (bad?) marketing for a new health food remedy called Noni Juice. This "miracle" is supposed to be just the thing for a host of problems, everything from tuberculosis to menstrual cramps.

<http://www.generation.net/~lord/> This site claims to have an herbal cure for AIDS. I tried to follow up on this one, but they got nervous on the phone.

<http://www.alternativemedicine.com/> This is the online version of *Alternative Medicine Digest*. It has some very strange health information. So strange that I am offering a prize for the best in-depth review of this site by a nutrition professional, skeptic, scientist, or investigative reporter. I will judge all submissions by July. Your prize is a surprise. A nice one. We may even publish some of the comments in *Nutrition Forum*. If your review is good enough, I may ask you to help me review other web pages. Please send your review by e-mail to drreener@msn.com.

ringing ears, dry mouth, scratchy throat, an odd taste in the mouth, tiredness, headache, nausea, dizziness, abdominal discomfort, tingling of the face or scalp, tightness or pressure in the head, disorientation, difficulty breathing, depression, chills, coughing, nervousness, intestinal gas or rumbling, and aching legs. The results clearly demonstrated that the patients' symptoms were placebo reactions. The study also tested the claim that "neutralizing" doses of offending allergens can relieve the patient's symptoms. All seven patients who were "treated" during the experiment had equivalent responses to extracts and saline (*New England Journal of Medicine*, 323:429-33, 1990).

Allergist John C. Selner, MD, and psychologist Herman Staudenmayer, PhD, of Denver, Colorado, have treated MCS patients for more than 17 years. Like Rea, they used an environmental chamber for testing sensitivity to airborne chemicals. However, they reject clinical ecology theories and practices. Using well-designed double-blind tests, they have demonstrated that "universal reactors" may develop multiple symptoms in response to the testing process without being allergic to any of the individual substances administered.

One of their reports describes how they used an environmental chamber to evaluate 20 patients with multiple symptoms attributed to chemical hypersensitivity. During the tests, the patients were exposed to measured amounts of purified air, compressed gasses, and air containing specific chemical concentrations, without knowing which situation was which. None of the patients demonstrated a response pattern implicating the chemicals supposedly responsible for their symptoms. Eighteen reported no symptoms at least once when the suspect chemical was

present. Fifteen reported symptoms at least once when the suspect chemical was absent. In other words, patients reacted to their feelings and beliefs about the test, rather than to the substance in question (*Regulatory Toxicology and Pharmacology*, 18: 44-53, 1993).

The treatment clinical ecologists offer is as questionable as their diagnoses. One observer has commented that the variety of treatments they prescribe "seems limited only by their imagination and resourcefulness." The usual approach emphasizes avoidance of suspected substances and involves lifestyle changes that can range from minor to extensive. Generally, patients are instructed to modify their diet and to avoid such substances as scented shampoos; aftershave products; deodorants; cigarette smoke; automobile exhaust fumes; and clothing, furniture, and carpets that contain synthetic fibers. Extreme restrictions can involve wearing a charcoal-filter mask, using a portable oxygen device, staying at home for months, or avoiding physical contact with family members. Many patients are advised to take vitamins, minerals, and other dietary supplements. "Neutralization therapy," based on the results of provocative tests, can involve administration of chemical extracts under the tongue or by injection.

MCS patients typically portray themselves as immunologic cripples in a hostile world of dangerous foods and chemicals. In many cases, their life becomes centered around their illness. Various companies cater to these beliefs by offering such items as "organic" foods; odor-free personal products; special clothing, household products, and building materials; and even specially outfitted travel trailers. A recent article in *Reason* described how one woman wore a

protective mask while shopping and another woman hung her mail on a clothesline for weeks before reading it, to allow the "toxins" in the ink to dissipate.

Case Studies

Many experts have studied MCS patients and concluded that their basic problem is psychologic rather than physical. The best current data suggest that certain psychologic factors predispose individuals to develop symptoms and to seek out someone who will provide a "physical" explanation of their symptoms. Many of these patients suffer from "somatization disorder," an emotional problem characterized by persistent symptoms that cannot be fully explained by any known medical condition, yet are severe enough to require medical treatment or cause alterations in lifestyle. Some are paranoids who are prone to believe that their problems have outside causes. Others suffer from depression, panic disorder, agoraphobia, or other anxiety states that induce bodily reactions to stress. Many patients are relieved when a clinical ecologist offers what they think they need and encourages them to participate actively in their care. However, the treatment they receive may do them far more harm than good.

In 1986, Abba I. Terr, MD, an allergist affiliated with Stanford University Medical Center, reported on 50 patients

Instead of testing their claims with well-designed research, MCS advocates are promoting them through publications, talk shows, support groups, lawsuits, and political maneuvering.

BE A NUTRITION FORUM CONTRIBUTOR!

If you find any news or information that may be of interest to our readers—such as published articles, news reports, press releases, or relevant personal experience—please send it to us. Mail it to Lewis Vaughn, *Nutrition Forum*, P.O. Box 664, Amherst, NY 14226-0664. We're especially interested in receiving information about enforcement actions by state agencies, lawsuits by victims of quackery, and health-fraud news that may have been overlooked by the national media.

Update on Jeffrey Bland

who had been treated by clinical ecologists for an average of two years. Each of these patients had made a workers' compensation claim for industrial illness. Their treatments included dietary changes (74% of the patients), food or chemical extracts (62%), an antifungal drug (24%), and oxygen given with a portable apparatus (14%). Fourteen of the patients had been advised to relocate to a rural area, and a few were given vitamin and mineral supplements, gamma globulin, interferon, female hormones, and/or oral urine. Despite treatment, 26 patients reported no lessening of symptoms, 22 felt worse, and only 2 had improved (*Archives of Internal Medicine*, 46:145-49, 1986).

In 1989, Terr reported similar observations on 90 patients, including 40 covered in the previous report. He also noted that 32 of the 90 patients had been diagnosed as suffering from "Candidiasis hypersensitivity"—a fad diagnosis considered "speculative and unproven" by the American Academy of Allergy and Immunology (*Journal of Occupational Medicine*, 31:257-61, 1989).

Psychiatrist Donald W. Black, MD, and colleagues at the University of Iowa College of Medicine have described how the misdiagnosis involved can produce psychosocial, financial, occupational, and psychological complications. The psychosocial complications usually stem from recommendations to avoid contact with offending agents. As a result, patients become socially constricted or reclusive. The financial cost can be enormous; for example, a patient may be instructed to add a "safe" room to his house, or rebuild his house according to EI principles. Relocating can be enormously expensive, particularly if it involves quitting one's job or moving long distances to seek a pollutant-free environment. Occupational complications can arise when a person is advised to quit a job or stop working, due to presumed exposure on the job.

Drs. Selner and Staudenmayer have concluded that most people said to be "universal reactors" develop multiple symptoms in response to the testing process without being allergic to any of the individual substances administered.

[continued on page 16]

Jeffrey S. Bland, PhD, of Gig Harbor, Washington, has been one of the health-food industry's most prolific interpreters of nutrition-related scientific developments. His interpretations consistently favor the use of supplements. A former chemistry professor, he has appeared frequently at trade shows, written and edited publications, produced audio- and videotapes, and conducted seminars for health professionals. He has also been a research associate at the Linus Pauling Institute of Medicine and has directed its nutrient analysis laboratory. Despite government regulatory efforts, he has persisted in making unsubstantiated claims for products he has marketed.

In 1991, the FTC charged that Bland and two of his corporations (HealthComm and Nu-Day Enterprises) had falsely claimed that their diet program could cause weight loss by turning up the body's "heat-producing machinery" so that fat is lost as body heat instead of being stored. The Nu-Day Diet Program, which cost about \$30 per week, included instructional materials, a meal-replacement formula, and a fiber-containing formula said to be a "natural appetite suppressant." The Nu-Day program was promoted with a 30-minute television program entitled "The Perfect Diet," which offered "amazing true stories of people like yourself losing 20, 30, 50 pounds or more, safely, quickly and naturally." Although the television program appeared to be an independent consumer news show that used interviews to report on its discovery of the Nu-Day Diet, it was actually a paid ad. The program identified Bland as "one of the nation's leading nutritional biochemists." The case was settled with a consent agreement in which Bland agreed to pay \$30,000 for redress and to refrain from making the claims that had been challenged. The consent order also requires

future programs of 15 minutes or longer to display messages identifying them as paid ads for the products offered.

In 1995, the FTC charged Bland and his companies with violating the consent order by making unsubstantiated weight-loss claims for several products. In addition, their *UltraClear* dietary program had been falsely claimed to reduce the incidence and severity of symptoms associated with gastrointestinal problems, inflammatory or immunologic problems, fatigue, food allergies, mercury exposure, kidney disorders, and rheumatoid arthritis. The settlement agreement included a \$45,000 civil penalty.

Last year, *Natural Foods Merchandiser* reported that Health-

Comm had acquired a minority interest in Keats Publishing of New Canaan, Connecticut, and that Bland had joined its board of directors. Keats is probably America's most prolific publisher of unscientific information about health, nutrition, and "alternative" health methods. Established in 1971, it has issued more than 400 books, of which over 200 are still in print. It also publishes over 100 "Good Health Guides," most of which promote the types of products sold through health-food stores.

During the past several months, Bland has invited practitioners to join him on the Functional Medicine Section of CompuServe's Natural Medicine Forum, which HealthComm cosponsors. Brochures accompanying the invitation claim that the company's *UltraClear Plus* "provides nutritional support for pathological or imbalanced detoxifiers and may be suitable for patients with" chronic fatigue syndrome, chemical and environmental sensitivity, alcohol and chemical dependency, food allergy, "management of endo- and exotoxicity," and arthralgia and myalgia. These claims are apparently illegal and have been reported to the FTC. **NF**

Despite government regulatory efforts, he has persisted in making unsubstantiated claims for products he has marketed.

[continued from page 9]

ANTIAMALGAMIST DELICENSED

In November and December 1995, the Colorado State Board of Dental Examiners held 12 days of hearings related to complaints brought against Hal A. Huggins, DDS, the leading proponent of unsubstantiated claims that mercury-amalgam fillings are dangerous. During the proceedings the administrative law judge concluded: (1) Huggins had diagnosed "mercury toxicity" in all patients who consulted him in his office, even some without mercury fillings; (2) he had also recommended extraction of all teeth that had had root canal therapy; and (3) his treatments were "a sham, illusory and without scientific basis." In February 1996, an administrative law judge issued a 71-page report recommending that Huggins's license be revoked. Huggins did not appeal, and his license was subsequently revoked. Copies of the judge's report are available for \$10 (\$12 in Canada) from LVCAHF, P.O. Box 1747, Allentown, PA 18105.

DENTISTRY'S CREDIBILITY CHALLENGED

A reporter who visited 50 dentists in 28 states found that their fees, examinations, and recommendations varied widely (*Reader's Digest*, February 1997, pp. 50-56). The visits cost from \$20 to \$141. The reporter brought along his own x-ray films and told the dentists he had ample insurance coverage. Only 21 of the 50 dentists conducted cancer screening as recommended by the American Dental Association, and only 14 did the recommended periodontal screening. Before embarking on the study, the reporter was checked by four dentists who agreed that he had only one immediate problem (one molar needed filling or a crown), and that work on another tooth might be advisable. Only 12 of the dentists agreed with this appraisal, and 15 failed to note a problem with the molar. One dentist recommended crowning all of the reporter's teeth, at a cost of \$13,440. Other estimates ranged from \$500 to \$29,850. The reporter also visited a dental school clinic where the student and a

department chairman independently recommended capping both teeth, which would cost \$460. When asked how consumers can protect themselves from overtreatment and overcharging, an ADA advisor suggested seeking a second or third opinion so they can have comfort with the practitioner's recommendations, particularly if there is a lot of work to be done. The reporter replied: "I got 50 opinions, and I am not comforted."

NORDICTRACK MISREPRESENTATION STOPPED

In 1996, the FTC settled charges that NordicTrack, Inc., had made unreasonable claims that 70% to 80% of those who had purchased NordicTrack cross-country ski exercisers had lost an average of 17 pounds and that 80% of those who had lost weight had maintained all their weight loss for at least a year. The FTC complaint stated that these figures were flawed because they did not take dietary habits into account and reflected only the experience of highly motivated purchasers who had integrated the machine into their regular exercise program. The company pledged not to make similar claims in the future unless they were backed by well-designed studies. The case is unusual because, unlike most items marketed with misleading claims, NordicTrack's products are well designed and are readily marketable without exaggeration.

NEW PRO-SCIENCE FORCE

The newly formed Council for Media Integrity intends to challenge the media to do a better job of debunking pseudoscientific ideas. Sponsored by the Committee for the Scientific Investigation of Claims of the Paranormal (CSICOP), council leaders expressed particular concern that the major networks broadcast numerous specials and talk shows that misrepresent pseudoscience and fringe science as genuine science. The council plans to monitor such programs and to attempt to persuade producers, directors, writers, and the general public to leave room for the appreciation of scientific methods of inquiry.

MALPRACTICE VERDICT

A jury in New York City has awarded \$2.5 million in actual damages and \$150,000

in punitive damages to a former patient of Nicholas Gonzales, MD. The woman testified that she had been diagnosed with an early stage of uterine cancer in 1991 and underwent a hysterectomy. Instead of following through with medically recommended radiation and chemotherapy, she consulted Gonzales who discouraged her from following her cancer specialist's advice. Based on his interpretation of a hair test, Gonzales prescribed up to 150 dietary supplement pills a day plus frequent coffee enemas. Later he claimed that the cancer was cured even though it was progressing. It eventually damaged her spine and left her blind. According to an article in the *New York Daily News*, this is the first time punitive damages were awarded in a malpractice case in New York State. In 1994, after investigating six other cases, New York State licensing authorities had concluded: (1) Gonzales's "alternative protocol" did not entitle him to an alternative standard of care; (2) he had failed to correctly interpret signs and symptoms of disease progression; (3) he had treated the patients incompetently; and (4) his record-keeping was inadequate. He was placed on probation for three years with a stipulation that he undergo retraining and his work be supervised by the Office of Professional Conduct.

OUTSTANDING NEWSLETTER

HealthNews, a monthly newsletter from the publishers of the *New England Journal of Medicine*, provides timely analyses of new research and controversial issues. Many of its articles are quackery-related. Subscriptions (\$29) can be ordered through LVCAHF, P.O. Box 1747, Allentown, PA 18105.

"CHIROPRACTIC EDUCATION"

The Foundation for Chiropractic Education and Research (FCER), which funds a large percentage of chiropractic research, is also one of the profession's most prolific sources of misinformation. Its biweekly *Alternative & Natural Medicine Letter* attacks the medical profession, opposes immunization, cites unreliable information sources, and promotes unsubstantiated uses of dietary supplements, herbs, homeopathic products, and "alternative" treatments. **NF**

Is It Right to Promote Unproven Treatments?

by Lewis Vaughn

What do you say to promoters of unproven nutritional treatments who declare, "Why shouldn't I encourage people to try chelated minerals or shark cartilage or megadoses of vitamin X? It can't hurt, and it might help." You could just as easily hear such a statement from a journalist, talk-show host, magazine editor, or health practitioner as you could from the president of a health-products company. The basic question here is whether it's ethical to recommend or promote any unproven treatment—one that has little or no scientific evidence supporting its efficacy. Most nutritionists, physicians, and other professionals would probably say no, but they rarely offer any justification for such an answer.

Generally, medical scientists and health officials oppose the promotion of unproven treatments, sometimes warning that there isn't yet enough evidence to recommend the treatments to the public. Promoters of unproven treatments strongly disagree and sometimes ridicule officials for being "overly cautious" or "too conservative." Their most plausible arguments usually involve an appeal to the relative costs and benefits of a treatment. "What's the harm?" they may ask. "If the treatment itself is harmless, why shouldn't suffering people be given a chance to try it? There may be no strong evidence that it works, but if it does, the benefits to many people would be substantial. The costs to people—in terms of potential physical harm—are low. So on balance, it's best to urge people to try it; the possible benefits outweigh the possible costs." Promoters may believe that

this argument is especially strong if the treatment has some preliminary evidence in its favor or if the monetary outlay for the treatment is low.

But is this really a good argument? Many on both sides in the debate would probably agree that weighing costs and benefits is a valid way to judge the issue. (This approach is based on the fundamental ethical insight that we ought to do what's likely to benefit people and avoid doing what's likely to harm them.) So the question reduces to whether promoting unproven treatments is likely to result in a net benefit to people. Does the promoter's argument show that his promoting leads to such benefit? Actually, this argument fails. It fails because it's too simplistic, neglecting to take into account important factors in the cost-benefit equation.

Slim Chances

One such factor is *probability*. Few people would judge a treatment solely on the magnitude of its proposed benefit or harm. Most would want to take into account the probability that the proposed effects would happen. Someone may claim that rubbing a stone on your belly will cure cancer. The alleged benefit is enormous—but the likelihood of receiving this benefit is almost nil. If someone wanted to sell you such a "cancer-curing" stone for ten dollars, would you buy it? Probably not. The proposed benefit is great but not likely to happen. The cost, though, is a sure thing: if you want the stone, you'll have to pay the price. So on balance, the likely cost, though small, outweighs the unlikely benefits, though great.

But what's the probability that any unproven remedy will be effective? The evidence relating to the remedy can't tell us; by definition, it's too weak to help us figure probabilities. We can, however, make a reasonable assumption. Scientists know that the chances of new hypotheses being correct are very low simply because it's far easier to be wrong than to be right. For the same reason, the likelihood of new health claims turning out to be true is also low. Historically, most health hypotheses, when adequately tested, have been found to be false. In drug testing, for example, scientists may begin with thousands of substances proposed as medicines, some with preliminary evidence in their favor. In the end, after assessing them all, only a meager handful are proven effective in humans. Some promoters misjudge the cost-benefit of recommending a treatment because they either overestimate the probability of its effectiveness or don't consider the factor at all. They seem to assume that the odds of any proposed remedy being effective are close to fifty-fifty, especially if there's some preliminary evidence in its favor. This assumption is false.

Scientists know that the chances of new hypotheses being correct are very low simply because it's far easier to be wrong than to be right.

When we plug realistic probabilities into our moral equation, the wisdom of promoting unproven treatments becomes suspect. Even if an unproven treatment has considerable possible benefits, is harmless, and costs little, it may be no bargain. In general, given the realistic probabilities, the most likely prospect is that the treatment will be ineffective. So, in fact, the odds are excellent that people who buy the treatment will waste their time and money. The likely cost outweighs the unlikely benefits. Promoting the treatment is not likely to result in a net benefit for people, but net harm. The possible benefit of a ten-dollar "cancer-fighting" rock may be great, but the low probability of its working makes buying it a bad deal. Promoting it would be unethical.

Condensed from *How to Think about Weird Things: Critical Thinking for a New Age* by Theodore Schick Jr. and Lewis Vaughn (Mountain View, Calif.: Mayfield Publishing Company, 1995). Reprinted by permission of the publisher.

Hidden Costs

Clearly, the higher the cost of an unproven treatment, the less likely that promoting it will result in a net benefit. But there's more to the cost of an unproven treatment than many promoters realize. The monetary cost can vary tremendously and may not be low at all. (Many unconventional treatments cost hundreds or even thousands of dollars.) Other costs include the direct physical harm that a treatment can cause (nearly all treatments—drugs, surgery, herbs, vitamins, and others—cause some side effects). There's also an indirect cost: A few people (maybe many people) may take the promoter seriously and stop, postpone, or refuse a proven therapy to try the unproven one—a gamble that sometimes has tragic consequences. Then there's the very real emotional pain that false hope can often bring. In these ways, even a harmless therapy can cause harm. All these costs must be factored into the cost-benefit equation. Usually, they just make the promoter's argument weaker.

Now, it's possible that people could apply the cost-benefit approach in their own life and rightly conclude that they *should* try an unproven remedy. They could calculate that any possible benefit, though very unlikely, is well worth the cost because no other treatment is possible or because they consider the cost inconsequential.

Promoters, however, aren't privy to such personal information about those who try unproven remedies. Promoters can only weigh the probable impact of their actions on other people. If they do so honestly, they'll have to conclude that, generally, promoting unproven treatments does more harm than good. **NF**

We want to know what you think... about important developments in nutrition misinformation and quackery and about previous articles in *Nutrition Forum*. We also invite questions on topics relevant to *NF*; we hope to answer selected questions in upcoming issues. Send your letters to *NF* Readers' Forum, P.O. Box 664, Amherst, NY 14226-0664.

[continued from page 13]

They have also found that once patients understand that this can happen, psychotherapy may cure them.

A court case illustrates what can happen when the patient's true problem goes untreated. In 1991, a jury in New York City awarded \$489,000 in actual damages and \$411,000 in punitive damages to the estate of a man who committed suicide at age 29 after several years of treatment by a clinical ecologist in New York City. Testimony at the trial indicated that the patient was a paranoid schizophrenic who thought "foods were out to get him." This type of mental problem may respond well to antipsychotic medication. However, the testimony indicates that the doctor had diagnosed the man as a "universal reactor" and advised that, to remain alive, he must live in a "pure" environment, follow a restrictive diet, and take dietary supplements. The doctor admitted that since 1974, when he began practicing clinical ecology, he had diagnosed every patient he saw as environmentally ill.

MCS in Court

Many claims and lawsuits have been filed to collect workers' compensation and Social Security Disability. Even when the ruling body does not recognize MCS as a disease, it may disregard causation and award benefits to a plaintiff considered disabled by a somatization disorder or other psychological impairment.

Many lawsuits have been based on allegations that chemical exposures cause disease by injuring the immune system. This notion is supported by a network of clinical ecologists and others who misinterpret laboratory data to support claims that virtually any symptom can be caused by exposure to almost anything. They testify that the immune system can become overactive (leading to numerous symptoms) or suppressed (leaving the individual at risk for infection, cancer, rheumatoid arthritis, and other diseases). Some cases involve people who are not physically ill but are afraid that low-dose exposure to environmental chemicals has affected their immune system and may make them susceptible to cancer or other diseases in the future.

Legitimate cases exist where exposure to large or cumulative amounts of toxic chemicals has injured people. But in many of the cases described above, serious immune disorders are being alleged merely because laboratory testing has detected traces of a chemical in the body or has found a minor deviation from "normal" in some measure of immune function. Fortunately, a 1993 U.S. Supreme Court decision has strengthened the ability of judges to exclude unscientific testimony.

Conclusion

"Multiple chemical sensitivity" is not a legitimate diagnosis. It is a phenomenon in which people misinterpret irritant or stress responses as "allergies" or "toxicities" and alter their behavior abnormally. Instead of testing their claims with well-designed research, its advocates are promoting them through publications, talk shows, support groups, lawsuits, and political maneuvering. Many are also part of a network of questionable legal actions alleging injuries by environmental chemicals.

Many people diagnosed with MCS suffer greatly and are very difficult to treat. Well-designed investigations suggest that most of them have a psychosomatic disorder in which they react to stress by developing multiple symptoms. If this is true—and I believe it is—clinical ecology patients run the risks of misdiagnosis, mistreatment, financial exploitation, and/or delay of proper medical and psychiatric care. In addition, insurance companies, employers, other taxpayers, and ultimately all citizens are being burdened by dubious claims for disability and damages. To protect the public, state licensing boards should scrutinize the activities of clinical ecologists and decide whether the overall quality of their care is sufficient for them to remain in medical practice. **NF**

Dr. Barrett, a retired psychiatrist, is a board member of the National Council Against Health Fraud. This article is condensed from a forthcoming 60-page report that can be ordered for \$8 from LVC-AHF, Inc., P.O. Box 1747, Allentown, PA 18105.

SHARK CARTILAGE FLUNKS TEST

A study presented in May 1997 at the American Society of Clinical Oncology's annual meeting found shark cartilage ineffective against advanced cancer in adults with a life expectancy of at least 12 weeks. The study followed 58 people who were prescribed a daily oral dose of shark cartilage as their only form of anticancer treatment. After 12 weeks none achieved a complete or partial response to the shark cartilage treatment. Only ten showed no progression of their cancer, and only two had a quantifiable improvement in quality of life. The researchers concluded: "Shark cartilage was inactive in patients with advanced stages of cancer, specifically in breast, colon, lung, and prostate cancer." The study was sponsored by the Cancer Treatment Research Foundation, Cartilage Technologies (a manufacturer), and Cancer Treatment Centers of America. Last December, Cartilage Technologies announced that it would support no additional research on shark cartilage as a cancer remedy.

BARIATRIC SURGERY CENTER

Two former co-owners of Cancer Treatment Centers of America (CTCA) are now advertising their Michigan-based Bariatric Treatment Centers (BTC) as "the leading center specializing exclusively in treating clinically severe obesity with surgery." A detailed investigative report can be obtained from Ken Garber, Ann Arbor Observer, 201 Catherine, Ann Arbor, MI 48104, or by e-mailing a request to ken@aaobserver.com.

GNC SUED

Charles DeMarco, of Alamonte Springs, Florida, has filed suit against General Nutrition Corporation. The suit papers state that in August 1996 DeMarco had telephoned a GNC store for advice about fatigue, weakness, and yellow skin color. Subsequently, he was advised by the store's "general head nutritionist" that he had jaundice and was referred to a book

Don't Buy Phony 'Ergogenic Aids'

The real story vs. a mountain of hype

by Stephen Barrett, MD

More than a hundred companies are marketing phony "ergogenic aids," combinations of various vitamins, minerals, amino acids, and other "dietary supplements" claimed to build muscles and/or enhance athletic performance. In 1991, researchers from the U.S. Centers for Disease Control and Prevention surveyed 12 popular health and bodybuilding magazines (one issue each) and found ads for 89 brands and 311 products with a total of 235 unique ingredients. *Health Foods Business* estimates that in 1996, total sales of such products through health-food stores exceeded \$204 million. They are also sold through pharmacies and superstores.

The Start of 'Ergogenic' Myths

The notion that massive amounts of protein are necessary during training have evolved from the ancient beliefs that great strength could be obtained by eating the raw meat of lions, tigers, or other animals that displayed great fighting strength. Today, although few athletes consume raw meat, the idea that "you are what you eat" is still widely promoted by food faddists.

During the early 1900s, when muscles were discovered to contain protein, athletes and coaches mistakenly concluded that protein was the principal component. (Actually, it is water.) These protein beliefs were further reinforced during the 1930s by

Bob Hoffman (1899-1985) and later by Joe Weider (1923-), both of whom published magazines that catered to bodybuilders and weightlifters. They asserted that athletes have special protein needs, that protein supplements have special muscle-building and health-giving powers, and that the most efficient way to get enough protein is by using supplements. The scientific facts are otherwise. Muscle-building is not caused by eating extra protein. It is stimulated by increased muscular work. Once basic protein needs have been met, the small additional amount needed during intense training is easily obtainable from a balanced diet. Few Americans fail to consume adequate amounts of protein.

Hoffman and Weider asserted that protein supplements have special muscle-building and health-giving powers.

Hoffman marketed supplement products and bodybuilding equipment through his York Barbell Company of York, Pennsylvania. A prolific writer, he published two magazines and more than 30 books on fitness and nutrition. For many years, York Barbell's nutritional products were promoted with false and misleading claims. In 1960, the company was charged with misbranding its Energol Germ Oil Concentrate because literature accompanying the oil claimed falsely that it could prevent or treat more than 120 diseases and conditions, including

FROM THE EDITOR

Why Nutrition Forum?

There should be no need for this newsletter. No need for a publication that devotes itself entirely to evaluating and reporting on unfounded claims in popular nutrition. Magazines, newspapers, and TV news programs should cover this beat just fine.

But they don't. In fact, many of them are responsible for the massive proliferation of nutrition misinformation.

In print and on TV, preliminary studies often somehow become *proof* that a nutritional therapy works. In the fantasy world of media hype, personal testimony validates a remedy as well as any scientific research ever could—and does so without a lot of technical mumbo jumbo. Here, health gurus and nutritional entrepreneurs get to say the soothing words that everyone wants to hear without the annoyances of nutritional naysayers and scientific evidence.

There should be no need for this newsletter in today's nutritional marketplace. In a perfect world, the FDA, the FTC, the U.S. Postal Service, and consumer common sense would make it impossible for anyone to make a buck promoting unproven treatments. The real world jolts me as I sift through reports of smart, educated people who have been harmed by a nutrition or health claim too good to be

true, wishful thinking taking its toll with hardly a dissenting voice to be found.

What is needed—and what *NF* offers—is the rational, scientific assessment of nutritional claims and products that are affecting people's lives.

People who promote unproven treatments are frequently single-minded—they offer only *one* explanation for a certain set of facts even though there are several other possible (better) explanations. For example, people may report feeling better after trying a remedy not because the remedy works—but because of natural variations in their condition, because of hidden factors (like changes in diet, exercise, medications, sleep habits, etc.), and because of the placebo effect. Preliminary research may appear to support a particular therapy, but there may be better explanations for the results—like small sample size, invalid control group (or no control group), or publication bias. So to get the whole story on a health claim or on a line of research, you need to consider the alternative explanations. This information is precisely what is so scarce these days—and what *Nutrition Forum* provides. This newsletter is not the *only* source for this information, but it is a major source and, in the field of nutrition, I think the *best* source.

As Editor, I intend to keep it that way. With the help of some of the most dedicated nutritional and medical experts in the nation, I will insure that *Nutrition Forum* continues to offer dietitians, nutritionists, doctors, and general readers this rare commodity.

Lewis Vaughn

JOURNAL SPOTLIGHT

GINKGO COMPLICATION REPORTED

Temporary episodes of blurred vision have been reported in a 70-year-old man who had been taking two tablets a day of Ginkoba for one week (*New England Journal of Medicine* 336:1108, 1997). Physical examination revealed a small area of bleeding into the iris of the eye (the colored portion surrounding the pupil). Ginkoba, an extract of the ginkgo biloba tree, is marketed as a "dietary supplement" to improve mental alertness. One of its chemical components (ginkgolide B) can interfere with blood clotting by inhibiting the action of platelets. Other cases of abnormal bleeding have been reported. For three years following surgery, the patient had been taking aspirin, which has similar anticoagulant action. No further bleeding occurred after he stopped taking Ginkoba but continued to take aspirin. The case should warn people tempted to combine aspirin (proven to reduce the incidence of heart attacks) with vitamin E, garlic, and ginkgo biloba, each of which can exert a significant anticoagulant effect.

HOMOCYSTEINE RISK-FACTOR UPDATE

A Dutch study has compared 131 patients with severe blockages in two coronary arteries, 88 patients with moderate blockage of one coronary artery, and another group of healthy individuals without heart disease. The researchers found a linear relationship between blood homocysteine levels and severity of the coronary blockages: For every 10% elevation of homocysteine, there was nearly the same rise in the risk of developing severe coronary heart disease (*Arteriosclerosis, Thrombosis, and Vascular Biology* 17:989-95, 1997).

[continued from page 17]

epilepsy, gallstones, and arthritis. In 1961, 15 other York Barbell products were seized as misbranded. In 1968, a larger number of products came under attack by the government for similar reasons. In 1972, the FDA seized three types of York Barbell protein supplements, charging that they were misbranded with false and misleading bodybuilding claims. In 1974, the company was again charged with misbranding Energol and protein supplements. The oil had been claimed to be a special source of vigor and energy. False bodybuilding claims had been made for the protein supplements.

Despite his many brushes with the law, Hoffman achieved considerable professional prominence. During his athletic career, first as an oarsman and then as a weightlifter, he received over 600 trophies, certificates, and awards. He was the Olympic weightlifting coach from 1936 to 1968 and was a founding member of the President's Council on Physical Fitness and Sports.

Weider began bodybuilding as a teenager and was 16 when he launched a newsletter called *Your Physique*. A few years later, he started a company that sold bodybuilding equipment and instructional booklets through the mail. In 1946, Joe's brother Ben joined the business, and they set up the International Federation of Bodybuilders, which promotes the sport worldwide and sponsors competitions. According to press reports, their business empire now grosses over \$500 million annually.

Weider Health & Fitness is the dominant player in the sports-supplement marketplace. It publishes seven magazines, sells bodybuilding equipment, broadcasts "Muscle Magazine" on ESPN, and sponsors many athletic and aerobic events throughout the year. The magazines are *Muscle & Fitness*, *Shape*, *Flex*, *Living Fit*, *Men's Fitness*, *Prime Health & Fitness*, and *Senior Golfer*. The supplements include Anabolic Mega-Pak, Dynamic Life Essence, Dynamic Super Stress-End, Dynamic Power Source, Dynamic Driving Force, Dynamic Fat Burners, Dynamic Liver Concentrate Energizer, Dynamic Sustained Endurance, Dynamic Recupe, Dynamic Body Shaper, and Dynamic Muscle Builder. None of these products appears capable of doing what its name suggests, and none contains any nutrients not readily obtainable from a balanced diet.

In 1984, the FTC charged that ads for Anabolic Mega-Pak (containing amino acids, minerals, vitamins, and herbs) and Dynamic Life Essence (an amino acid product) had been misleading. The FTC complaint was settled in 1985 when Weider and the company agreed not to falsely claim that these products can help build muscles or are effective substitutes for anabolic steroids. They also agreed to pay a minimum of \$400,000 in refunds or (if refunds did not reach this figure) to fund research on the relationship of nutrition to muscle development. Although the forbidden claims no longer appear in Weider ads, similar messages appear in arti-

None of these products appears capable of doing what its name suggests.

Hot but risky?

Creatine has been described as the "hottest" ergogenic supplement of the decade. It is popular because it can increase endurance and speed recovery from strenuous activities, which can enhance strength training for certain sports. However, a significant percentage of users experience cramps, muscle spasms, and pulled muscles. Scientific studies have shown that depletion of creatine stores may be associated with the onset of muscle fatigue and that supplementation can increase muscle creatine levels after a few days. The increase was greatest among vegetarians who were found to have the lowest stores. It is not known whether people with adequate dietary intake to begin with run the greatest risk of trouble with supplements. The NCAA Committee on Competitive Safeguards and Medical Aspects of Sports has urged that research be done to determine whether long-term use is safe and whether certain individuals might be predisposed to negative side effects.

WEB WATCH

Looking for nutrition and health information on the World Wide Web? Beware: You're entering a vast library sprinkled with booby traps. Is that a solid piece of nutrition reporting—or a pseudofact ready to explode on contact? This column helps you figure out which is which. Following is a list of some of the best (most reliable, useful) sites and some of the worst (most unreliable, deceptive, weird, and worthless). Ratings and commentary are by Internet-savvy John H. Renner, MD, president of the Consumer Health Information Research Institute.

BEST

<http://www.dietitian-online.screen.ie/> Clinical Nutrition Online can answer almost any dietary question you can ask. One of the most nourishing sites on the Internet. This site is for dietitians as well as the public.

<http://www.ncahf.org/> Site of the National Council Against Health Fraud—the place to surf to for information about quackery and fraudulent claims.

<http://www.fsci.umn.edu/> The Department of Food Science at the University of Minnesota. This is a super scientific site with a good internal search capability. No recipe for gopher meat was found.

<http://vm.cfsan.fda.gov/> This is the Center for Food Safety and Applied Nutrition at the FDA. A short address with a long list of resources and very accurate information. One of the finest nutrition sites on the Internet. Better mark it.

WORST

<http://utopia.knoware.nl/users/cvdk/urinetherapy/index.html> This site has everything you wanted to know (and did not want to know) about urine therapy. It demonstrates how far afield alternative medicine has evolved. From this site, you can get the details of the next world conference on urine therapy.

<http://www.alternativemedicine.com/> This site is the online version of *Alternative Medicine Digest*, mentioned in the last installment of Web Watch. It has such strange health information that I am offering a prize for the best in-depth review of this site by a nutrition professional, skeptic, scientist, or investigative reporter. I will judge all submissions by July. Your prize is one you're going to like. We may even publish some of the comments in *Nutrition Forum*. If your review is good enough, I may ask you to help me review other web pages. Please send your review by e-mail to drrenner@msn.com.

cles in the magazines and are implied by endorsements and pictures of muscular athletes as well as by names of the products themselves. False and misleading claims have also appeared in a series of 18 booklets published in 1990 by Weider Health & Fitness and marketed through GNC stores.

The Market Grows

During the 1970s, in addition to protein supplements and assorted vitamins, the main products touted to athletes were wheat germ oil and bee pollen (falsely claimed to boost energy and endurance). In the early 1980s, Weider Health & Fitness introduced an "Olympians" line said to have been developed by working closely with "Olympians and nutritional researchers." Most were sustained-release vitamin concoctions that included an exotic ingredient or two. As public interest in fitness grew, several drug companies began falsely claiming that multivitamin or "stress" supplements were just what active people needed.

Life Extension, by Durk Pearson and Sandy Shaw, was published in 1982 and was followed by appearances by the authors on hundreds of radio and television talk shows. The book claimed that supplements of certain amino acids would cause the body to release growth hormone, which would produce muscle growth and fat loss with little or no effort. These claims were based on faulty extrapolations of experiments in which animals were given large doses of these amino acids by injection. Swallowing amino acids does not cause humans to release growth hormone. But the massive publicity garnered by Pearson and Shaw inspired the health-food industry to market hundreds of new products for athletes and would-be dieters. Many of these products are falsely claimed to be "natural steroids" or "steroid substitutes." In the ensuing years, scores of other useless ingredients have been added to "er-

gogenic aids."

Some manufacturers make no claims in their ads but imply them in product names. Many use pictures of athletes to convey their messages. Some make explicit claims in their ads or product literature, while others use simple puffery. Several have published charts suggesting which products are good for specific purposes. Some even market products for specific sports.

False and misleading claims have also appeared in a series of 18 booklets published in 1990 by Weider Health & Fitness and marketed through GNC stores.

Just the Facts

Athletes who eat a balanced diet don't need extra protein or vitamins. In *The Complete Sports Medicine Book for Women*, sports medicine specialist Gabe Mirkin, MD, and gynecologist Mona Shangold, MD, explain why: "You don't need much extra protein even to enlarge your muscles.

For example, 1 pound of muscle contains only about 100 grams of protein, since it is composed of more than 72% water. So if you are gaining 1 pound of muscle every week in an excellent strength training program, you are adding only about 100 grams of protein each week, or about 15 grams of protein each day. Two cups of corn and beans will meet this need—far less than you would expect. In addition, requirements for only four vitamins increase with exercise: thiamin, niacin, riboflavin, and pantothenic acid. These vitamins are used up minimally in the breakdown of carbohydrates and, to a small degree, protein for energy. But you will find them abundantly in food. Furthermore, deficiencies of these vitamins have never been reported in athletes."

What about other products? The most thorough investigation has been conducted by David Lightsey, MD, an exercise physiologist and nutritionist who coordinates the National Council Against Health Fraud's Task Force on Ergogenic Aids. During the past several years, he has telephoned more than 100 companies that market "ergogenic aids." In a recent interview, Lightsey told me: "In each

case, I told a company representative that I had been asked to collect data on the company's product(s) and issue a formal report. After they described the alleged benefits, I would ask how data supporting these claims were collected. As my questions became more specific, their responses became more vague. Some said they could not be more specific because they did not wish to reveal trade secrets.

"I ended each interview with a request for written documentation. Fewer than half sent anything. Most of the studies they sent were poorly designed and proved nothing. The few that were well designed did not support product claims but were taken out of context.

"Some companies claimed that one team or another was using their products. In each such case, I contacted the team management and learned that although one or more players used the company's products, the management had neither endorsed the products nor encouraged their use."

Lightsey believes there are two reasons why many athletes believe that various products have helped them: (1) use of the product often coincides with natural improvement due to training, and (2) increased self-confidence or a placebo effect inspires greater performance. Any such "psychological benefit," however, should be weighed against the dangers of misinformation, wasted money, misplaced faith, and adverse physical effects—both known and unknown—that

BE A NUTRITION FORUM CONTRIBUTOR!

If you find any news or information that may be of interest to our readers—such as published articles, news reports, press releases, or relevant personal experience—please send it to us. Mail it to Lewis Vaughn, *Nutrition Forum*, P.O. Box 664, Amherst, NY 14226-0664. We're especially interested in receiving information about enforcement actions by state agencies, lawsuits by victims of quackery, and health-fraud news that may have been overlooked by the national media.

can result from megadoses of nutrients. Moreover, how many people who are involved in fitness programs or recreational sports need a placebo for inspiration?

Lack of Action

Little government effort has been made to protect consumers from wasting money on "sports nutrient" products. The FTC took the action noted above against Weider Health & Fitness, the market leader. In 1986, the agency acted against A. H. Robins and its subsidiary, the Viobin Corporation, which had been making false claims for wheat germ oil products for more than 15 years. The case was settled with a consent agreement prohibiting representations that the oil could help consumers improve endurance, stamina, vigor, or other aspects of athletic fitness, or that its active ingredient "octacosanol" is related in any way to body reaction time, oxygen uptake, oxygen debt, or athletic performance.

In 1992, the New York City Department of Consumer Affairs (DCA) published a report called "Magic Muscle Pills! Health and Fitness Quackery in Nutrition Supplements." DCA investigators found that manufacturers they contacted for information about their products were unable to provide a single published report from a scientific journal to back the claims that their products could benefit athletes.

Along with its report, DCA issued "Notices of Violation" to six companies whose products it had investigated. It also warned consumers to beware of terms like "fat burner," "fat fighter," "fat metabolizer," "energy enhancer," "performance booster," "strength booster," "ergogenic aid," "anabolic optimizer," and "genetic optimizer." Calling the body-building supplement industry "an economic hoax with unhealthy consequences," DCA officials urged the FDA and FTC to stop the "blatantly drug-like claims" and false advertising used to promote these products.

In 1994, the FTC reached a consent agreement under which General Nutrition, Inc., paid \$2.4 million to settle charges that it had falsely advertised 41 products, most of which had been pack-

Weight-Loss Herbs: A Review

by Varro E. Tyler

The large headline "12 Top Herbs for Weight Loss" prominently positioned on page 1 of the March 1997 issue of *Natural Pharmacy* proved irresistible.

The article that followed turned out to be an adaptation from the book *Feeling Light—the Holistic Solution to Permanent Weight Loss and Wellness* by herbalist S. Katzman and holistic health professional W. Shankin-Cohen, in collaboration with M. Marshall (Avon Books, 1997). Believing that herbs of any kind are minimally effective—if at all—in promoting weight loss, I read the article to see if there might be something I had overlooked.

A Dozen Errors

Here are the authors' selections of "weight loss herbs" followed by my comments.

Aloe juice: Not to be confused with aloe gel, the juice or latex is such a potent stimulant laxative that many authorities no longer recommend its use.

Burlock: Said to have diuretic properties. None of its purported effects has been confirmed by clinical testing.

Chickweed: There is no acceptable evidence that it possesses therapeutic value.

Dandelion: The leaves have a slight diuretic action; the root is a laxative.

Sassafras bark: Long prohibited from use as a flavor or food additive by the FDA because it contains safrole, a proven carcinogen in small animals.

Yellow dock: This is another stimulant laxative.

Buchu: An old-time diuretic. Once a very popular proprietary drug.

Cleavers: Another diuretic.

Flax: Primarily a bulk laxative.

Horsetail: Has a feeble diuretic effect.

Marshmallow: A soothing demulcent (mild pain reliever of mucous tissue) due to its mucilage; used both externally and internally.

Alfalfa: There is no scientific or clinical evidence to support any significant therapeutic activity of this herb.

None of the herbs in this deceptive dozen has any proven effect on weight loss.

Most of them have some laxative or diuretic action which promotes the temporary loss of water from the body, providing a passing illusion of weight loss. The protracted use of stimulant laxatives, such as aloe juice and yellow dock, and of diuretics (buchu, cleavers) may lead to hypokalemia, i.e., potassium depletion, which can result in cardiac irregularities and even respiratory arrest. Therefore, their long-term use suggested in the article—"Herbs that aid in elimination should become a permanent feature of one's daily diet"—is just plain bad advice. The inclusion of sassafras bark, a banned carcinogen, in an article advocating daily use of such herbs is incomprehensible.

Without Reason

The authors do warn against the use of preparations that contain ephedra and guarana (a caffeine-rich seed). Now this is good advice because chronic use of such preparations may cause severe side effects in patients with hypertension, diabetes, or thyroid conditions. However, they go on to caution against the use of yohimbe or damiana. This is an interesting warning since neither of these herbs has any folkloric reputation as a promoter of weight loss. Instead, they are said to act as aphrodisiacs.

That attribution is undeserved for damiana, an essentially inactive herb. Yohimbe, on the other hand, may be marginally useful in the treatment of psychogenic impotence. However, its use is precluded by undesirable side effects at therapeutic doses. These include nervous excitation, sleeplessness, hypertension, and tachycardia. What occasioned the mention—even negatively—of these alleged aphrodisiacs in a book or an article on possible weight-loss herbs?

Of course, they are just as effective for that purpose as the dozen herbs advocated in the article, which is to say, not at all! **NF**

Dr. Tyler is a Board member of Nutrition Forum; a Distinguished Professor Emeritus of Pharmacognosy, Purdue University; and the author of The Honest Herbal, a classic in the field.

[continued from page 17]

containing advice on what supplements and herbs might be useful. After ten days he became gravely ill and required two hospital admissions plus a stay in a nursing center. The suit alleges that, as a result of a delay in getting appropriate treatment, DeMarco has become disabled by "a weakened condition, a limp, carelessness, forgetfulness, and a limp." According to an article in *FDA Hotline* (a now-defunct newsletter philosophically aligned with the health-food industry), the store manager has stated that DeMarco's account is false and that no "prescribing" took place.

NEW ANTIQUACKERY FORCE

Dr. Stephen Barrett intends to help improve the quality of health information on the Internet. His Quackwatch web site is growing rapidly. He hopes to recruit hundreds of professionals to evaluate web sites and respond to individual questions. The project will be done under the auspices of Quackwatch, Inc., a nonprofit corporation that was founded in 1969 as the Lehigh Valley Committee Against Health Fraud and was recently renamed. Experts with web access who wish to donate a few hours per month to the project should explore <http://www.quackwatch.com> and contact Dr. Barrett by e-mail.

'HARMFUL VEGETABLES' CLAIM DEBUNKED

Data from a prospective study of 549 pregnant women show no relationship between the intake of various vegetables, the occurrence of vomiting early in pregnancy, and the incidence of adverse pregnancy outcomes (*American Journal of Obstetrics and Gynecology* 176: 179-81, 1997). The analysis, performed by researchers at the University of Minnesota, refuted the notion that eating broccoli, cabbage, cauliflower, garlic, and spinach might cause miscarriages or birth defects, as claimed in the book *Protecting Your Baby-To-Bc: Preventing Birth Defects in the First Three Months of Pregnancy*.

FISH OIL ADVISORY

The American Heart Association has updated its recommendation that fish be consumed as an excellent source of omega-3 fatty acids and a good protein source that is low in saturated fat. Several studies have shown that people who eat fish have fewer heart attacks and a lower overall mortality. The Association's nutrition committee does not recommend taking fish-oil capsules either to prevent coronary artery disease or prevent reclogging of arteries that have been opened by balloon angioplasty. The committee recommends supplements only for patients with high levels of triglycerides that cannot be lowered by drug treatment and who are at risk for pancreatitis and remain under medical supervision. A long-term study of 2107 men showed that those who were including fish in their diet when studied in 1957 subsequently had a lower death rate from coronary heart disease (*New England Journal of Medicine* 336:1046-53, 1997).

FREE HYDRAZINE SULFATE REPORT

In the mid-1970s, hydrazine sulfate was proposed for treating the progressive weight loss and debilitation characteristic of advanced cancer. Based on animal data and preliminary human studies, it has also been claimed to cause tumor regression and subjective improvement in patients. However, three recent trials sponsored by the National Cancer Institute (NCI) demonstrated no benefit attributable to hydrazine sulfate. The largest of the three found that nerve damage occurred more often and that quality of life was significantly worse in the hydrazine sulfate group. After these studies were published, proponents claimed that they were flawed because patients were permitted to ingest tranquilizers, barbiturates, or alcohol, which allegedly would nullify the effect of hydrazine sulfate. The NCI rejected these concerns, and an investigation by the United States General Accounting Office (GAO) found no difference in survival times between the patients who had taken these drugs and those who had not. For a free copy of the GAO report, call (202) 512-6000 and request Document No. HEHS-95-141.

ALCOHOL COUNTERADVERTISING

The National Council on Alcohol Abuse, Mothers Against Drunk Driving, and 22 other groups have petitioned the Federal Communications Commission to require stations that broadcast ads for alcoholic beverages to provide significant amounts of free time for warnings about the health and safety risks of excessive drinking. An Associated Press story states that about 2,000 radio and television stations air about \$750 million worth of beer and wine ads annually. The petitioners are worried that alcoholic beverage ads will increase sharply because, last year, the liquor industry abandoned its long-held voluntary ban on broadcast advertising. ABC, CBS, NBC, and Fox have said they won't accept liquor ads, but some television outlets have begun airing them.

HEALTH-FOOD STORE SALES

Health Foods Business estimates that 39.9% of sales in health-food stores last year were for vitamins and other supplements. Based on its annual survey, the magazine estimated that 9,789 stores grossed \$3.05 billion for these products, up 38% from 1995. Total sales for all products were \$7.74 billion (up 27%), including \$1.5 billion for herbs and herbal teas (up 62%) and \$267 million for books (up 44%). Homeopathic remedies accounted for 12.1% of the vitamins/supplements category.

IRON OVERLOAD SCREENING

The U.S. Centers for Disease Control and Prevention (CDC) recommends that adults be screened for hereditary hemochromatosis, a genetic disorder in which increased iron absorption in the gastrointestinal tract causes iron to accumulate in the body and causes arthritis, cirrhosis, diabetes, impotence, heart failure, and other problems. The screening can be done with a transferrin saturation test, which costs about \$2. The recessive gene for hereditary hemochromatosis was discovered in 1996. About 10% of Americans carry the gene, and about 1.5 million have the disease (*Morbidity and Mortality Weekly Report* 45:991-93, 1996). A gene test is available but costs about

\$200. Formal CDC guidelines are expected within the next year.

MCT OIL FLUNKS TEST

Health-food stores sell oil derived from medium-chain triglycerides (MCTs) as an alternative to olive or canola oil. It allegedly provides athletes with an energy boost without raising their serum cholesterol level. However, researchers at the University of Texas have demonstrated that the body converts MCTs into long-chain triglycerides, which do raise LDL cholesterol levels (*Southwestern News*, University of Texas Southwestern Medical Center, Jan 2, 1997).

PASSIVE SMOKING RISK

A prospective ten-year study has found that female nonsmokers who had been regularly exposed to cigarette smoke by co-workers or companions had a 91% higher incidence of heart attack or death than nurses who were not subjected to smoke. The project involved 32,046 nurses, ages 36 to 61, who had not been diagnosed with coronary heart disease when the study began in 1982. More heart attacks occurred with regular exposure than with occasional exposure. The data provide strong evidence that passive smoking is a major contributor to heart disease (*Circulation* 95:2374-79, 1997).

SUNRIDER PRESIDENT INDICTED

On January 7, 1997, the *Wall Street Journal* reported that Sunrider International's president Tei Fu Chen and his wife had been indicted for conspiracy, tax evasion, and smuggling. Sunrider is a multilevel company that markets herbal products. The article said that the Chens had (1) underreported their 1987-90 income by more than \$125 million, (2) used foreign companies they controlled to overcharge Sunrider for ingredients so the company could understate its profits, (3) wired millions of dollars to pay the inflated charges, but "recycled" the money to purchase U.S. real estate and Chinese antiques, and (4) filed falsely low customs declarations to reduce the import duty on dozens of art works.

'Wild Yam Cream' Threatens Women's Health

by Timothy Gorski, MD, F.A.C.O.G.

Many women are being encouraged to buy and use "Wild Yam Cream," which is said to offer relief from premenstrual and menopausal symptoms. The preparation is made by a company called "NATURAL efx" and is promoted with materials that include testimonials, the recommendation of a "Dr. Betty Kamen," and citations of the medical literature purported to support the claims being made.

According to this promotional literature, "Hormonal Imbalance!!!" and "Estrogen Dominance" cause "Cramps, Migraines, Bloat, Breast Tenderness, Hot Flashes, Can't Lose Weight, Lack of Energy, Depression—Mood Swings, Fibroid Tumors, Endometriosis—Infertility, Family History Female—Related Cancer, Foggy Thinking, Perimenopause, [and] Losing Height." These conditions are said to be effectively treated by the application of the product twice daily. Also claimed is that the cream "Enhances libido, Improves energy, stamina and endurance, Stimulates the body's own production of estrogen, progesterone, testosterone, [and] other hormones," and that "Women report [an] overall feeling of well being and euphoria." In addition, it's asserted that "synthetic progestins have serious side effects" whereas "natural progesterone has none" and that the only reason that the former is used is that it can be patented. Finally, even men are claimed to benefit from the product, which is said "to help balance testosterone with no feminizing effects."

There is, of course, reason to suppose that hormones play a part in several of the conditions mentioned. For some of these conditions, though, this role remains uncertain or unlikely. It is certainly unwarranted to say that "Estrogen Dominance" is the cause of all the disorders mentioned and that a progesterone product can prevent, alleviate, or cure them. In premenstrual syndrome, for example,

double-blind controlled trials have demonstrated that progesterone supplementation is no better than a placebo. Also blatantly false is the claim that synthetic progestins are dangerous whereas natural progesterone is harmless. Progesterone in any form may cause side effects. In addition, the major synthetic progestin now in use (medroxyprogesterone) has been off patent for some time. It is generally preferred over progesterone—which is also produced synthetically—because it is much better absorbed when taken orally.

The more blatantly erroneous claim is that the Mexican yam (*Dioscorea villosa*) from which the cream is supposedly made is a source of progesterone. It is not. In fact, the main hormonally active substances present in the plant would probably be estrogenic. Extracts of *D. villosa* do have significant amounts of the substance diosgenin. The plant is therefore very useful because in the lab—not in the human body—diosgenin can be used to synthesize steroid hormones including progesterone. Indeed, it was this discovery that led to the first commercially available oral contraceptives. The proges-

A NATURAL PREDICAMENT

Herbal marketers want to have their cake and eat it too. While claiming that their products are potent, they also demand complete freedom to market them. Each "natural" product is either (a) no better than a placebo or (b) exerts a pharmacologic effect. Products no better than placebos should be banned as frauds. Those that are potent should be regulated as drugs and carry adequate instructions for their intended uses. This is especially true for hormones and other products that can affect many body systems.

terone listed among the ingredients in Wild Yam Cream may very well have been derived in this way via the test tube from naturally occurring diosgenin. But that, of course, isn't mentioned in the product literature.

Also left unmentioned is the fact that, once introduced into the body by any effective means (including transdermally), the progesterone molecule can be metabolized into a wide variety of other compounds including estrogens, androgens, and even corticosteroids. Indeed, all of these vital hormones are the products of the continuous production of progesterone and its physiologic conversion into these hormones in the ovaries, testes, and adrenal glands. Part of the usefulness of synthetic progestins, on the other hand, is that they are not subject to these biochemical transformations but are able to exert their desired effects until metabolized and excreted.

Thus, not only is there little reason to suppose that Wild Yam Cream would be helpful for the medical conditions for which it is being promoted, but it is doubtful that it ever could be as useful as synthetic progestin.

The greatest danger posed by this product and its deceptive promotion is that it will lead many menopausal women to forego or even discontinue indicated hormone replacement therapy (HRT), which has enormous proven value in alleviating hot flashes, vaginal atrophy, and other symptoms; reducing bone loss; and preventing atherosclerosis. This is especially tragic since so many women already have trouble maintaining a consistent HRT regimen. The last thing American women need is another unproven "natural alternative" promoted by a campaign of deceit at the expense of their life and health.

Besides all these concerns, Wild Yam Cream costs more. A month's supply of it costs about \$27. A month's supply of the HRT prescription drugs Premarin[®] and Estrace[®] costs \$12 and \$18, respectively. **NF**

Dr. Gorski practices obstetrics and gynecology in Arlington, Texas, and is president of the Dallas-Fort Worth Council Against Health Fraud.

[Continued from page 21]

aged by other manufacturers. The products included Weider's Super Fat Burners, eleven other "muscle builders," and five other phony "ergogenic aids." No action was taken against the other manufacturers. The FTC's staff is well aware that the "sports nutrition" marketplace needs cleaning up, but it lacks the resources to pursue the majority of offenders. A Trade Regulation Rule that would govern the entire industry could make enforcement more efficient, but the agency has expressed no interest in this approach.

The FDA has the legal right to ban claims that the products stimulate hormone activity or alter the body's metabolism. (Claims of this type enable the agency to classify them as drugs and ban unapproved uses.) In 1994, David Light-

sey and I petitioned the FDA to ban all ingredients in these products that had not been proven safe and effective for their intended use and to issue a public warning that the FDA does not recognize them as effective. The agency replied that our petition "did not contain scientific evidence that the claims described in the petition were such that products are . . . unapproved new drugs" and that it "did not provide scientific evidence that would allow the FDA to evaluate the validity of the claims." **NF**

Dr. Barrett is board chairman of Quackwatch, Inc., and a board member of the National Council Against Health Fraud. His best-known book is The Vitamin Pushers: How the "Health Food" Industry Is Selling America a Bill of Goods (Prometheus, 1994).

READERS' FORUM

LEGAL DÉJÀ VU

I was interested to read the "Briefs" article (March/April, 1997) detailing the Access to Treatment Act reintroduced to the House of Representatives by Mr. DeFazio (D-Oregon). The details of this bill were startlingly familiar to me, as I recognized the similarity to House Bill 1255 introduced in to the South Dakota State Legislature this year.

During this legislative session, I had the pleasure of testifying against HB 1255 before the House Health and Human Services Committee and am happy to note that the bill was defeated *in committee*. In assisting the committee, I included information on reportable diseases as outlined by South Dakota law and provided a copy of the relevant Code of Federal Regulations (FDA 21 CFR Part 50 Subpart B). Additional testimony against HB 1255 was provided by the Director of the State Board of Nursing.

Despite this year's legislative success with HB 1255, I suspect that similar (or more sophisticated) legislation will surface in the upcoming 1998 session. I am virtually certain that South Dakota is not and shall not be the only state faced with legislation of this nature.

With this in mind, I am making available to interested parties a copy of the outline I developed for testifying before the committee (members of the com-

mittee commented that it was very helpful in achieving defeat of the bill). For copies, call (605) 341-8828.

THE INDEX, PLEASE

Now that we've a new Editor, retrieved name, and re-iterated roots, perhaps you can again publish a *yearly subject index*. I've found this invaluable in researching info and for fueling my debates. Please re-institute the index!

John B. Fenger, MD
Phoenix, AZ

Editor: We will indeed again provide a subject index to our readers. Look for it in the November/December issue. **NF**

JOIN THE FORUM

We want to know what you think . . . about important developments in nutrition misinformation and quackery and about previous articles in *Nutrition Forum*. We also invite questions on topics relevant to *NF*; we hope to answer selected questions in upcoming issues. Send your letters to Readers' Forum, P.O. Box 664, Amherst, NY 14226-0664; please include your daytime telephone number.

PHARMACISTS EMBRACING HERBS

Health-food trade publications report that the percentage of pharmacies carrying herbal products is growing rapidly. The increase is attributed to greater consumer interest and to decreased profits on conventional drugs (due to managed care). The percentage of pharmacy schools offering courses in pharmacognosy (the science of plant medicine) has also increased.

SUPPLEMENTS AND HEALTH-FOOD-STORE CUSTOMERS

In a recent study, consecutive health-food-store customers reported taking 5.9 products per person (*Journal of the American Board of Family Practice* 10:265-71, 1997). The participants were recruited during a 3-week period at two stores in Milwaukee suburban areas. Of the 194 customers who were asked to be interviewed later by telephone, 136 (70.1%) completed the interview process. The participants reported taking a total of 805 supplement products. Most (84.3%) considered themselves healthy but took supplements for preventive purposes. The rest took products to treat perceived health problems. Nearly 80% based their use on their own investigation rather than that of a health professional. About 10% of the customers were taking potentially toxic megadoses of vitamins A or B₆.

THE \$20 MILLION DUCK

Ocilloccoccinum, a homeopathic product "for the relief of colds and flu-like symptoms," is reportedly made by incubating small amounts of a freshly killed duck's liver and heart for 40 days. The resultant solution is then filtered, freeze-dried, rehydrated, diluted 1:100 repeatedly, and used to impregnate sugar granules. After 200 serial dilutions, the likelihood of a single molecule of duck heart or liver remaining would be 1 in 100²⁰⁰. The number 100²⁰⁰ vastly exceeds the estimated number of molecules in the universe. In its February 17, 1997 issue, *U.S. News & World Report* noted that in 1996 only one duck was needed to manufacture the product, which had total sales of \$20 million.

The 'Dietary Supplement' Mess

Commission Report Issued

by Stephen Barrett, MD

In the early 1990s, Congress began considering two bills to greatly strengthen the ability of federal agencies to combat health frauds. One would have increased the FDA's enforcement powers as well as the penalties for violating the Food, Drug, and Cosmetic Act. The other would have amended the Federal Trade Commission Act to make it illegal to advertise nutritional or therapeutic claims that would not be permissible on supplement labels. During the same period, the FDA was considering tighter regulations for these labels.

Alarmed by these developments, the health-food industry and its allies urged Congress to "preserve the consumer's freedom to choose dietary supplements." To whip up their troops, industry leaders warned retailers that they would be put out of business. Consumers were told that unless they took action, the FDA would take away their right to buy vitamins. These claims, although bogus, generated an avalanche of communications to Congress.

The end result was a law that greatly weakened the FDA's ability to protect consumers. Called the Dietary Supplement Health and Education Act (DSHEA) of 1994, it defined "dietary supplements" as a separate regulatory category and liberalized what information could be distributed by their sellers. It also created an NIH Office of Dietary

Supplements and directed the President to appoint a Commission on Dietary Supplement Labels to recommend ways to implement the act. The Commission's recommendations were released on June 24, 1997. (See "Recommendations from the Dietary Supplement Commission.")

Expanded Definition

The Food, Drug, and Cosmetic Act defines "drug" as any article (except devices) "intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease" and "articles (other than food) intended to affect the structure or function of the body." These words permit the FDA to stop the marketing of products with unsubstantiated "drug" claims on their labels.

To evade the law's intent, the supplement industry is organized to ensure that the public learns of "medicinal" uses that are not stated on product labels. This is done mainly by promoting the ingredients of the products in books, magazines, newsletters, booklets, lectures, radio and television broadcasts, and oral claims made by retailers.

DSHEA worsened this situation by increasing the amount of misinformation that can be directly transmitted to prospective customers. It also expanded the types of products that could be marketed as "supplements." The most logical

The end result was a law that greatly weakened the FDA's ability to protect consumers.

definition of “dietary supplement” would be something that supplies one or more essential nutrients missing from the diet. DSHEA went far beyond this to include vitamins; minerals; herbs or other botanicals; amino acids; other dietary substances to supplement the diet by increasing dietary intake; and any concentrate, metabolite, constituent, extract, or combination of any such ingredients. Although many such products (particularly herbs) are marketed for their alleged preventive or therapeutic effects, DSHEA has made it difficult or impossible for the FDA to regulate them as drugs. Since its passage, even hormones, such as DHEA and melatonin, are being hawked as supplements. DSHEA also prohibits the FDA from banning dubious supplement ingredients as “unapproved food additives.” The FDA considered this strategy more efficient than taking action against individual manufacturers who made illegal drug claims. Since DSHEA’s passage, the only way to banish an ingredient is to prove it is unsafe. Ingredients that are useless but harmless are protected.

‘Nutritional Support’ Statements

DSHEA allows dietary supplements to bear “statements of support” that: (1) claim a benefit related to classical nutrient deficiency disease, (2) describe how ingredients affect the structure or function of the human body, (3) characterize the documented mechanism by which the ingredients act to maintain structure or function, or (4) describe general well-being from consumption of the ingredients. The statement “calcium builds strong bones and teeth” is said to be a classic example of an allowable structure/function statement for a food. What constitutes an allowable statement for a supplement has not been specified either by law or by regulation.

To be legal, a “nutritional support” statement must not be a “drug” claim. In other words, it should not suggest that the product or ingredient is intended for prevention or treatment of disease.

The Dietary Supplement Commission expressed concern that “some statements of nutritional support are in fact akin to drug claims.” Some members be-

lieve that claims related to organs (such as “supports the eyes” or “supports the cardiovascular system”) are really drug claims and that DSHEA has created a loophole for such claims. Some members are particularly concerned about statements that mention an acute effect on the structure or function of a major system (such as “reduces heart rate”).

Actually, few statements about the biochemical or physiologic properties of nutrients have practical value for consumers. By definition, every essential nutrient is important to proper body function. Simple statements about nutrient function are more likely to be misleading than helpful. A statement such as “vitamin A is essential to good eye function” could suggest: (1) people need to take special steps to be sure they get enough, (2) extra vitamin A may enhance eyesight, and (3) common eye problems may be caused by vitamin A deficiency or remedied by taking supplements. To be completely truthful, a “nutritional support” statement about vitamin A would have to counter all three misconceptions and indicate that people eating sensibly don’t need to worry about whether their vitamin A intake is adequate. In other words, truthful statements about nutrient supplements would have to indicate who doesn’t need them. No vitamin manufacturer has ever done this or ever will.

Since herbs are not nutrients, the concept of “nutritional support” statements for herbs is absurd. The Dietary

If you find any news or information that may be of interest to our readers—such as published articles, news reports, press releases, or relevant personal experience—please send it to us. Mail it to Lewis Vaughn, *Nutrition Forum*, P.O. Box 664, Amherst, NY 14226-0664. We’re especially interested in receiving information about enforcement actions by state agencies, lawsuits by victims of quackery, and health-fraud news that may have been overlooked by the national media.

Supplement Commission noted: "Many botanicals now are being marketed with statements of nutritional support that suggest only indirectly the type of therapeutic use that is traditional for the product. . . . Most Commissioners believe direct therapeutic statements . . . may be more informative." The Commission's report urges the FDA to develop a review process that could enable herbs that have substantiated therapeutic use to be marketed as over-the-counter drugs.

A recent ad in *Veggie Life* magazine illustrates the absurdities that DSHEA has spawned. The headline states: "IT PROTECTS YOUR HEART THE WAY FORT KNOX PROTECTS GOLD." The body of the ad states: "MaxiLIFE Cardio Protector nutritionally supports healthy cardiovascular function on a whole new level of potency.* That's because it's no ordinary formula, but a nutritional all-star team of cardioprotective agents." The asterisk refers to the disclaimer that DSHEA requires with "support" statements: "This statement has not been evaluated by the Food and Drug Administration. The product is not intended to diagnose, treat, cure or prevent any disease." The Fort Knox analogy, which suggests complete cardioprotection, is printed in half-inch type. The disclaimer is in 4-point type, which is barely visible.

Under some circumstances, some ingredients in Cardio Protector might help protect a person's heart. Its B vitamins, for example, could lower elevated blood homocysteine levels, which are a risk factor for coronary artery disease. However, there is no reason for people whose homocysteine level is normal to use this product. The dozen or so other ingredients have little or no proven value for cardioprotection. People really interested in protecting their heart should follow an individually designed program based on risk-factor analysis. For these reasons, I believe that Cardio Protector has no rational use. Its manufac-

turer, Twin Laboratories of Ronkonkema, New York, also markets Prostate Protector and Brain Protector.

Under DSHEA, manufacturers who make statements of "nutritional support" must have substantiation that such statements are truthful and not misleading. The law also requires that the Secretary of Health and Human Services be notified no later than 30 days after the first marketing of a supplement for which the statement is being made. The law does not define substantiation.

Publications Connected to Sales

Historically, the FDA has considered literature used directly in connection with the sale of a product to be "labeling" for the product. DSHEA exempts publications from "labeling" if they: (1) are not false or misleading, (2) do not promote a particular manufacturer or brand, (3) present a "balanced" view of pertinent scientific information, and (4) are physically separated from the items discussed. However, since most "dietary supplements" are either useless, irrationally formulated, and/or overpriced, the supplement industry has little reason to provide literature that is not misleading.

The Dietary Supplement Commission concluded that the criteria listed above would be difficult to apply, particularly the requirement for balance. "Balance" is difficult or impossible to define, and standards, if they are developed, would be difficult to enforce. Moreover, no federal agency has the resources to regulate what individual retailers do in their stores.

Further Weakening Proposed

The Nutrition Labeling and Education Act of 1990 prohibits misleading health claims on foods. It requires such claims to be sup-

[continued on page 29]

WEB WATCH

Looking for nutrition and health information on the World Wide Web? Beware: You're entering a vast library sprinkled with booby traps. Is that a solid piece of nutrition reporting—or a pseudofact ready to explode on contact? This column helps you figure out which is which. Following is a list of some of the best (most reliable, useful) sites and some of the worst (most unreliable, deceptive, weird, and worthless). Ratings and commentary are by Internet-savvy John H. Renner, MD, president of the Consumer Health Information Research Institute (e-mail: drrenner@msn.com).

BEST

<http://arborcom.com/frame/arbormframe2.htm> This is the Arbor Nutrition Guide—one of the most complete and well-indexed nutrition sites on the Internet. It has almost everything on it and is fun to explore. Some linkages are about weird subjects.

<http://www.faseb.org/asns/> Site of the American Society for Nutritional Sciences (founded in 1928 as the American Institute of Nutrition) and home of the new *Journal of Nutrition Online*.

<http://www.nal.usda.gov/fnic/> The Food and Nutrition Information Center (FNIC) is one of several information centers at the National Agricultural Library (NAL), Agricultural Research Service (ARS), United States Department of Agriculture (USDA).

WORST

<http://members.aol.com/mankindrf/home/downs.htm> A site that promotes a nutritional treatment for Down's Syndrome. The treatment is called "NUTRIVENE-D Targeted Nutritional Intervention for Down's Syndrome." Where is the evidence?

<http://www.garynull.com/index.asp> Gary Null's Natural Living site—"exploring the nature and politics of medicine, health, nutrition, and the environment." Some really strange material here for a nutrition page even if we know its alternative logic.

<http://luff.latrobe.edu.au/~botbml/cyanotox.html> If you are curious about Super Blue Green Algae and the problems and debates surrounding it, you should look at this website.

DEBATABLE

<http://www.chromium.edu/index.html> The Chromium Information Bureau, a website that causes great debate. What do you think? You tell me: accurate or not; evidence or hype? An interesting page with good links.

NOTABLE QUOTE

"The words 'quack' and 'quackery' are never used by the 'alternative-complementary medicine crowd. Why not? Because they eschew skepticism. It's too bad. . . . People understand the words 'quack' and 'quackery' but are confused by psychobabble terms like 'alternative,' 'complementary,' and 'integrative' that are being used to sugar-coat quack medicine."

—NCAHF Bulletin Board, May–August 1997

Major Recommendations from the Dietary Supplement Commission

Safety

- Safety of supplement products must be assured.
- The FDA, the supplement industry, scientific groups, and consumer groups should work together to expand and improve postmarketing surveillance, including adverse reporting systems.
- Product information should include appropriate warnings.
- The FDA should take swift enforcement action to address safety issues, such as those posed by ephedra-containing products. The agency should be given additional resources to do this.

Health Claims

- The approval process for health claims should be the same for dietary supplements and conventional foods.
- The standard of "significant scientific agreement" is appropriate but should not require unanimous or near unanimous support.
- To determine whether significant scientific agreement exists for particular claims, the FDA should obtain broad input and use appropriate outside expert panels.

Statements of Nutritional Support

- Statements of nutritional support should provide useful information about the product's intended use.
- Statements of nutritional support should be supported by scientifically valid evidence substantiating that the statements are truthful and not misleading.
- Structure/function statements should not suggest disease prevention or treatment.
- Statements that mention a body system, organ, or function affected by a supplement using such terms as "stimulate," "maintain," "support," "regulate," or "promote" can be appropriate when the statements do not suggest disease prevention or treat-

ment or use for a serious health condition beyond the ability of the consumer to evaluate.

- Statements should not be made for products to "restore" normal or "correct" abnormal function where the abnormality implies the presence of disease. (For example, a claim to "restore" normal blood pressure when the abnormality implies hypertension.)
- Statements of nutritional support are not to be drug claims. They should not refer to specific diseases, disorders, or classes of diseases and should not use such drug-related terms as "diagnose," "treat," "prevent," "cure," or "mitigate."

Substantiation of Nutritional Support Statements

- The Dietary Supplement Health and Education Act (DSHEA) requires manufacturers marketing supplements labeled for "nutritional support" to notify the Secretary of Health and Human Services within 30 days after marketing of a product bearing such a statement. To satisfy this requirement, the notice should include: (1) the identity of the ingredient(s) for which the statement is made, (2) the product's intended use, including recommended dosage, (3) appropriate contraindications or warnings, (4) a brief summary of the evidence and conclusions about safety and effectiveness of the stated dosage, and (5) a consumer version of the evidence on which any claim is made.
- DSHEA requires manufacturers marketing supplements labeled for "nutritional support" to have substantiation. To satisfy that requirement, the manufacturer's substantiation files should contain: (1) a copy of the notification letter, (2) key evidence, including an interpretive summary by a qualified individual, (3) the identity and quantity of the pertinent dietary ingredients, (4) evidence substantiating the

ingredient's safety, (5) assurance that good manufacturing practices were followed, and (6) the qualifications of the individual(s) who reviewed the evidence for safety and effectiveness. A consumer version of the evidence should be made available to the public for each product bearing a statement of nutritional support. This version should not state or imply use for preventing or treating disease.

Publications Connected to Sales

- Articles provided to consumers must be balanced and truthful. The FDA should promptly issue warnings or undertake enforcement action if it becomes aware of violations.
- The FDA should monitor practices in this area and issue guidelines as needed.

Botanical Products

- The FDA should establish an OTC review panel to review botanical products intended for preventive or therapeutic use.
- For products unable to meet FDA review requirements, creation of an alternative approval system should be considered.

Assessment of Consumer Education

- Research should be done to determine whether consumers want and can use information required by existing FDA regulations, DSHEA requirements, and Dietary Supplement Commission recommendations. This would include statements of nutritional support as well as point-of-sale literature.

Expert Evaluation

- The dietary supplement industry should consider establishing an expert advisory committee to provide scientific review of label statements and claims and guidance on safety and appropriate labeling. Such a committee might be supported by one or more trade associations or might be established as an independent entity funded by grants and/or fees for services. **NF**

ported by "significant scientific agreement" and be cleared by the FDA before use in the marketplace. Section 618 of the FDA Modernization and Accountability Act (S. 830) would eliminate preclearance and enable claims to be based on statements by any federal agency, even if the agency's position is counter to the prevailing scientific view or fails to take overall diet into account. (Currently, for example, even though some agencies have recommended eating a low-fat diet, the FDA does not permit health claims to be made for low-fat foods that are very high in sodium.) The Food and Nutrition Labeling Group, a 21-member coalition of prominent professional and consumer organizations, has vigorously objected to Section 618.

The Bottom Line

The FDA has never had enough resources to cope with the enormous amount of deception in the supplement and health-food marketplace. DSHEA has made the problem worse. If I were FDA Commissioner, I would drop any pretense of being able to protect the public. Instead, I would announce that unless Congress provides an adequate law, the FDA cannot protect the public from the deceptive marketing of what DSHEA calls "dietary supplements." **NF**

Stephen Barrett, MD, a retired psychiatrist, is a board member of the National Council Against Health Fraud and webmaster of Quackwatch (<http://www.quackwatch.com>), a guide to quackery, health frauds, and intelligent decision making.

Sex Herbs: As Good as Love Potion Number 9?

by Varro E. Tyler

Of all the come-ons in the field of advertising, sex is by far the most appealing and the most widely used. Whether the commodity being touted is automobiles, cosmetics, or clothing, the promise of enhanced sexual appeal and activity is alluring. And for some consumers, the most irresistible hustle of all is the dream of better sex through *herbs*.

But at the heart of these herbal dreams, is there anything real?

renders the product suitable for females, but just how that takes place is also not explained.

Folklore attributes to cereal oats the properties of a mild sedative or sleep-promoting agent. However, the principles responsible for this activity are absent, or present in minimal quantity, in green oats. Although several herbal products containing it are currently marketed in the United States, there is no credible published evidence supporting the utility of green oats as an aphrodisiac.

Although several herbal products containing it are currently marketed in the United States, there is no credible published evidence supporting the utility of green oats as an aphrodisiac.

GREEN OATS GLORY

Here's an herbal product presently advertised in local newspapers with the promise that it "... can Put the Sizzle Back in Your Love Life." Wow! That sounds great. What is this magic potion?

The fine print indicates that it is a "... unique formulation of *Avena sativa*, a biologically standardized green oats extract that proves to be a powerful sexual enhancer and rejuvenator."

Researchers are said to have found (no reference given) that it stimulates the sex centers of the brain by freeing up "trapped" testosterone. Just how the extract was standardized is not explained.

A modification of the original man's formula is intended to increase sexual desire in women. It contains added saw palmetto, which is claimed to increase the potency tenfold. It also costs \$5.00 more than the men's formula for a 30-day supply-total: \$44.95 plus \$6.00 shipping and handling. Presumably, the addition of the saw palmetto somehow

The German Commission E (an agency similar to the U.S. FDA that investigates herbal claims) failed to approve the use of green oats for any purpose, including sexual disorders. That body found no documentation of its effectiveness and recommended against its use.

The rationale of including saw palmetto along with green oats in an aphrodisiac for women is elusive. Numerous clinical studies have shown saw palmetto to be beneficial in the treatment of benign prostatic hyperplasia in males. It probably functions there by several different mechanisms including inhibition of an enzyme that converts testosterone to the more active dihydrotestosterone (antiandrogenic effect), and by its anti-inflammatory action.

There appears to be absolutely no correlation between these activities and the inclusion of the product in one designed to stimulate the female libido. Ac-

[continued on page 31]

[continued from page 25]

SODIUM CLAIM DISPUTED

Since 1993, the FDA has permitted food labels to carry a health claim that diets low in sodium may reduce the risk of high blood pressure. Based on new findings, 16 scientists have challenged the idea that universal dietary sodium restriction should be encouraged (*Nutrition Reviews* 55:172-75, 1997). Their report was appended to the Salt Institute's 1996 petition asking the FDA to revoke permission for the claim. The article and the 65-page petition are available from the Salt Institute, 700 North Fairfax Street, Suite 600, Alexandria, VA 22314.

NEW REPORTS: FIBER, FACTS, AND FEAR

The American Council on Science and Health has published two excellent booklets: "Dietary Fiber" and "Facts Versus Fears: A Review of the 20 Greatest Un-

founded Health Scares of Recent Times." The latter report includes scares related to cranberries, DDT, cyclamates, DES in beef, nitrites, saccharin, hair dyes, Love Canal, asbestos in hair dryers, coffee, EDB, Alar, Perrier water, dental amalgam, and cellular phones. The booklets are available for \$3.85 each from ACSH, 1995 Broadway, 2nd Floor, New York, NY 10023-5860.

FLUORIDATION UNDER ATTACK

A group misnamed "Citizens for Safe Drinking Water" is circulating petitions to gather 500,000 signatures by October to place an initiative prohibiting fluoridation in California on the June 1998 statewide ballot. If passed, the measure would amend California's Health and Safety Code by inserting the words: "No fluoride or fluorine-containing substance may be added to public water systems. All laws to the contrary are hereby repealed." The referendum attempt is a response to a mandatory statewide fluoridation law enacted in 1995. Fluoridation reduces the incidence of cavities 20% to 40% in children and 15% to 35% in adults. More than 135 million peo-

ple in the United States are served by fluoridated water, and an additional 10 million have protective levels of naturally-occurring fluoride in their water.

NEW ANTIQUACKERY FORCE

The Committee for the Scientific Investigation of Claims of the Paranormal (CSICOP) has set up a Media Stock Fund to provide leverage in responding to irresponsible reporting of pseudoscientific claims. The principal targets are Westinghouse (CBS), General Electric (NBC), NewsCorp (Fox), Time Warner (WB, Turner Broadcasting), and Disney (ABC). Income from the fund will be used to fund the activities of CSICOP's Council for Media Integrity, a network of experts committed to monitoring the media, criticizing unbalanced presentations, and using shareholder resolutions to attack problems. Donations to the fund can be sent to P.O. Box 703, Amherst, NY 14226. CSICOP is also interested in hearing from shareholders willing to permit CSICOP to vote as their proxy at shareholder meetings. **NF**

New Journal Will Scrutinize 'Alternative Medicine'

The public, the media, and even some physicians seem enthralled by the unexamined promises of "alternative" or unconventional treatments. Yet there has been no scientific journal dedicated exclusively to carefully scrutinizing the onslaught of dubious claims. Until now.

The *Scientific Review of Alternative Medicine* will be launched soon to fill the void. It's a peer-reviewed medical journal whose aim is to provide objective, scientific assessments of the treatments, methods, and hypotheses of unconventional medicine. The Editor is *Nutrition Forum* editorial board member Wallace Sampson, MD, clinical professor of medicine at Stanford University; the Executive Editor is *Nutrition Forum* Editor Lewis Vaughn. Prometheus Books publishes the journal, and it has been endorsed by the Council for Scientific Medicine, a group of physicians, scientists, and others concerned about the lack of critical scrutiny of "alternative" medicine.

To affirm its support for scientific medicine and this new journal, the Council drafted a statement, which says in part:

We believe that the need for objective, scientific critiques of the claims of "alternative" or nonconventional medicine has never been greater. This conclusion seems inescapable because . . .

- There is a general lack of readily available, reliable information about the efficacy of such treatments. This impairs people's free choice and increases risks to their health. The potential harm is incalculable but appears to be growing. The trend is abetted by those who promote unproven treatments, especially those who are naïve, greedy, or unscrupulous.
- The media all too often dote on controversial and false claims but unfortunately provide few careful, critical examinations of them, usually preferring to titillate, pander, or entertain.

- Several new journals devoted exclusively to "alternative" medicine have appeared recently, but they merely advocate unconventional treatments and rarely assess them objectively.
- Both the public and some medical professionals seem unaware that credible, scientific assessments of many "alternative" medicine claims already exist—and that new evaluations based on available information are possible.

We therefore welcome the founding of the *Scientific Review of Alternative Medicine*—the first peer-reviewed journal dedicated entirely to the scientific, rational evaluation of unconventional health claims.

The journal will be issued twice a year (with the first issue appearing in September 1997) but frequency may increase later. A subscription is \$50 for individuals and \$90 for institutions. Those who want to subscribe can call (800) 421-0351 or send their credit card number via fax (716-691-0137) or e-mail (PBooks6205@aol.com), or mail to SRAM, Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197. **NF**

Ephedra Rules Proposed

According to the advertisement, testosterone has been shown to be responsible for stimulating sexual activity in both men and women. Assuming this to be true (it is supported by much less evidence in women than in men), the addition of saw palmetto with its antiandrogenic properties might be expected to inhibit, not increase, female sexual passion.

No references to pharmacological or clinical studies of the effectiveness of the male and female products are contained in the advertisement.

It does point out that they have been featured on "Inside Edition," "Hard Copy," "Geraldo," and "Leeza." Instead of using the age-old ploy of testimonials, efficacy is based upon statements from a New York sex counselor, a 77-year-old retired colonel, a doctor, and an osteopathic physician.

IMPOTENT APHRODISIACS

Green oats is just one of many purported aphrodisiacs on the American market whose activities remain unproven. A more common one is damiana, the leaves of the Mexican shrub *Turnera diffusa* var. *aphrodisiaca*. This herb has never been tested clinically, and its purported sexual activity has been exposed as an ancient herbal hoax. Muira puama wood obtained from *Ptychopetalum* species has likewise never been proven to be effective. Sarsaparilla from *Smilax* species has been promoted as an aphrodisiac, in the belief that the sarsapogenin contained in it could be converted to testosterone in the human body. Not true.

Of all the herbal aphrodisiacs, yohimbe, the bark of *Pausinystalia johimbe*, is both the most promising and the most disappointing.

It does contain the active principle yohimbine which, as a prescription drug, is used in treating erectile dysfunction in males. However, the risk/benefit ratio of yohimbe is unacceptably high; its use can result in hypertension, tachycardia, sleeplessness, anxiety, nausea, and numerous other undesirable side effects. As a result, Commission E failed to approve yohimbe, and its use must be discouraged. **NF**

During the past two years, the FDA has collected over a hundred supplement products labeled as containing an ephedrine alkaloid source such as ma huang. Some products contained ephedrine alkaloids as a single ingredient, but most had between 6 and 20 other ingredients, such as vitamins, minerals, amino acids, and other botanicals. Many were promoted for weight loss, bodybuilding, energy boosting, increasing mental concentration, enhancing sexual sensations, or producing euphoria, or as alternatives to illicit street drugs.

On June 4, the FDA proposed strict rules for marketing of "dietary supplements" containing ephedrine alkaloids (Federal Register 62:30677-30724, 1997). The agency acted in response to more than 800 instances of adverse reactions (including some deaths) reported since between 1993 and 1996. The proposal's Appendix describes 53 severe reactions. The proposed regulations include:

- No product can contain 8 mg or more of ephedrine alkaloid per serving.
- Labels may not suggest usage that would result in an intake of 8 mg or more in a 6-hour period or a total daily intake of 24 mg or more.
- Products cannot include sources of

other stimulants such as caffeine or yohimbine.

- Claims may not be made that long-term use is effective for weight loss or bodybuilding.
- Product labels must state: "Do not use this product for more than 7 days."
- Labels of products for short-term use must warn that "taking more than the recommended serving may result in heart attack, stroke, seizure, or death."

- Labels must caution against use by pregnant or nursing women, or by people with heart disease, thyroid disease, diabetes, high blood pressure, psychiatric conditions, glaucoma, difficulty in urinating, prostate enlargement, and seizure disorder.

The proposed rules do not apply to ephedrine-containing products that are now marketed as drugs. Ephedrine is an approved ingredient in oral bronchodilators used to treat mild cases of asthma. However, a proposed 1995 FDA rule to reclassify ephedrine as unsuitable for over-the-counter use may soon become final.

Federal Register documents can be accessed (or downloaded using Adobe Acrobat) from http://www.access.gpo.gov/su_docs/aces/aaces002.html. **NF**

The agency acted in response to more than 800 instances of adverse reactions (including some deaths) reported since between 1993 and 1996.

NEWSFLASH: SOMETHING NUTRITIONALLY STRANGE

On June 9, 1997, the *Sacramento Bee* reported (with accompanying Associated Press photo) that in Hyderabad, India, an estimated *half million people* had recently shown up at the house of Harinath Gaud to receive a cure for asthma: *a live sardine containing an herbal paste* (to be popped into the mouth on the spot). "The fish-and-herb medicine," the report said, "is given free to patients once a year on an astrologically favorable day in June, and patients are advised to begin a strict 45-day diet. The formula reputedly was given to the Gaud family by a saint 152 years ago."

Book Reviews

Analysis and Ratings

How accurate and useful is the nutrition information in that book? Would a reputable reviewer recommend the book to professionals and consumers? These are the two questions that Nutrition Forum book reviews are intended to answer. So the reviews not only offer analyses but also rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Another Arthritis 'Miracle'— on Thin Evidence

Manfred Kroger

The Arthritis Cure by Jason Theodosakis, Brenda Adderly, and Barry Fox (New York: St. Martin's Press, 1997), 201 pp., \$22.95 (hardback).

Like dozens of other books promising simple cures of complicated and perplexing diseases, this book will most likely end up as a remaindered publisher's venture and also be available for a quarter at neighborhood book sales. And years from now, arthritis will still be with us along with cancer, depression, and the common cold. My guess is that most professionals will agree.

Actually, this book is a concise, readable, and quite valuable review of an age-old disease, including its related conditions affecting the joints. The book's emphasis, however, is on osteoarthritis, not the psoriatic, gouty, or rheumatoid types. The book's subtitle is "The Medical Miracle that Can Halt, Reverse, and May

even Cure Osteoarthritis." The book's preventing and healing regimens are detailed in seven- and nine-point chapters, respectively. To prevent osteoarthritis, do the following: (1) Eat a healthful, joint-building diet. (2) Maintain your ideal weight. (3) Exercise regularly. (4) Prevent injuries. (5) Insure proper recovery if you are injured. (6) Optimize your biomechanics to counteract stress to your joints, and (7) Consider use of glucosamine and chondroitin sulfates prophylactically. And what is touted as the nine-step Arthritis Cure program (in reality aimed only at osteoarthritis) is as follows: (1) Have a thorough consultation with a physician. (2) Take glucosamine and chondroitin sulfates to repair damaged joints. (3) Improve your biomechanics to counteract stress to your joints. (4) Exercise regularly. (5) Eat a healthful, joint-preserving diet. (6) Maintain your ideal body weight. (7) Fight depression. (8) Use traditional medicine as necessary. and (9) Maintain a positive attitude.

It's the italicized statements above that shift this fact-based, easy-to-read medical monograph into the category of sales literature, alternative healing practices, possibly even quack treatment.

The authors may not have any financial stake in the sale of glucosamine and chondroitin sulfates whatsoever, but they are certainly sold on these chemicals, and sincerely believe in the thin evidence of their effectiveness. The senior author even provides positive case histories of his own patients.

The major argument is that in Europe these two substances are successfully being used as nutritional supplements against osteoarthritis, and 14 references are provided to scientific studies since the late 1970s. But none of these studies was good enough to be noticed by arthritis experts worldwide to embrace glucosamine and chondroitin sulfates as the "miracles" they are now made out to be. So the book's authors attack the American medical and drug establishments as "failing to see the light" and not pursuing any financial gains in these miracle substances be-

cause they are commonly available to everyone.

It is well known that both glucosamine and chondroitin sulfate are made by the body and are involved in cartilage manufacture, repair, and maintenance. Osteoarthritis results when the bone-protecting layer of joint cartilage is drying out, degenerating, or injured. The book's thesis and simple premise is that by eating glucosamine and chondroitin sulfate, cartilage will benefit. No evidence is provided as to the mode of ac-

tion, the metabolic mechanism, by which this is to occur. However, throughout the book the reader is assured that this "may" occur. And there's the rub. All those "may's" and the disclaimer in front of the book (to protect publisher and authors against litigation) indicate, maybe, that even its authors are not all too certain about the efficacy of the "miracle cure."

It would cost about \$2 per day to treat yourself; that's \$700 per year. With 16 million Americans suffering from osteoarthritis, and millions of others trying to prevent it, this looks like a lucrative potential market indeed. Both glucosamine and chondroitin sulfate are nontoxic, and no side effects have been reported. So what's the harm to someone who can afford the treatment? None, except the feeling of having been duped if no effect is experienced. And the few studies cited are not too persuasive on the point of effectiveness. But, fortunately, the authors assure us that more studies are underway to prove once and for all that these two miracle food supplements are actually doing what is claimed in this book. A rational person should wait that long and use current therapeutic methods and the more reliable advice of the authors—and contemplate how something that is swallowed and totally digested will reappear in the blood to augment the body's own glucosamine and chondroitin sulfate. **NF**

This book shifts into the category of sales literature, possibly even quack treatment.

HIGH-DOSE ANTIOXIDANTS FLUNK TEST

A six-month, double-blind clinical trial has found that patients who underwent balloon coronary angioplasty had less arterial relogging with probucol treatment than they did with antioxidant supplements given alone or combined with the drug (*New England Journal of Medicine* 337:365-72, 1997). More than 200 patients completed the study without protocol violations. After their surgery, patients in the antioxidant groups received 30,000 IU of beta-carotene, 500 mg of vitamin C, and 700 IU of vitamin E twice daily. All of the patients received aspirin, which is known to reduce the incidence of relogging. The rates of repeated angioplasty were 11% in the probucol group, 16.2% in the combined treatment group, 24.4% in the multivitamin group, and 26.6% in the placebo group. Probucol, which can lower LDL-cholesterol levels, also has antioxidant properties. However, it is no longer marketed in the United States because it lowers the level of HDL-cholesterol that protects against atherosclerosis.

FTC HITS SUPPLEMENT MARKETER

Nu Skin International, Inc., a multilevel marketer of skin-care products and nutritional supplements, has agreed to pay a \$1.5 million civil penalty to settle Federal Trade Commission (FTC) action against claims made for five products containing chromium picolinate and L-carnitine. The FTC charged that the company could not produce adequate substantiation and therefore had violated a 1994 FTC order requiring it to have adequate substantiation for its claims. The 1994 order, which carried a penalty of \$1.225 million, concerned unsubstantiated claims for a baldness product, a wrinkle lotion, and a burn cream. In the current case, the FTC challenged claims that "Metabotrim," "OverDrive," "GlycoBar," "Appeal Lite," and "Breakbar" could reduce fat, increase metabolism, and preserve or build muscle. For example, the ingredients in Metabotrim were claimed to have been

Hard Facts on Colloidal Minerals Cure-all or crushed rocks?

by Beth Fontenot, MS, RD

Colloidal mineral supplements are the current craze in "alternative" nutrition, promising to cure what ails you—and to confuse consumers. They are simply extra-small mineral particles suspended in a solution, and they are being promoted as the cure for acne, anemia, brittle nails, birth defects, cancer, constipation, depression, diabetes, goiter, graying hair, hair loss, hyperactivity, impotence, infertility, memory loss, PMS, and wrinkles.

Colloidal minerals are sold largely by multi-level marketing companies under such names as Clark's Mineral Formula, Mineral Toddy, Mineral Solutions, and Micro-Mins. They sell for up to \$50 for a month's supply. The fact that these products are sold by multilevel marketing companies should make one skeptical, and the numerous claims made by the marketers are dubious at best.

The Sales Pitch

The story behind colloidal minerals goes like this: In 1925, a Paiute Indian led an ailing Utah rancher, Thomas Clark, to a legendary spring known for its healing powers. Soon after drinking from the spring, Clark was healed of his ailment. As Clark followed the spring back into the

mountains, he discovered a deposit of minerals that was later determined to be the remains of a prehistoric rain forest. He created a "miracle tonic" by extracting the minerals from the spring and passed it among his friends who reportedly experienced remarkable results. Many manufacturers tout their product as coming from this "original source," but similar deposits are said to be found in a few other areas of the world.

Colloidal minerals, which have been described by some as "mud" or "crushed rocks," are sold as elixirs, capsules, and oral sprays. The mineral content varies by product, but the ingredient lists all read like the Periodic Table of Elements: aluminum, arsenic, cadmium, lead, lithium, platinum, silver, titanium, as well as an assortment of other less familiar minerals.

The promoters maintain that our soil is so depleted that the food we eat is lacking in the minerals our bodies need, and furthermore, we absorb only about 5% of the minerals we do get from food. A multitude of diseases and medical conditions, as well as deaths, are due to mineral deficiencies, they say.

The promotional materials declare that colloidal minerals have a natural negative charge that enhances their absorp-

They are being promoted as the cure for acne, anemia, birth defects, cancer, constipation, depression, diabetes, goiter, hyperactivity, impotence, infertility, memory loss, PMS, and wrinkles.

tion as well as the transport and availability of other nutrients. Toxins and heavy metals are supposedly attracted to this negative charge and are flushed from the body. In addition, the marketers assert that the small size of colloidal minerals, as opposed to the elemental minerals found in over-the-counter supplements, makes them more easily absorbed by the cells of the body. The ads also carefully point out that toxicity is not a concern, and one company's ad states that their product contains only "truly organic" minerals.

Reality Check

The claims for these mineral products are nothing more than imaginative sales gimmicks. Absorption of a nutrient is not affected by its charge, and even if colloidal minerals are better absorbed (and experts dispute that fact), that would not make them desirable. Some minerals are toxic at high levels, and many of those present in the products are not recognized as essential to humans. The fact is that for many minerals, absorption by the body is largely regulated by the need for the mineral. And as for the claim about "truly organic" minerals, the fact is that minerals are *inorganic*. (Organic materials contain carbon atoms, and inorganic materials do not.)

No scientific evidence can be found to support any of the claims made by the marketers of these products, including the claim regarding mineral deficiencies in foods.

Currently, there are 16 minerals recognized as essential to humans. The Committee on Dietary Allowances of the National Academy of Sciences has established a Recommended Dietary Allowance (RDA) for the major minerals calcium, phosphorus, and magnesium, and for the best-known trace minerals iron, zinc, iodine, and selenium. Estimated Minimum Requirements have been established for sodium, potassium, and chloride. Other minerals such as copper, manganese, fluoride, chromium, and molybdenum are known to be essential, and an Estimated Safe and Adequate Daily Dietary Intake (ESADDI) is published for these. Arsenic, nickel, silicon, and boron are recognized as essential to animals, but are not firmly established as essential for

humans. Very little is known about the need for cadmium, cobalt, lead, lithium, tin, and vanadium. At this time, the evidence that these are essential is weak.

Minerals play a critical role in the maintenance of health as well as in the management of some disease states. The fact that minerals are required only in small amounts and that they can be toxic in excess raises substantial concern about the indiscriminate use of supplements. There are mechanisms in the body that regulate the absorption and excretion of excessive amounts of the essential minerals; however, there does not appear to be such a mechanism for regulating the absorption and excretion of nonessential minerals. There also exists the potential for adverse mineral interactions and imbalances to occur in the body when mineral supplements are used haphazardly.

The bottom line is that a healthy diet that provides a wide variety of foods from both plant and animal sources is the safest, least expensive, and most practical way to ensure an adequate intake of the minerals required by the human body. The claims for colloidal minerals are just too hard to swallow. **NF**

An Herb to Forget— Cat's Claw

by Varro E. Tyler

There's a joke presently making the rounds about the woman who, not realizing that the herb cat's claw was so named for its long curving thorns, refused to take it because she was a vegetarian. Now science has come up with a far better reason for caution in consuming this ancient folkloric remedy derived from the tropical vine *Uncaria tomentosa*.

Commonly referred to by its Spanish name *uña de gato*, the herb has been popularized in the United States in recent years by South American immigrants. Several books in the Spanish language recommend it for a wide variety of diseases and syndromes ranging from arthritis, cancer, and AIDS to hemorrhoids, acne, and PMS. The evidence of its utility is anecdotal. No substantial clinical studies of the efficacy of cat's claw for any condition have ever been published in peer-reviewed medical journals.

Trouble Signs

Recent studies have shown that there is a significant problem associated with the consumption of the plant that has been collected at random in the Peruvian jungle. It turns out that there are two kinds of *Uncaria tomentosa* that are distinguishable one from another only on the basis of their chemical constituents. Such plants which look alike but differ markedly in their composition are referred to as chemotypes (chemical types) or chemovars (chemical varieties).

The root of one chemotype of *U. tomentosa* contains quantities of several

pentacyclic (5-ring) oxindole alkaloids, including pteropodine, speciophylline, and mitraphylline. Tests in small animals have shown that these compounds produced a number of effects which resulted in a general strengthening of the immune system. In other words, they helped the animals resist disease. Other animal tests showed acute toxicity to be low, and mutagenic activity was not detected.

The constituents of the other chemotype of *U. tomentosa* are quite different. It contains the

tetracyclic (4-ring) oxindole alkaloids rhynchophylline and isorhynchophylline, which counteract the immunomodulating action of the pentacyclic alkaloids found in the other variety. They also exert negative chronotropic and inotropic activities, slowing and decreasing the force of the heartbeat.

In addition, they have a sedative effect which in high doses depresses respiration and produces ataxia (lack of muscular coordination).

Obviously, none of these activities is desirable, and the tetracyclic chemotype of cat's claw when mixed with the pentacyclic variety—as is often the case in commercial samples—will simply neutralize whatever beneficial effect the latter may have on the consumer's immune system. The admixture is apparently not detectable by either macroscopic or microscopic examination of the herb; it is readily observed by simple chromatographic techniques (HPLC or TLC). Yet these analytical procedures are not routinely carried out on cat's claw products in the American market.

Because the two varieties are not

Recent studies reveal a big problem with cat's claw—there are two kinds of Uncaria tomentosa that are indistinguishable one from another except by chemical analysis, and one can hurt you.

WEB WATCH

Looking for nutrition and health information on the World Wide Web? Beware: You're entering a vast library sprinkled with booby traps. Is that a solid piece of nutrition reporting—or a pseudofact ready to explode on contact? This column helps you figure out which is which. Following is a list of some of the best (most reliable, useful) sites and some of the worst (judged unreliable, weird, or worthless). Ratings and commentary are by Internet-savvy John H. Renner, MD, president of the Consumer Health Information Research Institute (e-mail: drrenner@msn.com).

BEST

<http://www.hnrc.tufts.edu> This is the online presence of the Jean Mayer U.S. Department of Agriculture Human Nutrition Research Center on Aging at Tufts University. <http://vm.cfsan.fda.gov/label.html> Want to know just about everything about food labeling? This is the place to go—the FDA's online Center for Food Safety and Applied Nutrition, Food Labeling section. Lots of background info and articles on labeling history, law, and research as well as tips on using food labels to prevent or treat diseases like diabetes and hypertension.

<http://www.niaid.nih.gov/factsheets/allergy.htm> This is the National Institute of Allergy and Infectious Diseases' "Fact Sheet." It's a list of resources for patients living with allergies, including allergy hotlines, information sources and networks, and NIAID-supported centers (for treatment, education, and referrals).

<http://odphp.osophs.dhhs.gov/> Online site of the U.S. Office of Disease Prevention and Health Promotion. A good place to go to access publications online, including *Dietary Guidelines for Americans, Fourth Edition*.

WORST

<http://www1.mhv.net/~donna/conq.html> This is a multilevel sales page for Health Vision, an independent distributor of Prime-Quest Products and sponsor of the Diet & Weight Loss/Fitness Home Page. Features a weight-loss and performance supplement allegedly based on secret research done in the former Soviet Union. The site is loaded with weird references, testimonials, before-and-after pictures, and lots of unusual advice.

readily separated at the point of collection, it is difficult to prevent contamination of the potentially useful pentacyclic variety with at least some of the negative-acting tetracyclic one. Consequently, on practical grounds it is recommended that the content of the latter type oxindole alkaloids be limited to less than 0.02%.

Does It Work?

The jury is still out on the effectiveness of any type of cat's claw in stimulating the activity of the human immune system. We simply won't know its utility with any degree of accuracy until clinical trials have been conducted on a substantial number of subjects and the results published in peer-reviewed medical journals.

In the meantime, those wishing to use cat's claw are best advised to restrict consumption to products certified to be free (or at least not containing more than 0.02%) of tetracyclic oxindole alkaloids as determined by suitable analytical methods. Possibly at some future date, specific botanical characteristics will be found that will enable the two chemical varieties of *Uncaria tomentosa* to be distinguished in the field. That would greatly simplify collection of the proper variety. Until such time, the only assurance of possible immunomodulatory efficacy of cat's claw is to use products that have been identified unequivocally by suitable laboratory procedures. **NF**

The Gerson Diet and Coffee Enemas

by Saul Green

The use of diets and coffee enemas to treat cancer is based on the teachings of Max Gerson, a German MD who practiced about 75 years ago when the biology of cancer was virtually unknown. He believed that cancer was a degenerative disease that developed when aerobic energy metabolism in the liver and intestine was converted to anaerobic metabolism by "poisons" from processed foods.

An Old Idea

The idea that purges could rid the body of its "corrupt humors" has been practiced by "healers" since the fifth century. Proponents promoting coffee enemas still believe that "an unpoisoned body" possesses reserves that can recognize and destroy cancer. Gerson's treatment requires patients to have a prolonged period of detoxification with coffee enemas and to adhere, for life if possible, to a diet of juices from raw fruits, vegetables, and calf liver, all produced without pesticides or fertilizers and prepared without sugar, starch, salt, or artificial coloring.

Proponents of the Gerson treatment allege that normal cells depend on oxygen and oxidizing enzymes to maintain aerobic metabolism. When this system is poisoned by "toxins" in processed foods, it falls back into anaerobic metabolism, produces inferior energy, and becomes cancer. Detoxification is accomplished with enemas containing coffee because coffee stimulates liver bile production and activates an enzyme, glutathione-S-transferase, which neutralizes the free radicals in the blood. The coffee enema causes the toxin-laden bile to be flushed out of the gallbladder into the intestines and through the colon to be excreted. Gerson has stated that for a patient to be "healed," the patient's body must be detoxified. After

Excerpted from "Pseudoscience in Alternative Medicine," *Skeptical Inquirer*, Sept/Oct 1997. Reprinted by permission.

detoxification, he says, the essential organs will destroy the cancer by an inflammatory allergic reaction. Healing is activated by the special diet of natural non-toxic foods that include "ionized minerals of the potassium group, juices of green leaves and raw calves liver, thyroid extract, and iodine."¹

Litany of Errors

Over the last 30 years the scientific literature has shown that: carcinogens are not respiratory poisons; most respiratory poisons are not carcinogens; oxygen does not inhibit the growth of cancer cells either in vitro or in vivo; the absence of oxygen does not induce or accelerate cancer growth; effective anticancer drugs are the ones that affect DNA synthesis and not fermentation; energy from fermentation is not inferior by any measure; tumors increase oxidative metabolism of fats and carbohydrates to gain energy; and there is no evidence of the "poisoning" of aerobic metabolism in tumor cells.²

The hepatology literature does not show that bile is a vehicle for toxin removal. A primary function of bile is to move metabolites from the liver to body tissues. To conserve bile and to ensure that the metabolites it carries are not lost during transit through the intestine, more than 95% of the bile entering the intestine is reabsorbed and returned to the liver before it reaches the colon. If Gerson's postulate were true, toxins carried in the bile would not be excreted but would recirculate through the body endlessly.³

Coffee does not stimulate bile production; it causes release of bile from the gallbladder. Bile does not contain glutathione, and glutathione is not a precursor for bile formation.⁴

In the short term, the action of an enema causes an insignificant loss of bile from the intestine. But the amount of bile lost from frequent enemas over a period

of months is appreciable. Under such circumstances, severe nutritional consequences associated with malabsorption can and do result.⁵

The pathogenesis of inflammation and its role in the immune system have been defined in studies showing that inflammation suppresses fat metabolism and cellular oxidations, and increases the rate of glycolysis, tissue wasting, septic shock, and hemorrhagic necrosis in all cells, normal and malignant. Proponents of the Gerson treatment have never shown that there is a "healing" inflammatory process that focuses specifically on tumor cells.

Finally, Gerson proponents have never identified the "poisons" in processed foods and have never shown them to be present in voided enema fluids or that an all-natural diet of the juices of raw fruits, vegetables, and calf liver can stimulate any kind of "healing." All the evidence in the scientific literature today indicates that mutagenesis, and not the interference with oxidative metabolism, is the cause of cancer.⁶ **NF**

BRIEFS

[continued from page 33]

"scientifically shown to establish and maintain proper metabolic rates assisting the body in burning fat while preserving lean muscle mass."

RDAS ARE NOW DRIS

The Institute of Medicine has begun issuing a series of reports on Dietary Reference Intakes (DRIs), which will update and expand the Recommended Dietary Allowances (RDAs) set by the National Academy of Sciences since 1941. The first report reviews calcium, phosphorus, magnesium, vitamin D, and fluoride, all of which are related to bone health. Its key advice is that Americans and Canadians at risk for osteoporosis should consume between 1,000 and 1,300 milligrams of calcium per day. The report can be purchased by calling (800) 624-6242; or sending \$39 to the National Academy Press, 201 Constitution Ave, N.W., Washington, DC 20418; or ordering it at a discount online (<http://www.nap.edu/low>). The full text can also be read online. *Nutrition Forum* will carry a detailed summary in the next issue.

FTC SETTLES WITH PROMINENT AD AGENCY

In July, the FTC announced a proposed agreement settling charges that J. Walter Thompson USA, Inc., engaged in deceptive advertising practices. The ads involved variations of the claim that 9 out of 10 Jenny Craig clients would recommend the program to a friend. The FTC alleged that the ad agency had falsely claimed that competent research had supported the claims. One FTC commissioner noted that the ad agency had continued to base claims on a flawed study "even after it had received contradictory results from a more reliable study that it had commissioned." The case represents the fourth time that J. W. Thompson has settled FTC charges that it had misrepresented survey or test results in advertising for various clients. The case is significant because advertising agencies are not usually held responsible for their deceptive creations.

MOON BOOSTS NATUROPATHY

The University of Bridgeport has launched a naturopathy college, the fourth such school in the United States. The university, owned by the Rev. Sun Myung Moon's Unification Church, opened its chiropractic college in 1991. *Alternative and Complementary Therapies* (an offbeat journal) states that the new college, the Professors' World Peace Academy (PWPA), received a \$30 million grant "to explore eleven new areas, including alternative medicine." Naturopathic methods and modalities include "natural foods" diets, vitamins, herbs, tissue minerals, cell salts, manipulation, massage, exercise, diathermy, colonic enemas, acupuncture, natural childbirth, homeopathy, and minor surgery. Although naturopaths claim that their approach is preventive as well as therapeutic, they tend to oppose immunization. PWPA, founded by Rev. Moon, is described on its web site as "a tax-exempt non-profit educational organization founded to support the academic community's role in the pursuit of world peace."

ATTORNEY SUES AROMATHERAPY COMPANY

San Diego attorney Morsé Mehrban has filed a civil lawsuit against Aroma Vera, Inc., a leading manufacturer of aromatherapy supplies and other personal-care products. The suit charges that the company violated California's Business and Professions Code by advertising more than 70 false claims about various products. Mehrban disputes that the products can promote health and well-being, relax the body, relax the mind, enhance mood, purify the air, neutralize effects of air pollution, relieve fatigue, tone the body, nourish the skin, promote circulation, alleviate feminine cramps, or do various other things claimed by the company. Proponents describe aromatherapy as "the therapeutic use of the essential oils of plants." They describe the oils as highly

[continued on page 38]

Quotable Quote

"Advertising, not science, is the lifeblood of 'alternative' treatments."—Saul Green, PhD, *Skeptical Inquirer*, Sept/Oct 1997

[continued from page 37]

concentrated substances extracted from flowers, leaves, stalks, fruits, and roots, and also distilled from resins. Proponents allege that the oils contain hormones, vitamins, antibiotics, and antiseptics and represent the "life force," "spirit," or "soul" of the plant. The oils are usually administered in small quantities through inhalation, massage, or other skin applications. Mehrban's suit seeks restitution for consumers, cessation of these claims, and payment of reasonable attorney fees and costs. Earlier this year he filed a similar one against a colon therapist.

OSTEOPOROSIS REPORT

Harvard Publications Group has published an excellent 38-page booklet covering osteoporosis risk factors, consequences, prevention, treatment, and screening. It is available for \$16 from Dept. OST, P.O. Box 380, Boston, MA 02117.

CONSUMER PROTECTION BOOKLET

The 12-page booklet "Who Cares: Sources of Information About Health Care Products and Services" provides simple tips about hearing aids, prescription-drug switching, nursing homes, alternative medicines, cataract surgery, arthritis cures, direct-mail schemes, and abusive caregivers. Free copies are obtainable from the FTC Public Reference Branch, Room 130, 6th St. and Pennsylvania Ave., N.W., Washington, DC 20850.

'ALTERNATIVE MEDICINE' CLAIMS DEBUNKED

The Sept/Oct 1997 issue of *Skeptical Inquirer* magazine examines claims for shark cartilage, homeopathy, and four other aspects of "alternative medicine." Single copies cost \$7.50. An introductory (six-issue) subscription can be obtained for \$16.95 by calling (800) 634-1610.

HERBAL ECSTASY WARNING

In a settlement with the Federal Trade Commission (FTC), the company that makes Herbal Ecstasy, an herbal stimulant, has agreed to place a warning on its label about the safety and potential health risks of this "natural herbal high." The FTC alleged that Global World Media Corporation and its owner, Sean Shayan, advertised the product as "100% natural and absolutely safe" despite evidence of health risks and the death of a college student in Florida. The agreement also states that safety claims in future ads must be substantiated by scientific evidence. In addition, the company has agreed to quit advertising Ecstasy and other similar products in media with predominantly young audiences. (Ads appeared on Nickelodeon and MTV in some local cable markets.) Ephedra is the main ingredient in Herbal Ecstasy. It is a stimulant that affects both the central nervous system and the heart. The FDA has cited at least 800 injuries and 17 deaths linked to the herbal stimulant.

How to Spot a 'Quacky' Web Site

by Stephen Barrett, MD

The best way to avoid being quacked is to reject quackery's promoters. Each bulleted item below is an indicator that a web site is not a trustworthy information source because whoever selects the material is not trustworthy. Someone is deemed untrustworthy if they engage in deception (as defined below) or make false statements about nutrition, "alternative" methods, or dental care. (These criteria also work for other sources of information such as books, magazines, and even health professionals.)

General Indicators

- Any site used to market herbs or dietary supplements. Although some of these sites are useful, I do not believe it is possible to run a profitable business selling such products without some form of deception. Deception includes: (1) lack of full disclosure of the facts, (2) promotion or sale of products that lack a rational

use, or (3) failure to provide advice indicating who should not use the products. During the past 25 years, I have never encountered a seller who did not do at least one of these three things.

- Any site used to market or promote homeopathic products. No such products have been proven effective.
- Any site that generally promotes "alternative" methods. There are more than a thousand "alternative" methods. The vast majority are worthless.

False Statements about Nutrition

Untrustworthy promoters say that . . .

- Everyone should take vitamins.
- Vitamins are effective against stress.
- Taking vitamins gives people more energy.
- Organic foods are safer and/or more nutritious than ordinary foods.
- Losing weight is easy.
- Special diets can cure cancer.

- Diet is the principal cause of hyperactivity.

False Statements about 'Alternative' Methods

Untrustworthy promoters say that . . .

- Acupuncture is effective against a long list of diseases.
- Chelation therapy is an effective substitute for bypass surgery.
- Chiropractic treatment is effective against a large number of diseases.
- Herbs are generally superior to prescription drugs.
- Homeopathic products are effective remedies.
- Spines should be checked and adjusted regularly by a chiropractor.

False Dental Care Statements

Untrustworthy promoters say that . . .

- Fluoridation is dangerous.
- Mercury-amalgam ("silver") fillings should be removed because they make people sick.
- All teeth with root canals should be removed because they make people sick. **NF**

Book Reviews

Analysis and Ratings

How accurate and useful is the nutrition information in that book? Would a reputable reviewer recommend the book to professionals and consumers? These are the two questions that Nutrition Forum book reviews are intended to answer. So the reviews not only offer analyses but also rate each book as either RECOMMENDED, NOT RECOMMENDED, or RECOMMENDED WITH RESERVATIONS, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Hype and Hormones

Manfred Kroger

Natural Hormone Replacement by Jonathan V. Wright, MD, and John Morgenthaler (Petaluma, CA: Smart Publications, 1997), 128 pp., \$9.95 (paperback)

On July 2, 1997, *USA Today* reported the results of its CNN/Gallup poll on estrogen therapy for women. More than half of ages 30-49 surveyed said they would use estrogen replacement therapy (ERT) when menopausal. And about 41% of women 18-29 years old and over 65 said they would consider ERT. In the 50-64 age group only one-third would consider it.

One can easily calculate the tremendous market that exists for hormone replacement. It is so big that ours could be called the Age of Hormone Replacement. Most women do want to escape from the discomforts of "Menopause Hell," and now they can and do so with the products of American drug manufacturers. Provera® and Premarin® have become much-used terms among American women. This estrogen therapy is done under the guidance of physicians and is called "conventional hormone therapy" or replacement

therapy with patentable "synthetic" sex hormones.

The intention of this book is to popularize an alternative therapy, namely "natural hormone replacement." And it does an intensive job. However, very, very little evidence is provided that a switch might be better. So the book is aimed mainly at discrediting conventional ERT as practiced now, but specifically the allegedly ignorant members of the American Medical Association who the authors say should know better and not prescribe "synthetics" when "natural" chemicals are available (now extracted as highly processed and chemically converted substances from wild yams). The authors also portray the ethical drug industry as money-hungry and criticize it for searching for and mass-producing medicines that are "safe and effective" (a requirement under federal law).

The Food and Drug Administration receives brickbats also because it requires a lengthy and expensive approval process. So expensive, say the authors, that natural hormone adherents have not (yet) done the research to make a New Drug Application. What I, as an editor of the *Journal of Food Science*, find particularly noteworthy is the allegation that "the *Journal of the American Medical Association*, the *New England Journal of Medicine*, and other top-of-the-line medical journals are completely in the dark about the use of natural hormones. Their use isn't taught in any medical school or by any pharmaceutical company, the other source for nearly all conventional physicians. With no multinational drug industry to pay the enormous costs, the large definitive studies that might demonstrate the efficacy and safety of natural hormones will likely never be done." So here it is, a rigorous evaluation of those wild yam chemicals has not been conducted and, therefore, there is no reliable information about their safe use and effectiveness. Yet the authors want to vigorously promote them.

But when one believes in a concept, as the authors do, it's only natural to embrace it and to push it. The booklet is praiseworthy in that it uses lay language to teach female endocrinology, especially the menopausal phase. But instead of presenting clear evidence, with actual cita-

tions instead of allusions to "Japanese scientists or evidence accumulated in Europe," the authors attack the dominant therapy which they wish to eradicate. However, the 10-page chapter called "Hormone Replacement and Cancer" does list 13 references.

So the thread throughout the book is a harangue against synthetic hormone replacement. Premarin™ and Provera® are portrayed as contributors to various ailments, whereas natural hormone replacement comes out with flying colors (and only skimpy traceable evidence) not only with regard to menopause symptoms, but especially osteoporosis, heart disease, cancer, and senility. More than that, the book unabashedly claims and promises for natural ERT such major achievements as better sex drive; prevention of senility and Alzheimer's disease; improved sleep, mood, and memory; prevention and restoration of bone loss; protection against heart disease and stroke; reduced risk of cancer and depression; and improvement of cholesterol levels. Of course, "the other stuff" doesn't do all that.

Incidentally, the currently and freely available DHEA and melatonin are also praised as wonder drugs similar to estrone, estradiol, and estriol obtained from the Mexican wild yam.

The book is a broadside against the establishment and for alternative (natural) living. It will appeal to folks who have embraced the elimination/minimization of drugs; learned how to self-prescribe vitamins, minerals, and botanical remedies; harnessed the natural energies contained in homeopathic remedies; and who use acupuncture, massage, chiropractic, and osteopathy. Almost parenthetically, in an afterword, the authors rant against the evils of modern life: food additives, pesticide residues, impure drinking water, and water fluoridation/chlorination. Also, with one stroke, the authors would eliminate all sweetness from the supermarkets, sugar, and artificial sugar substitutes.

As scientific literature this book is embarrassingly shallow; as sales literature it is downright insulting to the questioning and critical consumer. If natural hormone replacement is to ever become more widely accepted, its proponents should come forth with a better marketing

scheme than this book and less of a discreditation of the "other side."

The book will not appeal to scientists and the majority of health professionals. It is obviously aimed at the mass market. There must be millions of people who will buy this book and even seek out practitioners of NHR. After all, the front cover promises, for women over 45, to "live longer, achieve vibrant health, enhance your sex life, and look and feel years younger." Insights into any one of those ought to be worth the price of the book. Look for your copy at the next charity book sale where people donate the things they don't consider valuable.

Editor's Note: Wright cofounded the now defunct American Quack Association and has served as board chairman and president of the National Health Federation, a group that has opposed government regulation of quackery.

NOT RECOMMENDED

Herbal Assertions

Varro E. Tyler

Ask the Doctor: Herbs and Supplements for Better Health by Derrick M. DeSilva Jr., MD (Loveland, CO: Interweave Press, 1997), 160 pp., \$12.95 (paperback)

This slim volume, written in a rather inefficient question-and-answer format, suggests remedies, many of them herbal, for a wide variety of common diseases and afflictions. Unfortunately, none of the assertions regarding the efficacy of the proposed remedies is referenced, so the only authority for them is the author, the physician-host of a popular syndicated radio show.

Here are just a few of Dr. DeSilva's assertions I would like to see documented: kava counteracts lethargy in depressed patients (p. 13); aloe vera gel is a stool softener (pp. 24, 138); cayenne pepper and prickly ash stimulate circulation of the blood (p. 49); motherwort regulates heartbeat (p. 52); horse chestnut is the same as the Ohio buckeye (p. 55); goldenseal boosts the immune system (pp. 73, 151); garlic has a strong antiviral action (p. 90); shark cartilage has anti-inflammatory properties (p. 107); dong quai

quickly relieves PMS symptoms (p. 116); burdock root purifies the blood (p. 122); wild yam has estrogenic activity (p. 125); and wild yam and damiana will help sustain penile erection (p. 131).

Then there are some curious omissions in the book: the tannin complex from balm is not mentioned as a well-researched and effective treatment for cold sores. Chasteberry is not discussed as the premier herbal treatment for premenstrual syndrome. Siberian ginseng (eleuthero), ginkgo biloba, and blue cohosh are all recommended as treatments for the symptoms of menopause, but none of these herbs has ever been proven to relieve them. Consideration of black cohosh, the best proven herbal treatment, is entirely lacking.

Several of the author's pet themes recur with amazing frequency throughout the book. The acidophilus bacillus is repeatedly recommended in connection with a wide variety of afflictions. The need to drink pure water is also a constant theme. I certainly agree with his judgment that bottled water provides no assurance of quality. Cayenne pepper (capsicum) is proposed again and again for many conditions, but no mention is made of the use of capsaicin ointment to relieve arthritis pain. The herb is said both to raise and to lower blood pressure. Again, references here would be most welcome.

I have a personal antipathy towards reference books that are not well indexed. This one certainly is not. The so-called index is really an expanded table of contents simply listing the conditions and diseases discussed. Not a single treatment, herb, or drug is listed in it.

The book is well printed with useful colored illustrations and an attractively designed paper cover. It is interesting to read, but for the reasons stated above, I can only rate it:

NOT RECOMMENDED

Studying Studies

Manfred Kroger

Studies Show: A Popular Guide to Understanding Scientific Studies by John H. Fennick (Amherst, NY: Prometheus

Books, 1997), 240 pp., \$17.95 (paperback)

Almost daily we hear about this or that study telling us about health risks, human behavior, environmental pollution, social trends, the benefits of nutrients or supplements, and much more. The decisions of consumers, professionals, and public policy makers are greatly influenced by these "news flashes." Original reports are largely incomprehensible to lay readers because they are addressed to research peers. The rest of us receive filtered, popularized, interpreted, simplified, condensed versions. That is good, but also reason for concern in that we now must also critically examine the secondary report which may or may not be accurate. Most studies suffer from scientific jargon and the intricacies of the subject itself, and research findings are invariably given various "mysterious" statistical examinations. These make the results meaningful. However, if and when data manipulation is misapplied, the conclusion of a study will become meaningless. John H. Fennick is a professional statistics analyst and just the right person to give us a clear, even humorous, introduction to statistics and steer us clear of such pitfalls. If you are a willing student, his book can enhance your critical thinking as well as help you make sense of science news reports. Your level of numeracy will rise and benefit you ever after.

In a lighthearted, conversational way, he takes us not only through the statistics vocabulary (average, sampling, correlation, confidence level, variable, variance, distribution, standard deviation, null hypothesis, probability, linear regression analysis, etc.), but also into the realm of statistical gamesmanship, risk analysis, and decision making based on data, facts, and scientific evidence (as opposed to emotions, wishful thinking, political expediency, or whatever other human frailty). An educated citizen must know about numbers and their meanings. The statistically challenged person will always be subject to fraud, trickery, and exploitation. This book is like a roadmap guiding you through the news of science and technology.

RECOMMENDED

SCIENTISTS WANT TO ABOLISH THE OAM

Prominent scientists are calling for the abolishment of the NIH Office of Alternative Medicine (OAM), saying that the office is tarnishing the good name of the NIH and that the OAM promotes theories that are incompatible with the laws of physics. In response to the introduction of H.R. 1055 by Rep. Peter DeFazio, a bill that would increase funding to the OAM and elevate it to the status of an NIH center, scientists are calling for funding to be drastically cut or eliminated entirely. The scientists oppose the OAM because they believe that it is not scientific in its approach to alternative medicine. They maintain that the OAM should be held to standards of scientific excellence and peer review and point out that the OAM is not planning or conducting any objective studies of alternative therapies. Robert Park of the American Physical Society says, "The OAM is providing cover for medical quackery of every sort." He contends that alternative medicine is a "hodge-podge of totally unrelated techniques" and that the therapies should be researched by appropriate institutes and centers within the NIH.

GINKGO BILOBA DOES WELL IN TEST

A well-designed 52-week clinical trial has found that a Ginkgo biloba extract helped some patients with mild to moderate dementia (*JAMA* 278:1327-1332, 1997). The study followed more than 200 patients, half of whom received a fixed dose of EGb761, a Ginkgo extract used in Europe. The authors concluded: (a) EGb was safe and appears capable of stabilizing and, in a substantial number of cases, improving the cognitive performance and the social functioning of demented patients for 6 months to 1 year; and (b) the trial does not indicate whether benefits would be sustained. Reprints can be obtained from Dr. Pierre L. LeBars, New York Institute for Medical Research, 150 White Plains Rd., Tarrytown, NY 10591.

Doing the DRIs

A no-nonsense guide to the nation's new nutritional yardsticks

by Stephen Barrett, MD

The Dietary Reference Intakes (DRIs) are nutrient-based reference values for use in planning and assessing diets and for other purposes. They are intended to replace the Recommended Dietary Allowances (RDAs) that have been published since 1941 by the National Academy of Sciences. They are being determined by the Standing Committee on the Scientific Evaluation of Dietary Reference Intakes of the Food and Nutrition Board, Institute of Medicine (IOM), National Academy of Sciences, with help from Health Canada. The IOM is a private, nonprofit organization that provides health policy advice under a congressional charter granted to the National Academy of Sciences.

The DRIs will be released in a series of seven reports. The first report, published in August 1997, covers nutrients related to bone health (calcium, phosphorus, magnesium, vitamin D, and fluoride). Subsequent volumes will consider: (1) folate and other B vitamins; (2) antioxidants (e.g., vitamins C and E, selenium); (3) macronutrients (protein, fat, carbohydrates); (4) trace elements (e.g., iron, zinc); (5) electrolytes and water; and (6) other food components (e.g., fiber, phytoestrogens). The first report was funded by the FDA, the USDA Agricultural Re-

search Service, and the National Heart, Lung, and Blood Institute. The IOM hopes that all of the reports will be released by the year 2000.

A New Approach

The RDAs have served as the benchmark of nutritional adequacy in the United States. More than 20 years ago, they were defined as: "The levels of intake of essential nutrients that, on the basis of scientific knowledge, are judged by the Food and Nutrition Board to be adequate to meet the known nutrient needs of practically all healthy persons."

Scientific knowledge about the roles of nutrients has expanded dramatically since the RDAs were first published. Many studies have examined relationships between diet and chronic disease. The Food and Nutrition Board has responded to these developments by changing its basic approach to setting nutrient reference values.

The DRIs reflect a shift in emphasis from preventing deficiency to decreasing the risk of chronic disease through nutrition. The RDAs were based on the amounts needed to protect against deficiency diseases. Where adequate scientific data exist, the DRIs will include levels that can help prevent cardiovascular

NUTRITION FORUM (ISSN 1093-4545), © 1997 Prometheus Books, is published bimonthly for \$35.00 (individuals in U.S. and Canada) or \$50 (institutional, overseas) per year by Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197. Second-class postage paid at Buffalo, NY. POSTMASTER: Send address changes to Prometheus Books at the address above. Subscription information: (800) 421-0351, (716) 691-0133; fax (716) 691-0137. Back issues \$7.00. Manuscripts and all editorial correspondence should be directed to Lewis Vaughn, *Nutrition Forum*, P.O. Box 664, Amherst, NY 14226-0664 or e-mail to fivaughn@aol.com.

disease, osteoporosis, certain cancers, and other diseases that are diet-related. Instead of a single category, the DRIs will encompass at least four:

1. **Estimated Average Requirement (EAR):** The intake that meets the estimated nutrient need of 50% of the individuals in a specific group. This figure will be used as the basis for developing the RDA and can be used by nutrition policy-makers to evaluate the adequacy of nutrient intakes for population groups.

2. **Recommended Dietary Allowance (RDA):** The intake that meets the nutrient need of almost all (97 to 98%) of the healthy individuals in a specific age and gender group. The RDA should be used in guiding individuals to achieve adequate nutrient intake aimed at decreasing the risk of chronic disease. It is based on estimating an average requirement plus an increase to account for the variation within a particular group. The amount of scientific evidence available allowed the DRI committee to calculate RDAs for phosphorus and magnesium. If individual variation in requirements is well defined, the RDA is set at 2 standard deviations above the EAR, which means it should be high enough to meet the needs of at least 97-98% of the population. If sufficient data are not available, the RDA is set at 1.2 x EAR.

3. **Adequate Intake (AI):** When sufficient scientific evidence is not available to estimate an average requirement, Adequate Intakes (AIs) will be set. These are derived through experimental or observational data that show a mean intake which appears to sustain a desired indicator of health, such as calcium retention in bone. The AIs should be used as a goal for individual intake where no RDAs exist. The DRI committee set AIs for calcium, vitamin D, and fluoride.

4. **Tolerable Upper Intake Level (UL):** The maximum intake by an individual that is unlikely to pose risks of adverse health effects in almost all healthy individuals in a specified group. The UL is not intended to be a recommended level of intake, and there is no established benefit for individuals to consume nutrients at levels above the RDA or AI. The term "tolerable upper intake level" was chosen to avoid implying a possible beneficial ef-

fect. For most nutrients, it refers to total intake from food, fortified food, and supplements.

What They Mean

The DRIs are intended to apply to the healthy general population. RDAs and AIs are dietary intake values that should minimize the risk of developing a condition or sign that is associated with that nutrient in question and that has a negative functional outcome. They refer to average daily intake over one or more weeks. They should not necessarily be expected to replete individuals who are already malnourished and may not be adequate for disease states marked by increased requirements.

Individuals known to have diseases that greatly increase requirements, or who have increased sensitivity to developing adverse effects associated with higher intakes, should be guided by qualified medical and nutrition personnel.

The committee cautioned that nutrient intake less than the RDA does not necessarily mean that a given individual is not getting enough of that nutrient. Healthy individuals who meet the AI have a low risk of inadequate intake. However, an intake well below the RDA or AI would be a reason to assess the individual's nutritional status through laboratory testing or clinical examination. The IOM

BE A NUTRITION FORUM CONTRIBUTOR!

If you find any news or information that may be of interest to our readers—such as published articles, news reports, press releases, or relevant personal experience—please send it to us. Mail it to Lewis Vaughn, *Nutrition Forum*, P.O. Box 664, Amherst, NY 14226-0664. We're especially interested in receiving information about enforcement actions by state agencies, lawsuits by victims of quackery, and health-fraud news that may have been overlooked by the national media.

Why Nutritionist Licensing Is Important

During the past 60 years, perhaps 50 individuals without valid credentials have pretended to be medical doctors and actually managed for a time to practice. It is unlikely that anyone has ever been exposed as a fake dentist, podiatrist, optometrist, or even chiropractor. But in nutrition, nonaccredited correspondence schools and other organizations have issued thousands of "degrees" and certificates that suggest that the recipient is a qualified expert in nutrition. These documents are promoted as though they are equivalent in meaning to established credentials—which they are not.

The most prominent nonaccredited school was Donsbach University of Huntington Beach, California, whose president, Kurt Donsbach, D.C., has been involved in dozens of questionable health and nutrition ventures. Most "textbooks" required for the school's basic curriculum were books written for the general public by promoters of dubious nutrition practices. A typical "degree" program took less than a year to complete. Graduates typically referred to themselves as "nutrition consultants," a term also used by some reputable nutritionists. The school ceased operations in 1987, but some of its "graduates" are still in practice.

Bernadean University, of Van Nuys, California, offered "nutritionist" and "cancer researcher" certificates, "master's degrees," and "Ph.D. degrees" in acupuncture, reflexology, iridology, naturopathy, homeopathy, and nutrition. Dietitian Virginia Aronson took the "nutritionist" course and reported that she got high grades on all tests whether she put down correct answers or not. In 1982, Bernadean was ordered to cease operations because it was not authorized by the state. However, it is still functioning. Bernadean's most prominent alumnus is "Dr."

Richard Passwater, author of *Supernutrition* and several other books.

"Nutrition consultants" who wish to acquire additional "credentials" can join the American Association of Nutritional Consultants, which issues certificates suitable for framing and publishes a directory and a monthly newspaper. Its "professional membership" application asks only for the applicant's name and address plus \$50. Several investigators, including Stephen Barrett, MD, have enrolled household pets as professional members.

In response to the flaunting of dubious credentials, dietitians have gained passage of laws to regulate nutritionists in 38 states and the District of Columbia. Some make it illegal for unqualified persons to call themselves dietitians or nutritionists, while others define nutrition practice and who is eligible to practice. The most basic requirement for licensure is completion of accredited training. Opponents claim that bills of this type are motivated by greed and an intention to create a monopoly for one school of thought. The real issues, however, is public protection.

It is unfair to expect people to check the credentials of every practitioner they encounter. Rather, it should be government's role to set licensing standards and to prevent individuals who don't meet the standards from representing themselves as equivalent to those who do. Licensing does not offer complete protection against all forms of nutrition practice conducted privately between consenting adults. (It does not, for example, protect people from the poor advice offered by many chiropractors, acupuncturists, naturopaths, and health-food retailers.) But it can deter untrained individuals from widely advertising that they are experts. **NF**

A dietitian who took one course received high grades on all tests whether she put down correct answers or not.

WEB WATCH

The World Wide Web is a treasure trove of information but loaded with booby traps. The sites listed below include some of the best (most reliable, useful) and worst (unreliable, deceptive, but in some cases still useful for viewing quack concepts in the raw). This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc. (<http://www.quackwatch.com>), which is working hard to improve the quality of health information on the Web. Listed below are, in our opinion, some of the best and worst sites on the Net.

BEST

<http://www.cyberdiet.com/> Cyberdiet, hosted by Timi Gustafson, RD, contains a wealth of information as well as interactive tools for assessing and planning diet and exercise programs. You can use it to calculate your BMI and your target heart rate, and to view nutrient contents as they would appear on the labels of hundreds of foods. Start with the "Guided Tour."

<http://www.ada.org/consumer/fluoride/fl-menu.html> The American Dental Association's gateway to dozens of well-written articles about fluoridation.

<http://www.intellihealth.com/> Johns Hopkins's information site contains a wealth of information and answers individual questions.

WORST

<http://www.newhope.com/nhnm.html> New Hope Natural Media's gateway to the contents of its health-food industry trade and consumer magazines, several of which can be read in their entirety online. The site provides a huge amount of information about industry trends, political maneuvering, claims made for supplements and herbs, retailer education, and the industry's interpretation of nutrition research.

<http://www.prevention.com/healing/oncall/> *Prevention* magazine's "Doctor on Call" provides largely unsubstantiated advice from a naturopath about taking supplement and herbal products. *Prevention's* unsubstantiated advice on using vitamins and minerals for health problems can be accessed through the "vitamin dispenser" page at <http://www.prevention.com/healing/vitamin/>. A disclaimer states that the site is "intended to heighten awareness of health information and does not suggest diagnosis or treatment."

expects future publications to provide more detailed advice on how the DRIs should be interpreted and used.

Revised Values

In many cases, various levels of intake can have different benefits. One level may be related to the risk of deficiency, for example, while another level can influence the risk of chronic disease for that nutrient. For this reason, "nutrient adequacy" should be expressed in terms of "Adequate for what?" For this reason, the DRIs are far more elaborate than the RDAs and cannot be expressed in a simple table of values.

- Calcium recommendations were set at levels associated with maximum retention of body calcium because bones that are calcium-rich are known to be less susceptible to fractures. The other factors known to affect bone retention of calcium and risk of osteoporosis include high rates of growth in children during specific periods, hormonal status, exercise, genetics, and other diet components. The new report advises Americans and Canadians at risk for osteoporosis to consume between 1000 and 1300 milligrams of calcium per day. These values (AIs) are higher than the 1989 RDAs, which ranged from 800 to 1200. The adult UL for calcium is 2.5 grams per day.

- Phosphorus, important for bone and soft tissue growth, is so prevalent in various foods that near starvation or a metabolic disorder is required to produce deficiency. Different from former RDAs, phosphorus values in the report are not derived in relation to calcium. The values recommended are considered sufficient to support normal bone growth and metabolism at various ages. The new RDAs are about 12% lower than the 1989 RDAs.

- Magnesium works with many enzymes to regulate body temperature, allow nerves and muscles to contract, and synthesize proteins. Although some researchers have argued that magnesium recommendations should be based on relationships with the risk of cardiovascular disease, the report does not find enough data available at this time to do so. The levels recommended, although somewhat higher, do not differ substantially from the 1989 RDAs but are higher than current Canadian recommendations.

- Vitamin D used by the body comes mostly through exposure to the sun. Vitamin D deficiency can exacerbate osteoporosis and other bone problems in adults. Dietary intake of vitamin D is unnecessary for people who spend adequate amounts of time in the sun. The levels recommended in the report are estimated to provide enough vitamin D even for individuals with limited sun exposure. The AIs of 10 micrograms from age 51 to 70 and 15 micrograms over age 70 are higher than their 1989 counterparts. The adult UL for vitamin D is 50 micrograms (2000 IU) per day.

- Fluoride is found naturally in some community water systems and is added to water in other areas to reduce dental decay. The levels recommended in the DRIs have been shown to reduce tooth decay without causing marked fluorosis, a discoloration of the teeth that could occur in children who use dental products with fluoride in addition to fluoridated water. The AIs for fluoride are similar to the corresponding values (ESADDIs) in the 1989 report. The American Dental Association, the American Academy of Pediatrics, and the Canadian Paediatric Society recommend that children living in nonfluoridated communities take fluoride supplements because the required amount is unlikely to be provided by food. The

amounts recommended for infants and children have been lowered during the past few years because of concern about fluorosis, a cosmetic defect that most commonly involves white patches that are barely visible on the teeth.

Except for fluoride, the greatest disparity between recommended values and current dietary patterns is in calcium, which comes primarily from dairy products. Surveys indicate that many do not consume the amount of calcium recommended in the report. Calcium intake can be increased by consuming more low-fat or nonfat dairy products or fortified food products or by taking supplements. The report states that taking supplements may be appropriate for those at high risk of health problems due to low calcium intake.

The report also states: (a) unfortified foods are advantageous for meeting the RDAs and AIs because they provide other food components for which RDAs and AIs may not be determined; (b) food fortification can increase or maintain nutrient intakes without major changes in food habits; and (c) nutrient supplementation may be desirable for some people.

The full report—*Dietary Reference Intakes: Calcium, Phosphorus, Magnesium, Vitamin D, and Fluoride*—can be purchased by calling (800) 624-6242; sending \$39 to the National Academy Press, 201 Constitution Ave., NW, Washington, DC 20418; or ordering it at a discount online (<http://www.nap.edu>). The full text can also be read online, although the process is cumbersome. **NF**

FDA WARNS CONSUMERS ABOUT SKIN-CAP

The FDA has issued a warning regarding the product "Skin-Cap." It is primarily used for the treatment of psoriasis and contains prescription-strength corticosteroids that may produce serious side effects. Those who are using the product are advised to see their physician immediately. An abrupt halt to the use of the product could cause psoriasis to worsen or lead to a serious flare-up of the disease that could be life-threatening. An FDA analysis has shown that Skin-Cap contains prescription levels of a potent topical steroid, clobetasol propionate. This steroid has many potentially harmful side effects, including dilation of tiny blood vessels, stretch marks, and thinning skin. Long-term use or large amounts of the drug can cause hypertension, diabetes, osteoporosis, and behavioral changes. It can also suppress the body's ability to produce its own corticosteroids. Skin-Cap is imported from Spain and is sold as a nonprescription spray, shampoo, or cream for psoriasis and other skin disorders. The FDA has also taken steps to detain imports of the product at all border entries.

META-ANALYSIS QUESTIONED

According to a recent report in the *New England Journal of Medicine* (NEJM 337:536-542), meta-analysis—the practice of combining several small medical studies into a single large study—may lead to inaccurate science and inappropriate conclusions. Large, randomized controlled studies are considered the gold standard in evaluating the effectiveness of clinical interventions. Meta-analysis has become popular in recent years to help study medical issues when there has not been one large, well-controlled study on an issue. Dr. Jacques LeLorier and others from the University of Montreal identified 12 large randomized, controlled studies and 19 earlier meta-analyses which addressed the same questions. They determined that meta-analyses failed to come to the same conclusions as the larger studies, which are presumed to be more

accurate. Responding to the study in an editorial in the journal, John C. Bailor III of the University of Chicago noted that sometimes even two meta-analyses using the same data arrive at incompatible or contradictory conclusions. He stated that frequent and serious problems with meta-analyses make it difficult to trust the overall "best estimates" that the method often produces.

DOCTOR SUSPENDED FOLLOWING ALOE DEATHS

The Virginia Board of Medicine has suspended the medical license of Donald L. MacNay, MD, whose practices the board described as "a substantial danger to the public health and safety." According to American Medical News, MacNay charged \$12,000 to treat cancer patients with intravenous injections of an aloe-based product. The board's action was triggered by the deaths of at least three patients he allegedly treated.

GERBER SETTLEMENT HOAX

Notices have been sweeping the country that "Gerber Baby Food lost a class-action suit against them. Gerber had been marketing their baby food as 'all natural' when, in fact, it was found to contain preservatives. In the settlement, Gerber Food is now responsible for giving every child born between 1985 and 1997 a \$500 savings bond. . . . To obtain the bond, send a copy of the child's birth certificate and Social Security number to . . ." Thousands of people have responded by sending information to a now-closed post office box in Minneapolis. Postal officials describe this notice as a hoax attributable to an Internet-based prankster. A class-action suit involving other infant formula makers was settled in 1996, but Gerber was not a party to the suit. The Council of Better Business Bureaus warns that personal information such as Social Security number should not be given to people who do not have a legitimate reason to have it.

AAFP ADOPTS NEW CME POLICY

In January 1997 the Commission on Continuing Medical Education of the American Academy of Family Physicians resolved not to approve continuing edu-

cation courses that espouse theories and techniques not generally accepted by the medical community. If a course or program includes information about "complementary" or "alternative" practices, the sponsoring organization must attest that "the proposed program will neither promote . . . nor . . . teach physicians how to use a particular type of complementary/alternative practice."

NEW ACSH REPORTS

The American Council on Science and Health, 1995 Broadway, New York, NY 10023, has published excellent booklets covering vegetarianism and colorectal cancer. The vegetarianism booklet concludes: "Some scientific studies indicate that vegetarians have lower risks of chronic diseases than do meat-eaters. However, some of the apparent benefits . . . may be attributable to aspects of the vegetarian diet other than the absence of meat, or to nondietary aspects of typical vegetarian lifestyles. It is not necessary to . . . become a vegetarian to enjoy the benefits of a healthy diet." The colorectal report includes myths about diet and cancer. The reports are \$5 each.

LAXATIVE INGREDIENT BANNED

The FDA intends to ban phenolphthalein as an ingredient in over-the-counter laxatives. The agency reported that animal studies have found that, in high doses, phenolphthalein can damage a gene that suppresses tumors and cause various cancers in laboratory rats and mice. Novartis Consumer Health, which markets Ex-Lax, announced that it would recall its current supply and, within 60 days, would sell a reformulated product containing senna.

CHOLESTEROL-LOWERING INSTRUCTIONS

The National Cholesterol Education Program has published an excellent booklet called "Live Healthier, Live Longer: Lowering Cholesterol for the Person with Heart Disease" (order #3805). A copy can be obtained for \$3 by calling (301) 251-1222 or by writing to the NHLBI Information Center, P.O. Box 30105, Bethesda, MD 20824. Multiple discounts are available. **NF**

The Sour Truth about Apple Cider Vinegar

by Beth Fontenot, MS, RD

Apple cider vinegar is an old folk remedy claimed to be beneficial in treating a long list of ailments. Proponents say that it can cure arthritis, guard against osteoporosis, lower blood pressure and cholesterol, prevent cancer, destroy infection, assist in digestion and weight control, maintain memory, and protect the mind from aging.

Vinegar is said to have been used for medical ailments for at least 10,000 years. The Babylonians first converted wine into vinegar in 5000 BCE using date palms, grapes, and figs, and believed vinegar had exceptional healing properties. Hippocrates is said to have used vinegar as an antibiotic. Samurai warriors supposedly used a vinegar tonic for strength and power. During the U.S. Civil War, soldiers used vinegar to prevent gastric upset and as a treatment for various ailments including pneumonia and scurvy. It was used to treat wounds during World War I.

The name *vinegar* comes from a French word meaning "sour wine." It is produced by the action of yeast and bacteria on grains or fruit juices. Vinegars take their name from the material used to make the vinegar, i.e., apple cider vinegar comes from apples, wine vinegar comes from grapes.

Apple cider vinegar is made by crushing apples and squeezing out the liquid. Sugar and yeast are added to the liquid to start the fermentation process, which turns the sugars into alcohol. In a second fermentation process, the alcohol is converted by acetic acid-forming bacteria into vinegar. Acetic acid gives vinegar its sour taste.

"Mother of vinegar" is a term used to refer to the mass of scum that forms on top of cider when alcohol turns into vinegar, or to the cloudy substance that sometimes develops in stored vinegar. It is actually bacteria and yeast cells that have died.

Folk Claims

In 1958 Dr. D. C. Jarvis, a "noted Vermont country doctor," wrote a book entitled *Folk Medicine* in which he extolled the virtues of vinegar.

Jarvis claimed that Vermonters knew how to cure migraine headaches, diabetes, chronic fatigue, arthritis, and more—they used apple cider vinegar.

He claimed that Vermonters knew how to cure migraine headaches, diabetes, chronic fatigue, arthritis, and a variety of other ailments. They used apple cider vinegar.

Among Dr. Jarvis's many tenets about apple cider vinegar was his advice to pregnant women to drink an apple cider vinegar tonic daily to assure that the infant is born with "an excellent chemical pattern with which to meet its new environment." He recommended the same tonic for those suffering from arthritis. Believing that apple cider vinegar would destroy bacteria in the digestive tract, he advised those with GI problems to consume a tonic with each meal. He also declared that the regular consumption of an apple cider vinegar tonic would make body fat disappear because the vinegar would cause the fat to be burned instead of stored.

His book quickly sold 500,000 copies and is still in print. Apple cider vinegar is still promoted as one of the chief "natural" remedies for arthritis.

Those who believe that apple cider vinegar has miraculous properties attribute its powers to an abundance of nutrients in the liquid. One company's sales

pitch states, "Each golden drop is a natural storehouse of vitamins and minerals." Marketers point to the trace minerals, bacteria, and enzymes present in their product as the ingredients that give apple cider vinegar its curative characteristics. Another company suggests that their apple cider vinegar is superior because it contains pectin, beta-carotene, and potassium in addition to enzymes and amino acids. Apple cider vinegar is also said to contain an abundance of complex carbohydrates and dietary fiber. Dr. Jarvis believed that the healing properties of apple cider vinegar were due in large part to its rich potassium content.

Some New Twists

Apple cider vinegar is sold today by "health food" companies and others who claim it has remedial properties. The claims are similar to those in the past, but some have taken on a modern twist based on more recent medical research.

Marketers contend that the beta-carotene in apple cider vinegar destroys free radicals in the body which are involved in the aging and mutation of tissues and in destroying the immune system. Apple cider vinegar's beta-carotene is said to be in a "natural, easy to digest form."

Its use as a remedy for arthritis is based on the notion that acid crystals harden in the joints and tissues which cause the joints to become stiff and the tissues to harden. These acid crystals also cause the body to age prematurely, so the ads state. Apple cider vinegar is supposed to put these acid crystals in solution so they can be flushed from the body.

Producers also claim that apple cider vinegar can lower cholesterol and blood pressure. These assertions are based on the assumption that people naturally crave acids when eating animal proteins in order to lessen the thickening influence of "heavy proteins and fat." Apple cider vinegar supposedly thins the blood so it can circulate more freely. Thick blood, they say, puts a strain on the heart and up goes the blood pressure. Another source states that the pectin present in apple cider vinegar works its way through the digestive system, binding to cholesterol and removing it from the body.

Apple cider vinegar is also available in tablet form. One brand is merchandised as a "digestive aid for vegetarians." The manufacturer of this product alleges that the tablets help acidify the stomach and help digest protein. Another tablet, which contains apple cider vinegar as one of its components, is sold as a fiber supplement and supposedly assists in weight loss. Still other companies add herbs to their apple cider vinegar "so people see relief from even more ailments."

The rubbery mass of goo called the "mother of vinegar" is reputed to have magical healing properties as well. Nibbling on a bit of this moldy slime every day is purported to prevent most infectious diseases and keep germs and parasites from invading the body.

One company's advertisement for organic, raw, unfiltered, unheated, unpasteurized apple cider vinegar is particularly alarming. This company's ad maintains that "there is nothing in this wonderful natural apple cider vinegar that can in any way harm your body!" Apparently, they have never heard of the danger of *E. coli* O157:H7 in unpasteurized fruit juices. Normally vinegar is too acidic to support bacteria. However, should the acidity weaken (pH reaching 4.6 or higher), then pathogens will survive and grow.

Jogging in a Jug

In 1985, Jack McWilliams, an Alabama farmer, concocted a potion he called "Jogging in a Jug." It consisted of apple cider vinegar combined with a variety of fruit juices to give it a more appealing taste.

Acetic acid, claimed McWilliams, was lacking in the modern diet, and this

deficiency was the root cause of many health problems. He claimed that the potion had cured his arthritis and heart disease, and it could reduce the risk of cancer in the internal organs. McWilliams marketed his product through the media, receiving extensive coverage in small community newspapers and broadcast outlets. He reportedly sold \$9 million worth of his potion in one year.

The FDA, however, did not look kindly on Mr. McWilliams's vinegar product and its advertised claims. The federal government seized the product in 1994 due to the unproven health claims.

In 1995, thousands of bottles of the potion were ordered destroyed because the product was considered an unapproved new drug due to the claims made by the producer. Subsequently, Mr. McWilliams's company, Third Option Laboratories, Inc., paid the Federal Trade Commission a \$480,000 fine to settle charges of false advertising. "Jogging in a Jug" is still on the market today with a new label that meets FDA guidelines.

The Real Story

There is no scientific evidence that apple cider vinegar has any medicinal properties. While the folksy anecdotes from those who claim to have benefited from apple cider vinegar tonics may be amusing to read, they are simply that—anecdotes.

Apple cider vinegar is anything but a

storehouse of nutrients. A nutritional analysis of one tablespoon (more than the one or two teaspoons suggested to make a tonic) reveals that the golden liquid contains less than a gram of carbohydrate; minuscule amounts of calcium, iron, magnesium, sodium, copper, manganese, and phosphorus; and a mere 15 mg of potassium. The fiber, vitamin, and amino acid content is zero.

As for the presence of any beneficial enzymes in apple cider vinegar or the "mother," food scientists doubt that any could thrive in the acid environment of the vinegar. Assuming any were present, though, they would be destroyed in the acid of the stomach when consumed and be of no use to the body.

The Arthritis Foundation calls vinegar a harmless, but unproven, arthritis remedy. It points out that arthritis symptoms come and go, and that a person using an unproven remedy may think a remedy worked simply because they used it at a time when symptoms were going into natural remission. Such is undoubtedly the case for many of the "cures" connected to vinegar. **NF**

READERS' FORUM

A DUCK QUESTION

Your interesting brief on the homeopathic remedy *occillococcinum* (July/August 1997) raises an intriguing ethical question: If he or she suffers from one of the illnesses for which *occillococcinum* [derived from duck's liver and heart] is reputed to be effective, can a strict vegetarian use the preparation in good conscience? The answer obviously hinges on

the question whether the substance he or she actually ingests contains a "memory" of the original duck, for surely it contains none of the unfortunate creature's molecules!

Book Reviews

Analysis and Ratings

How accurate and useful is the nutrition information in that book? Would a reputable reviewer recommend the book to professionals and consumers? These are the two questions that Nutrition Forum book reviews are intended to answer. So the reviews not only offer analyses but also rate each book as either RECOMMENDED, NOT RECOMMENDED, or RECOMMENDED WITH RESERVATIONS, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Love and Speculation

Manfred Kroger

The Blending Book: Maximizing Nature's Nutrients by Ann Wigmore and Lee Patterson (Garden City Park, NY: Avery Publishing Group, 1997), 146 pp., \$8.95 (paperback)

There are two major parts to this paperback: 75 pages of recipes and 42 pages of physiology textbook information (interlaced with strange statements that are totally new to traditionally trained nutritionists and dietitians).

Ann Wigmore, who died in February 1994, was probably as nice a lady as my grandmother who also worked in the garden and kitchen a great deal. Unfortunately, I had to relearn all that my grandmother taught me about nutrition. I'm afraid the same thing could probably be said about many people who read this book. It's mainly autobiographical, espousing much love; it also presents the views of self-educated health "professionals" and a subtle diatribe against everything that doesn't fit into the authors' worldview.

Like all books of this type, there are many restrictions and commands. Only organic, living plant foods are allowed. All

other supermarket items and the way we eat them are blamed for numerous ills that afflict us. If people would only prepare and drink a fluid, made over several days, of watered wheat grains, with slight fermentation, their vital life force would be restored and the body rejuvenated. Hence Ann Wigmore's choice of the name Rejuvelac for the grain water she so fervently advocated.

Thus, a well-meaning kitchen experimenter attempts to become a nutritional authority and asserts unsubstantiated claims, new theories, and repeated confusions. Even the interesting recipes can't bail out a book like this. Antitechnology believers, however, will gobble up both blended foods and the claims made for them.

It is totally unfounded to say that food enzymes are important nutrients and that their lack induces various types of ill health. Also astounding is the elevation of chlorophyll to nutrient status. The authors' animosity toward cooking and modern food processing and the complete omission of any substantial data or sources makes this book another curiosity item on the shelves of alternative eating/lifestyle libraries.

The book's key idea is that food enzymes effect the best type of digestion and optimal nutrient absorption. In the opinion of the authors, their followers should produce feces of no nutritional contents, whereas the rest of us excrete large amounts of unabsorbed nutrients. Where is the study comparing human feces that might back up the naive claims displayed here?

NOT RECOMMENDED

Stress Lore

Manfred Kroger

Stress and Natural Healing by Christopher Hobbs, L.Ac. (Loveland, CO: Interweave Press, Inc., 1997), 240 pp., \$16.95 (paperback)

With so much persuasive emphasis on natural healing these days in the media and in health-food stores, it is actually refreshing to read a book that is well written and quite comprehensive. The author, a fourth-generation herbalist, has probably read all the herbal books available to him. His many references to Traditional Chinese Medicine

give away "where he is coming from." I found the book quite readable and historically informative—"vital essence," "yin/yang," "digestive tonics to support the body's vital energy" are among the strange concepts for the noninitiated, all steeped in folklore, taught by word of mouth, never properly identified and measured, and largely ignored by modern medicine.

The book covers four areas relating to life with reduced stress: wholesome diet, herbal medicines, vital energy, and visualization and meditation. For the lay reader the book is a very good textbook review of all aspects of stress. But when the name of the world's most foremost stress researcher, Hans Selye, is misspelled, one wonders what other errors there may be.

The author never shows an antagonistic stance toward modern medical treatment, as so many books on "natural healing" do. He simply contrasts for each of the many stress conditions what a doctor will do and what a natural healer will do.

There are many good tables listing prescription and over-the-counter drugs against stress symptoms, and a 43-page chapter, "The Herbal," describing in detail 19 plant sources that have been recommended in stress treatment. For most herbs there is no experimental record of safety and efficacy, just the lore of the centuries with only occasional support from the literature of science. It also seems that much of the herbal information in this book has been filtered somewhat. Shouldn't a discussion of catnip also state that the Food and Drug Administration classifies catnip as an herbal of "undefined safety." All the herbs listed are home to hundreds of potent chemicals, and even a nonchemophobe ought to question whether physiological potency occasionally crosses the threshold of toxicological potency, as the author points out for caffeine, alcohol, tobacco, and ephedrine.

This book is not recommended as a source of guidance on how to treat stress-related illness. It gives the reader very little help in deciding which therapies are scientifically supported. But it is a well-documented catalog of "alternative" treatment methods for a common category of ills. As such, it offers interesting insights into how nonconventional practitioners think and work. **NF**

RECOMMENDED WITH RESERVATIONS

ANOTHER SUPPLEMENT SCAM

Former pediatrician Lendon Smith, MD, is promoting the Life Balances Program, which he describes as "a monitoring method that clearly shows if one is nutrient-deficient, or alkaline, or skewed in some metabolic, chemical, or enzyme department." Purchasers complete a questionnaire and undergo standard blood tests that include a chemistry profile and complete blood count. The test results are then fed into a computer, which issues a report stating which supplements are needed. The products, which are marketed by the International Health Foundation (IHF) of Portland, Oregon, include 20 bottles of vitamins and minerals, 6 dropper bottles of minerals, and an electrolyte solution. Smith claims that sniffing the bottled nutrients enables the user to determine current body needs. He states: "The sweeter or more delightful the smell, the more it is needed. If the contents smell repugnant, it is not to be taken at that particular time." The initial cost of the "complete program" is \$688 plus shipping. During the 1970s, Smith received massive publicity as a guest of Johnny Carson, Phil Donahue, and several other nationally broadcast programs. However, he faded from the limelight after being kept on probation by the Oregon medical board from 1973 through 1981, and he permanently surrendered his license in 1987 rather than face board action on charges of insurance fraud.

MEAT IRRADIATION APPROVED

The FDA has approved irradiation of meat products for controlling disease-causing microorganisms. The approval applies to fresh and frozen red meats such as beef, lamb, and pork. The agency has previously approved irradiation of (1) poultry to control pathogens, (2) pork for control of the hookworm parasite, (3) fruits, vegetables, and grains to control insects, and (4) spices, seasonings, and dry enzymes used in food processing to control microorganisms. The approval came in response to a 1994 petition by

The Unethical Behavior of Pharmacists

How to market dubious supplements and unproven remedies

by Stephen Barrett, MD

Most pharmacists who work in retail pharmacies have a serious potential conflict of interest. On the one hand, they are professionals, expected to be knowledgeable about drugs and to dispense them in a responsible and ethical manner. On the other hand, their income depends on the sale of products. Before the FDA's OTC (Over-the-Counter) Drug Review drove most of the ineffective ingredients out of OTC drug products, few pharmacists protested or attempted to protect their customers from wasting money on products that were ineffective, unnecessary, or irrationally formulated.

During the mid-1980s, two dietitians examined the labels of vitamin products at five pharmacies, three groceries, and three health-food stores in New Haven, CT. Products were considered appropriate if they contained between 50% and 200% of the U.S. RDAs and no more than 100% of others for which Estimated Safe and Adequate Daily Dietary Intakes exist. Only 16 out of 105 (15%) of the multivitamin/mineral products met these criteria (*Journal of the American Dietetic Association* 87:341-343, 1987).

Today the situation appears worse.

Although OTC drugs are generally effective, nearly all pharmacies still carry irrational supplements, and many stock dubious herbal and homeopathic products as well. Chain drugstores are more likely to do so than individually owned stores.

*Nearly all
pharmacies still
carry irrational
supplements,
and many stock
dubious
herbal and
homeopathic
products
as well.*

Marketing Ploys

Pharmacy schools appear to teach the facts needed to advise people that "nutrition insurance" is rarely needed, that "stress" supplements are a scam, and that doses above the RDAs are seldom appropriate. Yet pharmacists throughout America seem content to sell supplements to people who don't need them. Their professional journals rarely contain articles criticizing the fraud involved, and their trade publications talk mainly about vitamin promotion. In fact, most pharmacy trade publications carry articles urging pharmacists to compete with health-food retailers by using similar propaganda techniques!

Many pharmacies display posters or flyers telling what vitamins do in the body. Some also list the problems that occur with nutrient deficiencies. These items are obviously intended to promote sales by inducing customers to think that (a) if a little

is good, more is better, and/or (b) if they have any of the symptoms listed, a vitamin might be the answer to their problem.

Many vitamin promoters suggest that being busy, skipping meals, or "eating on the run" places people at risk for dietary deficiency. According to this notion, busy people don't take the time to consume nourishing food. These claims are misleading because preparing or eating a balanced diet takes no more time than preparing or eating an unbalanced diet.

Major vitamin manufacturers and trade associations play a significant role in spreading misinformation. During the early 1980s, for example, Hoffmann-La Roche advertised that "busy" people should take supplements. An article in a pharmacy trade publication later revealed that these ads were intended to influence pharmacists (who advise many customers) as well as the general public. During the same period, until stopped by the New York State Attorney General, Lederle Laboratories marketed Stresstabs with misleading claims that "stress robs the body of nutrients."

In 1989, the Council for Responsible Nutrition (CRN), a nutritional supplement industry association that mainly represents large manufacturers, began advertising that virtually everyone has a "vitamin gap." During the mid-1980s, market research had found that most Americans felt they were getting adequate nutrition from their diet. CRN's "Vitamin Gap" campaign was designed to convince people that supplements were still needed. First it falsely suggested that vitamins could help against stress. Then it falsely suggested that most Americans were not getting enough in their diet.

Lederle used the "vitamin gap" theme in a Centrum ad in the June 1997 *Journal of the American Dietetic Association*. Centrum is a sensibly formulated multivitamin/multimineral product that costs about 10¢ per day. However, the ad suggested that the majority of Americans are not getting the nutrients they need in their diet and should use Centrum to bridge the alleged "gaps." According to the ad: "Statistics

show that 9 out of 10 Americans don't get all the nutrients they need from what they eat, and, in fact, are missing out on important vitamins and minerals."

This statement was based on an analysis of data collected between 1976 and 1980 from the Second National Health and Nutrition Examination Survey. The survey found that only 9% of the participants remembered consuming the recommended five portions of fruits and vegetables on the day covered by the survey (*American Journal of Public Health* 80:1443-1449, 1990).

This does not mean that people who reported less were deficient in vitamins or minerals. Dietary surveys that measure nutrient intake for a single day or even a few days are not suitable for determining the overall quality of an individual's diet. Adequate nutrient intake can be achieved with fewer than the "recommended" number of portions of fruits and vegetables. Furthermore, Americans are eating more fruits and vegetables than they did 20 years ago. CRN used the same faulty reasoning to justify its original campaign.

CRN has produced two brochures that the National Association of Chain Drug Stores distributed to retail pharmacies. One contains a chart of "the health benefits of vitamins and minerals" and subtly suggests that many people don't get enough. Both refer to research developments and speculations that higher-than-RDA levels of various nutrients might help prevent disease. Both state that "appropriate use of nutritional supplements should be part of a healthy lifestyle," but neither provides the information an individual would need to judge whether supplementation makes sense. Both are posted to CRN's Web site (<http://www.crnusa.org/Consumer.htm>).

Investigative Reports

If asked directly for advice, most pharmacists will answer to the best of their ability. However, many are poorly informed.

If asked directly for advice, most pharmacists will answer to the best of their ability. However, many are poorly informed.

The Hying of DHEA

Long on claims, short on evidence

by Beth Fontenot, MS, RD

It's in magazines, on store shelves, in the news, on talk shows, on the Internet, and in books. Promoters promise youth and health to all who partake of it.

It is DHEA, short for dehydroepiandrosterone, a major steroid hormone secreted by the adrenal glands. Many believe that this hormone holds the key to aging, weight loss, memory loss, and a host of other diseases and disorders. No one knows exactly what DHEA does or how it works, yet many are being lured by the claims made for this "superhormone" long before all the evidence is in.

Hormones are powerful chemicals that act as messengers in the body and affect the biochemical reactions within cells. Estrogen and testosterone are two hormones that have been studied for many years and are routinely used for treating various conditions, but the role of other hormones—like DHEA—remains a mystery.

DHEA Basics

DHEA is made from cholesterol, and it is a substrate for the production of estrogen and testosterone. When it is metabolized in the liver, a sulfate is added, and it travels through the body in the form of DHEA-sulfate (DHEAS). It is produced only in primates and a few nonprimate species; however, only in humans and apes do DHEA levels change over the course of life. DHEA levels are very high before birth, drop to nearly none after birth, rise sharply at puberty, reach their peak during the twenties, and then gradually drop by about 2% each year to negligible levels in old age. Some suggest that the drop in DHEA levels is the cause of

aging, sickness, and death. Researchers have found that DHEA levels decrease during illnesses such as lupus, rheumatoid arthritis, and major depressive disorder, and that levels are higher in men than in women at all ages.

Synthetic forms of DHEA have not been approved by the FDA though they are available in Europe and are the versions used in most of the physiologic studies. The DHEA made by vitamin and pharmaceutical companies is produced in a laboratory by extracting sterols from dioscorea, a Mexican yam.

Oddly enough, DHEA is marketed as a dietary supplement even though it is not found in any food. Once sold in health-food stores as a nonprescription weight-loss aid, DHEA was removed from the market by the FDA in 1985 because the substance had never been reviewed for safety and effectiveness. Encouraged by the loose wording of the Dietary Supplement Health and Education Act of 1994, DHEA is now marketed as a "dietary supplement" and allowed to be sold over the counter.

Exaggerated Claims

DHEA is alleged to reverse the aging process and remedy almost any bodily ill. The merchandisers have taken preliminary research (mostly done on rodents) and exaggerated the claims to create an enterprise fueled, at least in part, by our culture's worship of youth and the hope of reversing the consequences of aging. The advertisements for DHEA are filled with "research-backed claims" that quote one

The advertisements for DHEA are filled with "research-backed claims" that quote one prominent researcher after another and frequently misrepresent their findings.

[continued on page 6]

WEB WATCH

The sites listed below include some of the best (most reliable, useful) and worst (unreliable, deceptive) sources on the Web for nutrition and health information. This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc. (<http://www.quackwatch.com>).

BEST

The Institute of Food Technologists site (<http://www.ift.org>) is oriented primarily for its members, but its news releases and "Communicator's Alert" newsletter are useful to others. One timely item is the backgrounder on IFT's Scientific Status Summary "Irradiation of Food," which was published in the January 1998 issue of *Food Technology*.

Large amounts of quackery-related information are available at the National Council Against Health Fraud (<http://www.ncahf.org>) and Health Care Reality Check (<http://www.hcrc.org>) maintained by the Georgia Council Against Health Fraud.

Newsworthy government documents can be accessed at the following URLs:

Federal Register and Congressional Record (http://www.access.gpo.gov/su_docs/aces/aaces002.html); federal legislation, past and pending (<http://thomas.loc.gov/> [Note: This URL contains no "www"]; FDA warning letters (<http://www.fda.gov/foi/warning.htm>).

WORST

The Gerson diet, falsely claimed to be effective against cancer and "other degenerative diseases," is described and is covered in detail on the Gerson Institute site (<http://www.gerson.com>). The program allegedly "works closely with nature to help the sick body to rid itself of disease through the supportive effects of simple foods, juices, and non-toxic medication." A Gerson facility opened in Arizona in 1997.

SEARCH TIPS

The Infoseek search engine (<http://www.infoseek.com>) is excellent for locating health and nutrition information because its "narrow these results" button enables searching within the results of previous searches. When searching for a word string, such as the name of an organization, placing hyphens between the words will search for that exact phrase and will bring up fewer irrelevant URLs. The resultant list can be narrowed by searching within those results with part of the name or a key word you expect to be on the site.

In 1985, reporters from *Consumer Reports* magazine visited 30 drugstores in Pennsylvania, Missouri, and California. The reporters complained of feeling tired or nervous, and asked whether a vitamin product might help. Seventeen were sold a vitamin product, and one was sold an amino acid preparation. Only 9 of the 30 pharmacists suggested that a doctor be consulted (*Consumer Reports* 51:170-175, 1986).

In 1987, two pharmacy school professors sent a questionnaire to 1000 pharmacists in the Detroit metropolitan area and received 197 responses. Among the 116 who identified their five most-common reasons for recommending vitamins or minerals, 66 (56%) listed fatigue and 57 (49%) listed stress (*Journal of Clinical Pharmacy and Therapeutics* 15:141-146, 1990). Neither reason is valid. In response to a question about homeopathy, 27.4% said it was "useful," 18.3% judged it "useless," and 54.3% "didn't know" (*Journal of Clinical Pharmacy and Therapeutics* 15:131-139, 1990).

What Happened to Ethics?

Merlin Nelson, MD, Pharm.D., coauthor of the above-mentioned survey, has asked pharmacists why they promote and sell food supplements to healthy individuals who don't need them. He concluded: "The most common reason is greed. Advertising creates a demand that the pharmacist can supply and make a profit. 'If I don't sell them, they'll just go to my competition down the street,' is a common response. Pharmacists are apparently more interested in a sale than in the patient's welfare. . . .

"Rather than just recommending a multivitamin to patients concerned about obtaining enough vitamins in their diet, pharmacists should offer sound nutritional advice or provide referrals to experts in nutrition such as registered dietitians" (*American Pharmacy* NS28(10) 34-36, 1988).

Pharmacists are also the only recognized health professionals who sell tobacco products, which cause more death and years of lost life than any other consumer product. Although some pharmacists have stopped, the majority do not consider tobacco sales unethical. Nelson is one of only a handful of pharmacists

who have criticized the misleading promotions of supplement manufacturers. As far as I can tell, no professional pharmacy organization has ever done so.

The American Pharmaceutical Association's code of ethics does not state that pharmacists have a duty to prevent dubious products from lining their shelves. Five states have laws declaring it illegal for pharmacists to sell ineffective products, but these laws have never been applied to the sale of OTC products.

I believe that pharmacists have as much of an ethical duty to discourage use of inappropriate products as physicians do to advise against unnecessary surgery or medical care. Very few pharmacists do so. Pharmacy journal editors ignore this problem. Hospital-based pharmacists generally exhibit a higher standard of practice, but very few of them are speaking out about the problems described in this article. **NF**

Stephen Barrett, MD, is a retired psychiatrist who resides in Allentown, Pennsylvania. His 44 books include The Vitamin Pushers: How the "Health Food" Industry Is Selling America a Bill of Goods.

Making Up for Lost Revenues

Pharmacy trade publications, such as *Natural Pharmacist*, suggest that "natural products" offer opportunities to make up for prescription drug revenues lost as a result of managed care and other cost-containment programs. One pharmacy supplier aligned with this trend is The JAG Group of San Clemente, California. According to its Web site (<http://www.jagenterprises.com/servmain.htm>), "natural products offer profit margins greater than those for prescription drugs." JAG's comprehensive program features:

- Product lines that typically produce a 100% markup or more.
- A three-day seminar covering "the importance of wellness" and how to "use natural products to prevent and/or improve chronic disease states."
- WellStore Software designed as a sales and marketing tool to: (1) capture customer information, including e-mail address, (2) categorize products to market directly to customer needs, (3) provide thank-you notes to encourage loyalty, (4) provide product information to print for customers, and (5) track patient-health histories to create fee-for-service revenue.
- Pharmacist Plus™ Software with causes, signs, and symptoms of 223 common ailments and specific dietary, homeopathic, and herbal recommendations. (I believe that providing such information to customers would be outside the scope of pharmacy practice and would constitute the illegal practice of medicine and would violate state laws against theft by deception. Furthermore, homeopathic products have no proven effectiveness.)

- Drug Depletion Software telling "what supplements patients need to replace vital nutrients that are depleted by many of the prescription drugs they are taking." (I do not believe there are many situations in which this is important.)
- Nutritional Analysis Software (an electronic nutritionist) to allow the pharmacist to charge a fee for providing consultations to patients—including assessment of "nutritional needs that best fit your patient's gender, age, lifestyle, analysis of food intake and identification of nutritional deficiencies" and "recommendations for optimum nutrient levels to maintain good health." (I do not believe any software can do this.)
- A TV commercial, radio spots, newspaper and yellow page ads, doctor letters, and a column that can be published under the pharmacist's own name.
- A personalized Internet Web page, which adds the pharmacist to a list of "complementary and natural healthcare practitioners worldwide" so that "when someone searches for a natural healthcare practitioner, they will find you." (I do not believe that pharmacists are qualified or legally permitted to be "natural healthcare practitioners.")
- An in-store display unit designed to let customers see a variety of products, books, and services in one place.
- Answers to questions needed "when a customer is standing in front of you" or when "you want to know about a new fad or product your customer just asked you about."
- "The best experts in the fields of pharmacy, natural products, and complementary medicine available" by picking up the phone or accessing the Internet.—**SB**

[continued from page 1]

Isomedix Inc., which operates an irradiation facility in New Jersey.

IRRADIATION LABELING CHANGED

Before November 1997 when the FDA Reform Act was passed, irradiated foods in the United States were required to be clearly labeled with a green radura symbol and the phrase "Treated by Irradiation" or "Treated with Radiation." The new act calls for the irradiation statement to be no more prominent than the product ingredient list. Irradiation benefits consumers by killing most of the pathogens (disease-causing germs) that may be present. The change was made because prominent labeling may mislead people into thinking that irradiated foods are risky (as falsely claimed by the health-food industry and its allies). Some health-food industry members see the situation as an opportunity to boost sales of nonirradiated meats by persuading consumers that irradiated meats are inferior.

OBESITY AND BREAST CANCER RISK

Researchers who followed more than 95,000 women for 16 years have concluded that avoiding weight gain during adult years may contribute importantly to the prevention of breast cancer after menopause, particularly among women who do not use postmenopausal hormone therapy (*JAMA* 278:1407-1411, 1997). Copies of this report are available from Walter C. Willett, MD, Channing Laboratory, Boston, MA 02115.

RIFE OPERATOR SUED

The attorneys general of Wisconsin and Minnesota have filed suit to stop Shelvie Rettman of Prior Lake, Minnesota, from representing that she can cure cancer. Rettman does not have a medical license in either state. Her approach includes treatments with a device called the Rife Frequency Generator, a special diet, dietary supplements, foot reflexology, and a regimen of baths. The Rife device allegedly generates radio waves with precisely the same frequency as alleged cancer-causing bacteria, shattering them

in the same manner as a crystal glass breaks in response to the voice of an opera singer. The American Cancer Society has noted that although sound waves can produce vibrations that break glass, radio waves lack sufficient energy to destroy bacteria (*CA-A Cancer Journal for Clinicians* 44:115-127, 1994).

NEW ANTIFLUORIDATION GROUP

The newly formed Global Alliance Against Fluoridation (GAAF), based in New York City, hopes to coordinate nationwide and worldwide efforts. Consuelo Reyes, the group's coordinator, states that it was formed in response to the American Dental Association's drive to achieve nationwide fluoridation through federal legislation by the year 2000. Fluoridation opponents have not had an effective national presence since the early 1980s.

ORGANIC CANDY FLAP

Natural Foods Merchandiser has reported that a six-year-old boy in Colorado Springs, Colorado, received a half-day school suspension after sharing organic lemon tart candies with schoolmates. According to the article, school officials assumed the brownish candies were drugs and called the fire department and ambulance rescue teams. The parents were also advised to take the boy to the hospital for tests.

HEALTH CLAIM SURF DAY

In October 1997, FTC officials joined with public health and consumer protection and information agencies from the United States, Canada, and Mexico to "surf" the Internet for potentially false or deceptive advertising claims concerning treatments for heart disease, cancer, AIDS, diabetes, arthritis, and multiple sclerosis. Within a few hours, the surfers identified more than 400 Web sites and many Usenet newsgroups using such promotions. The agency then sent hundreds of e-mail messages pointing out that advertisers must have evidence to back up their claims. FTC staff members plan to revisit the sites to determine whether changes were made.

CAMPANA ALERTA

The FTC has announced settlements with four companies pitching false and unsubstantiated claims to Spanish-speaking populations in the United States and Mex-

ico. One company falsely claimed that *uno de gato* (cat's claw) can strengthen the immune system, reduce abnormal inflammation, cure acne, and have no toxic effects. Another company falsely claimed that its Super Formula Reductora would control and regulate metabolism, reduce appetite, burn or dissolve fat, and cause weight loss. The third company made unsubstantiated claims for its "bioactive cellulite cream" and weight-loss tablets. The fourth represented that its dietary supplement Venoflas would remove dangerous clogs in the circulatory system and treat the symptoms of varicose veins and hemorrhoids. The actions were part of *Campaña Alerta*, a joint action by the FTC, FDA, seven state attorneys general, and the Mexican government. The agencies have also joined forces for an educational campaign.

NUTRI/SYSTEM CRITICIZED FOR PROMOTING 'PHEN-PRO'

Eli Lilly and Co., which manufactures the antidepressive drug Prozac, has notified Nutri-System Weight Loss Centers that it does not endorse the blending of Prozac and phentermine (phen-pro) as a weight-loss agent. Nutri/System has been using the combination for a year but began promoting it heavily after stopping the use of phen-fen (dextfenfluramine plus fenfluramine) at its 450 centers. Nutri/System claims there is a research basis for using phen-pro, but Lilly warned that the FDA has not authorized Prozac for weight control and that Nutri/System's commercial references to the antidepressant violate trademark law.

GLUCOSAMINE SULFATE CRITIQUED

The *Medical Letter for Doctors*, which provides top-quality evaluations of drug products, has concluded that glucosamine appears to be safe and might be effective for treatment of osteoarthritis (*Medical Letter* 39:91-92, 1997). However, it cautions: "Most published trials . . . lasted only four to eight weeks and *Medical Letter* consultants find them unconvincing. As with other 'dietary supplements,' the purity of the glucosamine products sold in pharmacies, health food stores and supermarkets in the USA is unknown." The Arthritis Foundation has called for more rigorously controlled studies. **NF**

prominent researcher after another and frequently misrepresent their findings.

The claims for DHEA are numerous: it boosts the immune system, prevents cancer, melts away body fat, prevents heart disease, enhances the libido, slows the aging process, prevents osteoporosis, treats Alzheimer's Disease, helps depression, lessens the symptoms of menopause and PMS, controls diabetes, slows the progression of AIDS, and provides relief from lupus.

Advertised as the "anti-aging miracle of the 21st century," DHEA is available in tablet, capsule, cream, ointment, drop, roll-on, gum, and sublingual lozenge form. It may also be purchased in combination with various herbs, vitamins, and minerals "for greater effectiveness and absorption."

The recommended daily dosage of DHEA varies widely among companies. Suggestions vary from 3 to 2000 mg per day. Some of the advertisements recommend that consumers have their DHEA level tested before beginning supplementation in order to determine the proper dosage, but because the product is readily available without a prescription, it's doubtful that many consumers will spend the \$70 to \$75 it would cost to have a blood test performed.

Extracts of ground dioscorea are sold in pill form as "natural DHEA" or a "DHEA precursor." These extracts are widely advertised in magazines and newspapers, on the Internet, and are sold in health-food stores. These products are not required to meet any government standards for quality or purity, and they do not convert to DHEA in the body as they are advertised to do.

Some DHEA sellers have devised creative marketing schemes. One company sells a "DHEA Home Test Kit" so consumers can collect a saliva sample, mail it to a laboratory, and receive a report which will supposedly help them determine the level of supplementation their body needs. Another company offers a "DHEA Symptom Survey Form" on the Internet with a list of symptoms ranging from moodiness to heartburn to high blood pressure. Twenty or more symptoms, they say, means you are likely to have a DHEA deficiency due to stress.

Weak Evidence

DHEA was first studied in 1934, and thousands of studies have been performed on it since. However, very few of these studies have involved human subjects. Most involved rodents that were fed daily doses of DHEA. These experiments showed that DHEA could increase life span, improve immunity, facilitate weight loss, and have positive influences on illnesses such as diabetes, cancer, and heart disease. However, rats and mice produce only minuscule amounts of the DHEA that humans produce, and scientists are well aware of the fact that what works in rodents won't necessarily hold true in humans.

The current interest in DHEA began three years ago after a three-month study of DHEA supplementation in humans showed an increase in perceived physical and psychological well-being and mood among a group of 30 men and women. The researchers went on to study the effects of a higher dose of supplemental

DHEA in a six-month study, with an even smaller sample size, to determine if a greater dose for a longer period of time would have a more significant effect. That study showed an increase in lean body mass in both sexes, some increase in muscle strength, and improved immune function. Despite claims to the contrary, no increase in libido was reported in these studies. These studies consisted of only small groups of people; long-term studies on larger populations are needed to confirm these results.

Several studies have suggested that there may be an association between low DHEA levels and heart disease in men, but not women. Other studies have produced contradictory results regarding the role of DHEA in heart disease, and the data from more than one study by the same researcher have produced conflicting results.

In short-term studies, DHEA appeared to improve the functioning of the immune system by elevating the number

of natural killer cells (T cells and B cells). Preliminary research also suggests that DHEA may improve the ability of the elderly to develop antibodies to the influenza vaccine when it is given along with the vaccine. In addition, DHEA supplementation appears to enhance the ability of T cells to produce interferon and interleukin-2, strong antitumor and antiviral chemical substances in the body. Long-term studies are needed in order to clarify DHEA's role in the immune system.

Other human research with DHEA suggests that it may improve insulin sensitivity in diabetics and maintain bone mineral density after menopause. The most promising use for DHEA appears to be related to its role in the treatment of systemic lupus erythematosus, an autoimmune disease. However, all of these studies have been conducted on small groups of people, and until more research is done, the results are considered preliminary.

There is no evidence at this time that DHEA can prevent cancer. Claims regarding DHEA's role in cancer prevention are based on studies done only in rodents. Cancer cells can take years to become tumors, and the longest studies done on humans have lasted only six months.

DHEA's role in weight loss is conjecture based on the possibility that DHEA can improve insulin sensitivity. Studies in humans have failed to show any beneficial effect of DHEA on body composition or energy expenditure.

In short, the studies that have been performed on DHEA and humans to date are preliminary, inconclusive, or contradictory.

At What Risk?

DHEA research also provides little solid information on the possible adverse effects of long-term administration. These may take years to become evident. As a powerful

steroid hormone, DHEA has the possibility to produce a wide range of side effects throughout the body.

Research has shown that too much DHEA lowers cortisol levels in the body. In women, DHEA has been shown to produce acne, increase facial hair, and cause breast tenderness. Because it can be converted in the body to potent androgens such as testosterone, it has the potential to masculinize women. In men, it could stimulate the growth of prostate cancer, and in women it could increase the risk of breast or ovarian cancer. There is some evidence that taking DHEA for even a short period of time may lead to liver damage.

Many researchers have spoken out against supplementation with DHEA, citing concerns about the lack of research information and the potential for harmful side effects. All of the media hype combined with its easy accessibility lead to concerns that selling such a potent chemical in health-food stores and by mail order may be a disaster waiting to happen.

Dr. Fernand Labrie, a leading DHEA researcher at the Laval University CHUL Research Center in Quebec, Canada, states, "We are very much worried . . . about the free availability of this drug, which, in fact, should be given exclusively following prescription by a physician who needs to adjust the dose according to the individual blood levels for each subject."

The Outlook

According to Dr. Frank Bellino, Endocrinology Program Administrator of the National Institute on Aging, the NIA is currently sponsoring various studies related to DHEA and its role in bone loss in women, atherosclerosis, and immunity. Several studies aimed at better understanding the process by which DHEA levels in blood decrease over the life span of humans are also underway at this time.

Many researchers have spoken out against supplementation with DHEA, citing concerns about the lack of research information and the potential for harmful side effects.

In addition, the NIA has solicited and is in the process of reviewing grant proposals for studies on the use of DHEA in humans that will attempt to determine the exact mechanisms by which DHEA works in the body and to confirm the results of some of the small-scale studies that have already been performed.

Other ongoing studies sponsored by the National Institutes of Health (NIH) include DHEA's effects on patients with Alzheimer's Disease, systemic lupus erythematosus, and its possible role in the prevention of cancer.

Large-scale, randomized, placebo-controlled clinical studies on DHEA are needed before there are answers to the many unanswered questions about DHEA. Until the questions are answered, supplementation is a risky business.

In the meantime, many of the alleged benefits of DHEA can be achieved with lifestyle changes. Eating a low-fat diet and participating in regular exercise can facilitate weight loss, increase lean body mass, reduce the risk of heart disease, diabetes, cancer, and osteoporosis, and ward off many of the problems associated with aging. Fortunately, the evidence for this approach is in. **NF**

Beth Fontenot is a nutrition consultant and freelance nutrition writer in Lake Charles, LA. She serves on the adjunct faculty at both McNeese State University in Lake Charles and Lamar University in Orange, TX.

BE A NUTRITION FORUM CONTRIBUTOR!

If you find any news or information that may be of interest to our readers—such as published articles, news reports, press releases, or relevant personal experience—please send it to us. Mail it to Lewis Vaughn, *Nutrition Forum*, P.O. Box 664, Amherst, NY 14226-0664. We're especially interested in receiving information about enforcement actions by state agencies, lawsuits by victims of quackery, and health-fraud news that may have been overlooked by the national media.

Book Reviews

Analysis and Ratings

How accurate and useful is the nutrition information in that book? Would a reputable reviewer recommend the book to professionals and consumers? These are the two questions that Nutrition Forum book reviews are intended to answer. So the reviews not only offer analyses but also rate each book as either RECOMMENDED, NOT RECOMMENDED, or RECOMMENDED WITH RESERVATIONS, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Meat Madness

Manfred Kroger

Slaughterhouse: The Shocking Story of Greed, Neglect, and Inhumane Treatment Inside the U.S. Meat Industry by Gail A. Eisnitz (Amherst, NY: Prometheus Books, 1997), 311 pp., \$25.95 (hardback).

Ninety years ago Upton Sinclair's novel *The Jungle* was aimed at Americans' hearts—it wanted people to feel for the exploited immigrant workers in the meat industry. But the book hit readers in the stomach instead with its graphic details of unsanitary and inhumane conditions. That book was largely responsible for the country's first meat inspection law. Now comes Gail Eisnitz, an untiring worker for the Humane Farming Association, an excellent writer-reporter, a thorough and persistent investigator, and spokesperson for animals faced with cruelty, especially during the last 10 minutes of life. She deserves as much credit as Sinclair (who was finally honored by the White House shortly before his death for his work's impact on national affairs).

However, what Eisnitz attempts to accomplish is not the creation of a new

law, but the enforcement of an existing one, the 1958 federal Humane Slaughter Act. In harrowing detail and in the words of numerous line workers (usually with a chip on their shoulders) the actual, unbelievably horrifying conditions in several slaughterhouses are described.

The act is simply not enforced. Those responsible for it or answering to it look the other way and are desensitized because they are literally forced by line speeds and fear of job loss to disassemble living creatures by any means possible. It is a riveting account, not for the faint of heart.

The book is an indictment of an entire industry: detached government regulators, profit-conscious managers, illegal practices, conditions harmful for man and beast alike—all condoned by a naïve public enjoying a steady supply of affordable meat products. This industry has the highest accident rate, and its workers include recent immigrants, school dropouts, disgruntled social misfits, prison inmates working under a release program, and some truly sadistic, despicable characters.

Gail Eisnitz has done a great service with this exposé. It remains to be acted upon now. I say this despite the book's very one-sided presentation and the author's zealotry. Her accounts desperately need to be counterbalanced by the industry's good side, if that is possible.

RECOMMENDED

Compassion and Sense

Manfred Kroger

Gilda's Disease: Sharing Personal Experiences and a Medical Perspective on Ovarian Cancer by M. Steven Piver with Gene Wilder (Amherst, NY: Prometheus Books, 1996), 184 pp., \$22.95 (hardback).

Here are four books in one: (1) film star Gene Wilder's touching account of his wife's battle with cancer from 1986 to 1989; (2) Gilda Radner's family history, career highlights (remember Roseanne Roseannadanna of "Saturday Night Live" in the '70s?), and excerpts from her best-selling autobiography, *It's Always Some-*

thing; (3) Dr. Piver's commentary on this patient's path through these three years; and (4) much information on ovarian cancer in easy-to-read language. Readers will experience both emotional and rational perspectives. A cancer patient's desperate search for answers is displayed, especially those regarding prevention, and an expert's state-of-the-art explanations are detailed. It is refreshing to see that so-called alternative therapies are fairly criticized and not blindly endorsed.

Dr. Piver is a cancer surgeon. He writes knowledgeably and compassionately about ovarian cancer, of which there are 30 types which kill 12,000 women in the United States every year. Twice as many are diagnosed to have this cancer. It is for these women and their families that this book was written and for all others who may want to learn about preventive measures. **NF**

NEW BILL INTENDS TO OUTLAW CONSUMER PROTECTION

The Health Free Speech Act, introduced by Rep. Ron Paul (R-TX), would amend the Federal Food, Drug, and Cosmetic Act by inserting the words "other than food" into its definition of the term "drug." The amended definition would read "articles (except devices), other than food, intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease in man." The bill's proponents believe that this would exempt not only foods but also herbs and dietary supplements. The bill's intention is to make it impossible for the FDA to regulate claims made for any product that a seller labels as a dietary supplement.

'NUTRITION COUNSELOR' DISCIPLINED

Jane Winterbottom Donigan, 79, a licensed nutrition counselor who owns a health-food store in Boca Raton, Florida, has signed a consent agreement to settle an administrative complaint that she was "guilty of committing an act of . . . misconduct in the practice of dietetics and nutrition." The complaint states that in 1995, Donigan was consulted by a 77-year-old woman who complained of numbness and tingling of her left arm, arthritis in her right hip, acid stomach, incontinence, mitral valve prolapse, rectal pains, neck and low back pain, bladder infection, low energy, intermittent nausea, frequent headaches, memory loss, sinus problems, and poor circulation of the legs. Without communicating with the woman's doctor, Donigan recommended that she take 400 mg of ginkgo biloba per day, an amount higher than the recommended dosage (150 mg). Four days later, the woman was hospitalized with a severe stroke. Donigan does not have accredited nutrition credentials but was licensed after being grandfathered by virtue of her "professional experience." Although ginkgo has anticoagulant properties, a connection between the ginkgo and the stroke cannot be established because the stroke could have occurred anyway.

[continued on page 13]

The Truth about Organic 'Certification'

Does it help ensure safer foods— or just costlier ones?

by Stephen Barrett, MD

"If you as a consumer have a desire to purchase a fake or a fraud of one kind or another, should your government guarantee your right to do so? More than that, is your government obligated to prosecute one who, knowing of your propensity for fraud, tricks you into buying the genuine in place of buying the fake? Remember—ing that 'your government' is all the rest of us, is it right for you to take our time and money to underwrite such ridiculous exercises as making sure you are cheated when you want to be cheated? And must we penalize the man who breaks his promise to cheat you?"

These astute questions were raised in 1972 by Dick Beeler, editor of *Animal Health and Nutrition*, who was concerned about laws being adopted in California and Oregon to certify "organic" foods. Those laws signaled the beginning of efforts that culminated in 1990 with passage of the U.S. Organic Foods Production Act, which ordered the U.S. Department of Agriculture (USDA) to set certification standards. Although the USDA had opposed passage of the act, the Alar scare plus a campaign by environmental, consumer, and farm groups persuaded Congress to include it in the 1990 Farm Bill (NF 8:25-29, 1991).

As directed by the law, the secretary of agriculture established a National Organic Standards Board to help develop a list of substances permissible in organic production and handling and to advise the secretary on other aspects of implementing a National Organic Program. In 1992, the secretary appointed 15 people, 8 of whom were industry members. The board held 12 full-board meetings and 5 joint committee meetings and received additional input through public hearings and written submissions from interested persons. It presented its recommendations to the secretary in 1994 and issued 30 subsequent addenda.

Studies have found that the pesticide levels in foods designated organic were similar to those that were not.

The Current Marketplace

Total retail sales of the organic industry have reportedly risen from \$1 billion in 1990 to \$3.5 billion in 1996. "Certified" organic cropland production expanded from 473,000 acres to 667,000 acres between 1992 and 1994 and is expected to reach two million acres by the year 2000. Despite this rapid growth, the organic industry represents a very small percentage of total agricultural production and sales.

The most common concept of "organically grown" food was articulated in 1972 by Robert Rodale, editor of *Organic*

Gardening and Farming magazine, at a public hearing: "Food grown without pesticides; grown without artificial fertilizers; grown in soil whose humus content is increased by the additions of organic matter; grown in soil whose mineral content is increased by the application of natural mineral fertilizers; has not been treated with preservatives, hormones, antibiotics, etc." However, in 1980, a team of scientists appointed by the USDA concluded that there was no universally accepted definition of "organic farming." Their report stated:

The organic movement represents a spectrum of practices, attitudes, and philosophies. On the one hand are those organic practitioners who would not use chemical fertilizers or pesticides under any circumstances. These producers hold rigidly to their purist philosophy. At the other end of the spectrum, organic farmers espouse a more flexible approach. While striving to avoid the use of chemical fertilizers and pesticides, these practitioners do not rule them out entirely. Instead, when absolutely necessary, some fertilizers and also herbicides are very selectively and sparingly used as a second line of defense. Nevertheless, these farmers, too, consider themselves to be organic farmers.

Today, approximately 4,000 farmers and 600 handlers are certified by 33 private or 11 state agencies. Each certifying agency has its own standards and identifying marks. No industrywide agreement exists about which substances should be permitted or prohibited for organic production and handling.

The Proposed Rule

On December 16, 1997, the USDA Agricultural Marketing Service proposed rules for a National Organic Program (Federal Register 62:65850-65967, 1997). The proposal includes: (1) national standards for production and handling, (2) a National List of approved synthetic substances, (3) a certification program, (4) a program for accrediting certifiers, (5) la-

beling requirements, (6) enforcement provisions, and (7) rules for importing equivalent products. A new USDA seal will be the only permissible marker.

The proposed rule defines organic farming and handling as:

A system that is designed and managed to produce agricultural products by the use of methods and substances that maintain the integrity of organic agricultural products until they reach the consumer. This is accomplished by using, where possible, cultural, biological and mechanical methods, as opposed to using substances, to fulfill any specific function within the system so as to: maintain long-term soil fertility; increase soil biological activity; ensure effective pest management; recycle wastes to return nutrients to the land; provide attentive care for farm animals; and handle the agricultural products without the use of extraneous synthetic additives or processing in accordance with the Act and the regulations in this part.

The weed and pest-control methods to which this refers include crop rotation, hand cultivation, mulching, soil enrichment, and encouraging beneficial predators and microorganisms. If these methods are not sufficient, various listed chemicals can be used. (The list does not include cytotoxic chemicals that are carbon-based.) The proposal does not call for monitoring specific indicators of soil and water quality, but leaves the selection of monitoring activities to the producer in consultation with the certifying agent.

For raising animals, antibiotics are not permitted as growth stimulants but are

The Creatine Craze

Such ergogenic promise—but at what price?

by Beth Fontenot, MS, RD

Each year athletes spend more than one hundred million dollars on dietary supplements in the hope of improving their physical appearance and athletic performance. Today's most popular ergogenic aid is creatine. Its use is prevalent in high school, college, and professional athletic programs, and some Olympic contenders have used it. More than one hundred companies sell a creatine product. You can buy creatine in gyms, in local "health-food" stores, on the Internet, and in General Nutrition Stores across the country. But creatine is not for everyone, and those who decide to take it should know the risks.

Why Creatine

Creatine was introduced as a potential ergogenic aid in 1993, and since then its use has grown dramatically. The National Collegiate Athletic Association (NCAA) Study of Substance Use and Abuse Habits of College Student-Athletes showed that 13.3% of those surveyed reported using creatine.

Creatine is an organic compound made by the liver, kidneys, and pancreas from the amino acids glycine, methionine, and arginine. From these sites of synthesis, creatine is transported to the skeletal muscles. Creatine exists in two forms in muscle: as free creatine and as creatine phosphate, which makes up two-thirds of the total creatine in the body.

In addition to being synthesized by the body, creatine also comes from the consumption of meat and fish products. There is no Recommended Dietary Allowance (RDA) for creatine, but 1 to 2 grams per day is what researchers have estimated as the daily requirement. Typically, about one gram per day is made by the body, and one gram per day is consumed in the diet.

During quick bursts of activity, creatine plays a role in energy production. When muscles contract, adenosine triphosphate (ATP) is used to fuel the movement. ATP provides energy by releasing one of its phosphate molecules, and then it becomes another compound called adenosine diphosphate (ADP). A muscle has only enough ATP stored to perform high-intensity muscle contractions for about 10 seconds. For the energy system to continue, more ATP must be produced.

Creatine phosphate gives its phosphate molecule up to ADP to create more ATP. The ability to regenerate ATP, then, depends on the supply of creatine phosphate in the muscles.

Creatine supplementation: No one knows the long-term effects.

Promise and Reality

Creatine is claimed to increase energy, increase muscular strength, produce greater and faster muscle gains, improve endurance, delay fatigue, and aid in burning fat. It is sold in a variety of forms: pills, powders, capsules, liquids, fruit-chew candy, and a "just-add-water" single-serving form. Some products combine creatine with other substances like citrate or dextrose, or with various vitamins, minerals, and amino acids. The marketers claim that these additives provide greater benefit to the athlete.

In the early 1990s researchers started to look at the impact of creatine supplementation on exercise performance. Since then, research has suggested that creatine may have a future as an ergogenic aid. In several studies, subjects taking creatine have demonstrated significant improvement in short bouts of activities that require both power and strength such as sprinting, knee extensions, and bench-press exercises.

According to current theory, creatine

Nutrition Forum rates the factual accuracy and usefulness of Internet sites containing nutrition and health information. This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc. (<http://www.quackwatch.com>), which is working hard to improve the quality of health information on the Web.

BEST

MedicineNet (<http://www.medicinenet.com/>) provides articles, written by experts, on hundreds of health-related topics.

The National Osteoporosis Foundation Web site (<http://www.nof.org>) tells how to prevent and treat osteoporosis.

The American Dental Association has extensive information on fluoridation at <http://www.ada.org/consumer/fluoride/fl-menu.html>

WORST

The International Health Foundation site (<http://www.ihf.com/people.html>) markets Life Balance products (<http://www.lbwic.com/>) said to be "based on individual body chemistry." The program's core is a 20-bottle vitamin regimen whose dosage is determined by smelling the bottles. ("The sweeter or more delightful the smell, the more it is needed. If the contents smell repugnant, it is not to be taken at that particular time.") The "sniff test" is a brainchild of Lendon Smith, MD, who retired in 1987 rather than face charges of insurance fraud brought by the Oregon Board of Medical Examiners.

Oxford Health Care (<http://www.oxhp.com>) describes the company's "comprehensive alternative medicine program" and its catalog of herbal products, supplements, homeopathic products, and publications.

The Vitamin Advisor link of Ask Dr. Weil (<http://cgi.pathfinder.com/drweil/>) leads to a questionnaire, which, when completed, provides Andrew Weil, MD's "personalized formula of my recommended vitamins, supplements and tonics." The site also links to an online store where the gullible can purchase the recommended items.

[continued from page 10]

permitted to counter infections. The rules permit up to 20% of animal feed to be obtained from nonorganic sources. This was done because some nutrients (such as trace minerals) are not always available organically. Irradiation, which can reduce or eliminate certain pests, kill disease-causing bacteria, and prolong food shelf-life, is permitted during processing. Genetic engineering is also permissible.

In an accompanying news release, USDA Secretary Dan Glickman stated:

What is organic? Generally, it is agriculture produced through a natural as opposed to synthetic process. The natural portion of the definition is fairly obvious, but process is an equally critical distinction. When we certify organic, we are certifying not just a product but the farming and handling practices that yield it. When you buy a certified organic tomato, for instance, you are buying the product of an organic farm. And, consumers are willing to fork over a little more for that tomato. They've shown that they will pay a premium for organic food. National standards are our way of ensuring that consumers get what they pay for.

BE A NUTRITION FORUM CONTRIBUTOR!

If you find any news or information that may be of interest to our readers—such as published articles, news reports, press releases, or relevant personal experience—please send it to us. Mail it to Lewis Vaughn, *Nutrition Forum*, P.O. Box 664, Amherst, NY 14226-0664. We're especially interested in receiving information about enforcement actions by state agencies, lawsuits by victims of quackery, and health-fraud news that may have been overlooked by the national media.

More Nutritious?

The USDA proposal applies to all types of agricultural products and all aspects of their production and handling, ranging from soil fertility management to the packaging and labeling of the final product. The document is intended to address production methods rather than the physical qualities of the products themselves. In fact, it states: "No distinctions should be made between organically and non-organically produced products in terms of quality, appearance, or safety." In other words, no claim should be made that the foods themselves are better—or even different!

Organic foods are certainly not more nutritious. The nutrient content of plants is determined primarily by heredity. Mineral content may be affected by the mineral content of the soil, but this has no significance in the overall diet. If essential nutrients are missing from the soil, the plant will not grow. If plants grow, that means the essential nutrients are present. Experiments conducted for many years have found no difference in the nutrient content of organically grown crops and those grown under standard agricultural conditions.

Safer?

"Organic" proponents suggest that their foods are safer because they have lower levels of pesticide residues. However, the pesticide levels in our food supply are not high. To protect consumers, the FDA sets tolerance levels in foods and conducts frequent "market basket" studies wherein foods from regions throughout the United States are purchased and analyzed. The agency has found that about two-thirds of the fruits and vegetables have no detectable pesticides and only about 1% of domestic and 3% of imported foods had violative levels. Its annual Total Diet Study has found that dietary intakes of pesticides for all population groups are well within international and EPA standards.

Studies conducted since the early 1970s have found that the pesticide levels in foods designated organic were similar to those that were not. In 1997, *Consumer Reports* purchased about a thousand pounds of tomatoes, peaches, green bell peppers, and apples in five cities and tested them for more than 300 synthetic

pesticides. Traces were detected in 77% of conventional foods and 25% of organically labeled foods, but only one sample of each exceeded the federal limit (*Consumer Reports* 63[1]:12–18, 1998).

Pesticides can locate on the surface of foods as well as beneath the surface. The amounts that washing can remove depends on their location, the amount and temperature of the rinse water, and whether detergent is used. Most people rinse their fruits and vegetables with plain water before eating them. *Consumer Reports* stated that it did not do so because the FDA tests unwashed products. The amount of pesticide removed by simple rinsing has not been scientifically studied but is probably small. *Consumer Reports* missed a golden opportunity to assess this.

Do pesticides found in conventional foods pose a health threat? Does the difference in pesticide content warrant buying "organic" foods? *Consumer Reports* equivocates: "For consumers in general, the unsettling truth is that no one really knows what a lifetime of consuming the tiny quantities in foods might do to a person. The effect, if any, is likely to be small for most individuals—but may be significant for the population at large." But the editors also advise, "No one should avoid fruits and vegetables for fear of pesticides; the health benefits of these foods overwhelm any possible risk."

NF Senior Associate Editor Manfred Kroger, Ph.D., Professor of Food Science at Pennsylvania State University, puts the matter more bluntly: "Scientific agriculture has provided Americans with the safest and most abundant food supply in the world. Agricultural chemicals are needed to maintain this supply. The risk from pesticide residue, if any, is minuscule, is not worth worrying about, and does not warrant paying higher prices."

Tastier?

Taste is determined primarily by freshness. In the early 1990s, Israeli researchers made 460 assessments of 9 different fruits and vegetables and found no significant difference in quality between "organic" and conventionally grown samples (*American Journal of Alternative Agriculture* 7:129–136, 1992). The

Consumer Reports study found no consistent differences in appearance, flavor, or texture.

Organically produced ("free-range") poultry are said to be raised in an environment where they are free to roam. To use this term, handlers must sign an affidavit saying that the chickens are provided with access to the outdoors. A recent taste test conducted by *Consumer Reports* rated two brands of free-range chicken as average among nine brands tested. Its March 1998 issue stated that few chickens choose to roam and that one manager said that free-ranging probably detracts from taste because it decreases the quality of the bird's food intake (*Consumer Reports* 63[3]:12-18, 1998).

Organic Proponents Object

Health-food-industry trade and consumer publications indicate widespread dissatisfaction with the proposed rules. The Organic Farmers Marketing Association (<http://www.ota.com>) states:

The definition of organic as written in the proposed national or-

ganic standards lacks the holistic approach central to organic practices. The proposed rules take a reductionist approach to organic food production that eliminates key concepts such as the health of the agro-ecosystem and biodiversity on the farm.

Industry sources state that the USDA has received more than 4,000 comments on the proposed rules. One distributors association official wrote that if the rules are implemented, his members would seek to buy its agricultural products from foreign sources. Others have complained that the proposed fees are too high.

Most objections pertain to the provisions that permit irradiation, genetic engineering, and the use of sewage sludge as fertilizer. Other objections include permitted use of amino acids as growth promoters, antibiotics (when necessary to save the animal's life), synthetic animal drugs, food additives, and animal feed from nonorganic sources.

Certification agencies with "higher standards" have objected that they are prohibited from stating this on their labels. Some poultry farmers have objected

to provisions enabling intermingling of free-range poultry and other poultry.

The Bottom Line

Organic certification, no matter what the rules, will not protect consumers. Foods certified as "organic" will neither be safer nor more nutritious than "regular" foods. They will just cost more and may lessen consumer confidence in the safety of "ordinary" foods.

(Copies of the proposed rule can be purchased for \$8 from the Federal Register by calling [202] 512-1800. Additional information can be accessed through the National Organic Program Web page at <http://www.ams.usda.gov/nop>. Comments on the proposed rule can be sent from the Web site or mailed to: Eileen S. Stommes, Deputy Administrator, USDA-AMS-TM-NOP, Room 4007-So., Ag Stop 0275, P.O. Box 96456, Washington, DC 20090. Comments will eventually be posted on the Web page.) **NF**

However, Donigan failed to comply with Florida's licensing law, which sets documentation standards and mandates medical consultation or referral under certain circumstances. The consent agreement requires her to pay a \$500 fine, take 10 hours of continuing education courses, and adhere to the standards required by the law.

NEW ANTIQUACKERY BOOK

Chemical Sensitivity: The Truth About Environmental Illness takes a close look at the myths and facts related to multiple chemical sensitivity, candidiasis hypersensitivity, sick building syndrome, the Feingold Diet, Gulf War syndrome, and false claims of mercury-amalgam toxicity. The book is written by Stephen Barrett, MD, and Ronald Gots, MD, Ph.D. Copies can be ordered from the National Council Against Health Fraud (NCAHF), P.O. Box

1747, Allentown, PA 18105. The price for NCAHF members is \$25.90 (\$26.80 Canada), postage included. The nonmember price is \$28.50 (\$29.40 Canada).

CAMPAIGN AGAINST FRAUD BY E-MAIL

The FTC and U.S. Postal Service have notified more than 1,000 junk e-mailers that the agencies are monitoring unsolicited e-mail for fraudulent schemes and are keeping track of schemers. Junk e-mail can be sent for review to the FTC's e-mailbox: uce@ftc.gov.

HOMOCYSTEINE AND B VITAMINS

A recent study that followed 80,000 women for 14 years found that the incidence of heart attacks was lowest among those who used multivitamins or had the highest intake of folic acid and B₆ from dietary sources (*JAMA* 279:359-364, 1998). These data parallel the finding that elevated homocysteine levels are associated with a higher incidence of heart disease. The researchers measured folic acid

blood levels but did not measure homocysteine or B₁₂ levels. Rather, they assumed that low folic acid levels were caused by inadequate dietary intake. Victor Herbert, MD, a leading expert on B₁₂ metabolism, has pointed out that the low folic acid levels among the experimental subjects could have been caused by decreased B₁₂ absorption related to getting older. Because folate can prevent the early signs of B₁₂ deficiency while neurological damage takes place, Herbert has petitioned the FDA to order the addition of vitamin B₁₂ to any folate fortification or supplement (*American Journal of Clinical Nutrition* 65:572-573, 1997).

NEW MILK LABELING

The labels of fat-reduced milk products are now required to follow the same requirements as those of other reduced-fat products. As of January 1, 1998, 2% milk must be called "reduced fat" or "less fat" rather than "low fat"; 1% milk can be called "low fat" or "little fat"; and skim can

[continued on page 14]

[continued from page 13]

retain its name or be called "fat-free," "zero-fat," or "no-fat" milk. In all cases, the nutrients provided (other than fat) must be at least equal to those in full-fat milk before fortification with vitamins A and D.

DONSBACH FACES PRISON

On November 24, Kurt W. Donsbach, D.C., was sentenced to a year in federal prison by a federal judge in San Diego. Last year Donsbach pled guilty to smuggling unapproved drugs into the U.S. and not paying income tax on the money he made from selling them. In a plea bargain with the U.S. attorney's office, he forfeited about \$165,000 and paid an additional \$150,000 in back taxes. Donsbach is scheduled to report to prison on April 27, 1998, but his attorney has said that sentence may be modified after Donsbach testifies in a trial scheduled for this year in Texas. In recent years, Donsbach has administered a Mexican clinic that offers dubious treatments for cancer and other serious diseases. Before that, he operated several supplement companies and a nonaccredited correspondence school that issued hundreds of dubious nutrition "degrees."

WEB SITE RATING SYSTEMS QUESTIONED

Two Canadian researchers examined 47 systems used to rate Web sites providing health information on the Internet and found that only 14 of these described their rating criteria, only 5 provided instructions for their use, and none provided information on whether they had been validated. The researchers concluded: "Many incompletely developed instruments to evaluate health information exist on the Internet. It is unclear, however, whether they should exist in the first place, whether they measure what they claim to measure, or whether they lead to more good than harm" (*JAMA* 279:611-614, 1998).

OFFBEAT LITERATURE AVAILABLE

Quackwatch has more than 200 surplus copies of health-food magazines, chiropractic journals, vitamin catalogues, and other sources of misinformation. Send \$10 for 10 assorted items or \$15 for 20

assorted items to Quackwatch, PO Box 1747, Allentown, PA 18105. If you prefer one or more of the above categories, indicate that with your order. Otherwise, a varied mixture will be provided. (Satisfaction not guaranteed.)

ALCOHOL IN GINSENG PRODUCTS

The Treasury Department's Bureau of Alcohol, Tobacco and Firearms is warning consumers that ginseng products sold at health-food and convenience stores may contain up to 34 percent alcohol. Of 55 different products tested by the agency, only seven contained no alcohol. Some products were as much as one-third alcohol. Ginseng is a bittersweet root that is purported to cure the common cold and failing memory, among other things. The BATF has asked the U. S. Customs Service to detain ginseng products determined to be alcoholic beverages and is also working to recall the products.

NEW RULES ON WEIGHT LOSS IN ATHLETES

Following the deaths of three college wrestlers last year, the National Collegiate Athletic Association (NCAA) has made changes in its rules that deal with how athletes "make weight." Effective January 13, the new rules prohibit the use of diuretics, rubber suits, and saunas as means of achieving the proper weight. In addition, a seven-pound weight allowance was added in each weight class. The NCAA Wrestling Committee and Committee on Competitive Safeguards and Medical Aspects of Sports will further examine the issue of changing weight-loss behavior in wrestling and consider more rule changes at the Wrestling Committee meeting scheduled for April.

AGENCIES ENCOURAGE CALCIUM INTAKE

The Department of Health and Human Services (DHHS) and the NIH National Institute of Child Health and Human Development have both implemented a campaign to increase calcium consumption. The DHHS program is entitled "Crash Course on Calcium" while the NIH campaign is called "Milk Matters." Both target young people and emphasize the importance of calcium for strong bone building

and a healthy body. The DHHS program has an Internet site (<http://www.whymilk.com>), and a brochure outlining the NIH program is available at <http://www.nih.gov/nichd>.

NEW BLOOD PRESSURE GUIDELINES

The National Heart, Lung, and Blood Institute of NIH has released new guidelines for the treatment of high blood pressure. The guidelines contain new treatment strategies and specific recommendations for drug use in the treatment of hypertension. The major emphasis is on lifestyle changes, including dietary modifications. The report encourages increasing fruit and vegetable consumption, using low-fat dairy foods, reducing saturated and total fat intake, reducing sodium intake, and maintaining adequate potassium. Weight loss is recommended in addition to limiting alcohol intake and increasing physical activity. Copies of the new guidelines are available at <http://www.nhlbi.nih.gov/nhlbi.htm>.

PSYLLIUM CLAIMS APPROVED BY FDA

The FDA has ruled that certain foods containing soluble fiber from psyllium seed husk (PSH) can claim that they may reduce the risk of coronary heart disease (CHD) when combined with a diet low in saturated fat and cholesterol. This action is an amendment to the FDA regulation published last year which allowed a health claim on the association between soluble fiber from whole oats and a reduced risk of CHD. The FDA evaluated placebo-controlled studies that tested the intake of 10.2 grams of PSH (about 7 grams of soluble fiber) per day as part of a low-saturated-fat and low-cholesterol diet on total- and LDL-cholesterol levels. The studies showed that PSH consistently lowered these levels. Foods that carry this claim must provide at least 1.7 grams of soluble fiber from PSH per serving. In addition, some foods carrying the PSH health claim will be required to have a statement on the label advising consumers to consume adequate amounts of liquid since certain foods containing PSH may be difficult to swallow. This new health claim is in response to a petition that was submitted by the Kellogg Company. **NF**

[continued from page 11]

supplementation increases the bioavailability of creatine phosphate in the skeletal muscle cells. This increase is believed to enhance muscle performance by allowing faster resynthesis of ATP to provide energy for brief, high-intensity activities, and by buffering the intracellular hydrogen ions that are associated with lactate production and muscle fatigue. So it's thought that creatine's ergogenic effect may be to increase the force of muscular contraction and prolong anaerobic exercise.

Studies also show that creatine supplementation may lead to an increase in body mass. The reported increase has ranged from 0.8 to 1.8 kg, with some reports of a 3-kg gain. It is unclear whether the weight gain is due to increased muscle mass or water retention.

Though the amount of creatine phosphate in muscle may be increased significantly with supplementation, there are factors that seem to affect the absorption of creatine ingested as a supplement. One such factor is the presupplementation level of the individual. Athletes with low to normal creatine levels, such as vegetarians, show a greater increase in creatine stores after supplementation, and they are more likely to benefit. Some research suggests that there may be an upper limit of creatine storage in human muscle. If this is correct, supplementation will be beneficial only to those whose creatine levels are below the maximum storage level.

Dietary factors may also influence the absorption of creatine. Some studies have suggested that caffeine consumption may decrease the benefits of creatine supplementation. Other studies show that creatine stores were increased significantly when creatine ingestion was followed by carbohydrate consumption since the uptake of creatine by the muscles is believed to be enhanced in the presence of insulin.

Research indicates that 20 to 25 grams of creatine per day increases the creatine content in muscle by 20% to 30%. So proponents of supplementation say that the dosage required to increase creatine stores to their maximum level is about 20 grams per day for 5 to 6 days (dividing the dose into 4 doses of 5 grams). After this "loading phase" of supplementation, 3 to 5 grams per day is supposed to be the maintenance dose.

Many athletes believe that "if a little is good, more must be better," and they take more than the maintenance dose of creatine. But no one really knows what such large doses will do in the body. Some health professionals worry that these doses may lead to dehydration or that very high doses may not be excreted by the kidneys. In any case, since there seems to be a saturation limit for creatine in the muscles, oversupplementation is pointless.

No Across-the-Board Help

Research suggests that only athletes who participate in activities that are intermittent or whose sport requires a large body mass may benefit from creatine supplementation. Such activities include powerlifting, bodybuilding, football, and track-and-field events such as shot-put and javelin.

Despite claims to the contrary, there is no evidence that creatine supplementation can enhance endurance-exercise performance, such as long-distance running or swimming. In fact, the weight gain associated with supplementation may actually have an adverse effect on such endurance activities.

The International Olympic Committee does not include creatine on its list of banned substances. Because creatine is a dietary component, it would be difficult to determine who might be taking creatine supplements and who might be eating large amounts of meat.

Is It Safe?

Athletes taking creatine have reported muscle cramps, pulls, and tears, as well as stomach distress. Far more worrisome is the uncertainty of how much is too much. Some health professionals are concerned that consuming more than 30 grams per month could lead to fat accumulation in the liver.

In addition, all of the studies that have been done to date have looked at creatine use for a short period of time, generally about a month. No one knows the effects of long-term creatine supplementation. The NCAA is currently reviewing proposals for research on the short- and long-term effects of creatine supplementation.

The research to date has been performed primarily on college-age, athletic males, and the results may not apply to

teenagers, women, older adults, or individuals with varying levels of fitness. Creatine supplementation should especially be discouraged among teenage athletes since supplementation has not been studied in this population, and its effect on growth and development are completely unknown. The NCAA has urged that all athletes view with extreme caution the prospect of taking creatine.

Currently, the Centers for Disease Control and Prevention and the Food and Drug Administration are investigating whether the deaths of three college wrestlers last year may have been related to the use of dietary supplements. At least one of the wrestlers was known to be using creatine.

As with many other alleged ergogenic aids, creatine seems so promising to so many—but the promise rests on a pile of unknowns, which in turn may hide dangers that no coach, athlete, or parent should ever accept. **NF**

Book Reviews

Analysis and Ratings

NF reviews rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Scaring the Scared

Manfred Kroger

How I Conquered Cancer: A Naturopathic Alternative by Eric Gardiner (Houston, TX: Emerald Ink Publishing, 1997), 118 pp., \$9.95 (paperback).

This book's back cover advises, "If you have prostate cancer, or if you are an American male 30 years old or older, you must read this book. An entire industry out there wants to take out your prostate. You don't have to play their game. Keep your prostate, your bladder control, your dignity. The other game in town is called Naturopathic Medicine and you owe it to yourself to find out about it." This argument sounds suspiciously like those we sometimes hear from well-meaning friends: "Yes, you could have your damaged car repaired by an established dealership garage, but instead why not take it to an alley shop owned by a friend's friend who is said to have put a few clunkers back on the road?" Actually, this book seems just as anecdotal—and about as reliable—as most thirdhand car-repair advice.

It's another book by an aging male who for a lifetime has recklessly abused his body and health, is suddenly confronted with the "big C," sets out to hastily live the rest of his life as he should have all along, and then wittily and with an upbeat voice touchingly instructs the rest of the world with his newfound insights.

When diagnosed with prostate cancer, Mr. Gardiner began seeing the medical establishment as "the enemy." He also in-

dicted others as contributors to his condition and to human misery in general—namely, the pharmaceutical and food-processing industries, conventional agriculture, and all air, water, soil, and food pollutants. On his enemies list are all these things he believes are linked to cancer: meat, metal in your mouth, aluminum in your kitchen, "poisonous" consumer products, parasites in your intestine, unfiltered air and water, "nonorganic" food, alcohol, tobacco, stress, and lack of exercise.

There is some good common sense here and some good advice from the "orthodox" literature. But when this information is diluted with the mishmash of sometimes conflicting naturopathic pronouncements, a thoughtful reader must conclude that this book is uneven and studded with sheer drivel. The author's naturopathy is a dangerous disregard for medical science, a blind trust in unproven remedies and questionable practices, and a declaration of war against the scientific method and most of what is praised as achievements in science and technology.

Worst of all are the recommendations for hopelessly scared cancer victims to use numerous regimens, products, and devices that have generally not been shown in tests to be safe and effective. Almost as bad are the many rigid, irrational do's and don't's.

We need sensible, sane, and truly helpful books for those confronted with the threat of cancer. This volume is not one of them.

NOT RECOMMENDED

Herbal Moods

Varro E. Tyler

St. John's Wort: The Mood Enhancing Herb by Christopher Hobbs (Loveland, CO: Botanica Press, 1997), 176 pp., \$12.95 (paperback).

St. John's wort (hypericum) is a popular herb with antidepressant properties. A reliable book offering the latest scientific information on this botanical is much needed. But, although this volume presents much of the latest findings on the herb in a useful fashion, it also contains some extraneous information and opinions that may be confusing to the lay reader.

About one-third of the book (chapters

2 and 3) is devoted to a discussion of the symptoms of depression and related syndromes and their treatment by various drug and nondrug regimens. This is useful background; the trouble comes in discussions of the herb itself.

In the remaining Chapters (1 and 4) devoted to the herb, the author repeatedly discusses its potential for inhibiting monoamine oxidase (MAO), even providing on page 37 a table of tyramine-rich foods and beverages to be avoided while consuming it. Yet, a few pages later (p. 39), it is correctly noted that the MAO activity of St. John's wort is insignificant even in large doses.

The likelihood of developing photosensitivity after consuming the herb is mentioned several times throughout the book, including the table on page 148. However, no such case has been reported in the medical literature in a patient consuming normal therapeutic doses of hypericum.

Hobbs's well-known antipathy toward standardization of phytochemicals is displayed once again on pages 22–23. Instead of the "mass-produced" standardized extracts, he recommends the use of handmade tinctures, the quality of which, in his opinion, can easily be determined. "Simply check the color and taste." But pharmacists know that the color and taste of a liquid preparation do not necessarily indicate the quantity of active principles present. They are also aware that most active principles are organic compounds which are almost always far less stable in solution than in a dry state. In spite of these drawbacks, the author provides on pages 27–28 detailed instructions for preparing a homemade tincture for internal consumption from the plant. Such preparations may be satisfactory, but the preparers will never know for certain unless they follow the author's example and send a sample to an analytical laboratory for a high-performance liquid chromatographic (HPLC) analysis. Obviously, the author did not depend just on color and taste to determine the quality of his preparation.

Nevertheless, if read selectively and critically, the volume can provide much useful information on one of the most popular herbs of this decade. **NF**

RECOMMENDED WITH RESERVATIONS

HERBAL CRITIQUES

The U.S. Pharmacopeia has criticized the use of comfrey, valerian, and ginger. Its expert advisory panel has concluded that comfrey is carcinogenic and can cause liver damage; that there is insufficient evidence that valerian is useful for the short-term treatment of insomnia; and that there is insufficient evidence that ginger can prevent nausea and vomiting. However, the panel recommended that valerian and ginger be studied further. Patient education leaflets on these topics can be viewed on the USP Web site <http://www.usp.org/did/mgraphs/botanica>. Full monographs are \$25 per topic from USP's Document Disclosure Dept., 12601 Twinbrook Parkway, Rockville, MD 20852.

FORMER PHYSICIAN INDICTED

Donald L. MacNay, formerly an orthopedic surgeon in Manassas, Virginia, has been indicted for allegedly defrauding cancer patients he treated intravenously with an unapproved aloe vera drug. MacNay's medical license was revoked in February 1998 by the Virginia Board of Medicine, which cited fraud, unprofessional conduct, and gross malpractice. Four patients he treated last year died shortly after receiving his aloe therapy. MacNay is also charged with improperly supplying narcotic drugs to an assistant.

ST. JOHN'S WORT DOSAGE PROBLEMATIC

A Good Housekeeping Institute analysis of six widely available St. John's wort supplement capsules and four liquid extracts revealed a lack of consistency of the suspected active ingredients, hypericin and pseudohypericin. The study found: (a) a 17-fold difference between the capsules containing the smallest amount of hypericin and those containing the largest amount, based on manufacturer's maximum recommended dosage, (b) a 13-fold difference in pseudohypericin in the capsules, and (c) a 7-to-8-fold differential from the highest to the lowest levels of liquid extracts.

Homeopathy

Much ado about little or nothing

by Stephen Barrett, MD

Homeopathic "remedies" enjoy a unique status in the health marketplace: They are the only category of quack products legally marketable as drugs. This situation exists for two reasons. First, the 1938 Federal Food, Drug, and Cosmetic Act, which was shepherded through Congress by a homeopathic physician who was a senator, recognizes as drugs all substances included in the *Homeopathic Pharmacopeia of the United States*. Second, the FDA has not held homeopathic products to the same standards as other drugs.

Basic Misbeliefs

Homeopathy dates back to the late 1700s when Samuel Hahnemann (1755-1843), a German physician, began formulating its basic principles. Hahnemann was justifiably distressed about bloodletting, leeching, purging, and other medical procedures of his day that did far more harm than good. Thinking that these treatments were intended to "balance the body's 'humors' by opposite effects," he developed his "law of similars"—a notion that symptoms of disease can be cured by extremely small amounts of substances that produce similar symptoms in healthy people when administered in large amounts. The word "homeopathy" is derived from the Greek words *homoios*

(similar) and *pathos* (suffering or disease).

Hahnemann and his early followers conducted "provings" in which they administered herbs, minerals, and other substances to healthy people, including themselves, and kept detailed records of what they observed. Later these records were compiled into lengthy reference

books called *materia medica*, which were and still are used to match a patient's symptoms with a "corresponding" drug.

Hahnemann declared that diseases represent a disturbance in the body's ability to heal itself and that only a small stimulus is needed to begin the healing process. He also claimed that chronic diseases were manifestations of a suppressed itch (psora), a kind of miasma or evil spirit.

At first he used small doses of accepted medications. But later he used enormous dilutions and theorized that the smaller the dose, the more powerful the effect—a notion often referred to as the "law of infinitesimals." That, of course, is just the opposite of the dose-response relationship that pharmacologists have demonstrated.

The basis for inclusion in the *Homeopathic Pharmacopeia* is not modern scientific testing, but homeopathic "provings," many of which took place during the 1800s and early 1900s. These provings had little consistency because meth-

The basis for inclusion in the Homeopathic Pharmacopeia is not modern scientific testing.

ods varied greatly from practitioner to practitioner. Some used a single dose; others dosed as often as three times a day for months; and potencies ranged from the undiluted original substance to dilutions so high that not one molecule of the original substance was likely to remain. The book's current (ninth) edition describes how more than a thousand substances are prepared for homeopathic use. It does not identify the symptoms or diseases for which homeopathic products should be used; that is decided by the practitioner (or manufacturer). The fact that substances listed in the *Homeopathic Pharmacopeia* are legally recognized as "drugs" does not mean that either the law or the FDA recognizes them as effective.

Because homeopathic remedies were actually less dangerous than those of nineteenth-century medical orthodoxy, many medical practitioners began using them. At the turn of the twentieth century, homeopathy had about 14,000 practitioners and 22 schools in the United States. But as medical science and medical education advanced, homeopathy declined sharply in America, where its schools either closed or converted to modern methods. The last pure homeopathic school in this country closed during the 1920s.

Many homeopaths maintain that certain people have a special affinity to a particular remedy (their "constitutional remedy") and will respond to it for a variety of ailments. Such remedies can be prescribed according to the person's "constitutional type"—named after the corresponding remedy in a manner resembling astrologic typing. The "Ignatia Type," for example, is said to be nervous and often tearful, and to dislike tobacco smoke. The typical "Pulsatilla" is a young woman, with blonde or light-brown hair, blue eyes, and a delicate complexion, who is gentle, fearful, romantic, emotional, and friendly but shy. The "Nux Vomica Type" is said to be aggressive, bellicose, ambitious, and hyperactive.

The "Sulfur Type" likes to be independent. And so on.

The 'Remedies' Are Placebos

Homeopathic products are made from minerals, botanical substances, and several other sources. If the original substance is soluble, one part is diluted with either nine or ninety-nine parts of distilled water and/or alcohol and shaken vigorously (succussed); if insoluble, it is finely ground and pulverized in similar proportions with powdered lactose (milk sugar). One part of the diluted medicine is then further diluted, and the process is repeated until the desired concentration is reached. Dilutions of 1 to 10 are designated by the Roman numeral X (1X = 1/10, 3X = 1/1,000, 6X = 1/1,000,000). Similarly, dilutions of 1 to 100 are designated by the Roman numeral C (1C = 1/100, 3C = 1/1,000,000, and so on). Most remedies today range from 6X to 30X, but products of 30C or more are marketed.

A 30X dilution means that the original substance has been diluted 10³⁰ times. Assuming that a cubic centimeter of water contains 15 drops, this number is greater than the number of drops of water that would fill a container more than 50 times the size of the Earth. Imagine placing a drop of red dye into such a container so that it disperses evenly. Homeopathy's "law of infinitesimals" is the equivalent of saying that any drop of water subsequently removed from that container will possess an essence of redness. Robert L. Park, PhD, a prominent physicist who is executive director of the American Physical Society, has noted that since the least amount of a substance in a solution is one molecule, a 30C solution would have to have at least one molecule of the original substance dissolved in a minimum of 100³⁰ molecules of water. This would require a container more than 30 billion times the size of the Earth.

The fact that homeopathic products are legally recognized as "drugs" does not mean that the FDA recognizes them as effective.

Can Nutrition Cure ADHD?

The facts about diets and dietary supplements

by Beth Fontenot, MS, RD

Few medical conditions lend themselves to more unproven claims, distortions of the truth, and controversial therapies than does Attention-Deficit/Hyperactivity Disorder (ADHD). Numerous dietary interventions and nutritional supplements have been claimed to ease or cure ADHD. Unfortunately, the promise of a quick solution or a cure that doesn't involve the use of drugs is often irresistible for vulnerable, well-meaning parents, even if that "solution" has no scientific basis or is outright quackery.

The American Psychiatric Association's *Diagnostic and Statistics Manual (DSM-IV)* lists three categories of ADHD: (1) predominantly inattentive type, (2) predominantly hyperactive-impulsive type, and (3) combined type. Specific criteria must be met for the diagnosis of each type. In most cases, the cause of the condition is unknown, but it is believed that ADHD may be the result of organic, genetic, and psychosocial factors.

Standard therapy for ADHD involves the use of stimulant medications such as Ritalin or Dexedrine, behavioral management, and/or special education. Various "natural" treatments have also been proposed, including defined diets, elimination diets, dietary supplements, megavitamin therapy, and herbal therapy.

Salicylates and Sugar

Benjamin Feingold, MD, was the first person to implicate diet as the primary cause of hyperactivity and advocate the use of a defined diet. The Feingold Diet, popularized in the 1970s, was based on the idea that hyperactivity in children was caused by salicylates (found naturally in some fruits and vegetables) and artificial colorings and flavorings in the food supply. The diet required that all of these substances be removed from a child's diet. Dr. Feingold estimated that 50% of his hyperactive patients responded favorably to this diet.

But there was a problem with Dr. Feingold's research. It was based on un-

controlled trials of children he had treated. Controlled double-blind challenge studies have not supported Dr. Feingold's claims. In addition, his diet is very difficult to follow since many foods that a child typically eats contain some type of additive, though the diet itself is not harmful. Nevertheless, many families follow the diet, and Feingold Associations are still active in some parts of the country.

Another food that has been implicated as a cause of ADHD in most children is sugar. However, there is no good evidence to support this claim. A meta-analysis in the *Journal of the American Medical Association (JAMA)*: 1617-1621, November 22-29, 1995) examined 16 articles reporting on 23 separate studies on the relationship between sugar and the behavior and cognition of children. The authors found that sugar did not affect the behavior or cognitive performance of children.

Many parents firmly believe that an excess of sugary foods causes hyperactivity or inattentive behavior in their children. In fact, avoiding sugar is one of the more popular pieces of advice that parents with ADHD children receive. Questions remain as to why the results of controlled studies differ from the impression of parents. It may be that popular folklore or publicity proposing a link between sugar and behavior may encourage parents to expect adverse behavior and selectively focus on it. In addition, high-sugar foods are commonly consumed at parties and gatherings where children tend to get excited, and parents may connect the intake of sugar with "hyperactive" behavior.

Dubious Products

A search on the Internet for nutritional treatments for ADHD uncovers numerous supplements claimed to relieve the symptoms of ADHD, improve a child's attentiveness, or control a child's behavior. These products cover the supplement

[continued on page 22]

Nutrition Forum rates the factual accuracy and usefulness of Internet sites containing nutrition and health information. This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc. (<http://www.quackwatch.com>), which is working hard to improve the quality of health information on the Web.

BEST

The *Journal of the American Medical Association (JAMA)* has begun publishing a "Patient Page" that interprets information from one or more of the original research articles running in each issue. The material will also identify Web sites and toll-free numbers for obtaining additional information. Starting with the April 22-29 edition, the page will be published at the back of each issue and on the AMA's Web site <http://www.ama-assn.org/consumer.htm>. Although pages are copyrighted, JAMA and the AMA are encouraging physicians to photocopy and distribute them for educational purposes.

At <http://cpmnet.columbia.edu/texts/gcps/>, Columbia University offers the U.S. Preventive Services Task Force's landmark 1996 report on the scientific basis and cost-effectiveness of dietary counseling and other interventions for more than 80 potentially preventable diseases and conditions.

WORST

A Pennsylvania chiropractor operates Vitamin Counsel, <http://www.vitamincounsel.com>, which offers a "customized nutrition program" based on the company's interpretation of a urinalysis and other data. The initial cost is about \$100 for a urine test kit, a questionnaire, and a month's supply of an "intestinal cleanser." The test procedure is alleged to reveal whether you are giving your body the right nutrients in the right amounts and whether the nutrients are being properly absorbed or you are "just making expensive urine." The "custom supplements" cost \$44.75 per month.

Homeotreat (<http://www.homeotreat.com>), operated by a Czech chiropractor, offers online consultation based on current symptoms, medical history, and 128 homeopathy-related questions. The proprietor claims that homeopathy has cured or relieved more than a hundred diseases and conditions and also offers long-term preventive benefits. The costs for his services are \$55 for the initial consultation, \$35 for follow-up consultations, and \$9 for the prescribed "remedy."

Occilococcinum, a 200C product “for the relief of colds and flu-like symptoms,” involves “dilutions” that are even more far-fetched. Its “active ingredient” is prepared by incubating small amounts of a freshly killed duck’s liver and heart for 40 days. The resultant solution is then filtered, freeze-dried, rehydrated, repeatedly diluted, and impregnated into sugar granules. If a single molecule of the duck’s heart or liver were to survive the dilution, its concentration would be 1 in 100^{200} . This huge number, which has 400 zeroes, is vastly greater than the estimated number of molecules in the universe (about one googol, which is a 1 followed by 100 zeroes). *U.S. News & World Report* has noted that only one duck per year is needed to manufacture the product, which had total sales of \$20 million in 1996. The magazine dubbed that unlucky bird “the \$20-million duck.”

Actually, the laws of chemistry state that there is a limit to the dilution that can be made without losing the original substance altogether. This limit, called Avogadro’s number, corresponds to homeopathic potencies of 12C or 24X (1 part in 10^{24}). Hahnemann himself realized that there is virtually no chance that even one molecule of original substance would remain after extreme dilutions. But he believed that the vigorous shaking or pulverizing with each step of dilution leaves behind a “spirit-like” essence—“no longer perceptible to the senses”—which cures by reviving the body’s “vital force.” This notion is unsubstantiated. Moreover, if it were true, every substance encountered by a molecule of water might imprint an “essence” that could exert powerful (and unpredictable) medicinal effects when ingested by a person. Dr. Park has noted that to expect to get even one molecule of the “medicinal” substance allegedly present in 30X pills, it would be necessary to take some two billion of them, which would total about a thousand tons of lactose plus whatever impurities the lactose contained.

Many proponents claim that homeo-

pathic products resemble vaccines because both provide a small stimulus that triggers an immune response. This comparison is not valid. The amounts of active ingredients in vaccines are much greater and can be measured. Moreover, immunizations produce antibodies whose concentration in the blood can be measured, but high-dilution homeopathic products produce no measurable response.

‘Electrodiagnosis’

Some physicians, dentists, and chiropractors use “electrodiagnostic” devices to help select the homeopathic remedies they prescribe. These practitioners claim they can determine the cause of any disease by detecting the “energy imbalance” causing the problem. Some also claim that the devices can detect whether someone is allergic or sensitive to foods, vitamins, and/or other substances.

No homeopathic product has been proven effective for any therapeutic purpose.

The procedure, called electroacupuncture according to Voll (EAV), electrodiagnosis, or electrodermal screening, was begun during the 1970s by Reinhold Voll, MD, a West German physician who developed the original device. Subsequent models include the Dermatron, Vegatest, Interro, and Omega AcuBase.

Proponents claim that these devices measure disturbances in the flow of “electro-magnetic energy” along the body’s “acupuncture meridians.” Actually, they are fancy galvanometers that measure electrical resistance of the patient’s skin when touched by a probe. Each device contains a low-voltage source. One wire from the device goes to a brass cylinder covered by moist gauze, which the patient holds in one hand. A second wire is connected to a probe, which the operator touches to “acupuncture points” on the patient’s foot or other hand. This completes a circuit, and the device registers the flow of current. The information is then relayed to a gauge that provides a numerical readout. The size of the number depends on how hard the probe is pressed against the patient’s skin. Recent versions, such as the Interro, make

sounds and provide the readout on a computer screen. The treatment selected depends on the scope of the practitioner’s practice and may include acupuncture, dietary change, and/or vitamin supplements, as well as homeopathic products. Regulatory agencies have seized several types of “electrodiagnostic” devices but have not made a systematic effort to drive them from the marketplace.

Unimpressive ‘Research’

Since many homeopathic remedies contain no detectable amount of active ingredient, it is impossible to test whether they contain what their label says. Unlike most potent drugs, they have not been proven effective against disease by double-blind clinical testing. In fact, the vast majority of homeopathic products have never even been tested.

Homeopathy’s favorite article is probably a 1994 report claiming that homeopathic treatment had been demonstrated to be effective against mild cases of diarrhea among Nicaraguan children (*Pediatrics* 93:719–725, 1994). The claim was based on findings that, on certain days, the “treated” group had fewer loose stools than the placebo group. However, the data were not properly interpreted. In a rebuttal article, Wallace Sampson, MD, and William London, EdD, noted that the data were oddly grouped and contained errors and inconsistencies (*Pediatrics* 96:961–964, 1995).

In December 1996, a lengthy report was published by the Homeopathic Medicines Research Group (HMRG), an expert panel convened by the Commission of the European Communities. The HMRG included homeopathic physician-researchers and experts in clinical research, clinical pharmacology, biostatistics, and clinical epidemiology. Its aim was to evaluate published and unpublished reports of controlled trials of homeopathic treatment. After examining 184 reports, the panelists concluded: (1) only 17 were designed and reported well enough to be worth considering; (2) in some of these trials, homeopathic approaches may have exerted a greater effect than a placebo or no treatment; and (3) the number of participants in these 17 trials was too small to draw any conclusions about the effectiveness of homeopathic treatment for any specific

condition. Simply put: Most homeopathic research is worthless, and no homeopathic product has been proven effective for any therapeutic purpose. The National Council Against Health Fraud has warned that “the sectarian nature of homeopathy raises serious questions about the trustworthiness of homeopathic researchers.”

Proponents trumpet the few “positive” studies as proof that “homeopathy works.” Even if their results can be consistently reproduced (which seems unlikely), the most that the study of a single remedy for a single disease could prove is that the remedy is effective against that disease. It would not validate homeopathy’s basic theories or prove that homeopathic treatment is useful for other diseases.

Placebo effects can be powerful, of course, but the potential benefit of relieving symptoms with placebos should be weighed against the harm that can result from relying upon—and wasting money on—ineffective products. Spontaneous remission is also a factor in homeopathy’s popularity. I believe that most people who credit a homeopathic product for their recovery would have fared equally well without it.

Homeopathic practitioners claim to

provide care that is safer, gentler, more “natural,” and less expensive than conventional care—and more concerned with prevention. The fact is, however, that homeopathic treatments prevent nothing and many homeopathic leaders preach against immunization. Equally bad, a report on the National Center for Homeopathy’s 1997 Conference described how a homeopathic physician had suggested using homeopathic products to help prevent and treat coronary artery disease. According to the article, the speaker recommended various 30C and 200C products as alternatives to aspirin or cholesterol-lowering drugs (*Homeopathy Today* 17(8):3, 1997).

Greater Regulation Is Needed

If the FDA required homeopathic remedies to be proven effective in order to remain marketable—the standard it applies to other categories of drugs—homeopathy would face extinction in the United States. However, there is no indication that the agency is considering this. FDA officials regard homeopathy as relatively benign (compared, for example, to unsubstantiated products marketed for cancer and

AIDS) and believe that other problems should get enforcement priority. FDA guidelines issued in 1988 permit manufacturers to sell nonprescription homeopathics for “self-limiting conditions recognizable by consumers,” provided that their labeling “adequately instructs consumers in the product’s safe use.” But if a product doesn’t work, the only truly adequate instruction for use is to avoid it.

In August 1994, 42 critics of quackery and pseudoscience petitioned the FDA to initiate a rulemaking procedure to require that all over-the-counter (OTC) homeopathic drugs meet the same standards of safety and effectiveness as non-homeopathic OTC drugs. The petition also asked the FDA to warn the public that although the agency has permitted homeopathic products to be sold, it does not recognize them as effective. The FDA has not yet ruled on the petition. On March 3, 1998, at a symposium sponsored by *Good Housekeeping* magazine, former FDA Commissioner David A. Kessler, MD, JD, acknowledged that homeopathic products do not work but that he did not attempt to ban them because he felt that Congress would not support a ban.

The Federal Trade Commission could take effective action against homeopathic manufacturers that make false claims in their ads. Since no homeopathic product now advertised has been proven effective, and since few if any have even been reliably tested, it is hard to imagine how therapeutic claims for them could stand up in court. However, the FTC has shown no inclination to regulate homeopathic advertising.

If the FDA and FTC attack homeopathy too vigorously, its proponents might even persuade a lobby-susceptible Congress to rescue them. Regardless of this risk, federal agencies should not permit worthless products to be marketed with claims that they are effective. Nor should they continue to tolerate the presence of quack “electrodiagnostic” devices in the marketplace. **NF**

Dr. Barrett, a retired psychiatrist, is board chairman of Quackwatch, Inc., and a board member of the National Council Against Health Fraud. His 44 books include The Health Robbers: A Close Look at Quackery in America (Prometheus, 1993).

Dubious Marketing

America’s most blatant homeopathic marketer appears to be Biological Homeopathic Industries (BHI) of Albuquerque, New Mexico, which, in 1983, sent a 123-page catalog to 200,000 physicians nationwide. Its products included BHI Anti-cancer Stimulating, BHI Antivirus, BHI Stroke, and 50 other types of tablets claimed to be effective against serious diseases.

In 1984, the FDA forced BHI to stop distributing several of the products and to tone down its claims for others. However, BHI has continued to make illegal claims. Its 1991 Physicians’ Reference (“for use only by health care professionals”) inappropriately recommended products for heart failure, syphilis, kidney failure, blurred vision, and many other serious conditions. The company’s publishing arm issues the quarterly *Biological Therapy: Journal of Natural Medicine*, which regularly contains articles whose authors make questionable claims. An article in the April 1992 issue, for example, listed “indications” for using BHI and Heel products (distributed by BHI) for more than 50 conditions—including cancer, angina pectoris, and paralysis. And the October 1993 issue, devoted to the homeopathic treatment of children, includes an article recommending products for acute bacterial infections of the ear and tonsils. The article is described as selections from Heel seminars given in several cities by a Nevada homeopath who also served as medical editor of *Biological Therapy*. In 1993, Heel published a 503-page hardcover book describing how to use its products to treat about 450 conditions. Twelve pages of the book cover “Neoplasia and neoplastic phases of disease.” (“Neoplasm” is a medical term for tumor.) In March 1998, during an osteopathic convention in Las Vegas, Nevada, a Heel exhibitor distributed copies of the book when asked for detailed information on how to use Heel products.

spectrum: antioxidants, amino acids, herbs, vitamins, minerals, and an array of other dietary supplements, some with questionable ingredients.

One such product that is highly promoted for the treatment of ADHD is "Pyc-nogenol," a commercial mixture of bioflavonoids that appears to exhibit antioxidative activity in animal studies. Bioflavonoids are naturally available from vegetables, and are found in the white matter inside the peel of citrus fruits. The impact of large amounts of bioflavonoids on the human body is unknown, as is their usefulness.

Advertisements for "Pycnogenol" state that it is a patented extract from the bark of the French Maritime Pine Tree, and it is described as "the most potent, natural antioxidant compound ever discovered." According to its promoters, "Pycnogenol" is important to brain function because it protects the brain cells from compounds that circulate in the blood. There is no evidence that Pycnogenol is effective to use, and reports of its beneficial effects on ADHD are strictly anecdotal.

Still another product which claims to be beneficial for children with ADHD is "beCALM'd." This product is sold by Technology Services Team, a multilevel marketing company. It is supposed to increase the production of neurotransmitters which will supposedly allow the brain to function better. The ad on the Internet states that beCALM'd is a patented "precise combination of amino acids, vitamins, and minerals."

The ingredients of beCALM'd include l-glutamine, d-phenylalanine, calcium, magnesium, chromium, folic acid, and vitamins A and B₆. The promoters for this product claim that in order to get enough of the right combination of these nutrients for the brain to function properly, one would need to consume "several pounds of fish, whole milk, cheese, and 2 or 3 pounds of turkey per day." In fact, the nutrient ingredients in beCALM'd are all available in adequate amounts in a balanced diet with normal portion sizes, and there is no known magic combination of nutrients that will make the brain work better.

Vaxa International, a "homeopathic nutraceutical company," has its version of a defined diet for ADHD on the Internet.

The diet requires eliminating many foods including dairy products, all yellow foods (like corn and squash), and fruit juices. The company claims that a high-protein shake for breakfast made with coffee and a protein powder is needed "to feed the brain." The ADHD program also encourages the use of colloidal minerals (see *Nutrition Forum*, September/October, 1997) and one or more of its three supplemental products, depending on which symptoms of ADHD need to be treated.

One of these supplements is "Attend"—claimed to be a "brain fertilizer." It is composed of amino acids, essential fatty acids, lipid complexes, homeopathic medicines, hormone precursors, and precursors to neurotransmitters. Vaxa's "Extress" is a supplement purported to be helpful with temper problems because it contains branched-chain amino acids. There is no scientific evidence that any of these products are effective.

There are also various herbal therapies that are supposed to treat ADHD. Gingko biloba, capsicum, veratrum album, eleuthero (Siberian ginseng), and evening primrose oil are just some of the botanicals that are advertised as beneficial for treating the symptoms of ADHD. But there is no evidence that any herb is beneficial in the treatment of ADHD. Without adequate testing, quality controls, and standardization of the active principles in herbs, parents just can't be sure of what they are purchasing and what they are giving their children.

Megavitamin therapy has also been proposed for the management of ADHD. Megavitamin therapy is defined as using one or more vitamins in doses at least 10 times the recommended dietary allowance. Some studies have reported benefit from megavitamin therapy for the management of ADHD, but these were poorly designed and lacked appropriate controls.

A study published in *Advances in Neurology* (58:303-310, 1992) was designed to determine whether megavitamin therapy could have a positive effect on children with ADHD. Forty-one children participated in the randomized, controlled trial, which monitored physical, behavioral, and biochemical parameters. The study concluded that megavitamin therapy was ineffective in the management of ADHD and posed a danger because of the potential for hepatotoxicity.

Advice from the Experts

The American Academy of Pediatrics has concluded that special diets and supplements do not relieve the symptoms of ADHD and warns that food modification alone should not be used as treatment for ADHD.

A statement from a National Institutes of Health Consensus Conference said that defined diets should not be universally used in the treatment of childhood hyperactivity, and a defined diet should not be initiated until a child and his family have been fully and appropriately evaluated and all traditional therapeutic options considered.

Some of the best advice for parents and professionals on the issue of nutrition and ADHD appeared in an article published in the *Journal of Child Neurology* (10 Suppl 1:S96-100, January 1995). The author says that professionals should be informed about controversial treatments proposed for children with learning disabilities so that they can educate parents on the facts about these treatments. The author also advises parents of children with learning disabilities not to accept controversial treatments without question and not to put their children through unproven treatments that are unlikely to help. **NF**

A Cautionary Note

Because the Feingold Diet does no physical harm, it might appear to be helpful in some instances. However, the potential benefits should be weighed against the potential harm of (1) teaching children that their behavior and school performance are related to what they eat rather than what they feel, (2) undermining their self-esteem by implanting notions that they are unhealthy and fragile, (3) creating situations in which their eating behavior or fear of chemicals are regarded as peculiar by other children, and (4) depriving them of the opportunity to receive appropriate professional help. —Stephen Barrett, MD

DUBIOUS VITAMIN PROMOTION

The Vitamin Shoppe, which operates a discount mail-order business and 30 retail stores, has purchased exclusive rights to advertise on Time Inc. New Media's "Ask Dr. Weil" Web site (www.drweil.com) beginning in April. Users who complete Weil's "Vitamin Advisor" questionnaire will get "personalized" advice and can click on a link to the Vitamin Shoppe's Web site where they can purchase the recommended products. Completion of the questionnaire invariably results in multiple recommendations for vitamin and herbal products. Time executives estimate that Weil's site draws about 1.2 million page views per week, equivalent to several hundred thousand visitors every week. *Advertising Age* reports that the ad rights involved a seven-figure amount.

IMPOTENCE SCAM

A new drug for the treatment of impotence was approved last March by the Food and Drug Administration, but a copycat herbal concoction is being targeted to men. Viagra, the newly approved drug, is marketed by Pfizer Pharmaceuticals and is the first oral medicine for impotence. Ads for Vaegra, "a proprietary blend of pharmaceutical-grade ingredients" according to its flyer, were apparently sent to a large number of older men around the country and touts the same claims as those made for Viagra. The advertisement for Vaegra contains quotations and research citations, but those quoted deny any knowledge of the product. Pfizer has filed suit against Vaegra's distributors, American Urological Clinic, and has been granted a temporary order restraining the clinic from using the look-alike name. Companies that market products with no proven effect often use a name similar to that of a proven drug. At \$89.00 a bottle, Vaegra could be an expensive spelling lesson.

ACSH MAGAZINE SURVEY

The American Council on Science and Health has evaluated the quality of nutri-

tion articles published in popular magazines during 1995 and 1996. The study covered eight randomly selected articles from each of 21 magazines. Four nutrition and food-science experts rated each article for accuracy, style of presentation, and validity of recommendations. *Consumer Reports*, *Better Homes & Gardens*, and *Good Housekeeping* topped the list. The full report can be obtained for \$5 from the American Council on Science and Health, 199 Broadway, 2nd Floor, New York, NY 10023.

VITAMIN ANGEL ALLIANCE

In 1994, Nutritech/ALL ONE PEOPLE, of Belgrade, Maine, joined forces with Direct Relief International to create the Vitamin Angel Alliance to fight blindness and malnutrition in children around the world. Direct Relief annually distributes over \$28 million in medical supplies, pharmaceuticals, and nutritional products to over 70 countries. The alliance intends to promote awareness and raise contributions of vitamin supplements within the natural-foods industry for distribution by Direct Relief. So far, it has collected and distributed more than six million doses.

BREASTFEEDING RIGHTS

Since 1993, at least 14 states and many cities and counties have passed laws protecting the right to breastfeed infants in public. The states include California, Connecticut, Delaware, Florida, Illinois, Michigan, Nevada, New Jersey, New York, North Carolina, Texas, Utah, Virginia, and Wisconsin.

TELEMARKETING/INFOMERCIAL CASE SETTLED

The attorneys general of Arizona, California, Illinois, Massachusetts, New York, Pennsylvania, Vermont, and Wisconsin have announced an Assurance of Voluntary Compliance with Talk America, Inc. (a national telemarketer) and Nature's Pure Body Institute, Inc. (a manufacturer). Both companies had been charged with making unsupported claims for three products during infomercials and telephone sales pitches: (1) Purifast 30 had been alleged to prevent cancer, remove waste from the

body, detoxify the bloodstream, and allow users to live without aches and pains; (2) Daily Harvest Vitamins had been claimed to reduce the risk of degenerative diseases, remove foreign chemicals, relieve constipation, and cause weight loss; and (3) Natural Hair Shampoo had been claimed to reverse baldness and increase hair growth. The agreement requires the companies to pay full refunds to consumers who ordered these products and to pay \$150,000 to the participating states for investigative costs and attorneys fees.

NEW DRI'S

The Institute of Medicine has released a lengthy report on its recommended intakes of B vitamins. The report notes that although most Americans and Canadians get enough vitamin B₁₂ in their food, between 10% and 30% of older adults have lost their ability to adequately absorb the naturally occurring form of B₁₂ found in food. For this reason, the report says, people over 50 should meet most of their recommended intake with synthetic B₁₂ from fortified foods or vitamin supplements. The full report—*Dietary Reference Intakes: Thiamin, Riboflavin, Niacin, Vitamin B₆, Folate, B₁₂, Pantothenic Acid, Biotin, and Choline*—can be purchased by calling (800) 624-6242; sending \$44 to the National Academy Press, 201 Constitution Ave, N.W., Washington, DC 20418; or ordering it at a discount online (<http://www.nap.edu>). The full text can also be read online, although the process is cumbersome.

VITAMIN E IS POPULAR

A nationwide survey conducted by Decision Analysts, Inc., of Arlington, Texas, found that vitamin E is now the second most popular single vitamin supplement after vitamin C. The survey reported that nearly one-third of U. S. adults take vitamin E as a dietary supplement. The survey reported that the use of vitamin E was particularly strong among women, with 25% of women surveyed stating that they take the vitamin. In addition, among adults aged 45 to 54, nearly 36% take it and in the over-age-55 group, 44% take the vitamin. **NF**

Book Reviews

Analysis and Ratings

NF reviews rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to *Nutrition Forum Book Reviews*, P.O. Box 664, Amherst, NY 14226-0664.

Honest Ergogenics

Joseph P. Cannon

The Ergogenics Edge by Melvin Williams, PhD (Champaign, IL: Human Kinetics Publishers, 1998), 316 pp., \$17.95, ISBN 0-88011-545-9 (paperback).

Dr. Melvin Williams, professor of Exercise Science, Physical Education and Recreation at Old Dominion University, is one of the country's foremost authorities on ergogenic substances. Dr. Williams has combined his more than 30 years of research experience into the *Ergogenics Edge*, a book devoted to the subject of sports performance-enhancing substances.

Early chapters of the book cover the basics such as factors that limit sports performance. They offer a very easy-to-understand yet comprehensive overview of energy systems, muscle-fiber types, and their interactions during exercise. Other topics include how sport psychology can help enhance one's exercise performance and how to evaluate the claims made for an ergogenic substance (including the perils of relying on testimonials).

The real beauty of this book is its coverage of over 60 ergogenic substances. These range from various over-the-counter vitamins, minerals, and amino acids to illegal substances such as steroids and cocaine. Few stones are left unturned. Besides the more conspicuous—and dubious—of ergogenic aids, such as chromium picolinate, DHEA, and antioxidants, Dr. Williams also covers more

low-profile aids such as nasal-airway expanders and oxygen supplementation. Very good synopses of relevant literature are included for creatine and beta hydroxy methyl butyrate (HMB), two of the new kids on the block that everyone seems to be talking about these days. Each substance is listed alphabetically for easy access, and each entry includes classification and usage of the compound, an explanation of how it's supposed to work, the effectiveness of the substance, safety issues associated with its use, legal and ethical issues, and recommendations—which basically gives the bottom line on whether or not the substance should be used. All recommendations for (or against) use are made solely on the basis of available scientific literature.

References, for those who wish to pursue matters further, are listed at the back of the book and are organized according to chapter. Most references are very recent, having been published within the past five years, with many others published within the past year.

The *Ergogenics Edge* is a rare find these days: it's unbiased, easy to understand, comprehensive, and up to date.

RECOMMENDED

Herbal Fake

Varro E. Tyler

Essiac: A Native Herbal Cancer Remedy by C. Olsen (Pagosa Springs, CO: Kali Press, 1996), 122 pp., no price given, ISBN 0-9628882-5-7 (paperback).

Most readers, with the possible exception of those who have spent the last decade or so in Antarctica, will be familiar with Essiac, the most visible of America's unproven herbal remedies for cancer. The formula was popularized by Canadian nurse Rene Caisse, who is said to have obtained it indirectly from an Ojibwa medicine man in 1922. Christening the mixture with her own name spelled backwards, nurse Caisse treated cancer patients with it until shortly before her death in 1978. Since then, the product has continued to be widely promoted and used by some alternative health-care practitioners.

This volume details the history of the remedy, provides a number of testimoni-

als regarding its purported efficacy, gives a formula for it as well as its mode of preparation and use, and then throws in a few space fillers, such as an illustrated description of the five Tibetan rites to normalize hormone production in the body. No mention is made of the tests conducted in 1983 by the National Cancer Institute (NCI) that found that Essiac lacked any significant antitumor activity.

Basically, Essiac is a tea consisting principally of burdock root (*Arctium* spp.), with lesser amounts of sheep sorrel (*Rumex acetosella*), slippery elm bark (*Ulmus fulva*), and Turkey rhubarb root (*Rheum scutatus*?). Actually, the book defines Turkey rhubarb as *Rheum palmatum*, a type of Chinese rhubarb often transshipped through Turkish ports. Just how this nonnative laxative herb could have been used in an ancient Ojibwa formula is not explained.

The book repeatedly notes that each of the herbs in Essiac has been used as a food. This assertion apparently confuses the root of rhubarb species containing anthraquinone derivatives that act as laxatives with the petioles of common rhapontic rhubarb that are edible. As for slippery elm bark with its tough lignified fibers, it can scarcely be regarded as a food.

In attempting to explain the presumed beneficial effects of Essiac ingredients, the book notes that sheep sorrel contains alkaloids that may play a part in the cytotoxic activity. Yet in his authoritative work on the distribution of alkaloids, Raffauf has indicated that the species gave negative tests for such compounds.

Another puzzling statement refers to the Essiac formula having been handed over to the Resperin Corporation in 1977 by Rene Caisse who insisted "the formula not be disclosed and is still under lock and key today." That being the case, what assurance is there that the Essiac recipe given in the book is at all authentic?

Aside from anecdotal information—testimonials by users—there is nothing to support the assertion that Essiac is an effective cure for cancer. Persons interested in the history and development of unproven cancer remedies, such as krebiozen, laetrile, and the like, will find this book of interest. **NF**

NOT RECOMMENDED

NEW SUPPLEMENT REGULATIONS

On April 29, the FDA proposed new rules for statements about the effects of dietary supplement products on body structure and function (Federal Register 63:23624-23632, 1998). The rules were drafted to comply with the Dietary Supplement and Health Education Act of 1994, which was intended to weaken the agency's authority. The proposed rules include: (1) Disease claims are not permitted; (2) Disease is defined as "any deviation from, impairment of, or interruption of the normal structure or function of any part, organ, or system (or combination thereof) of the body that is manifested by a characteristic set of one or more signs or symptoms"; (3) "Signs or symptoms" include laboratory or clinical assessments that are characteristic of a disease, such as an elevated cholesterol fraction, uric acid, or blood sugar, and characteristic signs of disease, such as elevated blood pressure; (4) A claim that a product helps protect against a disease (e.g., "reduces the stiffness of arthritis") is a disease claim; (5) A product name that implies an effect on a disease, e.g., "Hepatocure" would constitute a disease claim, but names such as "Cardiohealth" or "Heart Tabs" would not; and (6) suggestions that a product helps fight a specific disease or type of disease by stimulating the body's defenses would be disease claims, but general claims such as "supports the immune system" would not. The full text of the proposed regulations is available online at <http://www.fda.gov> (search for "dietary supplements"). The deadline for public comments is August 27.

COURT THWARTS FDA BAN

The FDA has determined that Cholestin, a product promoted as a dietary supplement intended to affect cholesterol levels, is not a dietary supplement, but is an unapproved drug under the terms of the Federal Food, Drug, and Cosmetics Act. Cholestin contains lovastatin, the active ingredient in Mevacor, a prescription drug used to modify cholesterol levels. The product is manufactured by Phar-

Nutritional Supplements for Down Syndrome

What happens when hope meets hype

by Len Leshin, MD

Down syndrome is a genetic disorder caused by the presence of a third 21st chromosome. It occurs once in every 600 to 700 births, making it the most common genetic disorder. Its common features include poor muscle tone, short stature, a small nose with flat nasal bridge, small skin folds on the inner corner of the eyes (epicanthal folds), dry skin, immune-system suppression, developmental delays, speech difficulties, and mental retardation.

Even before Down syndrome was found to be caused by a genetic abnormality, nutritional therapies were proposed, usually focusing on one or two items. Mixtures that included vitamins, hormones, and enzymes were advocated in the 1960s by Haboud, a German physician; however, other investigators found no beneficial effect. At about the same time, Henry Turkel, MD, in the United States claimed that a mixture of 48 different ingredients could improve intelligence and the appearance of children with Down syndrome. No double-blind study was ever performed with Turkel's formula. Dr. Turkel administered his formula to children with Down syndrome for almost 40 years; if there had been some benefit, we should have had such evidence by now. Yet no such group of children or adults has been identified to date.

In the 1980s, Ruth Harrell, MD, and

associates reported that supplementary vitamins and minerals and thyroid hormone improved IQ scores and caused "physical changes toward normal" among children with various types of mental deficiency, with the best results in three children with Down syndrome. However, the study was neither controlled nor blinded, and seven different studies during the next decade showed no positive results from Harrell's mixture. Harrell's formula gained notoriety because it was discussed in a scientific journal.

No double-blind study was ever performed with Turkel's formula.

Haps Caps, another mixture of vitamins, minerals, and enzymes that hit the marketplace during the 1980s, is frequently given with thyroid hormone. No study of Haps Caps has been published.

Haps Caps is promoted through traveling clinics run by Jack Warner, MD, of California.

In recent years, two formulas have become even more popular because of TV shows, Internet promotion, and seminars. In 1995, ABC-TV's *Day One* promoted a formula created by Dixie Lawrence Tafoya, owner/operator of an adoption agency that specializes in finding homes for disabled children. Lawrence initially based her formula on Turkel's original mixture but modified it for her own daughter. The TV program described how Lawrence had adopted a girl with Down syndrome and had "tapped into medical databases, scoured libraries, called re-

search departments, talked to anyone who knew anything about the biochemistry of Down syndrome." The result was a formula based on Turkel's original mixture but containing many more ingredients. Subsequently, the drug piracetam was added to the child's regimen. During the TV program, her daughter's school principal and a special-instruction teacher said the child had improved after taking the formula; whereas a National Down Syndrome Congress official said, "But until . . . it's proven that the position is what made that improvement, we would be irresponsible to tell people to go get that."

By the time *Day One* aired, Lawrence had arranged for her formula to be produced by Nutri-Chem Labs (a Canadian company) and the product was called MSB Plus, which differed considerably from previous formulas aimed at Down syndrome. In 1996, she withdrew her support from Nutri-Chem and began promoting a formula called NuTriVene-D, which is marketed by International Nutrition, Inc., of Baltimore, Maryland. Nutri-Chem still markets MSB Plus. Both formulas have more than 40 ingredients, most of them the same or similar, but with differences in dosage. Various formulas from other companies have not been as popular.

Common Ingredients

Down syndrome formulas contain four main groups of ingredients: vitamins, minerals, amino acids, and antioxidants. Newer additions include digestive enzymes and fat supplements.

Vitamins. Supplementation with both single vitamins and vitamin mixtures has been studied in children with Down syndrome. Although sporadic reports of vitamin deficiencies have been published, most studies reveal none, and many studies have found that vitamin supplementation with either RDA doses or megadoses have no effect on mental ability or behavior. The present supplements tend to use RDA values, although levels of vitamin A

high enough to be toxic are still occasionally promoted.

Minerals. Several studies have shown that zinc and selenium serum levels are decreased among children with Down syndrome. Some studies on zinc report increased growth, improved thyroid and lymphocyte functions, and increased survival of white blood cells with supplementation; however, these are mostly unconfirmed. Selenium is a cofactor in glutathione peroxidase, an enzyme that helps scavenge oxygen radicals. Selenium supplementation may improve certain indicators of immune functioning, but the supporting research has only been preliminary. There is no information on possible adverse effects of chronic zinc and selenium supplementation. No other mineral has been found either lacking or helpful in Down syndrome.

Amino acids. All three popular formulas (MSB Plus, NuTriVene-D, and Haps Caps) include amino acids. This supplementation is based on a study of adults with Down syndrome published in 1992 by Jerome Lejeune, MD. This study reported a consistent deficiency of serine and an excess of cysteine and lysine, which Lejeune felt were caused by overexpression of certain genes on the 21st chromosome. He postulated that the supplemental amino acids balanced the blood levels, making the biochemical workings of the body normal. However, a subsequent study of 22 children found no such abnormalities in serum or urinary amino-acid levels. Amino-acid supplements can cause an unpleasant odor in the user's urine and sweat.

Some proponents claim that overexpression of the cystathione beta-synthase gene causes a "functional" folic-acid deficiency in which serum levels are normal but the body can't use all of it and is unable to repair damaged DNA. Supplementation supposedly alleviates this alleged problem. This theory has yet to be supported in a scientific study. The FDA has just funded such a study, which should be completed

Vitamin supplementation with either RDA doses or megadoses have no effect on mental ability or behavior.

[continued on page 28]

Doing the DRIs, Part II

The second DRI report covers B-vitamins and choline

The National Research Council has released the second of its series of seven reports on Dietary Reference Intakes (DRIs). The first DRI report, published last year, discussed five nutrients related to bone health (see *NF*, Nov./Dec. 1997). This report covers the B-vitamins and choline. Except for folate and choline, the recommended intakes have not changed substantially since the 10th edition of NRC's *Recommended Dietary Allowances* was published in 1989.

As of January 1, 1998, U.S. food manufacturers are required to add folic acid to enriched bread, rolls, and buns; all enriched flour including bromated and self-rising flours; enriched corn grits and corn meals; enriched farina and rice; and all enriched macaroni and noodle products including vegetable macaroni, vegetable noodle, and nonfat milk macaroni products. In addition, breakfast cereals have added folic acid up to 400 mcg per serving.

This report stresses that adults need 400 micrograms per day of folate, a level that many Americans were not meeting before folate fortification began. To reduce the risk of spina bifida and other neural-tube defects, women capable of becoming pregnant should obtain the recommended amount from fortified foods, vitamin supplements, or a combination of the two, the report says. This is in addition to the naturally occurring folate they obtain from a varied diet.

Whether these women can rely totally on the folate in food is uncertain, since research has involved giving only additional amounts of folic acid.

The report recommends individual intakes for thiamin, riboflavin, niacin, vitamins B₆ and B₁₂, pantothenic acid, biotin, and choline. Most Americans and Canadians have adequate amounts of these nutri-

ents in their diet. The report notes, however, that between 10% and 30% of older adults have lost the ability to adequately absorb the B₁₂ in their food. Therefore, people over age 50 should meet most of their recommended intake with fortified foods or vitamin supplements.

In recent years, much research has centered on the roles that B-vitamins may play in reducing the risk of cardiovascular disease, cancers, and various mental disorders. Although promising, the research is not yet solid enough to justify recommendations for nutrient intake, the report says.

Therefore, rather than setting intake levels to reduce the risk of

these diseases, the DRI committee based its recommendations on values shown to guard against anemia or other conditions that can develop when these vitamins are lacking.

Consumption of folate and vitamin B₆ can reduce elevated levels of homocysteine in the blood, and some studies have linked lower homocysteine concentrations with a decreased risk of cardiovascular disease. But it is not yet

settled whether increasing folate or B₆ intake leads directly to less vascular and heart disease. Likewise, data showing that increased folate may protect against colorectal cancer do not provide conclusive evidence of a benefit, the report says.

The report lists an Adequate Intake level for choline, which is a departure from the previously issued *Recommended Dietary Allowances*. Choline is not generally considered a vitamin for humans, but recent research has shown that healthy males fed a choline-deficient diet developed liver damage. Concluding that sufficient human data are not available to

Except for folate and choline, the recommended intakes have not changed substantially since the 10th edition.

[continued on page 31]

WEB WATCH

This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc. (<http://www.quackwatch.com>), which is working hard to improve the quality of health information on the Web.

BEST

PubMed <http://www.ncbi.nlm.nih.gov/PubMed/> provides free MEDLINE searches and the ability to read abstracts of recent articles. The search engine also provides links to related articles and their abstracts.

Consumer Gateway to Health <http://www.consumer.gov/health.htm> and Healthfinder <http://www.healthfinder.org> provide links to a wealth of information from federal agencies and some nonfederal organizations. Most pathways lead to reliable information, but Healthfinder searches using key words related to "alternative" practices can lead to quacky sources. No links exist to the major antiquackery Web sites.

The table of contents and selected articles from the latest issue of the *Scientific Review of Alternative Medicine* are available at hcr.org/sram.index.html. This peer-reviewed medical journal publishes objective evaluations of the treatments and claims of "alternative medicine."

WORST

<http://www.healthfoodsbiz.com> is the new home page of *Health Foods Business*, a health-food-industry trade publication. The site contains current articles and a small archive of previously published ones.

Physicians Research Laboratories <http://www.physiciansresearch.com> is a multilevel company that markets many dietary supplements and herbal products. Its online retail catalog, which can be searched by inserting disease names, contains seven products said to be useful in preventing or treating cancer.

NEW DEVELOPMENT

Cable modems. Many cable companies now offer Internet connections that require no telephone line and download up to 50 times as fast as ordinary modems. The monthly cost is about \$40.

in 1999. However, it is not clear that cystathione beta-synthase levels are elevated in Down syndrome. One study showed increased amounts, but two others did not.

Another amino acid being promoted is tryptophan, which the body uses to synthesize serotonin. Decreased serum levels of serotonin have been found among people with Down syndrome. However, it is not yet possible to study serotonin levels in the brain, so it is not known whether the brain serotonin levels are also low. Oral administration of 5-hydroxytryptophan, a compound the body uses to make serotonin, has produced no apparent benefits.

Antioxidants. It has been known for many years that one of the genes overexpressed in Down syndrome is the one producing superoxide dismutase (SOD).

This enzyme converts oxygen radicals, which are normal by-products of cell metabolism, to hydrogen peroxide and water. Glutathione peroxidase then converts the hydrogen peroxide to water and oxygen. One theory states that if there is more SOD without a corresponding increase in glutathione peroxidase, then more hydrogen peroxide will be available to cause peroxidative damage to the cell. Experiments with cell cultures and postmortem tests seem to show that this oxidative damage might cause premature aging, damage leading to senile dementia of the Alzheimer's type, and the early loss of brain cells seen in infants with Down syndrome. The theory claims that antioxidant supplements may prevent and even reverse damage by peroxidation. However, no evidence of this oxidative damage has been found in living humans with Down syndrome, and the possibility of adverse effects from long-term use of large amounts of antioxidants has received little attention.

Digestive enzymes. Parents are being told that their children with Down syndrome lack certain digestive enzymes, making it harder for them to get needed nutrients from the diet. There is no evi-

dence that people with Down syndrome are deficient in any pancreatic or intestinal enzyme. In fact, most children with Down syndrome have trouble with constipation, whereas people deficient in digestive enzymes tend to have loose stools. There does seem to be an increase in celiac disease (a disorder of malabsorption of wheat gluten) in Down syndrome, but enzymes do not help in this condition.

Docosahexaenoic acid (DHA). This omega-3 fatty acid is an important constituent of cell membranes, especially in the retina and brain. Typically, DHA is synthesized in the body from other fatty acids in the diet. Studies have indicated that premature infants may not be able to synthesize enough on their own, so infant formulas for premature babies should be fortified with DHA. Because breast milk contains DHA, the World Health Organization and several

The use of DHA entails some risks. Too much can actually suppress the immune system.

other organizations have asked the FDA to include it in regular infant formulas in the U.S. (DHA is already a component in infant formula in several European countries.) Promoters of DHA for older children with Down syndrome claim that its use will improve eye and neurologic development. No research indicates that children with Down syndrome lack DHA, cannot make enough, or can benefit from DHA supplements.

Further, studies have shown that the critical period for supplementing DHA in preterm infants is the first two months of life, and little benefit beyond that should be expected. Likewise, the promotion of the use of other fatty acids has no proven benefit for children with Down syndrome. The use of DHA entails some risks. Too much can actually suppress the immune system, which is already impaired in people with Down syndrome.

Choline. Studies have shown that as children with Down syndrome age, there is a loss of neurons that produce the neurotransmitter acetylcholine. It is presumed that this loss may cause difficulties with memory and cognitive function. Choline is promoted for increasing myelination of neurons and for increasing levels of the neurotransmitter acetylcholine. However,

there is no evidence that oral choline supplements do either of these things in people with Down syndrome.

Piracetam. Another product mentioned on the ABC TV show profiling Dixie Lawrence was piracetam. Piracetam was developed in the 1970s and has been studied as a possible treatment for several diseases, including Alzheimer's disease, sickle-cell anemia, dyslexia, and a movement disorder called myoclonus. One study seemed to show cognitive improvement in children with Down syndrome given piracetam, but the study was not blinded or controlled by placebo. No other study on this topic has been published, though introductory studies are currently taking place. Piracetam has orphan drug status for myoclonus, but it is not FDA-approved for treating Down syndrome.

DMSO (dimethyl sulfoxide). The Sierra Clinic, located in Mexico, is treating children with muscular injections of amino acids and DMSO in an attempt to improve cognition and motor skills. One study supports such use, but the study was not blinded and has not been confirmed by any other researcher. One study on oral DMSO in children with Down syndrome found no benefit.

Adverse Effects

When use of supplementary nutrients began, many of the vitamins were in megadose quantities. However, in response to criticism of the danger of toxicity, most regimens are now within RDA ranges. Vitamins A and E continue slightly above the RDA in several supplements. There is still concern as to infants who are nursing or taking formula and being given these products getting too much vitamin A and a heavy protein load.

Information on side effects is not being collected systematically. However, at a meeting in late 1997 of the Down Syndrome Medical Interest Group, doctors caring for these children reported instances of diarrhea, hyperactivity, and insomnia. Another notable effect has been loss of appetite, related to the fact that these supplements are not usually palatable. Parents often hide them in food and drink. A few children have stopped eating, apparently suspicious that the supplement

was in all their food. Orange skin coloring (carotenemia) was occasionally reported before vitamin-A levels in these supplements were decreased.

Questionable Promotions

Supplement products have become a source of much debate and controversy in the Down syndrome community, largely because of the ways they are promoted. Here are some examples.

Stating speculations as fact. Supplement promoters commonly claim that “infants with Down syndrome become retarded largely because of the overexpression of” superoxide dismutase, and that supplements can compensate for this. Some promoters append a long list of scientific articles to their promotional pieces, implying that they all support what the promoter has written. Generally, however, many of the studies have little to do with nutritional supplementation, and of those that do, the vast majority actually conclude that supplementation is not beneficial. Such lists can be very misleading to the parent with no medical background or a physician who lacks the time to investigate the actual articles or even read the abstracts..

Dubious claims of benefits. The claims range from the mild, such as an increase in growth rate and decrease in rate of infections, to the extreme of normalizing such items as cognition, muscle tone, sleep habits, speech, visual acuity, and even facial features. The Sierra Clinic even claims on its Web site that its treatment “turns the Down syndrome patient into a normal healthy individual.”

Targeted nutrition. The NuTriVene-D program is said to be specifically designed for individuals with Down syndrome—to enable better absorption of nutrients and provide “essential nutrients that are typically deficient.” International Nutrition and the Trisomy 21 Research Institute refer to NuTriVene-D as “Targeted Nutrition Intervention” (“TNI”). However, they do not recommend testing vitamin and mineral levels before use of the product is begun (and do not recommend amino-acid testing at all). No definitive research has been published showing consistent nutrient deficiencies among children with Down syndrome. When asked why the supplement is called “targeted” if no

blood tests are done to determine whether deficiency exists before it is used, proponents reply that the stock formula fits the needs of approximately 85% of all children with Down syndrome and that adjustments can be made later. NuTriVene-D is also promoted for use by children with other “chromosomal deletions or mutations, and other abnormalities.”

Use of anecdotal evidence. Many parents report that their child improved after starting supplements. Stories of increased health, normal growth, children acting “brighter” or “more with it” are abundant and can be very alluring to the interested parent or doctor. However, such testimonials have been shown to be affected strongly by the parent’s bias. Curiously, two studies in the 1980s using Harrell’s formula showed that parents of the children taking the placebo were more likely to claim their child had shown improvement than were the parents of children taking the actual formula.

Misrepresenting the nature of Down syndrome. Some promotional literature refers to Down syndrome as a “progressive, metabolic, degenerative disease that if left untreated, would lead to poor health, mental retardation, and ultimately premature death.” Researchers and clinicians who have worked with adults with Down syndrome for years, if not decades, dispute this statement, as do current parents of adults with Down syndrome. The outlook for people with Down syndrome is not bleak, and each generation has had a healthier, longer life span. There is no evidence that any nutritional supplement enhances the prognosis. This tactic preys on parents of infants and young children with Down syndrome who are vulnerable to the suggestion that they might be bad or neglectful parents if they don’t give their children these products.

The Bottom Line

While a few vocal doctors have championed the idea that dietary supplements can help children with Down syndrome, most doctors who take care of these children on a day-to-day basis do not recommend supplements. In 1996, the American College of Medical Genetics stated that it knew of no scientific evidence that treatment with piracetam or amino-acid supplements can improve the mental func-

tioning of people with Down syndrome. In 1997, the National Down Syndrome Society cautioned parents that:

The administration of the vitamin related therapies—e.g., the vitamin/mineral/amino acid/hormone/enzyme combination—has not been shown to be of benefit in a controlled trial, that the rationale advanced for these therapies is unproven, and that the previous use of these therapies has not produced any scientifically validated significant results. Moreover, the long-term effects of chronic administration of many of the ingredients in these preparations are unknown. Despite the large sums of money which concerned parents have spent for such treatments in the hope that the conditions of their child with Down syndrome would be bettered, there is no evidence that any such benefit has been produced.

Despite all this, an estimated 5,000 children with Down syndrome have been placed on one of these supplements. The number still taking them is unknown, but interest in these treatments remains high. Told that the nutritional therapies can’t hurt and might help, many parents decide that the therapies are “worth a try.” Also, with so much research in Down syndrome focusing on prenatal testing or presenile dementia, many parents feel abandoned by the medical establishment. For these parents, the supplement promoters seem to be the only ones interested in “ending the implications of Down syndrome.” as one newsletter puts it.

No matter how alluring the theories are, or how convincing the anecdotal evidence may seem, it’s important to remember that these theories have not been proven, past experience with similar claims have been proven unhelpful, and the currently promoted formulas have not been scientifically proven safe or effective.

Dr. Leshin is a pediatrician in Corpus Christi, Texas. He is a member of the Down Syndrome Medical Interest Group and is the father of a young boy with Down syndrome. His Web site <http://www.davlin.net/users/lleshin> deals with medical matters relevant to this condition.

[continued from page 25]

manex, Inc., of Simi Valley, California, which extracts the main ingredient from red-yeast-rice powder imported from China. The FDA believes that Cholestin is not a dietary supplement because lovastatin was not "marketed as a dietary supplement or food" before the agency approved Mevacor as a drug. However, a federal court judge has ruled otherwise and issued a temporary restraining order preventing the FDA from stopping the importation of red yeast rice.

BREATHASURE CLAIMS ATTACKED

The Warner-Lambert Company, which manufactures Certs breath mints, Clorets mints and gum, Dentyne gum, and Listerine antiseptic mouthwash, is suing in federal court to stop Breathasure Inc., of Calabasas, California, from continuing to claim or imply that its "internal breath freshener products," Breathasure and Breathasure-D, get rid of bad breath for hours and give users clean, fresh breath, even after they consume onions, garlic, or other foods containing aromatic substances. Claims of this type have been made on product labels; in radio, television, and magazine ads; and on the Internet at <http://www.breathasure.com>. Since 1994, the Council of Better Business Bureau's National Advertising Division has investigated twice and concluded that such claims were unsubstantiated. The active ingredients in Breathasure are said to be parsley seed and sunflower oils. Breathasure-D, also said to aid digestion, contains these ingredients plus ginger, chamomile, and "true licorice." Warner-Lambert's suit charges that "taking Breathasure capsules with water is no more effective in fighting bad breath than drinking water alone."

MAJOR ST. JOHN'S WORT STUDY FUNDED

St. John's wort (*Hypericum perforatum*) is widely claimed to be effective as an antidepressant. The mechanism of action is unknown; and the active ingredient, if any, has not been ascertained. Extracts standardized for hypericin (one of the

herb's constituents) have been found to be about twice as effective as a placebo. A few studies have found hypericin somewhat more effective than a standard antidepressive drug. However, none of these studies lasted more than six weeks, which is not long enough to determine how long the herb would be effective or to detect any long-term adverse effects (*British Medical Journal* 313:253-258, 1996). In addition, some of the studies were not well designed (*BMJ* 313:241-242, 1996). The NIH Office of Alternative Medicine has funded a three-year, \$4.3-million clinical trial to compare the effects of hypericum, a placebo, and a standard antidepressant on patients who are followed for up to six months.

PROPOSED ORGANIC RULES CHANGED

On May 8, Agriculture Department Secretary Dan Glickman announced that the USDA will revise its proposed national organic standards to eliminate provisions that would have permitted "organic food" to be fertilized by human waste or to contain irradiated or genetically engineered materials. Natural Foods Merchandiser has reported that the change was triggered by more than 200,000 protest messages from the organic industry and consumers.

CONTAMINATED GINSENG

Pharmaprint, Inc., recently notified the Food and Drug Administration of its discovery of residues of quintozone, an agricultural-crop fungicide, in a shipment of raw ginseng root. The presence of the fungicide ranged from 3 parts per million (PPM) to 12 PPM in random samples of the shipment. The raw ginseng root had been shipped from Hauser Chemical Research, Inc., in Boulder, Colorado. Hauser is one of several sources of ginseng for American supplement makers. Pharmaprint rejected the shipment of ginseng from Hauser and notified the FDA because of concern that the contamination could affect other ginseng products on the market.

HERBAL PRODUCT SETTLEMENT

The family of a student who died from an overdose of Ultimate Xphoria, an ephedrine-containing herbal product, has settled with the manufacturers of the

product for \$2.5 million. Neither company, American Supplement Technologies, Inc., nor Alternative Health Research, Inc., would comment. The student, Peter Schlendorf, was on spring break in Panama City in 1996 when he died. A month later, both Florida and New York banned the sale of the product as well as other products containing ephedrine. The FDA has issued a warning about the use of ephedrine.

FTC ACTION AGAINST SUPPLEMENT MAKER AND AD AGENCY

The maker and ad agency for two dietary supplements have agreed to settle Federal Trade Commission charges that they made false and unsubstantiated health claims. The FTC alleged that Bogdana Corporation promoted two products, Cholestaway and Flora Source, as cures or preventives for a variety of serious diseases and health conditions even though they did not have a reasonable basis for any of the claims at the time they were made. In a separate complaint, the FTC alleged that Western Direct Marketing Group, Inc., knew or should have known that the claims for the products were deceptive. The FTC settlement with these two companies contains various reporting provisions that will assist the FTC in monitoring the companies' compliance with the provisions of the agreement.

TEEN DIES AFTER TAKING 'RIPPED FUEL'

An herbal supplement called Ripped Fuel, touted to boost athletic performance, may have been involved in the death of a 15-year-old girl who collapsed at a soccer game in California. The coroner's report said that the cause of death was Bland-White-Garland syndrome, a congenital heart defect; however, the supplement may have aggravated the girl's heart condition. Her heart condition was discovered by medical examiners from Boston where a 23-year-old athlete suffered fatal heart damage linked to Ripped Fuel in 1996. Ripped Fuel contains ma huang, a form of ephedrine, and is available in supermarkets and health-food stores. Twinlab, the company that produces Ripped Fuel, maintains that their product was not a factor in the girl's death. **NF**

determine whether choline is essential in the human diet, the report advises that this question be given high research priority.

Upper Limits

The committee set the tolerable upper intake level for vitamin B₆ at 100 milligrams per day for adults. Intakes above this amount could cause sensory neuropathy, a nerve disorder that can lead to pain, numbness, and weakness in the limbs. Likewise, adults with vitamin B₁₂ deficiency who take excess folic acid place themselves at greater risk of progressive, crippling neurologic damage. For folic acid, the committee set the tolerable upper intake level for adults at 1,000 micrograms (1 milligram) per day.

Individuals who consume too much niacin have been shown to feel a flush, warm sensation, itching, and other symptoms. The committee set the tolerable upper intake level for niacin at 35 milligrams per day. Some individuals who take high-dose, over-the-counter niacin supplements may exceed this amount regularly.

The report lists an Adequate Intake level for choline, which is a departure from the previously issued Recommended Dietary Allowances. However, choline has not been established as an essential nutrient for humans, and the American diet contains enough that deficiency has not been reported outside of unusual experimental conditions.

Because the committee was unable to identify studies conducted on the adverse effects of taking large doses of the other B-vitamins, it did not set upper limits for thiamin, riboflavin, vitamin B₁₂, pantothenic acid, and biotin.

For Further Information

The full report—*Dietary Reference Intakes for Thiamin, Riboflavin, Niacin, Vitamin B₆, Folate, Vitamin B₁₂, Pantothenic Acid, Biotin, and Choline*—will soon be available in both hardcover (\$34.95) and softcover (\$24.95) versions. It can be purchased by calling (800) 624-6242; sending payment to the National Academy Press, 201 Constitution Ave, NW, Washington, DC 20418; or ordering at a discount online (<http://www.nap.edu>). The full text can also be read online, although the process is cumbersome. **NF**

Book Reviews

Analysis and Ratings

NF reviews rate each book as either RECOMMENDED, NOT RECOMMENDED, or RECOMMENDED WITH RESERVATIONS, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Sugar Busters ... Busted!

Beth Fontenot

Sugar Busters! Cut Sugar to Trim Fat by H. Leighton Steward, Morrison C. Bethea, MD, Sam S. Andrews, MD, and Luis A. Balfart, MD (New York: Ballantine Books, 1998), 268 pp., \$22.00, ISBN 0-345-42558-8, hardcover.

Three physicians and a business executive have come up with the newest version of the “carbohydrates-are-bad-for-you” diet and have written a book that is selling like hotcakes (oops . . . those aren’t allowed on the diet). The main idea behind this so-called Sugar Busters diet is that sugar is “toxic” and that certain foods like bread, rice, potatoes, and bananas are bad for you because they have a high glycemic index. The glycemic index is a way of classifying foods based on how much they raise your blood sugar when you eat them. When your blood sugar rises, the body produces insulin, a hormone that lowers blood sugar. The creators of this diet claim that insulin is the “bad guy” because when you eat from their list of forbidden foods (foods with a high glycemic index), insulin will cause sugar to be stored as fat.

While there may be a grain of truth to the authors’ theory, they have exaggerated it, insisting in effect that eating a baked potato is like eating a potato skin filled with sugar. Yes, carbohydrates are broken down to sugar by the body. Yes, insulin does promote fat storage, but only when more carbohydrate is eaten than the body can use. The authors slam foods such as bananas, raisins, carrots, beets, corn, and

any food made with refined sugar or flour, and they okay eating foods like butter, bacon, eggs, and sausage. They say that fruit eaten in combination with other foods is harmful because it overstimulates insulin secretion, which, they say, will make you fat.

The truth is that weight gain occurs when foods are eaten in excess and not because of eating “wrong” foods, “bad” foods, or wrong combinations of food. Carbohydrates can be stored as fat, but only if they are eaten in excess. Anything you eat in excess of what your body needs is stored as fat. Carbohydrates are no more fattening than any other foods. In fact, excess carbohydrate in the diet is less efficient at producing body fat than excess fat in the diet.

Insulin is not a “bad guy.” It is needed to move sugar from your bloodstream into the cells of your body where it is used to fuel all of your activities. As for losing weight, what matters is calories—not carbohydrates and insulin.

You’ll probably lose a few pounds if you follow the Sugar Busters diet. But what you are losing is body water or muscle mass from depriving yourself of carbohydrates. When you restrict your intake of carbohydrates, your body loses its stored sugar (glycogen) along with the water in the stores. This causes a rapid weight loss when you first begin the diet. If carbohydrates are restricted too severely, your body makes another fuel source for itself—ketones. The excretion of excess ketones also causes water loss. In addition, if adequate sugar is not available to your body, your muscle mass is broken down to get to amino acids that can be converted to sugar. This again results in the loss of water stored in body proteins and of muscle mass.

The Sugar Busters diet ridicules established eating guidelines promoted by the American Dietetic Association, the American Heart Association, and other health organizations. An analysis of the suggested meal plan in the book using usual portion sizes shows that anywhere from 40 to 50% of the calories come from fat, and much of that is saturated fat. This exceeds the AHA’s recommendation that less than 30% of calories should come from fat with very limited amounts of saturated fat. The authors’ suggestion to limit certain grain foods, fruits, and veg-

etables contradicts the guidelines of the USDA's Food Guide Pyramid.

A joint report issued last year by the Food and Agriculture Organization (FAO) and the World Health Organization (WHO) emphasized the importance of carbohydrates in the diet and stated that a high intake of carbohydrates can reduce the risk of obesity and protect against other nutrition-related diseases. The report also declared that there is no evidence that sugars and starches promote obesity.

In short, the book is filled with inaccurate nutrition information, and the authors' claims (and success stories) are not supported by scientific data. The whole idea of the glycemic index is controversial at best. The Sugar Busters diet is nothing new. It's just a recycled version of the same old low-carbohydrate diet that's been around for years. If it really worked, would it have to be repackaged, renamed, and resold every few years?

Primitive Nutrition

Becky Chase

Traditional Foods Are Your Best Medicine: Improving Health and Longevity with Native Nutrition by Ronald F. Schmid, ND (Rochester, Vermont: Healing Arts Press, 1997), 270 pp., \$14.95, ISBN 0-89281-735-6, softcover.

Using anthropological data and some biological speculation, Ronald Schmid hopes to convince the reader that our biology requires us to eat a natural-foods diet similar to that of ancient cultures. By eating these "traditional" foods, he says, we can avoid arthritis, cancer, heart disease, allergies, and even headaches.

Our genetic structure has not changed significantly over the last 10,000 years, yet Schmid contends that the introduction of refined foods and an imbalance of animal-to-plant foods in the last century have changed our bodies. Schmid tells us that in addition to causing degenerative diseases previously seldom seen, the modern diet has lengthened the gastrointestinal tract, causing problems with meat digestion. The diet has created changes in the formation of the dental arch and the skull that are responsible for

dental problems and mental illness. It is even supposed to be responsible for genetic diseases like Down syndrome.

Much of the "evidence" presented comes from work performed earlier in this century by Weston Price, a dentist, and Francis M. Pottenger, a physician. Though the chapters on native diets are interesting and Schmid raises valid concerns with the modern diet, he fails at making a clear and valid argument. The core assertion—that the modern diet has changed our biology—is simply speculation backed only by suggestive or inconclusive evidence.

The types of foods available to us today obviously differ from those available centuries ago. Schmid's answer to that problem is to eat a natural-foods diet similar to modern-day hunter-gatherers that still exist in isolated pockets around the world. According to Schmid, that diet should consist primarily of two food groups, animal foods and vegetables. Animal foods should be from naturally raised animals and include meat, organ meats, and seafood eaten lightly cooked or raw. Also, raw dairy products, such as milk, cheese, yogurt, and a little butter, can be included. Vegetables should be eaten mostly raw, especially raw greens, along with other lightly cooked vegetables. But this particular mix of food groups in the suggested proportions conflicts with the recommendations of the Food Guide Pyramid. And there is no solid scientific evi-

dence that eating organic foods is more healthful than eating regular foods. In addition, though Schmid alludes to food-safety concerns, he gives only a cursory look at the issue of eating raw animal foods.

While the importance of omega-3 fats is covered thoroughly and accurately, other issues important to the author's argument are glossed over, such as specifics about the low nutrient density of refined foods. Many statements are simply wrong or unsubstantiated by references in the bibliography. For example, he claims that lamb fat is rich in EPA. According to nutrient analysis data, EPA appears in only small quantities in lamb, compared to fish, and only in the organ meats. He suggests the use of cod-liver oil as a reasonable alternative to eating fish, but then raises safety concerns without adequately addressing them. This curious mix of accurate and erroneous nutrition information, contradictions, and unsubstantiated assertions will leave the astute reader confused about specific recommendations.

The nutritional advice given in this book would be expensive and difficult for most people to follow. There are few practical guidelines that address implementation of the ideas or that demonstrate how to ensure nutritional adequacy and balance. **NF**

**RAW MILK AND DISEASE
OUTBREAKS**

In a report published in the August 1998 issue of the *American Journal of Public Health*, surveillance data on raw milk-associated disease outbreaks in the U.S. from 1973 through 1992 were reviewed. In early 1995, when the data were collected, 28 states permitted intrastate sale of raw milk. In all of these states, the volume of raw milk sold represented less than 1% of the total of all pasteurized and unpasteurized milk sold. There were 46 reported outbreaks involving 1,733 cases that were reported in 21 states. Forty of the outbreaks (87%) occurred in states where intrastate sale of raw milk was legal. For more than half the cases and outbreaks, *Campylobacter* was the pathogen implicated. The number of reported outbreaks per 10 million person-years was 0.14 in states where intrastate sale of raw milk was legal and 0.03 in states where intrastate sale was illegal. (*Am J Public Health* 88:1219-1221, 1998)

GARLIC FAILURE

A recent report (*JAMA* 279:1900-1902, 1998) examined the effect of garlic therapy on serum cholesterol levels. In a double-blind, placebo-controlled study of 25 patients with moderately high cholesterol, some patients received garlic oil and some received a placebo. Later in the study, all of the patients received the placebo for a period of time and then all were given the garlic oil for another period. The results of the study showed that the garlic oil preparations had no influence on cholesterol levels.

**FDA RECALLS
HERBAL SEDATIVE**

Sleeping Buddha, a dietary supplement promoted as a treatment for insomnia and restlessness, has been recalled after the FDA determined that the product contained a prescription-strength sedative not listed on the label. The ingredient, estazolam, can have serious side ef-

Pyruvate: Just the Facts

Why there's less than meets the eye

by Joseph P. Cannon

Every year a new batch of weight-loss products is touted to melt off excess pounds and increase muscle mass with minimal effort. This year is no different. One thing that's new, however, is that one new weight-loss product actually has scientific studies published in reputable journals that are alleged to back up its claims. The product is called pyruvate.

As promoted in health-food stores and in radio commercials, scientific evidence is supposed to show that pyruvate can:

- Enhance weight loss by 37% over dieting alone
- Enhance fat loss by 48% over dieting alone
- Decrease appetite
- Increase muscle endurance
- Inhibit the regaining of fat once dieting stops
- Increase metabolism

Pyruvate (also known as pyruvic acid) is a three-carbon compound generated as the end product of glycolysis, one of the body's energy-generating pathways. During the early 1980s, research showed that pyruvate could prevent fatty buildup in rat livers from chronic alcohol use. It was probably these studies that inspired University of Pittsburgh researcher Ronald Stanko to investigate whether pyruvate might also work as a weight-loss product. To date, Stanko is responsi-

ble for practically all of the studies on pyruvate and also holds the U.S. patent on "Pyruvate +," a form of pyruvate sold through Med Pro Industries.

The vast majority of studies done on pyruvate have in reality been mixtures of pyruvate and dihydroxyacetone, another three-carbon metabolite formed during glycolysis. Dihydroxyacetone is also found in over-the-counter pyruvate formulations but is rarely mentioned on the labels.

*To date,
Stanko is
responsible
for practically
all of the
studies on
pyruvate and
also holds the
U.S. patent on
"Pyruvate +."*

**Science and
Wishful Thinking**

How well, though, does scientific research support the claims made for pyruvate?

Claim #1: Enhances weight loss. There are few studies on pyruvate and its effects on weight loss. Those that have been done suggest that pyruvate works under laboratory conditions, but its effect is not very impressive. In one study, for example, obese women (defined as weighing over 200 pounds) added 30 grams of pyruvate to a 1000-calorie/day liquid diet for 21 days. This resulted in 37% more weight loss and 48% more fat loss compared to control subjects who were on the 1000-calorie/day diet only (*American Journal of Clinical Nutrition* 56:630-635, 1992).

These figures seem impressive until

one looks at the actual pounds of weight and fat lost. Specifically, the 37% enhancement in weight loss amounts to an average of only 3.5 pounds difference between the group taking the pyruvate and the one not taking it. With respect to the 48% increase in fat loss, this too is misleading because only 3.2 pounds more fat were lost in those consuming pyruvate.

In a second study, obese women were placed on a 500-calorie/day diet for 21 days, with some of the women supplementing with 16 grams of pyruvate and 12 grams of dihydroxyacetone (*American Journal of Clinical Nutrition* 55:771-776, 1992). Again, women supplementing with pyruvate did lose significantly more fat and weight than those not supplementing, but those using pyruvate lost an average of only 1.98 pounds more weight and 1.76 pounds more fat. It's important to note that these weight-loss studies took place under controlled laboratory conditions. No published peer-reviewed study to date has ever been conducted in real-life situations where calorie intake is not strictly controlled.

Claim #2: Decreases appetite. This claim is based on only one study—a study that was performed not on humans but on laboratory rats. In this investigation, laboratory rats were allowed to eat as much food as they wanted. At the end of the study, researchers found that the rats that received pyruvate and dihydroxyacetone consumed less food than rats not receiving the supplements (*Journal of Clinical Nutrition* 53:847-853, 1991). To date, however, such a study has never been performed on humans.

Claim #3: Increases muscle endurance. There is only one published peer-reviewed study suggesting that pyruvate can increase muscle endurance—and the only published study done on men (*Journal of Applied Physiology* 68[1]: 119-124, 1990). This is the study that is most quoted to people interested in increasing their exercise ability. The study showed that a mixture of 25 grams of pyruvate and 75 grams of dihydroxyace-

tone taken for 7 days increased triceps endurance by 20%.

Of course, until other studies are done, this study should be considered preliminary. What's more, this study did not look at traditional aerobic conditioning like jogging or bicycling but rather at how long the triceps muscle (on the back of the upper arm) took to totally exhaust itself. Muscles other than the triceps as well as those undergoing different types of exercise might react differently, so it's unknown how these results might translate over to exercising individuals. This problem is even mentioned in the study in light of the fact that one of the participants had a reduced triceps endurance capacity following ingestion of pyruvate. Therefore, individuals looking to pyruvate to enhance their exercise ability should save their money until more research is conducted in this area.

Claim #4: Inhibiting the regaining of fat once dieting stops. Everybody knows that when one stops dieting and goes back to old eating habits, that weight slowly creeps back. Anything that could slow this process would certainly appeal to dieters who fall off the wagon. But the claim that pyruvate can suppress appetite is based on only one published peer-reviewed study (*International Journal of Obesity* 20:925-930, 1996).

In this investigation, obese women (average weight 228 pounds) went on a 310-calorie/day diet for 21 days. Following this, they then went on a three-day high-calorie diet to purposely regain the weight. Some women used a mixture of 15 grams of pyruvate and 75 grams of dihydroxyacetone during the dieting process. After the study, it was found that those women who didn't receive any pyruvate regained an average of 6.38 pounds of weight, while women who used pyruvate regained an average of 3.96 pounds of weight. This amounts to only a 2.42-pound difference between the groups. With respect to the regaining of fat, women not using pyruvate regained

There is only one published peer-reviewed study suggesting that pyruvate can increase muscle endurance.

Juicing for Fun and Profit

Taking a good thing too far

by Therese Walsh

They say you can't have too much of a good thing, but as many marketers are proving, you can make too much out of a good thing—if that thing is juicing. Juicing is the consumption of juices from raw fruits and vegetables. Ever since Jay "The Juiceman" Kordich started promoting juicing years ago on television, it has become a trendy alternative to eating the real McCoy. And while juicing itself isn't inherently bad, the claims being made by advocates and companies selling juice extractors are often misleading at best and dangerous at worst.

Overselling Juice

Kordich himself claims that juices contain active enzymes that, by breaking food down in the digestive system, spare our bodies' own enzymes from having to put forth the effort. But the fact is, orally ingested enzymes will not significantly aid digestion and have no enzymatic activity in the human body.

Kordich's worst offense, however, comes from promoting the idea—without evidence—that juice by itself may be able to cure medical conditions including heart disease, impotence, and anxiety. The danger is that some naïve people will believe his claims and forego or abandon proven medical treatments to rely instead on an almost exclusively juice diet.

Naturopath Michael T. Murray, ND, makes unsubstantiated claims that specific juices can combat cancer, arthritis, kidney stones, and aging. In his book *The Complete Book of Juicing*, Murray recommends a true juice fast, just as a few other proponents of juicing do. Nutrition experts, however, point out that although brief fasts may not be harmful, depriving

the body of a well-balanced diet on a long-term basis can be very risky.

'Dried Juice'

Even more dubious are the many claims made for dried-juice products. Touted as the effortless way to meet the recommended quota of fruits and vegetables per day (because popping a pill is easier than peeling a banana), these products raise a host of critical questions. The most basic question is: Are there good scientific studies that back up any of the claims? But also:

Has research shown that the nutrient content of whole fruits and vegetables is fully maintained through processing? Are there side effects? Unfortunately, there appears to be *no solid research to answer these questions.*

One company, Juice Plus, has published a study in the *Journal of the American Nutritional Association*, but this rare piece of research is fatally flawed. This study looked at the effect of Juice Plus products or placebo on the body composition of 96 subjects.

The study authors hypothesized that subjects in the experimental group (who were fed two fruit and two vegetable capsules before meals, along with an undefined amount of "nutritionally enhanced protein drink mix" and two fiber chromium-laced wafers) would, by trial's end, have less fat mass and more lean muscle mass than their control group (who were given placebo capsules at unidentified times during the study).

The researchers report that this is exactly what happened. But there are other possible explanations for these results. It

[continued on page 38]

Kordich's worst offense comes from promoting the idea—without evidence—that juice by itself may be able to cure medical conditions.

WEB WATCH

This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc. (<http://www.quackwatch.com>), which is working hard to improve the quality of health information on the Web.

BEST

The Agricultural Research Service's Nutrient Data Laboratory <http://www.nal.usda.gov/tnic/foodcomp/Data/index.html> offers information on 6,000 foods in 22 food categories. Food composition data can be accessed by searching for individual foods or downloading by category.

The American Council on Science and Health <http://www.acsh.org> maintains a large site, full of excellent reports that can be purchased by mail or downloaded for reading with Adobe Acrobat.

WORST

The Acumin Corporation <http://www.acumins.com> offers a Personal Nutrition Program based on responses to online questionnaires for men and women. The "personal formulas" cost a minimum of \$39.95/month plus shipping. Above-RDA amounts of many nutrients are recommended regardless of the answers selected. Men who merely check "Yes" for "Are you concerned about heart disease or have your parents or siblings had heart disease?" raise the recommended levels of 11 vitamins at an additional cost of \$10 per month. The company offers hair analysis "to help you determine how well your body is absorbing the nutrients in your vitamins." Acumin is also seeking "Partners" to market from their own Web site and receive referral fees when visitors place orders.

RenewLife <http://www.renewlife.com> markets "intestinal cleansing" products to treat "leaky gut syndrome," an alleged condition in which the digestive tract is "overcome with parasites, Candida, and toxins." Product information and a free half-hour audiotape can be ordered by e-mail, or the tape can be audited online using RealPlayer software.

REPORTING HEALTH FRAUD

See a health claim on the Internet that looks a little suspicious? Fraudulent or dubious health products found on the Internet can be reported to the Food and Drug Administration by e-mail at otcfraud@cder.fda.gov or by calling 1-301-594-0070.

[continued from page 34]

an average of 3.96 pounds of fat while those using the pyruvate regained an average of 1.76 pounds of fat. Again, this amounts to only a 2.2-pound difference between them.

Claim #5: Increases metabolism. Much hype surrounds the claim that pyruvate can increase one's metabolism and therefore help one lose weight. Unfortunately there is no solid evidence to support this claim. Earlier studies in rats did show that pyruvate increased resting metabolism (the number of calories used at rest), but these results have never been confirmed in human studies. In fact, in the most recently published pyruvate study, the group of people who did *not* receive pyruvate had a higher resting metabolism at the end of the study than those who did receive the pyruvate. Therefore, the idea that pyruvate enhances human metabolism remains speculative at best.

With respect to side effects, the literature to date seems to show that pyruvate is relatively safe with the most noticeable problems being occasional diarrhea, loose or softened stools, and a rumbling sound in the gut which is caused by gas passing through the intestines. At the present time, nobody is sure of the physiological mechanism of action of the pyruvate/dihydroxyacetone mixture and how it relates to weight loss or any other reported claim.

All of the published peer-reviewed studies done to date except one have been either conducted on obese women on very restrictive diets or on laboratory rats. Therefore, results obtained from these populations may not indicate what would be gained from humans under more real-life situations where food intake is not strictly controlled. Also, the subjects in the studies consumed very large amounts of pyruvate and dihydroxyacetone, far in excess of the dose of 3 to 5 grams per day recommended in over-the-counter products. To date, no published peer-reviewed research exists showing that the 3- to 5-gram dose will produce the same effects as the higher dosages used in the studies.

Popular Hype

One prominent false claim that one is likely to encounter is "pyruvate is backed up by

25 years of extensive scientific research" (J. B. Roufs, *Muscle and Fitness*, December 1996). While it's true that research on pyruvate does appear in prestigious scientific journals, the fact is that there were no studies on pyruvate and weight loss published before 1986 or after 1996. That's only 10 years, not 25. Furthermore, if one were to look just at the human studies using pyruvate, then this number is even further reduced to only six years.

Some people selling pyruvate give out free audiotapes that boast of pyruvate's supposed amazing abilities. In one of these tapes, the person selling pyruvate (who is identified as a physician) states that when you are using pyruvate, "You are in the fat-burning mode—even when you are not exercising." This is very interesting because when you are resting, you are already in the "fat-burning mode." At rest, approximately 70% of the calories you derive energy from are coming from fat with the remaining 30% coming from carbohydrates (sugars).

Some people claim that pyruvate is an antioxidant. As is mentioned in a recent review of pyruvate in *Medicine and Science in Sport and Exercise* (30: 837-843, 1998), some evidence hints that pyruvate might act as an antioxidant. But only three studies show that pyruvate acts

as an antioxidant—and these studies were conducted not on humans but on rodent hearts. More research is necessary to determine the efficacy of pyruvate's antioxidant action in humans.

Claims that pyruvate aids in cardiac function are prevalent. But there is absolutely no published peer-reviewed evidence that either pyruvate or dihydroxyacetone aids the heart in pumping blood more effectively. In fact, those studies that did record pyruvate's effect on heart functions found no change after use. Therefore, if you have any cardiac abnormalities, pyruvate is not the answer to your problems. You are best served by following medical advice.

Pyruvate is also supposed to build muscle. There is no published peer-reviewed scientific evidence showing that pyruvate can build muscle tissue. In the only study of exercise and pyruvate ever conducted, no mention was made regarding pyruvate having any effect on muscular strength or hypertrophy. This claim seems to be specifically targeting those individuals interested in weight lifting and bodybuilding. **NF**

Joesph P. Cannon is an exercise physiologist and an NSCA-certified personal trainer.

Finally. Science meets alternative medicine.

The Scientific Review of Alternative Medicine (SRAM) is the only peer-reviewed medical journal dedicated exclusively to carefully assessing the claims, treatments, and hypotheses of unconventional medicine.

[continued from page 33]

fects, including the possibility of fetal damage if pregnant women take the supplement. In addition, it poses a risk to those who drive, operate heavy machinery, or take other sedative drugs or drink alcohol in addition to the supplement.

BRITISH BATTLE OVER B₆ DOSAGE

British nutrition authorities recommend daily intakes of pyridoxine (vitamin B₆) of 1.2 mg for adult women and 1.4 mg for adult men, amounts easily obtainable from food. In July 1997, the United Kingdom Ministry of Agriculture, Fisheries, and Food (MAFF) announced its intention to restrict sales of dietary supplements containing more than 10 mg of B₆. Higher-level products would continue to be available—through pharmacies (10–49 mg per day) or by prescription (50 mg or more)—but should carry a warning label.

According to Health Foods Business, all 13,000 U.K. pharmacies responded to the proposal by withdrawing such products, supermarkets followed suit, but health-food stores continue to sell them. MAFF states that its proposal was based on animal studies plus reports of nerve toxicity in humans taking as little as 50 mg per day over periods of months or years.

Opponents claim that the report was based on a single 1987 study that was seriously flawed. British and American manufacturers and trade groups have banded together to oppose the restrictions, which they fear could be followed by other European countries and be expanded to cover other nutrients. GNC and NTBY (Nature's Bounty) each contributed \$150,000 to British Consumers for Health Choice, a "consumer advocacy group" fighting the restrictions. In June 1998, a British parliamentary select committee recommended a voluntary limit of 100 mg. The controversy can be followed by searching for "pyridoxine" on MAFF's Web site (<http://www.maff.gov.uk>).

WEIGHT-LOSS DEVICE IS HOT

A Miami-based company, TV Store Corp./Body Fitness, Inc., is conducting a voluntary recall of a weight-loss product. The product, which is sold under the name "Moulding Body Electrical Body Belts" or "Personal Electro-Sauna," resembles a heating pad and can be wrapped around the waist, thighs, or arms. It has caused skin burns and fires. The FDA has alerted consumers to the recall and states that they are actively monitoring the situation.

MOST POPULAR SUPPLEMENTS

NBTY, Inc., a vitamin, mineral, and nutritional supplement manufacturer in Bohemia, NY, has released its consumer-tracking report of the ten most popular supplements in the United States. The report was compiled from data supplied by NTBY's retail chain, Vitamin World, Puritan's Pride catalogues, and Nature's Bounty products. The top nutritional supplements purchased by Americans are: (1) vitamin E, (2) vitamin C with rose hips, (3) St. John's wort, (4) calcium/magnesium, (5) echinacea, (6) ultra lecithin, (7) zinc, (8) E complex, (9) ginkgo biloba, and (10) cranberry caps.

SUPPLEMENT/HERB USE INCREASING

Hartman & New Hope, the market research division of New Hope Communications (publisher of the trade magazine *Natural Foods Merchandiser*), has asked 43,000 heads of American households about their use of vitamin, mineral, and herbal products. Its December 1997 survey found that 68% reported using at least one such product within the previous six months and that 31% of users took seven or more supplements regularly, averaging more than 12 per household. The magazine's June 1998 issue pegs 1997 natural-food-store sales at \$3.34 billion for vitamins and supplements, \$1.45 billion for bulk herbs and herbal products, and \$781 million for ayurvedic and homeopathic products.

VIAGRA IMITATOR STOPPED

On April 24, Missouri Attorney General Jay Nixon obtained a temporary restraining order (TRO) against the American Urological Clinic, a direct-mail marketer of an impotence treatment called Vaegra (VAY-gra), a name similar to the well-publicized new prescription drug for impotence. The company's solicitations included a *Newsweek* article on Viagra's success without making it clear that its product was not Viagra. A 75-day supply cost \$83.95. The company's brochure had stated that Vaegra was developed after years of scientific research at the clinic. However, the facility was nothing more than a Mailboxes, Etc. dropbox in Kansas City. The Missouri TRO prevents the American Urological Clinic from advertising, marketing, or selling its products in Missouri or from retrieving mail sent to its Kansas City dropbox. A few days earlier, Pfizer Inc., which makes Viagra, obtained a federal TRO against the clinic.

NUTRITION LITERATURE GUIDE

The *Good Nutrition Reading List*, published annually by the American Dietetic Association, is a consumer guide to books and newsletters that provide scientifically sound information. To obtain a copy, send \$3.50 and a self-addressed stamped 4 x 9 envelope to ADAF-GNRL, P.O. Box 77-6034, Chicago, IL 60678-6034.

UNFOUNDED HEALTH SCARES

The American Council on Science and Health has revised and expanded its excellent booklet *Facts Versus Fears: A Review of the Greatest Unfounded Health Scares of Recent Times*. The 52-page report includes scares related to cranberries, DDT, cyclamates, DES in beef, nitrites, saccharin, hair dyes, Love Canal, asbestos in hair dryers, coffee, EDB, Alar, Perrier water, dental amalgam, cellular phones, community water fluoridation, food irradiation, and bovine somatotropin (BST). Copies are \$5 each from ACSH, 1995 Broadway, 2nd Floor, New York, NY 10023.

[continued on page 38]

[continued from page 37]

CHOLESTAWAY ADS ATTACKED

Bogdana Corporation, a Beverly Hills, California, company, and its officers have agreed to settle FTC charges that they made false and unsubstantiated health claims for Cholestaway and Flora Source. Cholestaway, a chewable tablet or wafer made of calcium carbonate and other ingredients, was claimed to lower serum cholesterol and blood pressure and cause weight loss. Flora Source, a powdered combination of bacteria in a base of rice starch, was advertised for treating or preventing AIDS, chronic fatigue syndrome, and other serious illnesses and health problems by replacing "natural" intestinal flora and boosting the body's immune system. The FTC also charged that the advertising agency that had created television infomercials for Cholestaway knew or should have known that the claims for it were deceptive. The settlements prohibit Bogdana and the agency from making efficacy, performance, or safety claims for any food, drug, or dietary supplement unless they have competent and reliable scientific evidence to back the claims.

GENETIC ENGINEERING ATTACKED

A coalition of scientists, religious leaders, and consumers is suing the FDA to obtain mandatory safety testing and labeling of all genetically engineered foods. The suit alleges that current FDA policy, which permits at least 36 such foods to be marketed, violates the agency's legal mandate to protect public health and provide consumers with relevant information about the foods they eat. It also charges that the policy violates religious freedom. The suit was organized by the Alliance for Bio-Integrity of Iowa City, Iowa, and the Washington, DC-based International Center for Technology Assessment, nonprofit groups "dedicated to the protection of human health and the environment through sustainable and safe technologies." The FDA does not require safety testing because it regards genetically engineered foods to be as safe as their natural counterparts. **NF**

[continued from page 35]

is little wonder that the experimental group lost fat mass—the researchers filled the experimental group up with protein drinks and fiber wafers before their meals! And the extra attention bestowed upon that group could have made them more aware of not only their diet, but their exercise habits. Any increase in exercise in this group could easily have resulted in increased lean muscle mass. The researchers apparently did not control for such a possibility.

In addition, the study's design makes it impossible to attribute the results to any experimental component. What do the researchers wish us to believe is the key here? The mystery nutritional drink mix, the Juice Plus capsules, or the chromium-laced wafers? The manufacturers of Juice Plus capsules, who coincidentally also manufacture the wafers and the drink mix—and who funded the study—would likely have us purchase all of the above.

Juice Plus has also paid a journal called the *American Medical Review* to publish results of their so-called bioavailability studies. But this research too is seriously flawed.

Juice Plus capsules and many other dehydrated juice capsule products, including those from AIM and Juice For Life, are promoted as having enzymes that aid in digestion. These claims are just as false for juice capsules as for whole juice. Even the claim that juice capsules contain much the same nutritional value as the actual juice is unsubstantiated. It is odd that few, if any, labels for juice capsules list the amount of vitamins, minerals, and fiber that the capsules are supposed to contain.

Noni Juice

Recently, multilevel marketers have been promoting a juice product called Noni. Noni juice comes from the plant *Morinda citrifolia*, a tropical variety found in Polynesia. Used for hundreds of years by native folk, the juice is said to have special healing powers.

There has been some research conducted with Noni, which shows that it contains a volatile oil that is biologically active. The research, however, has yet to

identify how Noni affects the physiology of living things. Laboratory research with mice has shown that Noni can inhibit the growth of cancer cells. Although this may be an interesting preliminary finding, it is a long way from proven usefulness in treating or preventing human cancer. We don't know how Noni inhibits cancer cells, whether it is toxic to normal human cells in much the same way that chemotherapeutic agents are, or what other effects it may have. Many substances that have looked promising in animal studies have proved a bitter disappointment in human research.

Ralph Heinicke, a researcher at the University of Hawaii, claims to have identified the active substance in Noni. He claims this substance, proxeronine—a precursor to the alkaloid xeronine—is responsible for increased cellular function and improved uptake of vitamins and minerals. Although his findings are preliminary at best, Heinicke has been recommending Noni for a variety of ills, including high blood pressure, depression, and arthritis. Multilevel marketing companies have latched onto Heinicke's claims, citing him whenever they tout their Noni.

Morinda Corporation has, until recently, been the sole seller of Noni juice, but now Nature's Rx, Inc., is selling Noni juice capsules. Both these companies have made unsubstantiated claims regarding Noni's effectiveness in the treatment of infections, asthma, and diabetes—conditions that should be dealt with by a medical professional. Nature's Rx, Inc., even claims that Noni—containing an essentially untested, biologically active, volatile oil—is indicated for pregnancy and childbirth. **NF**

Cranberry Juice and UTIs

Maybe Grandma was right

by Beth Fontenot, MS, RD

Generations of women have regarded drinking cranberry juice as a simple preventive or treatment for urinary tract infections (UTIs). Is this just another dubious folk remedy, or has science shown that this bit of medical folklore has some merit?

Cranberry Science

About 75 years ago scientists determined that eating large amounts of cranberries could cause urine to become more acid. They speculated that this could prevent or treat recurrent UTIs since bacteria favor an alkaline medium for growth. Subsequently, commercial cranberry juice cocktails became a popular "cure" for women suffering from recurrent UTIs, and anecdotal evidence seemed to support the notion. It was years later that scientists found that the increase in urine acidity after drinking cranberry juice was small and transient, but this finding did not seem to sway those who believed in the benefits of the beverage.

More recent studies have suggested that cranberry juice's alleged effectiveness against bacteria is not in its ability to acidify the urine, but in its ability to prevent bacteria from sticking to the lining of the urinary tract where they can multiply and cause infection. Two anti-adhesion factors have been isolated from cranberry juice, fructose and another polymeric compound of unknown nature. Several fruit juices have been tested, but only cranberry and blueberry juice contain the latter inhibitor.

Recently a randomized, double-blind, placebo-controlled study of 153 elderly women was undertaken to determine whether the regular consumption of cranberry juice did indeed have an effect on the incidence of UTIs (*Journal of the American Medical Association* 271:751-754, 1994). This population was chosen because the condition is particularly prevalent in older women. The research-

ers found that women given 10 ounces of cranberry juice every day for 6 months were half as likely to develop a urinary tract infection as women who consumed a placebo beverage. The study also suggested that cranberry juice reduced preexisting bacteria in the urinary tract as well as the occurrence of new bacteria, and that the effects were unrelated to the acidity of the women's urine. The researchers concluded that prevalent beliefs about the effects of cranberry juice on the urinary tract may have microbiologic justification.

The researchers concluded that prevalent beliefs about the effects of cranberry juice on the urinary tract may have microbiologic justifications.

Pop a Pill Instead?

Cranberry pills and capsules are sold in health-food stores and pharmacies. One brand is marketed as a convenient way to get the benefits of cranberry juice "without the unnecessary, and nutritionally harmful, calories." The pills are purported not only to prevent or treat UTIs, but also to treat kidney stones and act as a "urine deodorizer" for those troubled by urinary incontinence.

A Good Housekeeping Institute study of cranberry pills, however, found that they vary greatly in the amount of cranberry concentrate they contain, in the number of pills recommended per day,

and in their price. The manufacturers base their claims about the pills' effectiveness against UTIs on studies using cranberry juice. But there is no scientific evidence that cranberry pills are effective. Nor is there evidence that cranberry pills prevent kidney stones or "deodorize" the urine.

Jerry Avorn, MD, of Brigham and Women's Hospital and Harvard Medical School, was a researcher in the *JAMA* study. He doubts the effectiveness of cranberry pills or capsules. Avorn told the Good Housekeeping Institute, "We don't know if the active component in cranberries survives the extraction process, or, if it does, if it's present in an amount that would help."

The Bottom Line

So is cranberry juice effective against urinary tract infections? The answer seems to be probably. *NF* Editorial Board member Varro Tyler, PhD, a top expert on the medicinal use of plants, says that an "appropriate cranberry product" does seem to be useful in the prevention and treatment of UTIs. He thinks that consuming about 3 ounces daily of cranberry juice cocktail (which is about 33% cranberry juice) may work as a preventive, while 12 to 32 ounces daily may be useful as treatment for a UTI. He cautions, however, that cranberry juice may be a useful addition to standard antibiotic therapy *but should never be used in place of such therapy.*

More research is needed before we're certain of cranberry juice's anti-UTI effects in older women. And more studies will be necessary to determine if cranberry juice is effective at all in younger women. Another question that needs to be answered: Does cranberry juice taken along with antibiotics offer any benefit over either antibiotics or cranberry juice alone? In any case, it seems clear that for an otherwise healthy individual, drinking moderate amounts of cranberry juice can't do any harm and might even do some good. **NF**

Book Reviews

Analysis and Ratings

How accurate and useful is the nutrition information in that book? Would a reputable reviewer recommend the book to professionals and consumers? These are the two questions that Nutrition Forum book reviews are intended to answer. So the reviews not only offer analyses but also rate each book as either RECOMMENDED, NOT RECOMMENDED, or RECOMMENDED WITH RESERVATIONS, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Phytochemical Feast

Lisa Waldron Martin, MA, RD

Eat to Heal: The Phytochemical Diet and Nutrition Plan by Kristine M. Napier, MPH, RD, LD (Warner Books, 1998), 282 pp., \$5.99, ISBN 0-446-60475-5, softcover.

This information-packed book is aimed toward a general audience, but nutritionists will find much of it worthwhile. Dietitians unfamiliar with the explosion of research being done on phytochemicals will certainly feel more informed after reading this book, and others will learn enough little-known food facts to make the effort worthwhile.

The book is organized in four sections to give more than one way to access information: by specific phytochemical, by plant foods, by diseases, and by recipes. If readers are searching for information on lycopene, tomatoes, prostate cancer, or recipes containing vegetables, they merely look for those headings.

Although a general audience would find nothing lacking in this volume, health professionals may wish the author had annotated her sources rather than just describing studies and quoting researchers. The author is an experienced nutrition writer and mentions studies that are well

known or from reputable institutions. Readers, however, have to remember not to draw conclusions based on a single study.

The primary usefulness of this book to nutrition professionals lies in its reviewing of the latest findings in the field. The book also engenders a greater appreciation of the disease-preventing potential of all types of plant foods including herbs and spices, whole grains, and even fruits and vegetables formerly thought of as nutritional lightweights, such as apples and onions. The author acknowledges that although most phytochemical research is still at the laboratory stage, the results so far correlate well with epidemiological studies. Some epidemiological findings have practical implications, such as the data showing that once-a-week soybean or tofu eaters have a significantly decreased risk of rectal cancer.

Some buying, preparing, and menu ideas may be elementary to experienced cooks, but useful information and ideas are there, especially on lesser-known foods. The recipes which comprise about one-third of the book are all low fat. They are especially helpful if looking for ideas on using more uncommon plant foods.

RECOMMENDED

Real Medicine?

Manfred Kroger

Rediscovering Real Medicine by Jean Elmiger (Boston, MA: Element Books, Inc., 1998), 281 pp., \$14.95, ISBN 1-86204-199-7, softcover.

If *Nutrition Forum* were a periodical *not* devoted to mainstream science, if its contents were *not* hinged on medical majority consensus thinking and steeped in the tradition of the scientific method to arrive at the truth—then this book could be recommended as a contribution to the literature of homeopathy.

Its subtitle is "The New Horizons of Homeopathy." The author sounds so sincere, so devoted, and so superior to us all, who could dislike him? He is not unlike my uneducated grandmother, may she rest in peace, who also distrusted all of orthodox (allopathic) medicine and sought refuge and healing powers in nature, in herself, in

the mysterious. In short, in the *unproven*. She too was fearful of inoculations and the evils you might meet in a hospital.

Elmiger's contempt for his fellow medical practitioners is immense and begins after his traditional European medical studies. His search for a new way of healing and preventing disease is so bizarre and unfathomable to a rational mind, it can only be relegated to the fringes of the medical arts. Nevertheless, his literary skills (this book is a translation of the 1985 French version), his devotion to patients, his learning and powers of persuasion are genuine. And therein lies the danger for gullible, ordinary people.

The author touts the book as a "revolutionary new approach to health"—then launches into an incomprehensible self-made theory of what constitutes health and disease. Much is taken from ayurvedic, Chinese, and astrological medicines, and, of course, he is totally sold on homeopathy and ridicules all those poor souls who are not. To believe what you read in these pages, you must have ultimate faith in the supernatural, in a construct of unproven and unprovable bioenergetic phenomena, and actually step back in time into premodern views of the body and the forces within. In short, the book teaches metaphysical mysticism and requires the reader to engage in "four-dimensional reasoning." Edgar Cayce is among Elmiger's role models, as are Hahnemann and other "pioneers" who brought us live sheep-cell therapy, biological catalysis/diathesis, the use of oligo-elements, the obsession with the spinal column, blocked energy circuits, Hering's law, Voll's electro-acupuncture machine, nosodes, and other such concepts grounded in mostly wishful thinking. **NF**

to order by credit card.

**MARK MCGWIRE AS
ROLE MODEL**

Along with home runs, baseball hero Mark McGwire is delivering mixed messages. On one hand, he is involved in discouraging youths from using chewing tobacco. Since July, the Alliance of the American Dental Association has distributed thousands of posters and hundreds of thousands of trading cards containing his picture and the warning, "Don't use spit tobacco, it's poison." On the other hand, revelation of his use of "dietary supplements" said to contain androstenedione has caused sales of this product to soar. Androstenedione is a steroid hormone that can raise the body's level of testosterone. In August, a panel of baseball officials was appointed to consider whether androstenedione use should be banned, as it is in most sports, here and abroad. The Endocrine Society has warned that the purity, effectiveness for athletes, and safety of commercially marketed products are unknown.

**SUPPLEMENT CLAIMS
PROHIBITED**

The FDA has rejected the first set of health claims submitted by a dietary supplement manufacturer (Weider Nutrition International) under provisions of the FDA Modernization Act of 1997. According to Natural Foods Merchandiser, the prohibited claims were: (1) vitamin A and beta-carotene may reduce the risk in adults of atherosclerosis, coronary heart disease, certain skin cancer; (2) vitamins C and E may reduce the risk in adults of atherosclerosis, coronary heart disease, certain cancers, cataracts; (3) B-complex vitamins may reduce the risk in adults of cardiovascular disease by lowering elevated cholesterol levels; (4) chromium in adults may reduce the risk of hyperglycemia (high blood sugar) and the effects of glucose intolerance; (5) omega-3 fatty acids in adults may reduce the risk of cardiovascular disease; (6) zinc in adults may increase the body's ability to fight infection and heal wounds; (7) garlic in adults may reduce serum cholesterol and the risk of cardiovascular dis-

[continued on page 46]

Fad Diagnoses*An epidemic of nonsense in nutrition
and 'fringe' medicine*

by Stephen Barrett, MD

The *American Heritage Dictionary* defines "fad" as "a fashion that is taken up with great enthusiasm for a brief period of time; a craze." A small percentage of physicians and large percentages of chiropractors, naturopaths, and bogus "nutritionists" are labeling patients with diagnoses not recognized by the scientific community. The diagnoses are, in fact, fads—with no scientific backing at all. More than a dozen such briefly popular labels have been promoted during the past 50 years. Some refer to actual disease (which the patients do not have), whereas others are not recognized by the scientific community (see box). Some unscientific practitioners apply one or more of these labels to nearly every patient they see. In many cases, they use non-standard laboratory tests to "diagnose" them and recommend "dietary supplements" to treat them.

Years ago, many people who were tired or nervous were said to have "adrenal insufficiency." The vast majority of these people were not only misdiagnosed but were also treated with adrenal gland extract, a substance that the FDA later banned because it was too weak to treat the actual disease. "Low thyroid" (hypothyroidism) was likewise unjustifiably diagnosed in many cases of fatigue or obesity. Today's "fad" diagnoses used to explain various common symptoms are chronic fatigue syndrome, hypoglycemia, food allergies, Lyme disease, parasites, "multiple chemical sensitivity," "candidiasis hypersensitivity," "Wilson's syndrome," "leaky gut syndrome," "mercury

amalgam toxicity," and "cavitational osteopathosis." The first six of these are legitimate conditions that unscientific practitioners overdiagnose. The rest are figments of pseudoscientific imagination.

Only a small percentage of people troubled by fatigue have chronic fatigue syndrome (CFS). According to criteria developed by the U.S. Centers for Disease Control and Prevention, CFS should never be diagnosed unless fatigue persists or recurs for at least six months and is se-

NUTRITION FORUM (ISSN 1093-4545), © 1998 Prometheus Books, is published bimonthly for \$35.00 (individuals in U.S. and Canada) or \$50 (institutional, overseas) per year by Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197. Periodicals postage paid at Buffalo, NY. POSTMASTER: Send address changes to Prometheus Books at the address above. Subscription information: (800) 421-0351, (716) 691-0133; fax (716) 691-0137. Back issues \$7.00. Manuscripts and all editorial correspondence should be directed to Lewis Vaughn, *Nutrition Forum*, P.O. Box 664, Amherst, NY 14226-0664 or e-mail to fivaughn@aol.com.

were enough to reduce the patient's activity level by more than half. In addition, the fatigue should be accompanied by several other symptoms, such as severe headaches, low-grade fever, joint or muscle pain, general muscle weakness, sleep disturbance, and various psychological symptoms. *Consumer Reports* has called CFS "a magnet for quacks" and warned that "some practitioners create CFS patients by finding the syndrome in people who clearly don't have it."

Real cases of hypoglycemia exist, but they are rare and should be carefully checked by laboratory testing before the diagnosis is made. The diagnosis should be reserved for patients who get symptoms two to four hours after eating, develop blood glucose levels below 45 mg. per 100 ml whenever symptoms occur, and are immediately relieved of symptoms when blood sugar is raised. The glucose tolerance test is not reliable for evaluating most cases of suspected hypoglycemia. Low blood sugar levels without symptoms have no diagnostic significance because they occur commonly in normal individuals fed large amounts of sugar. The way to reliably diagnose hypoglycemia is to prove that blood sugar is low whenever symptoms occur during the patient's usual living pattern. The most practical way to do this is probably with a home testing device.

Doctors who overdiagnose hypothyroidism often base their diagnosis on "low" temperature readings determined by placing the thermometer under the armpit. This is not a valid test of thyroid function. Proper diagnosis requires blood tests that measure thyroid hormone levels.

MCS

The expression "multiple chemical sensitivity" (MCS) is used to describe people with multiple symptoms attributed to environmental factors. Proponents claim that when the "total load" of physical and psychological stresses exceeds what a person can tolerate, the immune system goes haywire and hypersensitivity to tiny amounts of common foods and chemicals can trig-

ger a wide range of symptoms. Doctors advocating this notion call themselves "clinical ecologists" or specialists in "environmental medicine." They recommend avoidance of foods and environmental substances to which they consider the patient hypersensitive. Extreme restrictions can involve staying at home for months or living in a trailer designed to prevent exposure to airborne pollutants and synthetic substances. In many cases, the patient's

life becomes centered around the treatment. The American Academy of Allergy, Asthma and Immunology (AAAAI), the nation's largest professional organization of allergists, has warned: "Although the idea that the environment is responsible for a multitude of health problems is very appealing, to present such ideas as facts, conclusions, or even likely mechanisms without adequate support is poor medical practice."

Clinical ecologists base their diagnoses primarily on the results of "provocation" and "neutralization" tests, in which suspected substances are administered under the tongue or injected into the skin. If any symptoms occur, the test is considered positive and lower concentrations are given until a dose is found that "neutralizes" the symptoms. Researchers at the University of California have demonstrated that these procedures are not valid. In a double-blind study, 18 patients each received 3 injections of suspected food extracts and 9 of normal saline over a 3-hour period. The tests were conducted in the offices of clinical ecologists who had been treating them. In nonblinded tests, these patients had consistently reported symptoms when exposed to food extracts and no symptoms when given injections of saline (dilute salt water). But during the experiment, they reported as many symptoms following saline injections as they did after food-extract injections, indicating that their symptoms were nothing more than placebo reactions. "Neutralizing" doses were equally effective whether they were food extracts or saline.

The diagnoses are, in fact, fads—with no scientific backing at all.

Does Garlic Lower Cholesterol?

New studies tell the tale

by **Beth Fontenot, MS, RD**

Despite the long-held belief that garlic can lower blood cholesterol levels, it turns out that this odoriferous herb may not have cholesterol-busting properties after all. There have been numerous studies published on the health benefits of garlic, and many of those have looked at whether garlic can reduce elevated cholesterol levels. The results have been contradictory, and the findings of two new studies raise even more doubts.

Garlic 101

Garlic is a member of the lily family. Its active compound, allicin, is what gives garlic its distinctive odor and is the component believed to be responsible for its purported health benefits. These supposed benefits include not only lowering cholesterol levels, but also preventing cancer, lowering blood pressure, acting as an antibiotic, and preventing blood clots.

The results of early studies on garlic seemed to show that it lowered cholesterol levels. Undoubtedly, this belief helped to drive consumer interest in it. Americans spent \$71 million on garlic supplements in 1997, making it one of the most popular herbal supplements.

In the early 1990s, two meta-analyses of the research on garlic were published suggesting that garlic lowered cholesterol an average of 9% to 12% in people with high cholesterol levels (*Ann of Intern Med* 1993 Oct 1;119 (7 Pt 1): 599-605; *J R Coll Physicians Lond* 1994 Jan-Feb; 28(1):39-45). However, the reliability of these analyses has been questioned by researchers because of the poor design of some of the underlying studies and the possibility of publication bias. Some of the studies were not placebo-controlled, some did not control for the effects of diet, and some did not use standardized laboratory measurements. A later meta-analysis (*J R Coll Physicians Lond* 1996 Jul-Aug;30 (4):329-34) found that garlic was less effective in reducing total cholesterol than had been suggested by other analyses.

New Evidence

Subsequently a randomized placebo-controlled study of 50 people with high serum cholesterol levels was published (*Arch Intern Med* 158:1189-1194, 1998). The participants took either three tablets of dried, powdered garlic (the equivalent of one clove of fresh garlic) or placebo pills for four months. The study participants also followed a low-fat eating plan for two months before the study as well as during the study. The researchers concluded that garlic powder pills had the same effect on blood cholesterol levels as the placebo pills did—absolutely none.

Another study published about the same time supported the same conclusion (*JAMA* 279:1900-1902, 1998). It was a double-blind, randomized, placebo-controlled, crossover study consisting of 25 participants. The subjects took garlic oil capsules, a form of garlic thought to be more potent than powdered garlic. They took the capsules (equivalent to about two cloves of fresh garlic) for four months and then took a placebo pill for four months. The researchers found that garlic had no effect on blood cholesterol levels or on cholesterol metabolism and concluded that there is no evidence to recommend garlic supplements for lowering cholesterol levels.

Two concerns have been expressed about using garlic to lower cholesterol. One is that garlic has anticoagulant activity that could cause a problem, particularly in people who are also taking anticoagulants like vitamin E, ginkgo biloba, aspirin, and fish oil. The second concern is that people might depend on garlic supplements to lower one's cholesterol instead of following proven methods, such as dietary and lifestyle changes or the use of cholesterol-lowering medications, which could have serious health consequences. **NF**

Beth Fontenot is a nutrition consultant and freelance nutrition writer in Lake Charles, LA.

WEB WATCH

This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc. (<http://www.quackwatch.com>), which is working hard to improve the quality of health information on the Web.

BEST

The American Medical Association's Personal Nutritionist page <http://www.ama-assn.org/insight/yourhlth/pernutri/pernutri.htm> offers a quick diet assessment test that can be completed in 3-5 minutes.

In-depth nutritional assessments are available through the "123 Step" feature of CyberDiet's fee-based health club http://www.cyberdiet.com/new_health_club_site/health_club/

The American Heart Association now has full-text versions of its journals at <http://www.ahajournals.org> Access to 1998 issues will be free through December 31.

Medical World Search <http://mwsearch.com> searches its database of thousands of health-related Web sites that have been selected by an expert advisory panel.

WORST

Health Equations <http://www.healtheqs.com/frpage.shtml> is the Web site of Lynn August, MD, who bases supplement recommendations and food plans on interpretations of blood count and blood chemistry screening tests. Her Health Equations Blood Test Evaluation is claimed to be "the only evaluation that specifically addresses the physiology and pathophysiology of cells and tissues." Physicians who use the program can also obtain supplements to sell to their patients.

The Bahamas-based Centre for Nutrition and Natural Treatment <http://www.hansi.com> promotes treatment with a "hormonally-balanced diet" and an "herbal homeopathic preparation of primarily desert and rain forest plants which has been found to enhance the immune system in humans and other living organisms." The product is claimed to be effective against cancer and several other serious diseases.

Candidiasis Hypersensitivity

"Candidiasis hypersensitivity" is another bogus diagnosis whose symptoms are said to be multiple and include fatigue, depression, inability to concentrate, hyperactivity, headaches, skin problems (including hives), abdominal pain and bloating, constipation, diarrhea, respiratory symptoms, and problems of the urinary and reproductive organs. The main promoter of "candidiasis hypersensitivity" has been William G. Crook, MD, of Jackson, Tennessee, who wrote and published *The Yeast Connection*. According to Crook, "If a careful checkup doesn't reveal the cause for your symptoms, and your medical history [as described in his book] is typical, it's possible or even probable that your health problems are yeast-connected." To correct these alleged problems, he recommends allergenic extracts, antifungal drugs, vitamin and mineral supplements, and diets that avoid refined carbohydrates, processed foods, and (initially) fruits and milk.

The AAAAI regards the concept of candidiasis hypersensitivity as "speculative and unproven" and notes that everyone has some of its supposed symptoms from time to time. The Academy has warned that some patients who take the inappropriately prescribed antifungal drugs will suffer side effects and that overuse of these drugs could lead to the development of resistant germs that endanger everyone.

'Hidden Allergies'

Many dubious practitioners claim that food allergies may be responsible for virtually any symptom a person can have. In support of this claim—which is false—they administer tests purported to identify offending foods. The most notorious such test is cytotoxic testing. This test is performed by observing what happens to a patient's white blood cells when they are placed on microscope slides containing dried food extracts. The test results are then used to explain the patient's symptoms and to design a "personalized diet program" that includes vitamins and minerals—sold by those administering the test. Controlled studies have never shown cytotoxic testing

to be reliable, and some studies have found it to be highly unreliable.

Another test claimed to locate "hidden allergies" is the ELISA/ACT, which involves culturing the patient's lymphocytes and seeing how they react to up to 300 foods, minerals, preservatives, and other environmental substances. After the test is completed, the practitioner recommends dietary modification and supplements. Similar claims are made for ALCAT testing, which is done in a different way. Although these tests can assess the levels of certain immune responses, these are not necessarily related to allergy and have nothing whatsoever to do with a person's need for supplements. Moreover, many of the symptoms listed in brochures from the labs performing them are unrelated to allergy and are not appropriately treated with supplement products.

The correct way to assess a suspected food allergy or intolerance is to begin with a careful record of food intake and symptoms over a period of several weeks. If significant symptoms occur, the next step should be to see whether avoiding suspected foods for several weeks prevents possible allergy-related symptoms from recurring. If so, the suspected foods could be reintroduced one at a time to see whether symptoms can be reproduced. However, if the symptoms include hives, vomiting, swollen throat, wheezing, or other difficulty in breathing, continued self-testing could be dangerous, so an allergist should be consulted.

Mismanagement of Lyme Disease

Lyme disease is caused by a spiral-shaped bacterium (spirochete) that enters the skin at the site of a tick bite. The disease typically begins with a rash, often accompanied by fever, malaise, fatigue, and muscle and joint pains. The characteristic skin lesion where the bite occurs is a flat or raised red area that expands, often with clearing at the center, to a diameter of up to 20 inches. However, it does not always occur, which can make the diagnosis more difficult, especially when the patient is not aware of having been bitten by a tick. Other early signs can include small skin lesions, facial nerve paralysis, lymphocytic meningitis, and heart-rhythm disturbances. When diagnosed early, the disease

is easily cured with a few weeks of antibiotic therapy. However, if untreated or inadequately treated, neurologic, cardiac, or joint abnormalities may follow.

The diagnosis of Lyme disease should be based primarily on an evaluation of the patient's symptoms and the probability of exposure to the Lyme spirochete. Laboratory evaluation is appropriate for patients who have the arthritic, neurologic, or cardiac symptoms associated with Lyme disease, but it is not warranted in patients who have nonspecific symptoms, such as those of chronic fatigue syndrome. A true-positive test result consists of a positive enzyme-linked immunosorbent assay (ELISA) or immunofluorescent assay followed by a positive Western blot. However, positive tests, by themselves, do not provide sufficient basis for diagnosing Lyme disease. The diagnosis should be based on the overall picture, including history and physical findings. Negative antibody testing after the first few weeks strongly suggests that the patient does not have the disease.

How to Create and Promote a New Fad Disease

- Pick any symptoms—the more common the better.
- Pick any disease—real or invented. (Real diseases have more potential for confusion because their existence can't be denied.)
- Assign lots of symptoms to the disease.
- Say that millions of undiagnosed people suffer from it.
- Pick a few treatments. Including supplements will enable health-food stores and chiropractors to get in on the action.
- Promote your theories through books and talk shows.
- Don't compete with other fad diseases. Say that yours predisposes people to the rest or vice versa.
- Claim that the medical establishment, the drug companies, and the chemical industry are against you.
- State that the medical profession is afraid of your competition or trying to protect its turf.
- If challenged to prove your claims, say that you lack the money for research, that you are too busy getting sick people well, and that your clinical results speak for themselves.

Some practitioners are inappropriately diagnosing Lyme disease and administering inappropriate treatments such as malaria therapy, hyperbaric oxygen therapy, colloidal silver, dietary supplements, herbs, and long-term antibiotic therapy. Intravenous antibiotic therapy, when given appropriately, should not last more than a month. It should not be given unless oral antibiotic therapy has failed and persistent active infection has been demonstrated by culture, biopsy, or other bacteriologic technique. Physicians who use these treatments or who diagnose large numbers of patients with Lyme disease who live in areas where the disease is not endemic should be considered suspect.

'Wilson's Syndrome'

"Wilson's syndrome" entered the health marketplace in 1990, when E. Denis Wilson, MD, of Longwood, Florida, coined its name. Its supposed manifestations include fatigue, headaches, PMS, hair loss, irritability, fluid retention, depression, decreased memory, low sex drive, unhealthy nails, easy weight gain, and about 60 other symptoms. However, Wilson claims that his "syndrome" can cause "virtually every symptom known to man." He also claims that it is "the most common of all chronic" ailments and probably takes a greater toll on society than any other medical condition. Wilson claims to have discovered a type of abnormally low thyroid function in which routine blood tests of thyroid are often normal. He states that the condition is "especially brought on by stress" and can persist after the stress has passed. He claims that the main diagnostic sign is a body temperature that averages below 98.6° F (oral), and that the diagnosis is confirmed if the patient responds to treatment with a "special thyroid hormone treatment." (Note: Although "Wilson's syndrome" is a bogus diagnosis, there is a Wilson's disease, a rare condition caused by a defect in the body's ability to metabolize copper.)

In 1991, a 50-year-old woman died after excessive amounts of thyroid hormone prescribed by Wilson had caused rapid heartbeat that led to a heart attack. In 1992, the Florida Board of Medicine fined Wilson \$10,000, suspended his license for six months, and ordered him to undergo

psychological testing. If his license is reinstated, he would also be required to take courses in endocrinology, the scientific method, and medical ethics. As far as I know, Wilson has not resumed practice. However, he still operates a toll-free telephone hotline (800-621-7006) that dispenses information about his theories and publications. In September 1997, Richard A. Marschall, ND, a naturopath licensed in the state of Washington, was charged with unprofessional conduct for allegedly diagnosing and treating between 75 and 100 patients for Wilson's syndrome solely via telephone, mail, or through the Internet.

Parasites and 'Leaky Gut'

Another diagnosis popular among supplement promoters is "parasites," which may be "treated" with laxatives and other "intestinal cleansers," colonic irrigation, plant enzymes, dietary measures, and homeopathic remedies. Yet another, "leaky gut syndrome," is described by proponents as a condition in which the intestinal lining becomes irritated and porous so that unwanted food particles, "toxins," bacteria, parasites, and "Candida" enter the bloodstream and result in "a weakened immune system, digestive disorders, and eventually chronic and autoimmune disease." Treatment of this alleged condition can include dietary changes (such as not eating protein and starch at the same meal); "cleansing" with herbal products; "reestablishing good balance" of intestinal bacteria; and supplement concoctions claimed to strengthen and repair the intestinal lining.

Inappropriate Dental Care

A small but vocal group of dentists, physicians, and various other "holistic" advocates claim that mercury-amalgam ("silver") fillings are toxic and cause a wide range of health problems including multiple sclerosis, arthritis, headaches, Parkinson's disease, and emotional stress. They recommend that mercury fillings be replaced with either gold or plastic ones and that vitamin supplements be taken to prevent trouble during and after the process. Scientific testing has shown that the amount of mercury absorbed from fillings is only a tiny fraction of the average daily

intake from food and is insignificant. The American Dental Association considers the unnecessary removal of silver amalgam fillings "improper and unethical." In 1996, the leading anti-amalgamist, Hal A. Huggins, DDS, of Colorado Springs, Colorado, had his license revoked. During the revocation proceedings, the administrative law judge concluded: (1) Huggins had diagnosed "mercury toxicity" in all patients who consulted him in his office, even some without mercury fillings; (2) he had also recommended extraction of all teeth that had had root canal therapy; and (3) Huggins's treatments were "a sham, illusory and without scientific basis."

Some dentists maintain that facial pain, heart disease, arthritis, and various other health problems are caused by infected "cavitations" (within the jaw bones) that are not detectable on X-ray examination or treatable with antibiotics. Calling this condition "cavitation osteopathosis," advocates claim they can cure the patient by locating and scraping out the affected tissues. They may also remove all root-canal-treated teeth and most of the vital teeth close to the area where they say an infection exists. There is no scientific evidence to support this assertion or the diagnostic and treatment methods based on it.

The Bottom Line

I believe that the licenses of practitioners engaged in the above activities should be revoked and that the inappropriate products involved should be removed from the marketplace. **NF**

Dr. Barrett, a retired psychiatrist who resides in Allentown, Pennsylvania, is board chairman of Quackwatch, Inc., and a board member of the National Council Against Health Fraud. His Web site at <http://www.quackwatch.com> has additional information about fad diseases.

[continued from page 41]

ease; and (8) calcium consumption by adults and adolescents increases bone density and may decrease the risk of fractures. Although some of these nutrients may help prevent disease, the proposed claims were either false, simplistic, or too broad. The FDA Modernization Act requires that health claims be based on authoritative government agency statements and enable the public to understand the nutrient's significance in the context of a total daily diet. The FDA apparently concluded that the claims lacked sufficient authoritative support because they were based on research that was preliminary rather than conclusive.

DHEA MAY INCREASE CANCER RISK

Marshall Goldberg, MD, an endocrinologist and medical researcher at Jefferson Medical College in Philadelphia, says that the popular hormone supplement DHEA may increase the risk of prostate cancer. Researchers at McGill University in Montreal reported earlier this year that men with elevated levels of IGF-1 were 4½ times more likely to develop prostate cancer than men with lower levels. (IGF is a growth factor that helps to regulate cell turnover.) Dr. Goldberg has studied the effect of DHEA on his patients for nearly 10 years and says that doses as small as 25 mg. per day can raise IGF-1 levels significantly.

GINKGO REPORT

The *Medical Letter* has concluded: Extracts of Ginkgo biloba might improve mental function with some patients with dementia, but available data suggest that the benefits, if any, are modest. In a German postmarketing surveillance study, the drug appeared to be safe, but serious bleeding has been reported. . . . The purity and potency of ginkgo extracts sold in the USA are unknown (*Medical Letter* 40:63-64, 1998).

NHLBI ISSUES STATEMENT ON SODIUM AND HYPERTENSION

The controversy surrounding sodium's effect on blood pressure has raised questions among scientists and in the

media. In response, the National Heart, Lung, and Blood Institute (NHLBI) issued a statement announcing an upcoming workshop to review the latest findings on sodium and hypertension and to determine future research needs. The NHLBI continues to support the recommendation of various health organizations that sodium intake should be limited to 2,400 mg. a day. More information about high blood pressure can be found at <http://www.nhlbi.nih.gov/nhlbi/>

FDA INFO ON DIETARY SUPPLEMENTS

The September-October issue of *FDA Consumer Magazine* contained an article entitled "An FDA Guide to Dietary Supplements" as well as a list of dietary supplements, which have been associated with illnesses and injuries. The magazine is available on the Internet, and the article can be read at http://www.fda.gov/fdac/features/1998/598_guid/html

FOOD CONTAMINANTS IN JUICES AND ALFALFA SPROUTS

The FDA has issued warnings about potentially dangerous food contaminants in fruit and vegetable juices and in raw alfalfa sprouts. Designed to alert the public about the risk of microbial contamination in untreated juices, warning statements are now required at places where unprocessed fruit and vegetable juices are sold. It is estimated that untreated juices cause 16,000 to 48,000 cases of foodborne illness each year. In addition, the FDA has issued an interim advisory that people who are at high risk for foodborne illness should avoid eating raw alfalfa sprouts. Three salmonella and E. coli outbreaks occurred in California recently and 60 people were affected. The International Sprout Growers Association is taking steps to address the problem by pursuing ways to treat seeds before germination and growth. Those at high risk for foodborne illnesses include children, the elderly, and people with compromised immune systems.

NEJM CALLS FOR TESTING OF HERBS

In an editorial in the September 17, 1998, issue of the *New England Journal of Medicine* (NEJM 339:839-841,

1998), Drs. Marcia Angell and Jerome Kassirer call for rigorous scientific testing of alternative treatments, particularly herbal therapies. They state, "There cannot be two kinds of medicine—conventional and alternative. There is only medicine that has been adequately tested and medicine that has not, medicine that works and medicine that may or may not work." The issue carried several reports on the risks involved with using herbal remedies. The editorial can be found on the *NEJM* Web site at <http://www.nejm.org>

FEDERAL OBESITY GUIDELINES

The National Heart, Lung, and Blood Institute (NHLBI) has published guidelines for assessing overweight and obesity and principles for safe and effective weight loss. The guidelines recommend basing assessments on body mass index (BMI), waist circumference, and risk factors for obesity-related diseases. About 97 million Americans (55% of the adult population) fit the report's criteria for overweight or obesity. The 228-page report, titled "Clinical Guidelines on the Identification, Evaluation, and Treatment of Overweight and Obesity in Adults" can be obtained by contacting NHLBIIC@dgsys.com or visiting its Web site <http://www.nhlbi.nih.gov/nhlbi/nhlbi.htm>

FOOD SAFETY COUNCIL CREATED

On August 25, President Clinton issued an executive order establishing an eight-member President's Council on Food Safety (Federal Register 63:45661-45662, 1998). The Council's mission is to develop a comprehensive plan "to improve the safety of the food supply through science-based regulation and well-coordinated inspection, enforcement, research, and education programs." The members include the Secretaries of Agriculture, Commerce, and Health and Human Services; the Director of the Office of Management and Budget; the Administrator of the Environmental Protection Agency; the Assistant to the President for Domestic Policy; the Director of the National Partnership for Reinventing Government; and the Assistant to the President for Science and Technology/Director of the Office of Science and Technology Policy.

NEW WARNING LABELS

New FDA regulations require unpasteurized apple cider products to carry a warning stating "This product may contain harmful bacteria that can cause serious illness in children, the elderly, and persons with weakened immune systems." All other unprocessed packaged fruit and vegetable juices must carry a warning label or sign, but by the fall of 1999, labels will be required.

LOS ANGELES FLUORIDATES

Los Angeles, which for decades has been the only large American city without fluoridation, has begun to fluoridate its water. Fluoridation for approximately 80% of the city's 3.6 million residents was initiated on September 23. The rest will receive it next year when additional facilities are built.

REGULATORY ACTION AGAINST TAHITIAN NONI

On August 26, 1998, the Attorneys General of Arizona, California, New Jersey, and Texas announced a multistate settlement with Morinda, Inc., a multilevel company headquartered in Linden, Utah. The AGs had charged that Morinda had made unsubstantiated claims in con-

sumer testimonials and other promotional material that its "Tahitian Noni" juice could treat, cure, or prevent diabetes, depression, hemorrhoids, arthritis, and many other diseases and conditions. In a consent agreement, Morinda agreed to pay \$100,000 in investigative costs, to issue refunds on request, and to refrain from making claims that Noni can cure, treat, or prevent any disease unless the claims are substantiated and the product is approved and cleared for those uses by the FDA.

FAT ADDED TO COOKIES

Faced with sagging sales, Nabisco has reformulated its nonfat SnackWell line by adding fat. One advertising strategy, based on survey and focus group data, will be to link the new taste with self-fulfillment, self-worth, and feeling good. According to *Promo* magazine, one ad will state that "snacking shouldn't be just about feeding yourself, but, in some small way, about feeding your self-esteem."

ONE-A-DAY HERBAL PRODUCTS

Bayer Corporation's Consumer Care Division has become the first major over-the-counter drug manufacturer to introduce a line of herbal formulas in the

United States. Its new One-A-Day Specialized Supplements are "Cold Season," "Energy," "Bone Strength," "Tension & Mood," "Memory and Concentration," "Cholesterol Health," "Menopause Health," and "Prostate Health." The products include herbs, vitamins, and minerals allegedly blended to address common health problems. However, many of the ingredients have no proven value for the usage implied by their product name. American Home Products has announced that it will add six herbal products to its popular Centrum line.

NEW EFFORTS AGAINST TELE-MARKETING FRAUD

More than 80 members of the American Association of Retired Persons (AARP) joined telephone company and law-enforcement officials in educating 3,100 consumers about fraudulent telemarketing tactics. The phone numbers of the people called were obtained from lists used by fraudulent telemarketers. AARP is also promoting model legislation to require telemarketers to be registered and bonded and to prohibit pickups of money by couriers, a procedure intended to bypass postal laws. Several states have passed laws of this type. **NF**

A NATIONAL CONFERENCE FOR MEDICAL AND NUTRITION PROFESSIONALS

Science Meets 'Alternative Medicine'

How strong (or weak) is the scientific evidence? What's the impact on patients and physicians?

FEBRUARY 26-28, 1999 • WARWICK HOTEL, PHILADELPHIA

Sponsored by the *Scientific Review of Alternative Medicine* and **CSICOP**

Keynote Speakers

George Lundberg, Editor of the *Journal of the American Medical Association*

Marcia Angell, Editor of the *New England Journal of Medicine*

Other speakers include

Wallace Sampson, James Alcock, Barry Beyerstein, Stephen Barrett, Robert Park, Saul Green, William Jarvis, Lewis Vaughn, John Renner

T O P I C S I N C L U D E

- Acupuncture

Book Reviews

Analysis and Ratings

How accurate and useful is the nutrition information in that book? Would a reputable reviewer recommend the book to professionals and consumers? These are the two questions that Nutrition Forum book reviews are intended to answer. So the reviews not only offer analyses but also rate each book as either RECOMMENDED, NOT RECOMMENDED, or RECOMMENDED WITH RESERVATIONS, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

'Myth-Information' Detector

Beth Fontenot, MS, RD

Fad-Free Nutrition by Fredrick J. Stare, MD, and Elizabeth Whelan, ScD, MPH (Alameda, CA: Hunter House Publishers, 1998), 302 pp., \$24.95 hard cover, \$14.95 paperback. ISBN 0-89793-237-4.

Whether you are a health professional trying to keep up with the latest developments in nutrition or you are a consumer needing to sort out nutrition facts from myths, *Fad-Free Nutrition* deserves a place on your bookshelf. The authors address a variety of nutrition topics including dietary supplements, food myths, weight loss quackery, fat substitutes, nutrition and disease states, and irradiation of food. Each topic is put in proper per-

spective with a discussion of the relevant scientific facts. The last chapter of the book explains how to assess nutrition information and describes the elements of a legitimate scientific study.

Included in this volume are reviews of several popular nutrition and weight-loss books. These reviews provide the reader with an excellent overview of the nutrition "myth-information" (authors' term) that consumers confront every day.

Written from a scientific perspective yet in simple and clear language with an occasional touch of humor, the book is good reading for both lay and professional readers. It would make a good adjunct to a nutrition text for a university-level nutrition course.

RECOMMENDED

Anticancer Eating

Laurel Klayman, RD, LD

A Perfect 10: Phyto "New-trients" Against Cancers by Laura Pawlak (Biomed General Corp., 1998), 241 pp., \$25 softcover (available only from Biomed, [510] 450-1650).

This book is about preventing cancer through a diet rich in plant chemicals (what the author calls "phyto-newtrients"). There has been an explosion of recent scientific evidence uncovering the presence of hundreds of such potentially healthful substances. The author, who is a registered dietitian with a doctorate in biochemistry, calls this burgeoning field "New-trition." She explains that the development of cancer is a multistep process and that there are phyto-newtrients that can act as "missiles, speed-bumps, and imposters" to interfere with the steps that lead to cancer.

The main message then is anything

but new or radical: eat more fruits, vegetables, grains, and legumes to decrease the risk of cancer and other chronic diseases. But the author is a cheerleader for the message, and her motivational style is likely to encourage many to, at the very least, eat more vegetables. The author's enthusiasm, however, can also be a drawback when it gives the impression that following the recommendations in the book can guarantee a cancer-free life. People need to keep in mind that there is still much for scientists to learn about nutrition and cancer prevention.

The recommendations in the book are not advocated as a treatment for already existing cancer. Also, supposing that some readers might be inclined to circumvent healthy eating by taking pills, the author repeatedly points out the reasons why foods are better sources for most nutrients than supplements are.

Ten foods are highlighted in a "starter plan." Each of the ten has a "runner-up" in case the reader dislikes one of the ten. The idea is to make it easy for anyone to incorporate more plant foods into his or her diet.

Unfortunately, flax oil and green tea are included in the starter plan. It is premature to recommend consumption of these for cancer prevention. Though neither are likely to be harmful in the amounts recommended (except to the pocketbook—a bottle of flax oil in some health-food stores is \$12), a more prudent course of action would be to await further study to confirm their efficacy.

A Perfect 10 includes an extensive bibliography of well-respected journals and newsletters. The book might be of particular interest to someone who wants to take a proactive role in prevention. **NF**

NIH-ODS AWARDS GRANTS TO STUDY SUPPLEMENTS

The National Institutes of Health's Office of Dietary Supplements (NIH-ODS) has announced that it will fund four new research projects that will examine dietary supplements and their potential role in health promotion and disease prevention. The four studies are: (1) A project at Brown University to evaluate the possible relationship between low dietary intake of the amino acid tryptophan, a precursor of serotonin, and the susceptibility to problems associated with alcohol abuse in a tribe of rural Native Americans, (2) a study conducted at the Harvard University School of Dental Medicine on the relationship between poor dental health and heart disease, the hypothesis being that poor dentition may lead to a decreased intake of fiber and phytochemicals which may be important in heart health, (3) a study at Florida State University to examine the actions of zinc and copper and their relationship to neuropathologic diseases of aging such as Alzheimer's disease and stroke, and (4) a project at the Baylor College of Medicine in Houston, TX, to study the role of metallothionein, an enzyme that regulates zinc levels in body tissues.

ST. JOHN'S WORT QUESTIONED

A study commissioned by the *Los Angeles Times* found that out of ten brands of St. John's Wort examined, three products had about half the potency shown on the label, and four products had less than 90 percent of the potency shown on the label. The study examined 10 pills from each of three containers of one lot of each of 10 products. Identified by only a code, the brand names were unknown to the laboratory. Five independent experts reviewed the research procedures and found the study to be sound.

Debunking the Detoxification Theory

Truth over toxicity

by Therese Walsh

Detoxification is an amazingly popular health fad. There are books written about it, seminars given on it, centers dedicated to it, and an overwhelming amount of information about it on the Internet. It's based on the notion that we take in so many toxic substances through food, drink, and air that our bodies become toxic, and the only road to true health is through banishing these poisons. Curiously, the poisons have yet to be identified. But this has not stopped people from creating and promoting programs to get rid of the invisible toxins. Here's how proponents say that the unidentified and invisible can be eliminated.

Fasting

The idea that fasting can cleanse your body of toxins is thousands of years old. Current-day detoxifiers rarely advocate a true fast (no food or liquid) for any length of time because it can quickly become life-threatening. Most recommend a water or juice fast, or a modified food fast including only some fruits, vegetables, juices, and teas. Some, like the detoxification guru Elson M. Haas, MD, author of the book *Detox Diet: A How-To Guide for Cleansing the Body of Toxic Substances*, recommend drinking 8-12 glasses a day of a concoction of maple syrup, lemon juice, and water for the duration of the fast.

Fasts can last anywhere from a few

days to weeks. Detox proponents, including Haas, often advocate one or more weeks, though medical professionals say that long-term fasting (more than a few days) can be dangerous because that's when the body begins, essentially, to "eat itself." Zealots have even suggested that short-term fasting is safe for those with kidney failure, liver disease, pregnant/nursing women, and even infants.

Proponents claim that fasting allows the body, especially the liver, to "rest," shifting its emphasis from dealing with daily toxic intake to cleaning up past toxic "stores" that will eventually cause illness. Unfortunately, the body doesn't

know the difference between "fasting" and "starving." The body is never at rest during a fast, but works feverishly to prevent starvation and death.

The liver is especially taxed during a fast, converting fat into energy for the body to use.

And during a lengthy fast, the liver is working overtime dealing with dangerous by-products from muscle and tissue breakdown as the body searches for protein stores.

According to Haas, fasting also "increases the process of elimination and the release of toxins from the colon, kidneys and bladder, lungs and sinuses, and skin." This toxic download is supposed to be so powerful that it can cure and prevent illness as well as forestall the aging process. Some medical conditions that might sig-

Curiously, the poisons [of detox theory] have yet to be identified.

nal the need for a detoxifying fast, according to Haas and others, are frequent headaches, coronary artery disease, diabetes, and mental illness. Ironically, fasting actually can exacerbate or cause these health problems. Fasting often results in headaches or depression; cardiac problems can arise; and glucose regulation for the diabetic will be difficult or impossible and perhaps even life-threatening.

Haas and others argue that one of the greatest contributions of the fast is that it can prevent serious illness such as cancer by cleansing the body of poisons before they have the opportunity to do damage. This is, of course, wishful thinking and completely without scientific basis.

People who fast commonly experience irritability, nausea, weakness, headaches, and lightheadedness. (One fasting enthusiast claimed that you should not feel hungry, "but may feel a desire to have food in your mouth.") Some experience nightmares, low blood pressure, fainting, and vomiting. Detoxification advocates claim that these negative symptoms are a sign that poisons are being released into the bloodstream. The real causes of these symptoms, however, are well understood. Lightheadedness, for example, is caused by decreased blood flow to the brain, and nausea can be caused by hunger or fasting-induced hormonal changes.

Haas and others speak of fasting as an opportunity for enlightenment, claiming that it brings about more emotional and mental clarity. But studies have shown that cognitive abilities decrease during a period of fast.

'Internal Cleansing'

The notion that putrefaction of the stool causes disease dates back to ancient Egypt. The belief was that fecal matter would be absorbed into the body, thereby poisoning it and causing illness. (As with fasting, the invasive poisons are never identified or measured.) This idea has

long since been disproved. But some fanatics persist, claiming that a "slow" or "unclean" colon will cause everything from a cold to coronary artery disease. In fact, many claim that 90-99% of all illness begins in the colon.

Colon zealots insist that we need to excrete as often as we intake—at least three times a day for most people. They claim that defecating less often than that will result in "ancient meals encrusted on your colon walls," poisoning the body and preventing nutrients from being absorbed. The longer these meals are allowed to accumulate, the more likely they are to cause illness, so they must be cleaned away regularly.

These claims are bogus, with no scientific basis whatever. With today's technology, we can see inside the colon, and no such toxic buildup has ever been documented.

People who buy into these claims soon find themselves in a world of enemas, colonic irrigation, and "high colonics," on a quest to remove the "ancient meals" or forestall any new toxic buildup. Some proponents even claim that the intestines are filled with parasites that should be flushed from the body. While an enema irrigates only the rectum with a small amount of water, a colonic flushes the colon with many pints via a tube inserted into the rectum. A "high colonic" is even more extreme, flooding the colon with 20 or more gallons of water and usually via machine.

Throughout detoxification Elson Haas recommends enemas every other day and a colonic as often as three times. This sort of behavior is completely unnecessary and is possibly dangerous. Colonic irrigation is not well regulated—anyone can market the procedure. Pain, severe cramping, infection, perforated bowels, heart failure, and even death have been reported due to colonics. Neither enemas nor colonics "detoxify" the body, and they are not needed to maintain health.

With today's technology, we can see inside the colon, and no such toxic buildup has ever been documented.

Nutrition and Fibrocystic Breast Disease

Is there a connection?

by Beth Fontenot, MS, RD

Women diagnosed with fibrocystic breast disease (FBD) and experiencing its uncomfortable symptoms may find themselves bombarded with all manner of nutritional advice: No coffee. No cola. No chocolate. Take evening primrose oil. Take flaxseed oil. Take vitamin E. Take vitamin A. Don't take vitamin A. Drink an herbal tea. Avoid herbal teas. Take natural hormones. Limit fat and sodium. Take iodine. Take vitamin B₆. Eat raw foods. Try some coenzyme Q10. Rub evening primrose oil on your breasts! What's a woman to believe?

FBD is essentially the presence of benign breast lumps (cysts). They can often be felt in the breast and can fluctuate with the menstrual cycle. The condition may become progressively worse until menopause. Pain and swelling are the most common complaints, and the discomfort increases as menstruation approaches. The symptoms usually subside once menstruation begins. It is estimated that 30% of American women have FBD. Relatively few women with FBD develop breast cancer.

The cause of FBD is unknown but is believed to be related to hormonal stimulation. In particular, excessive amounts of estrogen, the main female hormone, and prolactin, the milk-release hormone, have been implicated. Dietary factors have also been traditionally thought to be a factor. The most common advice given to women is to avoid caffeine and to take supplemental vitamin E.

Is E the Key?

Early research on the effectiveness of vitamin E against FBD seemed promising, but clinical trials in the past few years have not backed up the original optimism. In the 1960s a study published in the *New England Journal of Medicine* (272:1080-

1081) suggested that vitamin E was beneficial in the treatment of FBD, and studies that followed appeared to confirm that belief. However, since then several better-designed studies have cast doubt on vitamin E's ability to provide relief for women with FBD.

In a double-blind, randomized, placebo-controlled trial of 128 women, published in 1985, researchers concluded that vitamin E had no effect on FBD (*Obstet Gynecol* 1985 Jan; 65[1]:104-106). Later that year, another study of 73 women confirmed those findings (*Surgery* 1985 Apr; 97[4]:490-494). More recently, a double-blind, placebo-controlled crossover study of 105 randomly selected patients with FBD also indicated that vitamin E was not beneficial in the treatment of FBD (*Surgery* 1990 May; 107[5]:549-551).

Despite these findings, vitamin E is still commonly recommended for treating FBD. Some health professionals recommend doses as high as 1,500 IU a day. But at high doses, vitamin E can interfere with blood clotting. This could increase the risk of excessive bleeding and could be especially dangerous in people who are taking anticoagulant drugs or herbs that act as a blood thinner (like Ginkgo biloba).

Some women with FBD do report favorable results when taking vitamin E. But in the studies cited above, many who took a placebo also reported favorable results. The bottom line? It is unlikely that vitamin E is an effective treatment for FBD.

Caffeine and More

Avoiding caffeine or, more specifically, foods containing methylxanthines also seems to be standard advice for a woman with FBD. (Methylxanthine-containing

The New Hope Clinic, in Tijuana, Mexico (<http://newhopeclinic.com/>) offers BioResonance Tumor Therapy for cancer and training to become a "certified" therapist." Its treatment is claimed to cure cancer by "reactivating" a suppressed gene.

World Health Products (<http://www.worldhealthproductsinc.com>) distributes various "alternatif" products, including a disc claimed to reshape the body when passed over it.

[continued from page 2]

Herbal Remedies and More

Multilevel marketers have found their detoxification niche with herbal remedies, claiming their own special brand of magic for clearing out the poisons coursing through our bodies. Some claim that their herbal formulas can fight mold and expel worms from the intestines. Fasting folks can pop a few pills with their juice to add a new dimension of clean ("Milk Thistle Complex" and "Liver Complex," for example). To prevent a colon layered with decade-old waste, people can try other pills, like "Colon Helper," "UnDo," and "Ultra Flush Internal Cleanser." Companies that are touting these kinds of herbal potions include AIM, Beneficial International, Inc., and Ancient Power Inc.

In reality, many of the herbal supplements contain cascara sagrada, a powerful herbal laxative that should not be used regularly. Its laxative effect is so intense that nerve cells in the colon can be damaged, resulting in a dulled urge to defecate and leading to constipation and dependence.

Elson Haas has claimed that: elderberry detoxifies the blood, sarsaparilla root detoxifies the lymph system, Oregon grape root detoxifies the skin, goldenseal root detoxifies the kidney, and black walnut hulls remove parasites from the intestinal tract. These vague claims are undefined, untested, unsubstantiated, and unbelievable.

Other Odd Claims

According to detoxification advocates, there are a few other ways to rid yourself of "toxins." You can sweat them out through exercise, scrape them off your skin with a brush, wash them off your skin in the bath (pure water only), and even bounce them out on a mini-trampoline!

Haas believes that "niacin-sauna" therapy shows promise. It entails taking mega-doses of niacin up to 2-3 grams a day while sweating out "toxins" in a sauna. This level of niacin could be valuable for cholesterol control. However, it can cause nausea, flushing and burning of the skin, and liver dysfunction and should

not be taken without the guidance of a physician.

It's unfortunate that some detoxification zealots promote its use for cancer patients. There is even a report of a center in Tijuana, Mexico, supported by U.S. promoters, that treats cancer patients with detoxification therapy in lieu of real medical treatment. Some in the United States, like Rich Anderson, author of the book *Cleanse and Purify Thyself: The Clean-Me-Out Program—A Method of Self-Healing*, tiptoe around the cancer claim while making their intent perfectly clear: "The medical world claims no cure for cancer and, what's more, no one else (does) either. It's against the law—even for those who know the cure. Therefore, I hereby announce that I do not claim the 'clean-me-out-program' will cure cancer. Should you find your cancer disappearing when you use this system, I will not accept responsibility." And neither will he accept responsibility when it doesn't work. **NF**

Therese Walsh is a freelance health journalist in Binghamton, NY.

[continued from page 3]

foods include coffee, tea, caffeinated soft drinks, and chocolate.) This advice was apparently based on one uncontrolled clinical study. According to several more recent studies, however, caffeine may not be the culprit after all.

A case-control dietary study published in the late 1970s included 854 women diagnosed with FBD. The researchers found no association between coffee or methylxanthine consumption and FBD (*JAMA* 1985 Apr 26; 253[16]: 2388-2392). At least two subsequent studies agreed with these findings (*Surgery* 1986 May;99[5]:576-581; *Surgery* 1987 Jun;101[6]:720-730). So the best available evidence suggests that cutting out caffeine won't help with FBD.

Vitamin A has also been suggested as a treatment for FBD. In a single study, 12 women who were treated with 150,000 IU of vitamin A daily for three months showed improvement in symptoms, leading the researchers to conclude that vita-

min A may be effective for FBD (*Prev Med* 1984 Sept;13[5]:549-554). But the study was too small to support any such conclusion. In addition, that amount of vitamin A is 30 times the Daily Value, and women of childbearing age should limit their intake of vitamin A to 100% of the Daily Value or about 5,000 IU due to the potential for birth defects.

Evening primrose oil has received some attention as an FBD treatment. A British study of 200 women was conducted to evaluate its effectiveness. This randomized, double-blind trial showed a slightly lower—but not significant—incidence of cyst formation in the group given evening primrose oil (*Ann NY Acad Sci* 1990;586:288-294). Other studies are needed before we can conclude that evening primrose is any help.

Some believe that a low-fat diet may help to prevent or treat FBD. Studies indicate that the risk of developing FBD rises with an increased intake of fats, particularly saturated fats. When dietary fat is reduced to 20% of calories, blood levels of

the female hormones estrogen and prolactin also decrease. A reduction in these hormones is linked to a decreased risk of developing cancer, but the relationship to FBD is not certain.

While there is much published research and an abundance of anecdotal evidence, there seems to be little solid information about the relationship between diet and FBD.

There is no scientific evidence that any dietary manipulation or supplementation is effective as a preventive or treatment for FBD. Until more is known, it seems prudent for women with FBD to follow a low-fat, nutrient-dense diet. **NF**

The Herbal Minefield

What we don't know is scary

by Stephen Barrett, MD

In 1997, health-food-store patrons spent over a billion dollars for capsules, tablets, bulk herbs, and herbal teas. Although many of these items are consumed for their flavor, most are probably used for supposed medicinal qualities. Sales by multilevel distributors and pharmacies amount to hundreds of millions more for products that are obviously intended for self-medication. Herbs are also marketed by naturopaths, acupuncturists, iridologists, chiropractors, and unlicensed herbalists, many of whom prescribe them for the entire gamut of health problems. Many such practitioners are not qualified to make appropriate medical diagnoses or to determine how the products they prescribe compare to proven drugs.

Herbal advocates like to point out that about half of today's medicines were derived from plants. (Digitalis, for example, was originally derived from leaves of the foxglove plant.) This statement is true but misleading. Drug products contain specified amounts of active ingredients. Herbs in their natural state can vary greatly from batch to batch and often contain chemicals that cause side effects but provide no benefit.

When potent natural substances are discovered, drug companies try to isolate and synthesize the active chemical in order to provide a reliable supply. They also attempt to make derivatives that are more potent, more predictable, and have fewer side effects. In the case of digitalis, derivatives provide a spectrum of speed and duration of action. Digitalis leaf is almost never used today because its effects are less predictable. Many herbs contain hundreds or even thousands of chemicals that have not been completely catalogued. Some of these chemicals may turn out to

be useful as therapeutic agents, but others could well prove toxic.

In the United States, herbs intended for preventive or therapeutic use would be regulated as drugs under federal laws. To evade the law, these products are marketed as "foods" or "dietary supplements" without health claims on their labels. Since herbs are not regulated as drugs, no legal standards exist for their processing, harvesting, or packaging. In many cases, particularly for products with expensive raw ingredients, contents and potency are not accurately disclosed on the label.

Many products marked as herbs contain no useful ingredients, and some even lack the principal ingredient for which people buy them. Some manufacturers are trying to develop industry-wide quality-assurance standards, but possible solutions are a long way off.

The Dietary Supplement Health and Education Act of 1994 included herbal products in its definition of "dietary supplements," even though herbs have little or no nutritional value. (The bill was spearheaded by the health-food industry in order to weaken FDA regulation of its products.) Herbal or other botanical ingredients include processed or unprocessed plant parts (bark, leaves, flowers, fruits, and stems) as well as extracts and essential oils. They are available as teas, powders, tablets, capsules, and elixirs, and may be marketed as single substances or combined with other herbs, vitamins, minerals, amino acids, or nonnutrient ingredients. The fact that an herb is known to be toxic does not ensure its removal from the marketplace. When the FDA concludes that an herb is dangerous, it usually issues a warning rather than a ban.

To make a rational decision about an

The fact that an herb is known to be toxic does not ensure its removal from the marketplace.

herbal product, it would be necessary to know what it contains, whether it is safe, and whether it has been demonstrated to be as good or better than pharmaceutical products available for the same purpose. For most herbal products this information is incomplete or unavailable. Even worse, most published information about herbs is unreliable. Varro E. Tyler, Ph.D., former dean of the Purdue University School of Pharmacy and a leading authority on pharmacognosy (the science of medicines from natural sources), has observed:

More misinformation about the safety and efficacy of herbs is reaching the public currently than at any previous time, including the turn-of-the-century heyday of patent medicines. The literature promoting herbs includes pamphlets, magazine articles, and books ranging in quality from cheaply printed flyers to elaborately produced studies in fine bindings with attractive illustrations. Practically all of these writings recommend large numbers of herbs for treatment based on hearsay, folklore, and tradition. The only criterion that seems to be avoided in these publications is scientific evidence. Some writings are so comprehensive and indiscriminate that they seem to recommend everything for anything. Even deadly poisonous herbs are sometimes touted as remedies, based on some outdated report or a misunderstanding of the facts. Particularly insidious is the myth that there is something almost magical about herbal drugs that prevents them, in their natural state, from harming people.

Two of Tyler's books (*The Honest Herbal* and *Herbs of Choice*) summarize what is known about many commonly used herbs. However, with safe and effective medicines available, treatment with herbs rarely makes sense, and many of the conditions for which herbs are recommended are not suitable for self-treatment. The recent entry of drug companies into the herbal marketplace may lead to standardization, but the best strategy for the consumer is still caveat emptor. **NF**

Dr. Barrett, a retired psychiatrist, is board chairman of Quackwatch, Inc., and a board member of the National Council Against Health Fraud.

[continued from page 1]

"Zinc: What Role Might Supplements Play." Leading experts in zinc research spoke at the conference on the current state of knowledge regarding zinc nutrition and on potential roles for zinc supplements. Based on data from the National Health and Nutrition Examination Study (NHANES III), only about half of Americans receive an "adequate" amount of zinc, reported Ronette Briefel of the National Center for Health Statistics. While many nutrition experts believe that Americans may not be getting enough zinc in their diets, estimates of daily zinc requirements cannot be made until further studies are conducted.

LACK OF NUTRACEUTICAL REGULATION

Speakers at the 10th Nutraceutical Conference in New York concluded that more regulation of the nutraceutical industry is needed due to an increased demand by consumers for nutritional and botanical products. Stephen L. DeFelice, chairman of the Foundation for Innovation in Medicine (FIM), sponsor of the event, told the conference attendees, "The consumer demand for nutraceuticals is way ahead of regulations and way ahead of doctors' awareness of these products." Dr. Felice noted that about one-third of Americans currently take vitamin E, about 100 million take dietary supplements, and 60 million take herbal remedies and botanicals. He expressed concern that these supplements may increase the toxicity of prescription drugs or interfere with the efficacy of prescription drugs taken by consumers. Dr. Felice encouraged Congress to enact the Nutraceutical Research & Education Act (NREA) to expedite the establishment of a research-oriented nutraceutical industry.

FTC CREATES GUIDE FOR SUPPLEMENT ADVERTISERS

The Federal Trade Commission (FTC) has created a guide to help dietary supplement manufacturers ensure that their ads are truthful. The guide describes the basic principles of the law and addresses such

products as vitamins, minerals, herbs, hormones, and amino acids. "A Guide for the Dietary Supplement Industry" is available online at <http://www.ftc.gov/opa/1998/9811/dietary.htm>.

SOY PROTEIN RULE PROPOSED

The FDA is proposing to permit soy products to be marketed with claims that soy protein included in a diet low in fat may reduce the risk of coronary heart disease (Federal Register 63:62977-63015, 1998). Based on a review of approximately 40 studies, the agency tentatively concluded that a minimum level of approximately 25g of soy protein per day can have a clinically significant effect on total and LDL-cholesterol levels without lowering HDL-cholesterol levels. The *New England Journal of Medicine* published a meta-analysis with similar conclusions in 1995 (333:276-282). The full text of the proposed FDA rule is available online at <http://www.fda.gov/ohrms/dockets/98fr/111098a.txt>.

FRAUDULENT LABELING UNCOVERED

Weider Nutrition Group, which markets many products for athletes, has settled a class-action lawsuit alleging that the company misrepresented the fat, sodium, vitamin, and mineral content of several "Steel Bar" nutrition products that it distributed. The suit charged, for example, that in 1995, coconut bar labels stated that the product contained 4 grams of fat, even though the company knew that independent laboratory tests had found four times that amount. The settlement called for buyers to receive \$1 for every bar purchased between December 20, 1994 and April 24, 1998, with an individual maximum of \$5 and a collective maximum of \$750,000.

ANTIOXIDANT DRI PROPOSAL ANNOUNCED

The Institution of Medicine has proposed a definition and will consider establishing antioxidant-related Dietary Reference Intakes for beta-carotene, other carotenoids, vitamin C, vitamin E,

and selenium. The proposal can be accessed at <http://www.nap.edu> by searching the National Academy Press's "Reading Room" for "antioxidants."

GARCINIA CAMBOGIA INEFFECTIVE

A study has found that taking 1,500 mg/day of hydroxycitric acid (the active ingredient in the herbal compound *Garcinia cambogia*) did not produce significant weight or fat loss beyond that observed with placebo. The study followed 135 obese participants, 84 of whom completed 12 weeks of treatment. All followed a low-calorie, high-fiber diet and lost a significant amount of weight. However, the hydroxycitric acid group did no better than the placebo group (*JAMA* 1998;280:1596-1600).

SAW PALMETTO DESERVES FURTHER STUDY

A meta-analysis has examined whether saw palmetto extract may be helpful for men with symptomatic benign prostatic hyperplasia (BPH). The authors evaluated 18 randomized controlled trials involving 2,939 patients. The studies were mostly short-term and varied considerably in design, products used, and reports of outcomes. The authors concluded that further research should be done with standardized preparations to determine long-term effectiveness and ability to prevent BPH complications (*JAMA* 1998;280:1604-1609).

CHILD NUTRITION GUIDE

The American Council on Science and Health has published a 46-page booklet, *Growing Healthy Kids: A Parents' Guide to Infant and Child Nutrition*. The booklet can be read online (<http://www.csh.org>) or ordered for \$5 from the council at 1995 Broadway, 2nd Floor, New York, NY 10023.

FDA POLICY UPHELD

The U.S. Supreme Court has rejected an attack against the FDA's policy of requiring "significant scientific agreement" to substantiate health claims on supple-

ment labels. A suit challenging the FDA had been filed by the Nutritional Health Alliance, a group of manufacturers, retailers, and consumers. The lawsuit contended that the labeling restriction amounts to an unlawful prior restraint of truthful commercial speech. However, a federal judge in New York and the 2nd U.S. Circuit Court of Appeals had upheld the regulations.

BOGUS DEVICE OPERATOR ORDERED TO STOP

The attorney general of Minnesota has obtained a judgment against Shelvie Rettmann of Prior Lake, Minnesota, an unlicensed individual who falsely represented that she could cure cancer. Her ap-

proach included treatments with a Rife Frequency Generator, a special diet, dietary supplements, foot reflexology, and a regimen of baths. The Rife device is claimed to generate radio waves that shatter "cancer-causing bacteria." The judge prohibited Rettmann from providing health-care services or products, ordered refunds upon request to injured consumers, and imposed civil penalties of \$50,000 plus the state's attorney fees and costs. However, refunds are uncertain because Rettmann filed for bankruptcy.

COURT HALTS BREATHASURE CLAIMS

The Warner-Lambert Company, which manufactures Certs breath mints, Clorets

mints and gum, Dentyne gum, and Listerine antiseptic mouthwash, has obtained a federal court order to stop BreathASURE Inc., of Calabasas, California, from continuing to claim or imply that its internal breath freshener products, BreathASURE and BreathASURE-D, get rid of bad breath for hours and give users clean, fresh breath, even after they consume onions, garlic, or other foods containing aromatic substances. Warner-Lambert had charged that taking BreathASURE capsules with water is no more effective in fighting bad breath than drinking water alone. Following the court ruling, BreathASURE removed information about its products from its Web site (<http://www.breathasure.com>). **NF**

A NATIONAL CONFERENCE FOR MEDICAL AND NUTRITION PROFESSIONALS

Science Meets 'Alternative Medicine'

How strong (or weak) is the scientific evidence? What's the impact on patients and physicians?

FEBRUARY 26-28, 1999 • WARWICK HOTEL, PHILADELPHIA

Sponsored by the *Scientific Review of Alternative Medicine* and **CSICOP**

Keynote Speakers

George Lundberg, Editor of the *Journal of the American Medical Association*
 Marcia Angell, Editor of the *New England Journal of Medicine*

Other speakers include

Wallace Sampson, James Alcock, Barry Beyerstein, Stephen Barrett, Robert Park, Saul Green, William Jarvis, Lewis Vaughn, John Renner

T O P I C S I N C L U D E

- Acupuncture
- Chiropractic
- Naturopathy
- Mind/Body Therapies
- Herbs and Supplements
- Physics, Scientific Law, and Homeopathy

- Biochemistry, Cancer, and Unconventional Treatments
- Biology and 'Life Forces'
- The Psychology of Believing What Isn't So
- Why Worthless Therapies Seem to Work
- The Ethics of 'Alternative' Approaches

- Medical Journals, Medical Schools, and Critical Thinking for Physicians

Conference Fees: \$250—Admission to all sessions • \$125 for students • \$125 for one day only • \$30—Banquet, Saturday night, February 27

For more details and registration, contact:

CSICOP Attn: Barry Karr, P.O. Box 703, Amherst, NY 14226

Book Reviews

Analysis and Ratings

The following reviews not only offer analyses but also rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Reviews by Manfred Kroger, PHD

Alternative Nutrition?

The Complete Illustrated Guide to Nutritional Healing . . . The Use of Diet, Vitamins, Minerals, and Herbs for Optimum Health by Denise Mortimore (Boston, MA: Element Books Inc., 1998), 256 pp., \$24.95 paperback, ISBN 1-86204-176-8.

The author is a "nutritional therapist" who lectures, teaches adult education courses, and runs a "thriving business" in England. Organized "nutritional therapy" stands outside the traditional dietetic/nutritional/medical establishment. It is truly an alternative healing discipline, and the 90 sources listed under "Bibliography" and "Further Reading" point to that fact. The book is a mélange of discussions of human physiology (quite accurately depicted), human illnesses (relatively well described, but often with alleged causes not backed by science thrown in), food composition (according to standard compendia), herbalism (as dealt with by current and old herbals and herbalists), nutritional recommendations (heavily laced with claims based on unproven assumptions), and practical dietary advice with many recipes and food combinations (presumably developed by the author and gleaned from the literature such as the Feingold diet, detoxification diet, and hypoallergenic diet).

The book is extremely handsome: colorful, excitingly illustrated, well orga-

nized, and laid out for efficient perusal. But it is heavily tainted by the author's unwarranted fears of, among other things, processed foods, additives, nonorganically grown produce and animal products, environmental contaminants, and technology in general.

Furthermore, the author does not endorse the currently accepted Food Guide Pyramid promoted by nutrition professionals. Instead, she proposes her own "new pyramid" based on the three macronutrients. The authoritative tone in making recommendations is reminiscent of earlier discredited diet gurus.

This volume may be welcome by the nutritionally illiterate who want to be told exactly what to eat. But a critical reader will find it objectionable, mostly because of all the contradictions and the confusing, detailed dogma instead of clear and rational science. What looked so nice turned out to be so unpalatable in many parts.

NOT RECOMMENDED

Allergic Fantasies

Allergies: Your Guide to Complementary Therapies, Alternative Techniques, Conventional Treatments by Moira Crawford (Boston, MA: Element Books, Inc., 1997), 134 pp., \$5.95 paperback, ISBN 1-86204-114-8.

As with the other booklets in this series entitled "The Natural Way," the intent is obviously to promote and popularize "natural therapies." These alternative, and often old, therapies most certainly stand outside current medical practice. And scientific support. For allergies and intolerances, the following are recommended and described as major therapies: acupuncture, acupressure, shiatsu, Chinese herbal remedies, herbal medicines, homeopathy, hydrotherapy, osteopathy, cranial osteopathy/craniosacral therapy, massage, reflexology, aromatherapy, and buteyko (a method of breathing alleged to have been kept secret within the Soviet "evil empire" and only revealed after its demise).

Most of these therapies are aimed at stress relief since stress is one of the symptoms (as well as a causative agent) in this multifactorial and often complex condition called allergy. There is no ratio-

nal relationship or physicochemical mode of action to link specific allergies with the therapies and techniques touted in this booklet. The first 55 pages describe allergies adequately, how they affect people, and what the conventional treatments are. It's the second half of the book that has no scientific/rational basis and slips into fantasy, faith, and wishful thinking.

NOT RECOMMENDED

A Dangerous Way

Cancer: Your Guide to Complementary Therapies, Alternative Techniques, Conventional Treatments by Philip Baron (Rockport, MA: Element Books, Inc., 1998), 136 pp., \$5.95 paperback, ISBN 1-85230-799-4.

Another in the "Natural Way" series, this slender booklet steers the reader away from conventional mainstream medical practice. It is "approved by the British and American Holistic Medical Associations." It actually does a fairly good job in the first half explaining to the lay reader what cancer is and what the many causes may be. But even here, among the good, some outlandish statements appear. For example, to "eat against cancer" you must reduce sugar intake and eat organic foods as much as possible. Also, modern food-packaging materials are suspect and must be avoided.

The second half of the paperback is a subtle condemnation of modern medical practices in cancer treatment and a persistent argument for "natural approaches," namely, the "gentle alternatives" in cancer therapy. Many approaches are discussed, accompanied by the (false) claim that they are effective cancer fighters: acupuncture/acupressure, aromatherapy, Ayurvedic medicine, homeopathy, herbalism, massage, naturopathy/hydrotherapy, nutritional therapy, reflexology, yoga, tai chi, hypnotherapy, faith healing, meditation/relaxation, psychotherapy, visualization or imagery, counseling, and art, music, and drama therapies.

The information provided is largely promotional for the emerging profession of natural therapists and a broadside against science-based medical approaches in cancer research and treatment. **NF**

NOT RECOMMENDED

FTC ATTACKS**CHELATION THERAPY**

Chelation therapy is a series of intravenous administrations of an EDTA plus various other substances. Proponents claim that chelation can reverse atherosclerosis, is an effective alternative to bypass surgery, and works against many other diseases. EDTA chelation (using a different protocol) is useful in some cases of lead poisoning. However, there is no scientific evidence that chelation therapy modifies any disease process. The primary organization to which chelationists belong is the American College for Advancement in Medicine (ACAM), which was founded in 1973 as the Association for Chelation Therapists. In 1998, the FTC charged that ACAM's Web site and a brochure had made false or unsubstantiated claims that chelation therapy: (a) is a safe, effective, and relatively inexpensive treatment to restore blood flow in victims of atherosclerosis without surgery; (b) can reverse symptoms of hardening of the arteries; (c) promotes health by correcting the major underlying cause of arterial blockage; (d) improves blood flow throughout the entire vascular system; and (e) claims that "every single study of the use of chelation therapy for atherosclerosis which has ever been published, without exception, has described an improvement in blood flow and symptoms." In December 1998, the FTC announced that it had secured a consent agreement barring ACAM from making unsubstantiated advertising claims that chelation therapy was effective against atherosclerosis or any other disease of the circulatory system.

**IOC CONSIDERS
CREATINE A FOOD**

The International Olympic Committee (IOC) has decided that creatine will not be added to its banned-substance list. The head of the IOC medical commission, Prince Alexandre de Merode, said that creatine is considered a food, and it could not be compared to testosterone or anabolic steroids, so it should not be prohibited. Many National Olympic

The Roaring Mouse

A tribute to the FTC

by Stephen Barrett, MD

The Federal Trade Commission, among its many functions, has primary jurisdiction over the advertising of foods, nonprescription drugs, cosmetics, devices, and services that are marketed in interstate commerce. It administers a powerful law and has been enforcing it vigorously during the past few years. In fact, it has addressed more health-related frauds during the past two years than in all previous years combined.

The FTC has broad powers to investigate complaints. If it concludes that the law has been violated, it may attempt to obtain voluntary compliance by entering into a consent order with the violator. Signers of a consent order need not admit that they have violated the law, but they must agree to stop the practices described in an accompanying complaint. If a consent agreement cannot be reached, the FTC may issue an administrative complaint that leads to an adjudication by an FTC Administrative Law Judge. If a problem is considered serious enough, the FTC can seek a federal court order (injunction) to stop the improper practices. In egregious fraud cases, it can ask the Justice Department to file criminal actions.

Cease-and-desist orders obtained by the FTC usually remain in effect for 20 years. The penalties for violating them can include prison sentences, corrective advertising, and fines of up to \$11,000 per day. FTC actions can also result in restitution to consumers and/or a disgorgement of profits. In cases where the offending party is willing to settle without a fight, the settlement is negotiated and the con-

sent agreement and complaint may be announced simultaneously. In fiscal year 1997, the FTC Consumer Protection Bureau announced 46 consent agreements, of which 31 were related to health claims (Table 1 gives several examples).

New Strategies

Although the FTC has a very effective law, it can take legal action against only a small percentage of the violations it detects. During the 1980s, it averaged about five health-related cases per year. After Bill Clinton took office, the number increased sharply. In June 1997, at a health-fraud conference cosponsored by the FTC, a staff attorney indicated that the agency's consumer-protection bureau had adopted new strategies for targeted enforcement actions, public education, and warnings to entrepreneurs.

Much of this activity involves the Internet. The FTC operates Consumer Sentinel, a computerized consumer-fraud database that provides secure online access to consumer complaints for over 150 law-enforcement organizations across the United States and Canada. The complaints concern telemarketing and direct-mail problems, as well as Internet fraud. The database contains over 200,000 complaints and is growing rapidly. In June 1998, the FTC announced that it had brought 35 Internet-related enforcement actions. The agency's online complaint form is at <http://www.ftc.gov/bcp/conline/fraud.htm>.

The FTC has actively sought Internet

companies and trade groups to join as partners in disseminating consumer-protection information to consumers online. As a result, the Interactive Services Association, a leading online trade association, and companies such as AT&T, NetCom, America Online, Circuit City, Compaq, Micron, Borders, and American Express have helped circulate public-service announcements over the Internet, cautioning consumers to avoid particular scams and "hot linking" consumers to the commission's Web site where they can find "Cybershopping" guides, "safe surfing" tips, and other helpful information.

Another creative activity is the posting of "teaser sites" that mimic pyramid schemes, scholarship scams, deceptive travel programs, false weight-loss claims, and fraudulent vending opportunities—typical frauds that have been practiced on consumers through direct mail, telemarketing, and other means. The teaser sites are registered with major search engines so that they may be encountered by consumers about to become ensnared by plausible but untrue come-ons. Instead of being swindled, of course, visitors are warned about the deceptive nature of the scams.

Internet 'Surf Days'

Since December 1996, the FTC has conducted nine "Surf Days" aimed at providing information to entrepreneurs who may be violating the law. For the first, staff attorneys and investigators were joined by scores of others from federal, state, and local agencies. Over a three-hour period, this ad hoc task force located over 500 Web sites or newsgroup messages promoting apparent pyramid schemes. The FTC staff e-mailed a warning message to the individuals or companies that had posted these solicitations, explaining that pyramid schemes violate federal and state laws and providing a link back to the FTC Web site for more information. A month later, the investigative staff checked and found that a substantial number had disappeared or been improved.

In November 1997, the FTC conducted North American Health Claim Surf Day with help from other federal agencies, 18 state attorney general's offices, many nonprofit health organizations, and

consumer-protection and information agencies from the United States, Canada, and Mexico. The participants surfed the Internet for potentially false or deceptive advertising claims related to preventing or treating heart disease, cancer, AIDS, diabetes, arthritis, and multiple sclerosis, and sent hundreds of e-mail messages to Web site advertisers pointing out that they must have evidence to back up their claims. In November 1998, the process was repeated by an international coalition of 80 government and private agencies and organizations from 25 countries whose participants issued more than 1,200 warnings.

New Advertising Guidelines

The 1994 Dietary Supplement Health and Education Act (DSHEA) permits manufacturers to make "structure/function" claims as long as their products are not falsely promoted for cure, mitigation, treatment, or prevention of disease. Manufacturers have responded by making hundreds of questionable claims that they previously were afraid to make. In December 1998, the FTC issued *Dietary Supplements: An Advertising Guide for Industry*, a detailed document to clarify the need for substantiation. The guide describes the steps the FTC uses to make its analyses and provides a roadmap for others who wish to do the same.

To determine whether an ad complies with FTC law, the first step is to identify all express and implied claims that the ad conveys to consumers. Once the claims are identified, the scientific evidence can be assessed to determine whether they are adequately supported. Advertisers must make sure that whatever they say expressly is accurate. Often, however, an ad conveys other claims beyond those expressly stated. Advertisers cannot suggest claims that they could not make directly. When identifying claims, advertisers should consider the ad as a whole, assessing the "net impression" conveyed by all elements of the ad, including the text, product name, and depictions.

For example, if an ad claims that "university studies prove" that a mineral supplement can improve athletic performance, the advertiser should have

[continued on page 12]

Why Health Professionals Become Quacks

Looking beneath the layers

by William T. Jarvis, PHD

It is especially disappointing when an individual trained in the health sciences turns to promoting quackery. Friends and colleagues often wonder how this can happen. Some reasons appear to be:

Boredom. Daily practice can become humdrum. Pseudoscientific ideas can be exciting. The late Carl Sagan believed that the qualities that make pseudoscience appealing are the same that make scientific enterprises so fascinating. He said, "I make a distinction between those who perpetuate and promote borderline belief systems and those who accept them. The latter are often taken by the novelty of the systems and the feeling of insight and grandeur they provide." Sagan lamented the fact that so many are willing to settle for pseudoscience when true science offers so much to those willing to work at it.

Low professional esteem. Non-physicians who don't believe their professions are sufficiently appreciated sometimes compensate by making extravagant claims. Dental renegades have said, "All diseases can be seen in a patient's mouth." Fringe podiatrists may claim to be able to judge health entirely by examining the feet. Iridologists point to the eye, chiropractors the spine, auriculotherapists the ear, some registered nurses an alleged "human energy field," and so on.

Even physicians are not immune from raising their personal status by pretension. By claiming to cure cancer or to reverse heart disease without bypass surgery, general physicians can elevate themselves above the highly trained specialists in oncology or cardiology. By claiming to heal diseases that doctors cannot, faith healers advance above physicians on the social-status chart (physicians are normally at the top of the chart while preachers have been slipping in modern times). Psychologists, physicians, actors, or others who become

health gurus often become darlings of the popular press.

Paranormal tendencies. Many health systems are actually hygienic religions with deeply held, emotionally significant beliefs about the nature of reality, salvation, and proper lifestyles.

Vegetarianism, chiropractic, naturopathy, homeopathy, energy medicine, therapeutic touch, crystal healing, and many more are rooted in vitalism, which has been defined as "a doctrine that the functions of a living organism are due to a vital principle ('life force') distinct from physicochemical forces" and "the theory that biological activities are directed by a supernatural force." Vitalists are not just nonscientific; they are antiscientific because they abhor the reductionism, materialism, and mechanistic causal processes of science. They prefer subjective experience to objective testing and place intuitiveness above reason and logic. Vitalism is linked to the concept of an immortal human soul, which also connects it to religious ideologies.

Paranoid mental state. Some people are prone to seeing conspiracies everywhere. Such people may readily believe that fluoridation is a conspiracy to poison America, that AIDS was invented and spread to destroy Africans or homosexuals, and that organized medicine is withholding the cure for cancer.

Though individuals who complain about conspiracies directed toward themselves are likely to be regarded as mentally ill, those who perceive conspiracies as directed against a nation, culture, or way of life may seem more rational. Perceiving that their political passions are unselfish and patriotic intensifies their feelings of righteousness and moral indignation. Many such people belong to the

[continued on page 13]

WEB WATCH

This month's evaluations are by Stephen Barrett, MD, board chairman of Quackwatch, Inc. (<http://www.quackwatch.com>), which is working hard to improve the quality of health information on the Web. He also operates Chirobase (<http://www.chirobase.org>), a site devoted to chiropractic history, theories, and current practices.

BEST

The FDA Special Nutritionals Adverse Event Monitoring System lists reports to the FDA of adverse events associated with the use of dietary supplements and herbs. It has been maintained by the FDA Center for Food Safety and Applied Nutrition since 1993. Its database can be searched online at <http://vm.cfsan.fda.gov/~dms/aems.html>. The data must be interpreted cautiously because listing in the database does not establish a cause-and-effect relationship.

HealthCalc Network (<http://www.healthcalc.net/hcn>) offers a simple but sensible health assessment that covers the major risk and lifestyle factors. The test is free and can be completed online.

WORST

The Nutritional Consultants Organization of Canada (<http://www.canlink.com/ncoc/>) offers a Registered Nutritional Consultant (RNC) credential to people with a "bachelor's degree in holistic nutrition from an approved school or by training which is deemed equivalent" by NCOC's Board of Examiners. The site links to several holders of the credential, including Freda Newman, RNC, whose Web site (<http://www.fredacare.com>) offers a computerized nutritional analysis to "pinpoint nutritional deficiencies." The analysis supposedly tests for 54 types of "nutritional imbalances," based on answers to a 392-item "nutrition symptom questionnaire." The cost is \$50 for a "complete" analysis or \$30 for one of 21 "specialty analyses." The end result is an online report that includes findings, recommendations, and charts.

For \$25, the Running Doctor Sportsmedicine Clinic (<http://www.runningdr.com/runningdr/nutritional.html>) will provide information on the individual's "acid/alkaline balance" and various body systems. The site claims that "if you suffer with symptoms suggestive of weakness or fatigue in any of these areas, there are tremendously beneficial nutritional products which will provide the necessary support and balancing properties to promote improved wellness in your life." Its 82-item questionnaire asks mainly about symptoms, many of which are not nutrition-related.

"university studies" that document the benefit as well as evidence that the studies are methodologically sound. And if advertisement for a vitamin supplement claims that 90% of cardiologists regularly take the product, the advertiser should have adequate support for both the percentage and the implied representation that taking the product is beneficial for the heart.

A statement about a product's effect on a normal "structure or function" of the body may also imply that the product is beneficial for treatment. If elements of the ad imply that the product provides a dis-

ease benefit, the advertiser must be able to substantiate the implied claim even if the ad contains no express reference to disease. Thus if an ad for "Arthricure" shows an arthritic woman using a walker before taking the products and dancing afterward, the manufacturers should be able to substantiate the implied claims that the product can cure or mitigate arthritis.

The FTC typically requires claims about the efficacy or safety of dietary supplements to be supported with "competent and reliable scientific evidence." Anecdotal evidence about the individual experience of consumers is not sufficient to substantiate claims. Even if those experiences

are genuine, they may be attributable to a placebo effect or factors unrelated to the supplement. Individual experiences are not a substitute for scientific research. Ads that include testimonials should be backed by adequate substantiation that the testimonial experience represents what consumers will generally achieve when using the product. Vague disclaimers like "results may vary" are likely to be insufficient. Whenever an expert or consumer endorser is used, the advertiser should disclose any material connection between the endorser and the advertiser of the product that consumers would not reasonably expect.

Nutrition-Related FTC Consent Agreements Settled During Fiscal Year 1997

- Abbott Laboratories, Inc., settled allegations related to its promotion of Ensure for healthy, active adults. The FTC alleged that Abbott represented without adequate substantiation that many doctors recommend Ensure as a meal supplement and meal replacement for healthy adults, including those in their thirties and forties. The consent order prohibits unsubstantiated claims about the extent to which doctors or other professionals recommend any food or dietary or nutritional supplement, or about any other recommendation, approval, or endorsement of such products.
- Abflex, U.S.A., Inc.; Kent & Spiegel Direct, Inc.; Marsha Kent; Peter Spiegel; and Martin Van Der Hoeven settled allegations that advertising for the Abflex abdominal exerciser contained unsubstantiated claims for weight loss and spot reduction.
- Amerifit, Inc., settled allegations in connection with the marketing of diet supplements sold under the trade names "Fat Burners" and "Fast Burners." The order required the company to pay \$100,000 and to have scientific substantiation for any future claim that a food, drug, or dietary supplement will cause weight loss or reduce body fat.
- A consent order with BodyWell resolved charges related to the marketing of shoe insoles that purportedly cause weight loss by stimulating certain areas of the feet. The order required payment of \$100,000 in redress and prohibits use of the name "Slimming Soles" without scientific substantiation that the product actually causes weight loss.
- Dean Distributors, Inc. (d/b/a Advanced Health Care System, Cambridge Direct Sales, and Medibase), settled charges related to the marketing of low-calorie and very-low-calorie diet programs, including the Food for Life Weight Management System and the Cambridge Diet, through a multilevel distribution system. The order requires substantiation for weight-loss and weight-maintenance claims. It also requires that advertisements disclose that weight loss may be temporary and clearly disclose the need for physician-monitoring to minimize potential health risks.
- Gerber Products Company settled allegations that the company made false and unsubstantiated "doctor recommended" claims for Gerber baby food. The order bars the company from misinterpreting the results or existence of any survey, test, or research.
- Grey Advertising, Inc., settled charges that a commercial falsely implied that some of the flavors in the Dannon Company's Pure Indulgence frozen yogurt line were low in fat and calories.
- Icon Health and Fitness, which bills itself as the world's largest manufacturer of home-fitness equipment, and two related companies settled charges that they had made unsubstantiated claims about the weight-loss benefits of the Proform Cross Walk Treadmill. The order requires substantiation for future claims and requires that testimonial ads either represent the typical experience of users or disclose that the results are not typical.
- Interactive Medical Technologies, Ltd., and several other parties settled allegations related to Lipitol and SeQuester, two cellulose-bile products that were claimed to aid in weight loss and fat and cholesterol reduction. Three separate orders prohibit unsubstantiated claims and call for total payment of \$185,000 for consumer redress.
- Life Fitness, which markets a variety of exercise equipment, settled allegations that it had made unsubstantiated claims about the weight-loss benefits of its Lifecycle stationary exercise cycle. The order requires substantiation for future claims about the weight-loss, calorie-burning, or fat-burning benefits of any exercise equipment.
- Nutrition 21, Selene Systems, and Herbert Boynton settled charges that advertising claims for their weight-loss and health-care products containing chromium picolinate were unsubstantiated. Nutrition 21 is the sole U.S. supplier for chromium picolinate and sells it to the public through distributors. Similar orders were obtained against Universal Merchants, its president, Steven Oscherowitz, and Victoria Bie, d/b/a Body Gold.
- A company doing business as United Research Center, Inc., and its president, Patrice Runner, settled allegations related to their marketing of Svelt-PATCH, a skin patch that purportedly melts away body fat. The order requires scientific substantiation for future claims that any product or program controls appetite, increases metabolism, reduces body fat, causes weight loss, reduces cholesterol, or provides any weight-related benefit. It also required payment of \$375,000 in consumer redress.
- Uno Restaurant Corporation and two subsidiaries, Pizzeria Uno Corporation and Uno Restaurants, Inc., settled allegations that they had falsely advertised their Thinzettas line of thin-crust pizzas as low fat.

Claims based solely on traditional use should avoid implying that the product has been scientifically evaluated for efficacy. Claims that, if unfounded, could present a substantial risk of injury to consumer health or safety will be held to a higher level of scientific proof. For example, a claim that a mineral supplement has been a popular American folk remedy for shrinking tumors should not be made without scientific evidence that the product is effective.

An advertisement can also be deceptive because of what it fails to say. For example, if an herbal weight-loss product contains an ingredient that, when regularly consumed, can result in a significant increase in blood pressure, the advertiser should disclose this potentially serious risk.

When the disclosure of qualifying information is necessary, that information should be presented so that it is actually noticed and understood by consumers. A fine-print disclosure at the bottom of a print ad, a disclaimer buried in a body of text, a brief video superscript in a television ad, or a disclaimer that is easily missed on an Internet Web site, are not likely to be adequate.

How to Keep Track

The FTC's activities are reported in the weekly *FTC News Notes* and an annual report, both of which are available free of charge to interested parties. Annual (fiscal year) reports, news releases, consent agreements, policy statements, consumer advisories, and many other important documents are posted to the agency's Web site (<http://www.ftc.gov>), which receives about 100,000 hits per day on its home page. The 1997 annual report, covering October 1, 1996 through September 30, 1997, can be viewed at <http://www.ftc.gov/os/ar97/index.html>. The 1998 report should be posted early in 1999. The most efficient way to search for a specific topic is to go directly to the search page at <http://www.ftc.gov/search.NF>

Dr. Barrett, a retired psychiatrist who resides in Allentown, Pennsylvania, is board chairman of Quackwatch, Inc. and a board member of the National Council Against Health Fraud.

[continued from page 11]

world of American fascism, Holocaust deniers, tax rebels, the radical militia movement, and some "libertarian" causes. Liberty Lobby's newspaper, *The Spotlight*, champions such causes and also promotes unproven cancer cures and attacks fluoridation.

Reality shock. Everyone is vulnerable to death anxiety. Health personnel who regularly deal with terminally ill patients must make psychological adjustments. Some are simply not up to it. Investigation of quack cancer clinics have found physicians, nurses, and others who became disillusioned with standard care because of the harsh realities of the side effects or limitations of proven therapies.

Beliefs encroachment. Science is limited to dealing with observable, measurable, and repeatable phenomena. Beliefs that transcend science fall into the realms of philosophy and religion. Some people allow such beliefs to encroach upon their professional practices. Though one may exercise religious or philosophical values of compassion, generosity, mercy, and integrity (which is the foundation of the scientific method's search for objective truth), it is not appropriate for a health professional to permit metaphysical (supernatural) notions to displace or distort scientific diagnostic, prescriptive, or therapeutic procedures.

The profit motive. Quackery can be extremely lucrative. Claiming to have a "better mousetrap" can cause the world to beat a path to one's door. Greed can motivate entrepreneurial practitioners to set ethical principles aside.

The prophet motive. Just as Old Testament prophets called for conversion and repentance, doctors have to "convert" patients away from smoking, obesity, stress, alcohol, and other indulgences. As prognosticators, doctors foretell what is going to happen if patients don't change their way of life. The Prophet role provides power over people. Some doctors consciously avoid it. They encourage patients to be self-reliant rather than dependent, but in doing so they may fail to meet important emotional needs. Quacks, on the other hand, revel in, encourage, and exploit this power. Egomaniacs are commonly found among quacks. They enjoy

the adulation and discipleship that their pretense of superiority evokes.

Psychopathic tendencies. Studies of the psychopathic personality provide insight into the psychodynamics of quackery. Dr. Robert Hare, who investigated psychopathology for more than 20 years, states, "You find psychopaths in all professions . . . the shyster lawyer, the physician always on the verge of losing his license, the businessman with a string of deals where his partners always lost out."

Hare describes psychopaths as lacking a capacity to feel compassion or pangs of conscience, and as exhibiting glibness, superficial charm, grandiosity, pathological lying, conning/manipulative behavior, lack of guilt, proneness to boredom, lack of empathy, and other traits often seen in quacks. According to Hare, such people suffer from a cognitive defect that prevents them from experiencing sympathy or remorse.

The conversion phenomenon. The "brainwashing" that North Koreans used on American prisoners of war involved stress to the point that it produced protective inhibition and dysfunction. In some cases, positive conditioning causes the victim to love what he had previously hated, and vice versa; and in other cases, the brain stops computing critically the impressions received. Many individuals who become quacks undergo a midlife crisis, painful divorce, life-threatening disease, or another severely stressful experience—and radical personal changes ensue.

The conversion theory is supported by a study of why physicians had taken up "holistic" practices. By far the greatest reason given (51.7%) was "spiritual or religious experiences."

Many people—including far too many health professionals, law-enforcement officials, and judges—exhibit a cavalier attitude toward quackery. Although most reject the idea that quackery is "worth a try" for a sick person, they may not fully understand quackery's harmful potential. And they may be completely unaware of the true, disconcerting reasons why some turn away from science and evidence to the unproven and fraudulent. **NF**

Dr. Jarvis is Executive Director of the National Council Against Health Fraud (NCAHF).

[continued from page 9]

Committees had been trying to get creatine added to the IOC's banned substance list because of short-term problems such as muscle cramping and dehydration associated with its use.

FDA IMPOSES LARGE FINE ON JUICE COMPANY

Odwalla, Inc., a California juice company, has been fined \$1.5 million by the FDA in the aftermath of the 1996 *E. coli* outbreak linked to the company's tainted apple cider juice. The fine is one of the largest ever to be imposed by the federal agency. Money received from Odwalla will be used in part to increase public awareness of the dangers associated with unpasteurized juice. Fifteen children were affected by the 1996 outbreak—14 of them becoming seriously ill and one dying. The surviving children may live with serious effects of the outbreak, which can cause kidney failure, for years to come. Odwalla is currently serving five years of probation for ignoring safety standards leading to the outbreak. Recently tested samples of Odwalla apple juice have tested negative for *E. coli*.

JAIL TERM FOR HEALTH HOAXING

An FDA investigation into a man posing as a physician, but without a medical license, has ended with the man being sent to prison. Edwin E. Kokes was charged and convicted after FDA officials uncovered his fraudulent business, Independent Testing Labs of Grand Island, Nebraska. According to the *FDA Consumer*, Kokes had been "diagnosing and treating nonexistent conditions and purchasing and selling unapproved drugs since 1989." Among the treatments he offered his patients was the application of "M-Bone" (actually diluted sulfuric acid) to the skin to treat various fabricated ailments. He sold the acid for \$300/four ounces. Kokes boasted that he could diagnose medical conditions by analyzing hair and fingernail samples with a high-tech NASA laser. FDA agents had disproved that claim by submitting hair and nail samples to Kokes, includ-

ing those of a guinea pig. From these samples, Kokes had diagnosed human diseases including allergies, glandular problems, toxicity, and organ malfunctions. Kokes is now serving a two-and-a-half-year prison term.

JUICE MAKERS GIVEN TIME TO MEET REQUIREMENTS

In October 1998, the FDA granted citrus juice manufacturers eight additional months to meet their new safety guidelines meant to ensure the lowest possible risk of food-borne illness due to contaminated fruit. Manufacturers will now be required to either develop a system to reduce the number of pathogens in their fruit juices to a specified level or place a warning label on their juices stating the risk of food-borne illness to those with weakened immune systems, the elderly, and children. The new stringent guidelines had been met with frustration by the manufacturers, who felt that they had not been given enough time to develop a new approach. The new deadline for implementing either approach is July 8, 1999. In the meantime, manufacturers must show that they are following strict safety rules to minimize potential pathogen risk in their products.

'GOD'S RECIPE' RUNS AFOUL OF THE FTC

In the first-ever case involving claims over attention deficit and attention deficit hyperactivity disorders (ADD and ADHD, respectively), the manufacturer of a dietary supplement regimen called "God's Recipe" has agreed to settle with the Federal Trade Commission.

The manufacturers, New Vision International, based in Scottsdale, Arizona, and its affiliate, NVI Promotions, L.L.C., had been making claims that their supplements—a trinity of minerals, antioxidants, and enzymes—could cure ADD and ADHD. New Vision also claimed that "God's Recipe" would be a safer, natural alternative to the traditional treatment for the disorder, the prescription drug Ritalin. The FTC released a statement on December 8, 1998, stating that "New Vision lacked the substantiation the Commission requires for that claim." Under the proposed settlement (under public comment for 60 days be-

fore becoming final), New Vision will be prohibited from making claims that its product can "cure, prevent, treat or mitigate" either ADD or ADHD or its symptoms. It will also be forbidden from suggesting its drug as an alternative to Ritalin unless it is able to support its claims through scientific documentation. In addition, the proposed settlement prohibits the use of atypical testimonials to deceptively represent their product line.

NEW DRINKING WATER STANDARDS ANNOUNCED

President Clinton has issued the first new health standards under the Safe Drinking Water Act Amendments of 1996. The new standards will help to protect against potentially harmful by-products caused by disinfecting the public water supply. They will also help to protect against pathogens that are difficult to disinfect, such as the potentially life-threatening *Cryptosporidium protozoa*, among others. A fact sheet can be found at <http://www.epa.gov/OGWDW/mdbp/mdbp.html>.

FOLIC ACID AND COLON CANCER

New findings published in the October 1998 issue of the *Annals of Internal Medicine* show that colon cancer risk was reduced by as much as 75% in women taking multivitamins containing folic acid. The study, a part of the larger Nurses' Health Study conducted by researchers at Brigham and Women's Hospital in Boston, looked at women who had taken multivitamins for a specific number of years. Though women who took multivitamins for less than 5 years showed no benefits with regard to colon cancer reduction, those who took them for more than 15 years had significant reductions—68 new cases of colon cancer per 10,000 women compared to 15 new cases, respectively. There were also moderate decreases in colon cancer risk when folic acid was consumed through diet alone. For a variety of reasons, researchers believe that folic acid played a central role in these reductions. This type of study, however, cannot rule out the possibility that other lifestyle factors were the true causes of decreased risk. **NF**

Book Reviews

Analysis and Ratings

The following reviews not only offer analyses but also rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to *Nutrition Forum Book Reviews*, P.O. Box 664, Amherst, NY 14226-0664.

Insult to Injury

Manfred Kroger, PhD

Controlling Herpes Naturally . . . A Holistic Approach to Prevention and Treatment by Michele Picozzi (Colorado Springs, CO: Southpaw Press, 1998), 114 pp., \$12.95 paperback. ISBN 0-9658600-0-0.

The meaning of this thin volume is clear: "take control and rely on natural products and procedures," it says; "distrust doctors and what they prescribe and mosey on down to the health food store where health is gained and regained."

As a student's term paper, this book would get a failing grade; maybe a charitable D. (It's not really a book. Why is the first page numbered 15? There are no more than 85 pages of text.) The facts about herpes in these pages are indeed sparse. The author should have focused on the fact that herpes is a contagious disease and is spread by direct contact. A few pages are devoted to describing this viral illness, its many symptoms, and its connections to other conditions. Two pages deal with current therapy. Since 1982 the prescription drug acyclovir has been used. It's ironic, but typical for this type of book, that the success of acyclovir is downplayed and all negatives thereof accentuated. Eight other drugs are in various stages of development and approval.

Most of this booklet is an endorsement of dozens of "natural" health-food-store products. Also, nutritional advice, stress management, yoga postures, home-

opathy, and aromatherapy are described as related to herpes, but it is not clear whether as preventive, curative, or suppressive factors.

The author is a journalist who has written on yoga and "natural" medicine during the past few years. This "book," unfortunately, is a mere review paper based on writings about herpes drawn from "alternative" medicine sources and promotional materials. There is hardly any serious science in these pages and no rational science-based information. And the little there is is frequently faulty, confusing, and contradictory.

Dietary do's and don'ts abound and make no sense. Organic foods are in; sugar and sweets are out. Garlic and quinoa are good, but tomatoes and peanuts are bad. Avoid acid-producing foods and go for, you guessed it, alkaline-producing edibles. And foods high in arginine are definitely pro-herpes (there go chocolate, nuts, grains, and much more). And why making your own yogurt is given a whole page is a puzzlement.

This report is incoherent, irrational in places, too lop-sided toward alternative self-help medicine, antagonistic to what Americans find in supermarkets, and insulting to readers previously exposed to biology or medicine (or even a course in critical thinking).

NOT RECOMMENDED

Beyond Cholesterol

Cinda Williams Chima, MS, RD

The Homocysteine Revolution by Kilmer S. McCully, MD (New Canaan, CT: Keats Publishing, 1997), 242 pp., \$14.95 paperback, ISBN 0-87983-767-5.

In 1933, an eight-year-old boy was admitted to the Massachusetts General Hospital with mental retardation and symptoms of an apparent stroke. The boy's condition continued to deteriorate, and he died three days later. The autopsy determined that the boy died of severe arteriosclerosis of the carotid artery with brain infarct (stroke). The unusual case was published in the *New England Journal of Medicine* that same year.

This case was the first clue in a medical mystery that enthralled a young Massachusetts General pathologist named Kilmer S. McCully more than thirty years later. By that time, the boy had been retrospectively diagnosed with homocystinuria, a genetic metabolic disease first identified in Ireland in the early 1960s. In homocystinuria the liver is unable to dispose of homocysteine, an amino acid, because of a number of enzyme defects. Researchers had found that many children with homocystinuria die of complications relating to blood clots and arterial changes despite normal cholesterol levels.

In 1969, McCully published a paper in the *American Journal of Pathology* outlining the framework for what he called the "Homocysteine Theory of Heart Disease." He suggested for the first time that homocysteine could play a role in arteriosclerosis in those without the frank genetic defect. According to this theory, which McCully continued to develop over the ensuing decade, heart disease is a problem of what he calls "protein intoxication" rather than "fat intoxication" as has been generally believed. Homocysteine is derived in the body from the amino acid methionine, found primarily in meat protein and in smaller amounts in plant proteins. Because vitamins B₆, B₁₂, and folic acid contribute to enzyme activity and can lower serum homocysteine in people without the defect, he suggested that a diet high in methionine and low in B₆ and folic acid could cause heart disease.

McCully's theory initially drew little attention from adherents to what he calls the "cholesterol-fat approach." Indeed, he attributes his failure to attain tenure and subsequent departure from the Harvard Medical School at the end of 1978 to criticism of his "homocysteine theory." After leaving Harvard, he was appointed pathologist at the Veterans Administration Hospital in Providence, Rhode Island, where he has continued to pursue the relationship between homocysteine and heart disease. *The Homocysteine Revolution* is his first book on the topic targeted at the lay public.

McCully suggests that the homocysteine theory explains many observations

about heart disease that are inconsistent with the cholesterol/fat hypothesis. For example, he relates the dramatic rise in U.S. heart disease through the early 1960s to the switch to a diet high in meat and processed and refined foods and low in the B vitamins. He says that the subsequent decline in heart disease since that time reflects the addition of vitamin B₆ to the food supply in 1961. In McCully's view, hyperhomocysteinemia is the primary risk factor for heart disease. Other risk factors are secondary at best.

The complexity of the homocysteine theory as well as the fact that a number of other studies failed to replicate McCully's early results may in part explain the initial resistance of other researchers to his hypothesis. McCully is critical of what he calls the "cholesterol/fat" camp and attributes their failure to accept his theory to "the inadequate, flawed, or misinterpreted experiments of a few investigators." He even suggests that the lack of interest in a vitamin deficiency as a cause of heart disease relates to a lack of potential profit. At times he appears to fit the evidence to his theory rather than the other way around, emphasizing those studies that support it and downplaying those that don't.

But it is not necessary to discard the cholesterol/fat theory to embrace homocysteine as a risk factor. The development of cardiovascular disease is clearly multifactorial.

While McCully is a Harvard-educated physician and scientist who is an expert in the esoteric field of amino acid metabolism, it is clearly difficult for him to translate that expertise into simple language. Despite a general grasp of the principles involved, I found myself reading and rereading pages and paragraphs to make sense of them. This is not a book to take to the beach!

It is, however, a story of perseverance and redemption. The '90s have spawned several studies that appear to support McCully's findings. For example, a survey of subjects in the Framingham heart study showed a relationship between high blood homocysteine and low intakes of folic acid, B₁₂, and B₆. In another study of 1,000 Framingham subjects, high serum homocysteine was

found to be a stronger risk factor for heart disease than many traditional risk factors including elevated cholesterol, high blood pressure, and cigarette smoking. According to a 1995 article in the *New England Journal of Medicine*, more than 20 case-control and cross-sectional studies involving more than 2,000 subjects have suggested that persons with cardiovascular disease have higher blood homocysteine than those without the disease. Based on these findings, it has been estimated that the recent FDA decision to require folate fortification of bread and grain products may save 50,000 lives a year.

Many in the medical community, however, are awaiting the results of the first randomized clinical trial of folic acid supplementation before they fully accept the homocysteine theory. Ironically, this study is to be carried out at Harvard.

For those who can get through it, the book is a well-referenced, fascinating medical detective story that demonstrates that scientific research does not always progress seamlessly but by fits and starts. McCully also presents rather convincing evidence that current RDAs for folate and B₆ are too low. Fortunately, the plant-based low-fat minimally processed diet he recommends is consistent with current recommendations for a heart-healthy diet.

False Formula

Manfred Kroger, PhD

Psoriasis: Your Guide to Complementary Therapies, Alternative Techniques, Conventional Treatments by Hilary Bower (Rockport, MA: Element Books, Inc., 1998), 134 pp., \$5.95 paperback. ISBN 1-85230-832-X.

There are at least 17 of these booklets dealing with as many diseases or conditions. This is the third I have read and my displeasure has been growing. They seem to have been commissioned to fit a prescribed format. Accordingly, the first half describes the disease and its conventional medical treatment. This part in the psoriasis booklet is quite factual, but current standard treatments are belittled. The entire tone throughout is derisive of main-

stream medicine. It is assumed that an alternative to an exploitative and rigidly scientific health establishment must be the answer, and this alternative is natural therapists.

The second half of the booklet, as with the others, is a shallow promotional treatise of many natural therapies. The specific ones claimed to be useful with regard to psoriasis are homeopathy, acupuncture/acupressure, reflexology, and Chinese and Western medicines. Most of these whole-system therapeutic approaches make little rational sense in the alleviation of this baffling, multifactorial, and multifaceted skin ailment which is said to bother two to three out of every 100 human beings. Of course, some convenient case histories attest to effectiveness of the natural approaches.

There are numerous errors and contradictions throughout the book, many the result of the writer's incomplete grasp of physiology and other biological principles, such as liver, stomach, and intestinal functions. She blindly parrots the silly accusations of antitechnologists, naive environmentalists, and seekers of alternative truths that modern living, supermarket foods, and synthetic chemicals are the causes of most of human ill health, psoriasis included. I have looked at the Web site of the National Psoriasis Foundation. Now there is an authoritative and all-encompassing source for all aspects of this condition. In it I found no references to homeopathy or any of the many treatments touted in this guide for the misguided. **NF**

BETA-CAROTENE AND LUNG CANCER

A six-month study of ferrets—which metabolize beta-carotene much like humans—found that excess amounts stored in the lungs became oxidized into substances that decreased a tumor suppressor and increased a tumor promoter in the animals' lungs. The finding may explain why very high doses appeared to increase lung cancer rates among smokers in two large clinical trials in 1994 and 1996. The ferrets were divided into four groups. One received beta-carotene and was exposed to cigarette smoke equivalent to a human smoking 1.5 packs per day. Two other groups got either the supplement or smoke exposure, and a control group got neither. The first group had the strongest precancerous changes. The study was conducted by researchers at the Jean Mayer USDA Human Nutrition Research Center at Tufts University.

BREATHASURE FALSE CLAIMS PROHIBITED

Warner Lambert, Inc., has secured a federal court order permanently barring BreathASURE, Inc., from making 21 unsubstantiated claims for BreathASURE, BreathASURE D, or any other similar product. The prohibited claims include: "works from the inside out," "cleans bad breath for hours," "provides users with clean breath," "lasts for hours," "will stop bad breath caused by the foods you eat," and "will help stop morning breath."

ALLIANCE OF GNC AND RITE AID

General Nutrition Centers, Inc., and Rite Aid Corp. have formed a "strategic alliance" in which GNC will manufacture and the two companies will jointly market PharmAssure products through 3,900 Rite Aid pharmacies and 3,650 GNC domestic stores. The plan includes placing GNC kiosks staffed by Rite Aid employees "specially trained in nutrition" into 1,500 Rite Aid stores. The companies will also develop a nutritional information and supplement sales Web site at <http://www.gnc.riteaid.com>.

Chiropractic Nutrition

The good, the bad, and the patently false

by Samuel Homola, DC

Chiropractic is based on the notion that most ailments are the result of spinal problems. Its "discovery" was announced in 1895 by Daniel David Palmer, a grocer and "magnetic healer" who allegedly restored the hearing of a partially deaf janitor by "adjusting" a bump on his spine. Soon afterward he declared that the basic cause of disease is "nerve interference" caused by misaligned spinal bones ("subluxations"). Most of today's 60,000+ chiropractors still regard subluxations as a direct or underlying cause of ill health and maintain that spinal "adjustment" can restore and promote good health.

Chiropractic surveys suggest that at least 80 percent of chiropractors are giving nutrition advice to their patients. Some chiropractors are able to counsel their patients about sensible eating, weight control, and other nutrition-related health matters. Many, however, are engaged in questionable nutrition practices.

All chiropractic colleges teach courses in basic and clinical nutrition. Although most courses rely on standard nutrition textbooks, it is not clear whether students put what they learn to good use. Practicing chiropractors have little exposure to science-based nutrition. Chiropractic journals, magazines, and textbooks provide very little nutrition information, and most of what they provide is not valid. Postgraduate seminars are available, but the vast majority are sponsored by supplement distributors for the purpose of boosting sales. During my 43-year career, I have seen hundreds of advertisements for such seminars. I cannot recall a

single one that appeared to provide valid teachings. Many state chiropractic associations promote similarly questionable seminars that yield credits toward license renewal. Many exhibitors at chiropractic conventions hawk supplements that are sold in chiropractic offices. Some exhibitors promote inappropriate diagnostic tests, and some even distribute literature stating which products supposedly are effective against various diseases.

Chiropractors interested in science-based nutrition can pick up the basics from other sources or by studying on their own. It is not difficult to learn enough to answer the questions patients typically ask about food composition, dietary balance, osteoporosis prevention, exercise principles, low-fat eating, and other dietary strategies. However, many chiropractors mix nutrition and subluxation theory, use dubious tests, or engage in bizarre treatment systems that result in inappropriate use of supplement products.

Supplement Promotion

Chiropractors can greatly augment their income by selling nutritional products to their patients. More than 50 companies market them primarily or exclusively through chiropractors. Some handle just a few products, while others sell hundreds. These products are typically sold for two to three times what the chiropractor pays for them.

Many chiropractors become distributors for multilevel companies that sell supplements, herbs, and/or homeopathic

products. Multilevel marketing (MLM) is a form of direct sales in which "independent distributors" can buy products "wholesale," sell them "retail," and recruit other distributors who can do the same. When enough distributors have been enrolled, the recruiter is eligible to collect a percentage of their sales. During the past 20 years, Dr. Stephen Barrett has investigated over a hundred health-related MLM companies and found that every one of them has marketed products that were overpriced, misrepresented, or both.

To persuade patients to buy nutritional products, chiropractors may use several dubious tests:

- **Functional Intracellular Analysis (FIA)**, formerly called **Essential Metabolics Analysis (EMA)**, is a test in which a sample of the patient's blood is sent to a laboratory that isolates the patient's lymphocytes (a type of white blood cell) and places them into petri dishes containing various concentrations of certain nutrients. Company literature states that the procedure can find hidden "functional" nutrient deficiencies in nearly everyone. Although properly performed lymphocyte cultures have a legitimate role in testing for certain deficiencies, they are not appropriate for screening as advocated by the laboratory.

- **Hair analysis** is done by clipping a sample of the patient's hair—usually from the nape of the neck—and sending it to a laboratory for analysis. The lab then issues a report (often with a copy for the patient) stating the concentrations of various minerals and how these amounts compare to the lab's reference values. Some reports also contain specific recommendations for supplements. The scientific viewpoint is that hair tests of this sort do not provide a valid basis for determining the body's nutritional state or for making supplement recommendations.

- **Live blood analysis**—also called **live cell analysis**, **nutritional blood analysis**, and **Hemaview**—is done by placing a drop of the patient's blood on a microscope slide and using a glass cover slip to keep it from drying out. The slide is then viewed with a special microscope that forwards the image to a television monitor that the practitioner and patient can view. Although certain blood characteris-

tics (such as the relative size of the red cells) are visible with this setup, live-cell analysts invariably misinterpret other things, such as the extent of red blood cell clumping and changes in the shape of the cells that occur as the blood sample dries. The results are then used as a basis for prescribing supplements. Chiropractors using this approach typically advise patients to take vitamins and/or enzyme pills and to return periodically for check-ups. The Web site of one imaginative chiropractor advises that, "By checking the blood, we check the oil of the body. It can tell us a great deal about the body, and whether or not it is able to keep up with the stress of everyday life, or if it is on its way to problems down the road."

- "Nutrient deficiency" questionnaires typically contain a long list of symptoms and conditions that the patient checks off. The information is then fed into a computer that reports what products the patient should take. Some symptoms might occur in a vitamin deficiency disease or glandular disorder, but many have nothing to do with nutritional status. The questionnaire might also ask about diet, health habits, or other lifestyle factors. The computers are programmed to recommend products for everyone.

Dubious Treatment Systems

Many chiropractors use elaborate systems that include a nutrition component. The numbers using such systems range from a few hundred to many thousands.

- **Applied kinesiology (AK)** is based on the idea that every organ dysfunction is accompanied by a specific muscle weakness, which enables health problems to be diagnosed through muscle-testing procedures. Testing is typically carried out by pulling on the patient's outstretched arm. Proponents claim that nutritional deficiencies, allergies, and other adverse reactions to foods or nutrients can be detected by having the patient chew or suck on them or by placing them on the tongue so that the patient salivates. Some practitioners have the test material held in the patient's hand or placed on another part of the body. A few even perform "surrogate testing" in which the arm strength of a parent is tested

[continued on page 20]

Kava

Controversial claims, questionable evidence

by Beth Fontenot, MS, RD

Who could resist a product that lures you with promises of relief from stress, feelings of relaxation and euphoria, enhanced mental alertness, and more harmonious feelings toward others—all legal, nonaddictive, and without the side effects of prescription antianxiety drugs. These are but some of the claims made by marketers of kava, an herbal product promoted as an alternative to prescription tranquilizers such as Valium and Xanax. It is also touted as a pain reliever and treatment for insomnia and seizures.

Kava is the name for both the shrubby pepper plant that is native to the South Pacific Islands, and for the mildly narcotic beverage made from the crushed rhizome and roots of the plant. For centuries Islanders have ground the root into a powder, mixed it with water, and consumed it as a beverage. Kava drinks are used in the South Pacific much as alcoholic beverages are used elsewhere. In small doses, kava is supposed to reduce anxiety and relax muscles. Taken in large doses, it is intoxicating, causing drowsiness, nausea, muscle weakness, and blurred vision.

In the 1970s, kava was sold as a "street drug" through counterculture publications. Today, extracts from the root are placed in capsules, often combined with other herbal ingredients, and sold as a dietary supplement in supermarkets, "health-food" stores, and on the Internet. The ground root can also be purchased to create kava beverages. Last year Americans spent over \$50 million on kava.

The primary active components in kava are called kavalactones, although there appear to be other active constituents as well. It is generally thought that the "beneficial" effects of kava are obtained through the use of root extracts because they contain the full range of the many components found in the root. How kava produces its effects in the brain is

largely unknown, but it is thought to be through mechanisms other than those used by traditional sedative drugs. Some studies suggest that it may directly influence the limbic system, the part of the brain associated with emotions and other brain activities.

Questionable Studies

Five studies totaling several hundred people have been published in Europe comparing kava with a placebo for mild to moderate anxiety. Most of the study participants had been diagnosed with at least one anxiety disorder. The Hamilton Anxiety Rating Scale (HAMA), a standardized tool used in testing antianxiety drugs, was used to evaluate anxiety levels. In each study, those taking kava showed significant relief of their anxiety symptoms compared with those taking the placebo. The longest study, conducted at Jena University in Germany, showed after 24 weeks decreases in HAMA scores for both those taking kava and placebo. However, the kava-takers' scores were lower, indicating less anxiety (*Pharmacopsychiatry*. 1997 Jan.;30[1]: 1-5).

The reliability of these studies is questionable because people with mental or emotional disorders often feel better after taking anything at all, including inactive substances. In fact, in the Jena University study, three-fourths of the study participants reported significant improvement when taking kava, and half of those who took the placebo also reported feeling better. By the end of the study, nearly everyone reported feeling better than at the beginning of the study. Another problem with the reliability of the European studies is that it's unclear what the initial diagnoses of the subjects were.

This month's ratings are by Stephen Barrett, M.D., board chairman of Quackwatch, Inc., who is working hard to improve the quality of health information on the Web. He now operates three Web sites: Quackwatch (<http://www.quackwatch.com>), Chirobase (<http://www.chirobase.org>), and MLM Watch, a site focusing on multilevel marketing tactics (<http://www.mlmwatch.org>).

BEST

Dairy Council Digest, which published its final print version in December 1998, is now available online at <http://www.nationaldairycouncil.org/medcent/mcbddcd.html>. Each bi-monthly issue covers a topic related to food and nutrition.

The National Guideline Clearinghouse (<http://www.guideline.gov>) contains information about 500 healthcare guidelines. The site is cosponsored by the Agency for Health Care Policy and Research, the American Medical Association, and the American Association of Health Plans.

Hoovers Online (<http://www.hoovers.com>) is a gateway to news and to Security and Exchange Commission filings on publicly held corporations, including many that market supplement products.

WORST

The Doctors' Medical Library at <http://www.medical-library.net> is described on its Web site as "a network of over 225 integrated Web sites containing enough information to constitute a complete course of study in natural medicine." Questionable information on many topics is conveniently available through the site's main window. Its features include professional directories, an e-mail newsletter, bulletin board discussions, and the ability to search for articles related to symptoms.

The International Clinic of Biological Regeneration at <http://www.icbr.com> provides information on "cell therapy," an unsubstantiated treatment based on the idea that injecting animal cells into a human can rejuvenate the corresponding organs in the patient. The clinic claims that the therapy "acts like an organ transplant and actually makes the old cells 'act younger.'"

to diagnose problems in a child held by the parent. Many muscle-testing proponents assert that nutrients tested in these various ways will have an immediate effect, that "good" substances will strengthen specific muscles, whereas "bad" substances will cause weaknesses that indicate trouble with the associated organ or tissue. The recommended "treatment" can include special diets, food supplements, acupuncture, and spinal manipulation.

The International College of Applied Kinesiology (ICAK) maintains that practitioners who do not follow its standards are not doing AK, and that muscle-testing results should be combined with other clinical findings and not be used by themselves. However, critics respond that the nutrition-related claims and practices of those affiliated with ICAK are no less bizarre than those of other muscle-testers who do not.

• Biological Terrain Assessment (BTA) uses a computerized analysis of blood, urine, and saliva specimens to recommend nutritional programs, vitamin and mineral supplements, homeopathic products, and/or herbs. Proponents claim that BTA gives evidence of disease at the cellular level which enables "imbalances" to be detected and corrected in their early stages. Neither the rationale nor the recommended strategies make sense.

• Biomagnetic Therapy is based on the idea that disease cannot exist when the body is "biomagnetically balanced" and "all nutrition" is available. It has been promoted through seminars at which chiropractors are taught how to use magnetic and nutritional procedures for "normalizing organs and systems."

• Contact Reflex Analysis (CRA), an AK offshoot, involves pushing down on the patient's outstretched arm while touching "reflex points" located in various parts of the body. Proponents claim that "the testing arm," which is like a circuit breaker, "will remain strong if there

is no interruption of nerve energy" but will "draw excessive electrical energy" and become weak if it becomes unhealthy. Proponents further claim that "weakness" of the arm points to problems in corresponding areas and that nutritional supplementation can solve these problems.

• The Enzyme Replacement System is based on identifying and treating "enzyme deficiency states." Its developer, Howard F. Loomis, DC, offers seminars sponsored by the National College of Chiropractic and markets products "targeted to organs stressed by subluxation." The alleged deficiency states are identified by taking a history, examining the patients, obtaining a "24-hour urinalysis," and correlating this information with "recurring spinal subluxation patterns." The products listed in Loomis's 1995 catalog include ChiroZyme, a line of "carefully formulated combinations of herbs, vitamins and minerals with plant enzymes," each of which is named with an abbreviation for certain spinal segments and an organ or body function.

• Iridology, also called iris diagnosis, maintains that each area of the body is represented by a corresponding area in the iris of the eye (the colored area around the pupil) and that the body's state of health and disease can be diagnosed from the color, texture, and location of pigment flecks in the eye. The leading proponent, Bernard Jensen, DC, has written that "Nature has provided us with a miniature television screen showing the most remote portions of the body by way of nerve reflex responses." Iridology practitioners claim to diagnose "imbalances" that can be treated with vitamins, minerals, herbs, and similar products. Some also claim that the eye markings can reveal a complete history of past illnesses as well as previous treatment. Several well-designed studies have found that iridology practitioners who examined the same patients (or photographs of their eyes) disagreed among them-

selves and were unable to state what was medically wrong with the patients.

• The Morter HealthSystem, described in its literature as "a complete alternative healthcare system," combines Bio Energetic Synchronization Technique (B.E.S.T.) and nutritional supplementation. B.E.S.T. is based on the notion that development and repair of the body is controlled by its electromagnetic field. Advocates claim that electromagnetic imbalance causes unequal leg length, which the chiropractor can instantly correct by infusing his own electromagnetic energy at "contact points" on the patient's body until "pulsation" is felt and the patient's legs test equally long. The nutritional component includes supplements that supposedly "alkalize" the body. Proponents recommend lifelong testing and treatment beginning early in infancy.

• NutraBalance is one of several systems in which the results of legitimate blood and urine tests are fed into a computer which determines alleged "metabolic types," lists supposed problem areas, and recommends dietary changes and food supplements from a manufacturer chosen by the chiropractor. Neither the existence of the types nor the recommended nutritional strategies have been substantiated.

• Neuro Emotional Technique (NET) focuses on "releasing patients' emotional blocks stored in the body's memory." Its proponents claim that everyone has such blocks and that the body "replays" these old memories, which can adversely affect health. The practitioner then uses muscle-testing (applied kinesiology) to "isolate a troublesome event" and asks the patient to hold in mind a "snapshot" of the emotional state while the chiropractor adjusts the patient's spine and acupuncture points and prescribes supplement products and homeopathic remedies.

• NUTRI-SPEC testing is performed by measuring the patient's breathing rate, blood pressure, body temperature, pulse, breath-holding ability, blood pressure, pupil size, tongue thickness or coating, several characteristics of the patient's saliva and urine, abdominal reflexes, and certain other reflexes. NUTRI-SPEC's scoring system is then used to determine whether the patient is in or out of "water/electrolyte balance," "anaerobic/

Many chiropractors use elaborate systems that include a nutrition component. The numbers using such systems range from a few hundred to many thousands.

dysaerobic balance,” “acid/alkaline balance,” and “sympathetic/parasympathetic balance” and whether the patient has “sex hormone insufficiency,” “myocardial insufficiency,” “pineal stress,” “thymus stress,” or another fanciful condition. The findings are then used to recommend dietary changes and supplements that are purchasable from the company marketing the system.

‘Cookbook’ Approaches

Many supplement manufacturers offer nutritional products intended for the treatment of disease. The majority of these products do not work and are not legal to market for this purpose. In addition, many are marketed for conditions that chiropractors are not trained to diagnose or treat. Instead of making therapeutic claims openly, the manufacturers market through distributors who make the claims for them by sponsoring seminars at which speakers describe how to use the products. Some distributors give out manuals listing which products to use for which diseases.

Some manufacturers sell “glandular” products containing small amounts of freeze-dried animal tissue claimed to strengthen or rejuvenate the corresponding parts of the user’s body. Such claims make about as much sense as the primitive notion that eating the heart of a lion will make you courageous.

“Glandular” products are not legally permitted to contain hormones. Like plant-based oral enzyme products, their main ingredients are proteins that are broken down during digestion and exert no significant effect on body function.

Questionable Food Allergies

Some chiropractors use various test procedures that supposedly determine “hidden allergies” responsible for a broad range of diseases or symptoms. The most notorious of these was cytotoxic testing, which was performed by observing what happens to the patient’s white blood cells after they are placed onto slides containing dried foods.

Cytotoxic testing was banned by the FDA, but other tests are used for the same purpose. The most notable of these are ELISA/ACT and ALCAT testing. Some

chiropractors diagnose “food allergies” with a computerized galvanometer that merely reflects skin moistness and how hard the operator presses a probe against the patient’s skin.

Actual and Potential Harm

Most of the practices described above are used to varying degrees by offbeat medical doctors, dentists, naturopaths, acupuncturists, and various other practitioners who consider themselves qualified to do “nutrition counseling.” However, the number of chiropractors using them appears to be much higher than that of any other practitioner type.

Although no statistics indicate how much harm is associated with these practices, there is good reason to believe it is considerable. Most of the harm is economic. Supplements sold through chiropractic offices tend to be expensive, and some are recommended for lifelong use. Psychological harm occurs when healthy people are persuaded that they are ill. To this must be added the cost of unnecessary medical diagnostic procedures required to reassure patients that they do not have the diseases suggested by dubious tests. It also seems probable that chiropractors who think nonsensically about nutrition may be prone to other errors of professional judgment.

Physical harm, although uncommon, can occur when excessive dosages are prescribed. In 1992, a 50-year-old Pennsylvania woman, in apparently good health, was treated by a chiropractor for hip and leg pain resulting from an automobile accident. When the pain resolved, she told the chiropractor that she felt no further need for treatment. The chiropractor, who practiced Contact Reflex Analysis, then checked her “thyroid reflex,” said the woman had a “thyroid problem,” and recommended dietary supplements that contained significant amounts of io-

dine. The standard way to diagnose a thyroid problem is to take a medical history, perform an examination of the neck while the patient swallows, and order laboratory tests, but the chiropractor did none of these. The pills he prescribed contained more than ten times the Recommended Dietary Allowance of iodine. Within three months, they stimulated the woman’s thyroid gland to produce excessive amounts of thyroid hormone, which triggered weight loss, severe diarrhea, and other symptoms of thyroid toxicity. The iodine also triggered Graves disease, a thyroid condition in which the eyeballs bulge. Despite medical treatment, her eyeballs swelled enough to crush the optic nerves, which caused her to become legally blind.

Although some chiropractors give rational nutrition advice to their patients, it is clear that a substantial percentage of them do not. Despite their senselessness, nearly all of the approaches described here have been promoted by articles or advertisements in chiropractic publications, and a few have been promoted through chiropractic schools and organizations. They are very much a part of the chiropractic marketplace and have been subjected to little or no criticism by their colleagues or by professional organizations. In fact, some chiropractic organizations and publications encourage their use, suggesting that chiropractors are qualified to diagnose and treat a broad spectrum of disease. **NF**

Well-designed studies have found that iridologists who examined the same patients or photos of their eyes disagreed among themselves and were unable to state what was medically wrong.

This article was adapted from Inside Chiropractic: A Patient’s Guide (1999), a 280-page book written by Dr. Homola and edited by Stephen Barrett, M.D. Copies are available for \$23.95 plus postage from Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197; telephone (800) 421-0351. Further information about the book can be viewed at <http://www.chirobase.org/03Edu/C/homola.html>.

BRIEFS

[continued from page 17]

'INTERACTIVE FOODS'

Advertising Age has noted that several food companies have begun marketing foods that offer a playful element for children. The products include Kellogg Co.'s Wild Magicburst Pop-Tarts, which feature sprinkles that change colors when toasted; Quaker Oats's Dino Eggs, which hatch in hot water to reveal edible dinosaurs; General Mills Squeeze-It drink, which has marketed a crystal that changes the color of the drink when dropped into it; and Unilevel Good Humor's Tongue Splashes, a Popsicle product that "paints" the tongue and lips.

ANTIOXIDANT UPDATE

The American Heart Association's nutrition committee has issued a science advisory discussing relationships between antioxidants and heart disease (*Circula-*

tion, 1999;99:591-595). The statement concludes:

Considerable evidence now suggests that oxidants are involved in the development and clinical expression of coronary heart disease and that antioxidants may contribute to disease resistance. Consistent with this view is epidemiological evidence indicating that greater antioxidant intake is associated with lower disease risk. Although this increased antioxidant intake generally has involved increased consumption of antioxidant-rich foods, some recent observational studies have suggested the importance of levels of vitamin E intake achievable only by supplementation. There is currently no such evidence from primary prevention trials, but results from secondary prevention trials have shown beneficial effects of vitamin E supplements on some disease end points. In contrast, trials directly addressing the effects of beta-carotene supplements have not shown beneficial effects, and some have suggested deleterious effects, particularly in high-risk population subgroups.

In view of these findings, the most prudent and scientifically supportable recommendation for the general population is to consume a balanced diet with emphasis on antioxidant-rich fruits and vegetables and whole grains.

The full report is available online at <http://www.americanheart.org/Scientific/statements/1999/029901.html>.

BAD INFO ON DRUG/JUICE INTERACTIONS

A brochure recently distributed by the FDA and the National Consumers League contains false information regarding drug/juice interactions. The brochure, which has been released only to the press in advance, states that grapefruit juice can interact with the prescription drugs fexofenadine (Allegra) or loratadine (Claritin), resulting in a risk of serious heart problems. This information is without evidentiary value and will be removed from all future brochure printings. **NF**

[continued from page 19]

An article in the *Archives of General Psychiatry* (1998 Nov.;55[11]:1033-1044) described the evidence for kava as a treatment for insomnia and anxiety as "opinions...based on clinical experience, descriptive studies, or reports of expert committees." The evidence for kava's usefulness in seizure disorders was described as "insufficient...to warrant conclusions about efficacy or safety."

Safety Issues

A serious concern with kava is that like most dietary supplements, the long-term effects are unknown. Therefore, it clearly should not be taken by children or teens or by pregnant or lactating women.

In addition, kava should not be combined with alcohol or other central nervous system depressants since it may increase their effects. In 1996, a Georgia man began taking kava as he weaned himself off Xanax. He became ill and slipped in and out of consciousness. His physicians identified the interaction between kava and Xanax as the culprit. Otherwise, little is known about how kava may interact with prescription medicines or other

herbs like St. John's wort or valerian that also affect the central nervous system.

Another reported adverse reaction to kava is that it may interfere with dopamine and thus worsen Parkinson's disease, a condition of decreased dopamine activity in the brain. So patients with Parkinson's *should not take kava*. Also, at very high doses for long periods of time, biochemical abnormalities may occur (low levels of serum albumin, protein urea, and bilirubin), hypertension may develop, blood may appear in the urine, red blood cell volume may increase, platelet and lymphocyte counts may decrease, and shortness of breath may occur. Problems with equilibrium have also been reported.

Long-term use of kava beverages has been shown to cause "kava dermatopathy"—a condition of the skin characterized by a generalized scaly rash. It was thought at one time that this may be due to interference with niacin, but that does not appear to be the case. The only effective treatment for kava dermatopathy is a reduction or cessation of kava consumption.

A Dose of Caution

Large, well-designed, placebo-controlled studies are needed before it will be known

whether kava has a rational place in treating anxiety disorders and, if so, what dose may be appropriate and safe. Also, studies need to determine what other drugs or herbs kava may adversely interact with, and whether there are any other side effects with kava usage.

Ads for kava state that it will not decrease reaction time or the ability to concentrate, but given its reputation as a sedative, studies are needed to confirm this. Kava is sold without restrictions on its use. With little publicity about negative effects of kava, its easy accessibility may lead to tragic consequences.

Anyone suffering from anxiety serious enough to warrant treatment should be under professional care and not self-medicating with a questionable over-the-counter product. **NF**

Book Reviews

Analysis and Ratings

The following reviews not only offer analyses but also rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Label Weirdness

Varro E. Tyler

What the Labels Won't Tell You by Logan V. Chamberlain (Loveland, CO: Interweave Press, 1998), 120 pp., \$9.95 paperback. ISBN 1-883010-49-7.

Titles and promotional statements on book covers greatly influence my expectation of their contents. On the cover of this volume on herbs are three bullet points listing the principal subjects covered. The first of these is "Choose the best manufactured products." I therefore expected a number of tables listing data from published scientific analyses of the active constituents of various herbal products. Such studies on feverfew, St. John's wort, garlic, ginseng, saffras, and yohimbe products have been carried out by various consumer organizations, as well as by the FDA and university laboratories. I thought perhaps the book might even contain some new ones not previously published, so I turned its pages in great anticipation.

Sadly, such information was entirely lacking. What I did find was the author's somewhat equivocal personal comments on a few herbal medicines.

For example, in discussing echinacea products, the author prefers a whole-plant product over a standardized extract because of the *potential* synergy among its constituents. He prefers a root product because he believes roots are less likely to be adulterated than dried plants. (Apparently he is unaware of the scandal in the

1980s involving adulteration of echinacea root with that of *Parthenium integrifolium*.) He prefers *E. purpurea* to *E. angustifolia* because more research has been done on the former, but then adds, "That doesn't mean it's better, though." He would choose a tincture over a capsule form because he *feels* that it would be faster acting (no comment on reduced stability of many compounds in solution).

The second bullet point on the cover reads, "Understand herb supplement labels." The author does a credible job in dissecting the label of encapsulated echinacea powdered herb. Omitted, however, is any comparison with the label of a standardized echinacea product. Many persons fail to understand exactly what standardization means and what to look for on the label of such products. Additional diagrams covering this would have been most helpful. In judging the continuing dispute between scientists who prefer standardized herbal extracts and traditionalists who prefer crude herbs, the author simply says, "Both are right."

The third bullet point promises information on how to "Design your own herbal program." After discussing his own wellness routine utilizing ginkgo biloba, saw palmetto, Siberian ginseng (eleuthero), bilberry, milk thistle, kelp, multivitamins, coenzyme Q10, and selenium, the author has this advice for readers: "It's up to you how far you want to go with treating your problems with herbal medicine. . . ."

A table recommending herbs for minor conditions includes such unproven remedies as goldenseal for colds and flu (it has no systemic activity on oral administration) and hops and passion flower for anxiety and stress (both unproven). Similar assertions are found throughout the book.

In my opinion, this volume fails to provide adequate information on two of the three specific subjects listed on the cover, and the third area is only partially explored. If you are looking for definitive advice on how to select the best quality herbal products, this volume will be of little assistance. The thorny problem caused by differences between labeled content and actual content of herbal preparations—perhaps the most significant issue facing herbal medicine today—is not even addressed.

NOT RECOMMENDED

Horse-and-Buggy Herbalism

Varro E. Tyler

Handmade Medicines: Simple Recipes for Herbal Health by Christopher Hobbs (Loveland, CO: Interweave Press, 1998), 120 pp., \$12.95, paperback. ISBN 1-883010-50-0.

Except for their use in the preparation of non-caffeine-containing beverage teas, the age of unstandardized ground-up herbs and products prepared from them is rapidly passing. Scientific herbal medicine based upon extracts standardized by sophisticated techniques such as high-performance liquid chromatography for a variety of constituents and subjected to controlled clinical testing in humans is rapidly replacing such outmoded usage.

This causes one to view a 1998 book devoted to *Handmade Medicines* in the same light as a post-Henry Ford volume on the manufacture of buggy whips. With so many high-quality, standardized, clinically tested herbal products available in pharmacies, health-food stores, and supermarkets of all kinds across the nation, this volume, dealing largely with what once was, is principally of historical interest to persons other than herbal Luddites.

I shall skip over the introductory chapters, except to mention that the section "The Top Medicinal Garden Herbs" must be read with caution: burdock is not an antibiotic, that designation being reserved for products of microorganisms; California poppy has never been proven safe for children; unless analyzed to assure minimal pyrrolizidine alkaloid content, comfrey should not be taken internally; so many chemical races of feverfew exist that one

simply cannot tell without testing if a plant is active or not; the heating and cooling effects of Asian and American ginseng are Asian philosophical concepts, not supported by science; simple filtering does not produce the necessary sterility required to assure safety of goldenseal eyewash; hops have never been proven to facilitate sleep; and so on and so on.

The chapter "Preparing Herbs for Use" is generally quite good but somewhat limited in scope. It would have been helpful to explain the differences between tinctures, which are discussed, and flu-

idextracts and extracts, which are not. The latter term, in particular, is much misused in herbal medicine. No discussion of encapsulation of powdered herbs, also easily carried out at home, is included.

Some formulas for tinctures, oils, salves, and the like are provided in the chapter "The Recipes: Combining Herbs for Healing," but the majority are for herbal teas. Many of these contain six or seven ingredients and are thus more reminiscent of Chinese or European traditional medicine than of simple herbal recipes. Needless to say, the effectiveness

of such complex mixtures has never been scientifically validated.

If you are curious about how some types of herbal dosage forms are prepared, this book will provide easily understood explanations. If you want to use an herbal remedy for maximum and uniform effects, purchase a standardized, clinically tested product marketed by a reliable manufacturer. **NF**

SCIENCE MEETS ALTERNATIVE MEDICINE

Conference tapes now available

Audio tapes of the landmark CSICOP/*Scientific Review of Alternative Medicine* conference "Science Meets Alternative Medicine" are now available. Hear the entire conference, including all concurrent sessions, on 17 90-minute audio cassettes, or order the sessions you wish to hear. A 10% discount on the full-conference set of tapes.

PLENARY SESSIONS

- SESSION I—Opening Addresses**
Paul Kurtz,
Wallace Sampson
(1) tape: \$7.25
- SESSION II—Science and Alternative Medicine: Exploring Points of Conflict**
Robert Park: "Physics and Homeopathy"
Saul Green: "Biochemistry and Cancer"
William Jarvis: "Biology and 'Life Forces'"
Timothy Gorski: "How Prevalent Is Alternative Medicine?: Examining the Eisenberg Study"
(2) tapes: \$14.50
- SESSION III—Keynote Address by George D. Lundberg, M.D., former editor of the *Journal of the American Medical Association***
(1) tape: \$7.25
- SESSION IV—Alternative Medicine and the Psychology of Belief and Perception**
James Alcock: "The Psychology of Belief"
Barry Beyerstein: "Why Worthless Therapies Seem to Work"
John Renner: "Personal 'Conversions' to Alternative Medicine Therapies"
Steve Novella: "The Theory of 'Hidden Cures'"
(2) tapes: \$14.50
- SESSION V—Banquet Entertainment**
Presentation of Historic Quack Medical Devices by Robert McCoy, director of the Museum of Questionable Medical Devices
(1) tape: \$7.25
- SESSION VI—Scientific Critiques of AM Therapies and Theories**
Willem Betz: "The Crisis of Herbal Cures in Europe"
William Jarvis: "Acupuncture"
Stephen Barrett: "Chiropractic"
Barry Beyerstein: "Naturopathy"
Wallace Sampson: "Mind/Body Therapies"
Rebecca Long: "A Study of Therapeutic Touch"
Rosemary Jacobs: "A Tragedy of Colloidal Silver"
(3) tapes: \$21.75
- SESSION VII—Keynote Address by Marcia Angell, M.D., editor of the *New England Journal of Medicine***
(1) tape: \$7.25

CONCURRENT SESSIONS

- SESSION VIII—Alternative Medicine and Medical Ethics**
Dónal P. O'Mathúna: "Therapeutic Touch: What Is the Harm?"
Lawrence J. Schneiderman: "The Ethics of Alternative Medicine"
Lewis Vaughn: "Believing Without Evidence: The Ethics of Promoting Unproven Treatments"
(2) tapes: \$14.50
- SESSION IX—Alternative Medicine, Government, and the Law**
Stephen Barrett: "The FDA and Unproven Health Claims"
Willem Betz: "Alternative Medicine and European Governments"
(2) tapes: \$14.50
- SESSION X—Educating Physicians and Consumers**
Wallace Sampson: "Alternative Medicine in Medical Schools"
John Renner: "Critical Thinking for Physicians"
Arnold Relman: "Andrew Weil: Public Perception and Reality"
(2) tapes: \$14.50
- FULL CONFERENCE (17 90-minute audiotapes): (10% discount)**

FTC ATTACKS 'VITAMIN O' PROMOTION

A federal court judge has ordered Rose Creek Health Products and The Staff of Life—both owned by Donald L. Smyth—to stop making unsubstantiated claims about their "Vitamin O." The defendants had advertised that (a) many people suffer disease and diminished health as a result of oxygen deprivation caused by pollution, deforestation, stress, or other causes; (b) "Vitamin O" contains "nearly 30,000 parts per million of dissolved "stabilized oxygen"; (c) oral administration would cause oxygen to be absorbed into the body through the gastrointestinal system and enrich the oxygen content of the bloodstream; (d) this would provide the amount of oxygen needed for optimum health; and (e) the product was effective against cancer, cardiovascular disease, lung disease, and many other health problems. About a dozen other companies are making various false claims for "stabilized oxygen" products.

ANTIOXIDANTS AND MACULAR DEGENERATION

A team of Australian researchers has found no association between age-related maculopathy (ARM) and antioxidants among 3,654 subjects age 49 or older, of whom 2,900 (74.9%) kept detailed food records (*Ophthalmology* 1999;106:761-767). The study found no statistically significant association between ARM and dietary intake of either beta carotene, zinc, or vitamins A or C, either from diet, supplements, or both. Other published studies have had conflicting results, with some finding correlations and others finding none.

TASTY NEW VEGETABLE

Broccolini, also called baby broccoli, is a cross between broccoli and Chinese kale that resembles asparagus, tastes milder and sweeter than broccoli, but is less fibrous. Developed by the Sakata Seed America of Morgan Hill, California, it is grown in California and Arizona. An eight-stalk portion provides 35 calories, 1g dietary fiber, 3g protein, 2g sugars,

[continued on page 30]

Sizing Up Naturopathy *Sense and nonsense in nutrition and health*

by Stephen Barrett, MD

Naturopathy, sometimes referred to as "natural medicine," is a vitalistic and largely pseudoscientific approach said to "assist nature." Naturopaths assert that diseases are the body's effort to purify itself, and that cures result from increasing the patient's "vital force." They claim to stimulate the body's natural healing processes by ridding it of waste products and "toxins." The American Association of Naturopathic Physicians (AANP) states that "naturopathic medicine has its own unique body of knowledge, evolved and refined for centuries" and is "effective in treating all health problems, whether acute or chronic." According to a 1989 AANP brochure:

The main difference [between naturopathic and conventional medicine] is in philosophic approach. Naturopathic physicians treat patients by restoring overall health rather than suppressing a few key symptoms. Naturopathic physicians are more concerned with finding the underlying cause of a condition and applying treatments that work in alliance with the natural healing mechanisms of the body rather than against them. Naturopathic treatments result less frequently in adverse side effects, or in the chronic conditions that inevitably arise when the cause of disease is left untreated.

A Brief History

Modern-day naturopathy can be traced to the concepts of Sebastian Kneipp (1821-1897), Benedict Lust (1872-1945), Henry Lindlahr (1853-1925), Bernarr

Macfadden (1868-1955), and John H. Tilden, MD (1851-1940). Father Kneipp, a German priest, opened a "water cure" center after becoming convinced that he and a fellow student had cured themselves of tuberculosis by bathing in the Danube River. Kneipp also developed herbal methods using whole plants. Lust, also German, was treated by Kneipp and in 1892 was commissioned to establish Kneipp's practices in the United States. In 1895, he opened the Kneipp Water-Cure Institute in New York City and began forming Kneipp Societies whose members had been using Kneipp's methods or other "drugless therapies." Subsequently, he acquired degrees in osteopathy, chiropractic, homeopathic medicine, and eclectic medicine.

In 1901, Lust organized a national convention and chaired a committee that endorsed the use of massage, herbs, homeopathy, spinal manipulation, and various types of occult healing. In 1902, he purchased the rights to the term "naturopathy" from John H. Scheel, another Kneipp disciple, who had coined it in 1895. That same year, he began referring to himself as a naturopath, opened the American Institute of Naturopathy, and replaced the Kneipp Societies with a national naturopathic organization. Lindlahr further systematized naturopathy and opened a sanitarium and a school in a Chicago suburb. Macfadden popularized exercise and fasting. Tilden contributed notions about "auto-intoxication" (said to be caused by fecal matter remaining too long in the intestines) and "toxemia" (al-

leged to be “the basic cause of all diseases”).

Naturopathy’s grandiose claims attracted the sharp pen of Morris Fishbein, MD, who edited the *Journal of the American Medical Association* and spearheaded the AMA’s antiquackery campaign for several decades. During the 1920s he noted:

Whereas most cults embrace a single conception as to the cause and healing of disease, naturopathy embraces everything in nature. . . . The real naturopaths were, of course, such healers as Father Kneipp . . . and others whom advocated natural living and healed by use of sunlight, baths, fresh air, and cold water, but there is little money to be made by these methods. Hence the modern naturopath embraces every form of healing that offers opportunity for exploitation.

The practices Fishbein debunked included: aeropathy (baking the patient in a hot oven); Alereos system (spinal manipulation plus heat and mechanical vibration); astral healing (diagnosis and advice based on reading the patient’s horoscope); autohemic therapy (giving a solution made by modifying and “potentizing” a few drops of the patient’s blood); autotherapy (treating infections with potions made from the patient’s infected tissues or excretions); biodynamochromic diagnosis and therapy (administering colored lights while thumping on the patient’s abdomen); bloodwashing (with herbs); chromopathy (healing with colored lights); electrotherapy (with various devices); geotherapy (treating disease with little pads of earth); irido-diagnosis (diagnosis based on eye markings—now called iridology); pathiatry (self-administration of spinal adjustment, massage, and traction); porotherapy (treatment applied through the pores of the skin to the nerves said to control internal organs); practotherapy (a fancy term for intestinal irrigation); sanatology (based on the notion that acidosis and toxicosis are the two basic causes of all disease); somapathy (spinal adjustment followed by applications of cold or extreme heat); tropo-therapy (special nutritional foods); Vit-O-Pathy (a combination of 36 other systems); zodiac therapy (combining astrology and herbs);

and zonotherapy (pressing on various parts of the body to heal disease in designated body “zones”—now called reflexology). Most of these methods disappeared along with their creators, but some (or their offshoots) are still used today.

Education

A 1927 AMA study listed 12 naturopathic schools with fewer than 200 students among them. During the 1920s and 1930s, about half the states passed laws under which naturopaths and/or “drugless healers” could practice. However, as modern medicine developed, many of these laws were repealed and all but a few mail-order schools ceased operations. The doctor of naturopathy (ND) degree was still available at several chiropractic colleges, but by 1961, the last of these colleges stopped issuing it. The National College of Naturopathic Medicine (NCNM) was founded in 1956 in Portland, Oregon, but, until the mid-1970s, had very few students. From 1960 through 1968, the average enrollment was eight, and the total number of graduates was 16.

Today the ND credential is available from four full-time schools of naturopathy and at least seven nonaccredited correspondence schools. Training at the full-time schools follows a pattern similar to that of chiropractic schools: two years of basic science courses and two years of clinical work. Three years of preprofessional college work are required for admission. The leading naturopathy school, Bastyr University, in Seattle, Washington, was founded in 1978. Besides its ND program, Bastyr offers a BS degree program in Natural Health Sciences with majors in nutrition and oriental medicine; a BS program in psychology; BS and MA programs in applied behavioral sciences; MS programs in nutrition and acupuncture/oriental medicine; and a certificate in midwifery. Bastyr has also provided health-food retailers and their employees with home-study programs that promote “natural” approaches for the gamut of diseases. Students in the naturopathic degree program are required to take three courses in homeopathy and can elect to take three more.

Can Vitamin E Prevent Heart Disease?

To E or not to E?

by Beth Fontenot, MS, RD

Some of the most interesting nutrition research in recent years has produced preliminary evidence that large doses of vitamin E may reduce the occurrence of heart attacks. As a result, vitamin E has received a great deal of media attention, prompting consumers to spend \$300 million a year on vitamin E supplements. A few health and nutrition experts are ready to jump on the bandwagon and recommend supplementation, but others are asking whether the evidence really warrants such a move.

Judging by sales, vitamin E is one of the most sought-after dietary supplement among Americans. The nutrient is popular, it seems, even among professionals.

And no wonder. The claims for the nutrient's benefits are prevalent and appealing. "Health-food" literature and the media would have us believe that taking vitamin E will prevent arthritis, cataracts, stroke, diabetes, cancer, and heart disease. In addition, it's supposed to boost the immune system, ease symptoms of premenstrual syndrome, delay symptoms of Alzheimer's disease, and protect the body from aging.

Vitamin E Basics

Vitamin E was discovered in the 1920s when rats fed a basic diet became unable to reproduce viable offspring but were cured when given tocopherol, a substance that had been isolated from vegetable oils. In fact, the term "tocopherol" comes from Greek words meaning "to bear offspring." Vitamin E became the name given to a group of eight fat-soluble compounds—four tocopherols (designated alpha, beta, gamma, and delta) and four tocotrienols (designated with the same Greek letters). It was not until 1966 that vitamin E was considered essential for humans.

All of these compounds have different degrees of biological activity. The

most active form of the vitamin is the "d" isomer of alpha-tocopherol, which is found in many supplements. Recent research has indicated that other forms, such as gamma-tocopherol, may also be important to the body. Though gamma-tocopherol has only one-tenth the biological activity of alpha-tocopherol, it is more widely distributed in foods. It's found in foods such as sunflower seeds, almonds, and wheat germ.

Vitamin E requires the presence of fats and bile in the gut to be absorbed. The degree to which vitamin E is absorbed by the body is dependent on the total absorption of dietary fat. Absorption can be as high as 70%. However, when taken in doses well above the Recommended Dietary Allowance (RDA), the absorption rate of vitamin E drops to less than 10%. Vitamin E travels through the body by way of chylomicrons and other lipoproteins, and it is distributed to almost all tissues in the body. It is most concentrated in tissues containing an abundance of fatty acids, such as cell membranes.

The primary function of vitamin E appears to be to act as an antioxidant. When incorporated into the lipid portion of cell membranes and carrier molecules, it protects these structures from toxic compounds, heavy metals, drugs, radiation, and free radicals. It also appears to protect cholesterol from oxidative damage.

The recommended intake for vitamin E is expressed in alpha-tocopherol equivalents (α -TE). One α -TE is equal to 1 mg of alpha-tocopherol. Vitamin supplement labels usually express vitamin E content in IUs (international units). One IU is equal to 1 mg of synthetic vitamin E or about 0.74 mg of natural α -tocopherol. The current RDA for vitamin E is 10 mg for men (15 IU) and 8 mg (12 IU) for

WEB WATCH

This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc., which is working hard to improve the quality of health information on the Web. He now operates three Web sites: Quackwatch (<http://www.quackwatch.com>), Chirobase (<http://www.chirobase.org>), and MLM Watch (<http://www.mlmlwatch.org>).

BEST

Health Scout (<http://www.healthscout.com>) publishes weekly Web site ratings by NF editorial board member John Renner, MD. To access the reviews, use the search box with the word "Renner."

Children and Adults with Attention Deficit/Hyperactivity Disorder (CHADD) (<http://www.chadd.org>) provides comprehensive information about AD/HD, including an excellent fact sheet on "controversial treatments."

WORST

The International Center for Nutritional Research (<http://www.icnr.com>) is the business name under which Gerald H. Smith, DDS, of Langhorne, Pennsylvania, dispenses misinformation and markets questionable supplements, devices, books, and other educational materials. The "ICNR Store" link leads to most of the site's dubious promotions.

The Synergy Group of Canada (<http://216.71.26.86/truehope>) provides an online newsletter and invites people with six types of mental or neurologic disorders to submit their symptoms, get nutritional recommendations, and report their experience as part of a "research" process. The site also contains reports of people who say they or their children have benefited from supplementation.

The Soil and Health Library (<http://soilandhealth.org/>) contains sections on Natural Hygiene (a naturopathic offshoot) and "longevity and nutritional anthropology." The "Health Library" section contains full-text versions of several out-of-print books about "toxemia," fasting, alleged vaccination dangers, and other naturopathic concepts.

vitaminbuzz.com promotes dietary supplements, herbs, and homeopathic products, which can be purchased online. The site is sponsored by Vitamin Shoppe, Inc., which also operates a discount mail-order service and many retail stores on the East Coast. A recent press release stated that the site is "the most comprehensive informational health resource on the Internet" and is "geared toward savvy consumers who want usable answers to tough health questions."

The Southwest College of Naturopathic Medicine and Health Sciences in Scottsdale, Arizona, was founded in 1992. The University of Bridgeport College of Natural Medicine in Bridgeport, Connecticut, began classes in 1997. Naturopathy schools receive much of their financial support from companies that market dietary supplements, homeopathic products, and/or herbal remedies.

In 1987, the U.S. Secretary of Education approved the Council on Naturopathic Medical Education (CNME) as an accrediting agency for the full-time schools. As with acupuncture and chiropractic schools, this recognition is not based upon the scientific validity of what is taught but on such factors as record-keeping, physical assets, financial status, makeup of the governing body, catalog characteristics, nondiscrimination policy, and self-evaluation system. NCMN, Bastyr, and Southwest are accredited.

The total number of practitioners is unknown but includes chiropractors and acupuncturists who practice naturopathy. The AANP was founded in 1986 and is closely allied with the four-year naturopathic colleges. Its membership is said to be limited to individuals who are eligible for licensing in states that issue licenses. Its online directory contains about 500 names. The American Naturopathic Medical Association (ANMA), founded in 1981, claims to represent about 2,000 members worldwide. Although some have recognized credentials in other health disciplines, others merely have an "ND" degree obtained through a nonaccredited correspondence school. The Homeopathic Academy of Naturopathic Physicians (HANP), which requires a recognized professional degree and additional homeopathic training, lists about 50 members.

The AANP publishes the *Journal of Naturopathic Medicine*, which has been

issued six times between 1990 and 1996. The issues have run from about 80 to 100 pages. The third issue is devoted to "Non-Standard HIV/ARC/AIDS Management." The fifth, which attacks immunization, contains papers suggesting that vaccines may be a factor in causing cancer and that homeopathic prophylaxis using nosodes would be effective and safer than standard vaccines. (Nosodes are dilute products made from pathological organs or tissues:

causative agents such as bacteria, fungi, ova, parasites, virus particles and yeast; disease products; or excretions.) The sixth issue promotes the use of "natural" products for cancer and contains an absurd article claiming that measuring the electrical resistance of the skin may be a useful way to diagnose the early stages of cancer and AIDS.

**Naturopathic
licensing boards
have done little or
nothing to protect
the public from
naturopathy's
widespread
quackery.**

Legal Status

Naturopaths are licensed as independent practitioners in eleven states and the District of Columbia and can legally practice in a few others. The AANP and the four-year schools have joined forces to press for licensure in the remaining states. They assert that licensing is needed to protect the public from unqualified practitioners. However, the existing naturopathic licensing boards have done little or nothing to protect the public from naturopathy's widespread quackery.

Since the proposed laws would set educational requirements that many of ANMA's members could not meet, ANMA has vigorously opposed the licensing efforts. The National Council Against Health Fraud has pointed out:

The difference between more and less educated naturopaths is . . . like comparing more and less educated witch doctors. It could actually be argued that less schooled naturopaths are safer because they may have a smaller bag of tricks and, because they don't consider themselves "primary health physicians" are more apt to refer patients to MDs for additional care.

Naturopathic services are not covered by Medicare or most insurance policies. Expansion of naturopathic licensing will make naturopaths appear more legitimate and could help them gain passage of laws forcing insurance companies to cover their services.

Scope of Practice

Most naturopaths allege that virtually all diseases are within the scope of their practice. They offer treatment at their offices and at spas where patients may reside for several weeks. Their current methods include fasting; "natural food" diets; vitamins; herbs; tissue minerals; homeopathic remedies; cell salts; manipulation; massage; exercise; colonic enemas; acupuncture; Chinese medicine; natural childbirth; minor surgery; and applications of water, heat, cold, air, sunlight, and electricity. Radiation may be used for diagnosis, but not for treatment. Many of these methods are said to "detoxify" the body.

Naturopaths assert that their "natural" methods, when properly used, rarely have adverse effects because they do not interfere with the individual's inherent healing abilities. This claim is nonsense. Any medication (drug or herb) potent enough to produce a therapeutic effect is potent enough to cause adverse effects. Drugs should not be used (and would not merit FDA approval) unless the probable benefit is significantly greater than the probable risk. Moreover, medically used drugs rarely "interfere with the healing processes." The claim that scientific medical care "merely eliminates or suppresses symptoms" is both absurd and pernicious.

The most comprehensive naturopathic publications are *A Textbook of Natural Medicine* (for students and professionals) and two editions of the *Encyclopedia of Natural Medicine* (for laypersons). The text, which has more than 40 contributors and more than a thousand pages, was issued in 1986 and updated with loose-leaf inserts until 1996. A bound second edition is scheduled for publication this year. The encyclopedia had 630 pages in its first (1990) edition and has 958 in the second (1998) edition. Joseph E. Pizzorno, ND, presi-

dent of Bastyr University, and Michael T. Murray, ND, a faculty member, edited the textbook and coauthored the encyclopedia. Both books recommend questionable dietary measures, vitamins, minerals, and/or herbs for more than 70 health problems ranging from acne to AIDS. For many of these conditions, daily administration of ten or more products is recommended—some in dosages high enough to cause toxicity. Some treatments are recommended even though the authors indicate that the evidence supporting them is preliminary, speculative, or even conflicting. Both books discuss dubious diagnostic tests as though they have validity.

Pizzorno and Murray have claimed that “in most instances, the naturopathic alternative offers significant benefits over standard medical practices.” For the few illnesses where their encyclopedia acknowledges that medical treatment is essential (because otherwise the patient may die), they propose naturopathic treatment in addition. In many passages, they describe prevailing medical practices inaccurately.

The encyclopedia claims, for example, that medical treatment of hypothyroidism involves the use of desiccated thyroid or synthetic thyroid hormone, but that naturopaths prefer desiccated thyroid. Pizzorno and Murray also claim that “health-food-store thyroid preparations . . . may provide enough support” to help a mild thyroid problem, even though the FDA requires such products to be hormone-free. Scientific physicians consider desiccated thyroid (made from dried animal glands) inferior because its potency can vary from batch to batch. Synthetic thyroid hormone does the job efficiently. Using a product that might contain no hormone is even more ridiculous. The book also claims (incorrectly) that taking one’s armpit temperature upon awakening is a reliable test for thyroid function.

The chapter on angina gives a glowing recommendation for chelation therapy, which the scientific community regards as worthless. The chapter on “detoxification” claims that 25% of Americans suffer from heavy-metal poisoning and advocates periodic fasting plus various supplements and herbs. The

chapter on “cellulite” claims that a gotu kola extract has “demonstrated impressive results.” The “Candidiasis” chapter espouses Dr. William Crook’s fad diagnosis of “candidiasis hypersensitivity” and includes Crook’s three-page questionnaire for determining the probability that “yeast-connected problems are present.” The questionnaire does not have the slightest validity.

The AANP claims that “naturopathic physicians are not opposed to invasive and suppressive measures when these methods are necessary [and] make referrals for such treatment when appropriate.” I doubt that the majority of naturopaths fit this description. Many naturopaths espouse nutrition and lifestyle measures that coincide with current medical recommendations. However, this advice is often accompanied by nonstandard advice that is irrational. Although naturopaths claim to emphasize prevention, most oppose or are overly critical of immunization.

Recently, as part of a child-custody evaluation, I examined records from nine naturopaths who had treated a child whose mother was antagonistic to medical care and was briefly enrolled as a naturopathy student. The child was not properly immunized and did not see a medical doctor until she developed insulin-dependent diabetes mellitus (IDDM) shortly before her eighth birthday. Although episodes of “chest congestion,” “chronic cough,” “vaginitis,” “urinary burning,” and “asthma” were noted in the records, there were no indications that these problems had been adequately diagnosed or appropriately treated. (One episode of “chest congestion,” for example, was treated with homeopathic remedies.) Three of the practitioners used a Vegatest device to diagnose “allergies” to sugar and many other foods and had recommended severe dietary restrictions, even though the child had not reacted adversely to any of the foods. (The Vegatest is a quack device that merely measures the amount of moisture on the skin

and how hard the practitioner presses a probe against the patient’s fingers or toes.) Another practitioner recommended chelation therapy after diagnosing “heavy-metal poisoning” with a hair analysis. The recommended treatments for both actual and nonexistent conditions included regimens of up to 35 pills a day, including some supplements in potentially toxic doses. The only medical referral took place after the child developed severe signs of diabetes. Although the nine naturopaths do not constitute a random sample, their unscientific practices were consistent with typical naturopathic writings.

The Bottom Line

In 1968, the U.S. Department of Health, Education, and Welfare (HEW) recommended against Medicare coverage of naturopathy. HEW’s report concluded:

Naturopathic theory and practice are not based upon the body of basic knowledge related to health, disease, and health care which has been widely accepted by the scientific community. Moreover, irrespective of its theory, the scope and quality of naturopathic education do not prepare the practitioner to make an adequate diagnosis and provide appropriate treatment.

Although some aspects of naturopathic education have improved in recent years, I believe this conclusion is still valid. I believe that the average naturopath is a muddlehead who combines commonsense health and nutrition measures and rational use of a few herbs with a huge variety of unscientific practices and antimicrobial double-talk. **NF**

Dr. Barrett, a retired psychiatrist who resides in Allentown, Pennsylvania, is board chairman of Quackwatch, Inc. and a board member of the National Council Against Health Fraud. The Quackwatch Web site (<http://www.quackwatch.com>) contains additional information on naturopathy and links to most of the organizations mentioned in this article.

Although naturopaths claim to emphasize prevention, most oppose or are overly critical of immunization.

[continued from page 25]

2g other carbohydrates, 30% of the Daily Value for vitamin A (as beta-carotene), 130% of vitamin C, 6% of calcium, and 4% of iron. The cost is similar to that of asparagus. Retailer locations are available by e-mail from info@broccoli.com or by calling (800) 884-6266.

VITAMIN A AND HIP FRACTURES

A Swedish study has found a positive association between high retinol (vitamin A) intake and the incidence of osteoporosis and hip fractures in women (*Annals of Internal Medicine* 1998;129:770-778).

DIETARY FAT AND BREAST CANCER

An analysis of data from the Nurses' Health Study, which followed 88,985 women from 1980 through 1994, has found no evidence that a low intake of fat reduced the incidence of breast cancer. The researchers noted, however, that a low intake of saturated fat was still desirable for preventing heart disease (*JAMA* 1999;281:914-920).

EGGS AND BLOOD CHOLESTEROL LEVELS

An eight-year study has concluded that consuming up to one egg per day is unlikely to have substantial overall impact on the risk of coronary heart disease or stroke among healthy men and women, but may be unhealthy for diabetics (*JAMA* 1999;281:1387-1394). For a reprint, contact Frank B. Hu, MD, Dept. of Nutrition, Harvard School of Public Health, 665 Huntington Ave., Boston, MA 02115.

MILK TASTE TESTS

Blinded tests conducted this year by the Bethlehem (PA) Health Bureau have found that most people have difficulty distinguishing between whole milk, 2% milk, 1% milk, and skim milk. Of 1,512 participants, only 98 (6%) correctly identified all four kinds. The study also found that 93% said they liked the flavor of 1% or skim milk. A similar study conducted in 1998 in nearby Allentown found that only 5% of the participants

correctly identified the four types and that 85% said they liked 1% or skim milk. The study was performed as part of a program to persuade residents to lower the fat content of their diet. Following the test (plus other educational activities), 68% of whole and 2% milk drinkers said they would switch to 1% or skim milk, and sales at five participating supermarkets reflected a 5% switch that Health Bureau officials regarded as significant (*The Morning Call*, Allentown, PA, April 2, 1999).

OTC GROUP EXPANDING FOCUS

The Nonprescription Drug Manufacturers' Association has voted to change its name to Consumer Healthcare Products Association and to refer to its members as "producers of quality nonprescription medicines and dietary supplements for self-care." The change was made because several members are marketing supplements and others are expected to follow. According to a report in *Natural Foods Merchandiser*, the change signals that OTC manufacturers will increase their involvement in regulatory, legislative, and educational matters related to supplements.

QUESTIONABLE GROUP

EarthSave International, with about 40 chapters worldwide, promotes vegan eating and claims to be "the only international organization dedicated to educating people about the powerful connections between our food, our health and the environment, with the mission of helping to create a better world by promoting the benefits of healthy and life-sustaining food choices." John Robbins founded it in 1988 after many readers responded to his 1987 book *Diet for a New America*. His 1996 book, *Reclaiming Our Health*, promotes "alternative" methods and falsely portrays antiquackery efforts as totalitarian. Experts who analyzed EarthSave brochures distributed in 1995-96 in the Louisville, Kentucky, School District concluded that they contained many false or misleading statements (*Scientific Review of Alternative Medicine* 1998;2[1]:36-42).

MELATONIN PROBLEM

Tests at the University of Maryland School of Pharmacy revealed problems with the

quality of 5 out of 11 melatonin products (*Journal of the American Pharmaceutical Association* 1999;39:237-231). Some immediate-release products did not dissolve properly. One time-release product reached 90% release in 4 hours, while the other took 12 hours. Variations in bio-availability can make it difficult to predict the effect of such products.

NOTABLE QUOTE

"The new National Institutes of Health (NIH) directives label [55%] of Americans overweight and instruct their doctors to try to motivate them to lose weight, even though they can offer no safe and effective ways to do this. Unfortunately, these recommendations can do a great deal of harm, and there is no evidence they can benefit people or help them lose weight in a lasting way. Claiming to be evidence-based, the guidelines bring together much valuable background information, but offer no help for today. Rather, they are dangerous in that they focus on weight loss, not health. Instead of improving health, they will likely increase weight cycling and the obsession with thinness, and put even more dieting pressure on children and young girls."—Frances M. Berg, Editor, *Healthy Weight Journal*.

ALGAE WARNING

The Canadian Health Protection Branch has warned that blue-green alga products have been found to contain microcystin levels that exceed those considered safe for daily consumption. Microcystins, which some alga species naturally produce, accumulate in the liver and can cause liver damage. The contamination potential appears greatest for products made from the algae in natural lakes. Adverse symptoms from long-term use of these products (weeks to months) may not be obvious, but could range from a feeling of general malaise or gastrointestinal discomfort to jaundice. Children appear more sensitive to these effects, which are more likely to manifest as nausea, vomiting, or diarrhea. The agency also noted that it has not received any evidence that blue-green algae is effective against attention deficit disorder in children and has not authorized the marketing of any blue-green algae product for any therapeutic purpose. **NF**

[continued from page 27]

women. The RDA can be met with a tablespoon of corn oil.

Since many people medicate themselves with large amounts of vitamin E, it is fortunate that its toxicity is relatively low. However, the known toxicity of the other fat-soluble vitamins suggests that caution should be taken with long-term megadoses of vitamin E. High intakes of vitamin E can interfere with intestinal absorption of vitamins A and K. And at dosages exceeding 1,000 mg per day, vitamin E has been shown to enhance the effects of Coumadin therapy and to be antagonistic to the blood-clotting action of vitamin K.

Vitamin E and Heart Disease

The oxidation of lipoproteins appears to play an important role in the development of atherosclerosis, the disease process that leads to heart attacks as well as strokes. Considerable evidence exists that antioxidant vitamins from both the diet and from supplements may prevent lipoprotein oxidation and its biological effects in the body. The strongest evidence seems to be for vitamin E.

Support for the role of antioxidant vitamins in heart disease prevention has come from observational studies, particularly two cohort studies that were published in 1993. In the first study, the Nurses' Health Study, the researchers concluded that among over 85,000 middle-aged women in the study, there was a 40% reduced risk of coronary artery disease for those who took vitamin E supplements compared to those who did not (*N Engl J Med* 1993;328: 1444-9). The second study, the Health Professionals Follow-up Study, involved over 39,000 males and provided evidence of a significant association between a high intake of vitamin E from supplements and a lower risk of heart disease (*N Engl J Med* 1993; 328:1450-1456).

Though these observational studies have pointed to the possibility of beneficial effects of vitamin E, they cannot establish cause and effect. And there has been very little direct evidence of benefit from randomized trials, which can establish a causal connection. Recently pub-

lished results from the Alpha-Tocopherol, Beta-Carotene Cancer Prevention (ATBC) Study did not support the results of the observational studies. This randomized trial tested the effects of daily doses of 50 IU of vitamin E, 20 mg of beta carotene, both, or placebo on over 29,000 male smokers for five to eight years. The researchers found that with vitamin E supplementation, there was an increase in the risk of hemorrhagic stroke. And with beta-carotene supplementation, there was an increase in mortality from lung cancer and ischemic heart disease. This trial raised the possibility that antioxidant supplements may have harmful as well as beneficial effects (*N Engl J Med* 1994; 330:1029-1035).

Two more recently published observational studies produced conflicting results. In a seven-year study of over 34,000 postmenopausal women, researchers found that the intake of vitamin E from food was inversely associated with the risk of death from heart disease and concluded that postmenopausal women could lower their risk of heart disease without using supplements (*N Engl J Med* 1996; 334:1156-1162). However, in the Rotterdam Study, researchers did not find an association between dietary vitamin E and heart disease in an elderly population (*Am J Clin Nutr* 1999;69:261-266).

Last March at the Conference on Cardiovascular Disease Epidemiology and Prevention, Dr. Lori Mosca of the University of Michigan presented a study suggesting that vitamin E supplements provide little benefit to health and may cause harm in women after menopause. The study found that women who obtained vitamin E from their diet experienced significant reductions in LDL oxidation while the women who obtained vitamin E from supplements experienced increased LDL oxidation. Dr. Mosca believes that it may be the gamma-tocopherol in food that is protective instead of alpha-tocopherol found in supplements.

The results of secondary prevention trials (and those with known heart disease) have been more supportive of potential benefits of antioxidant vitamins. The Cambridge Heart Antioxidant Study (CHAOS) examined the effects of 400 to 800 IU of alpha-tocopherol on subsequent cardiovascular events. The risk of heart

attack and other cardiovascular events was reduced in the group receiving vitamin E supplements (*Lancet* 1996;346: 781-786). A secondary analysis of the ATBC study also found that the risk of a second heart attack was reduced in those taking vitamin E supplements (*Lancet* 1997;349:1714-1720).

AHA Position

According to a recent Science Advisory from the American Heart Association (AHA), there are not enough data on the long-term safety and efficacy of vitamin E supplementation to justify any population-wide recommendations for supplementation for the primary prevention of heart disease. The advisory also states that the role of vitamin E in secondary prevention is encouraging and leaves open the possibility of future recommendations regarding vitamin E supplementation in those with heart disease if further studies confirm the findings (*Circulation* 1999; 99:591-595).

It is still unknown whether there are serious negative effects associated with taking vitamin E supplements. It is also unknown whether some other unidentified component in foods may actually be responsible for a reduced risk of heart disease. The Food and Drug Administration (FDA) is examining the scientific data to determine whether there is adequate evidence to support a health claim for antioxidants and disease prevention. A decision is expected next year.

Over time, a clearer picture should emerge, but for now, the AHA advises that based on current knowledge about vitamin E (and other antioxidant vitamins), "the most prudent and scientifically supportable recommendation for the general population is to consume a balanced diet with emphasis on antioxidant-rich fruits and vegetables and whole grains." **NF**

Beth Fontenot is a freelance nutrition writer and the Nutrition Coordinator on the faculty of the Louisiana State University Medical Center-Shreveport Family Practice Residency Program at Lake Charles Memorial Hospital in Lake Charles, LA.

Book Reviews

Analysis and Ratings

The following reviews not only offer analyses but also rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to *Nutrition Forum Book Reviews*, P.O. Box 664, Amherst, NY 14226-0664.

Touting False Hope

Jane Reinhardt-Martin, RD, LD

The Breast Cancer Prevention Diet: The Powerful Foods, Supplements, and Drugs That Can Save Your Life by Bob Arnot, MD (New York: Little, Brown & Company, 1998), 258 pp., \$24 hardback, ISBN 0-316-05114-4.

Bob Arnot is well known as NBC's chief health correspondent. His breast cancer prevention diet book caught the attention of American women last fall when it was introduced on the TV shows *Oprah* and *Today*. A hefty debate ensued. Critics of the book emerged, and national organizations, such as the American Council on Science and Health, labeled the book "unscientific and deceptive—a disservice to American women."

Part one of the book discusses what makes breast cancer grow and suggests foods that could prevent the disease. Part two explains Arnot's 12-step program for preventing breast cancer, offering advice on everything from exercise to how to drop a glucose overload. Part three details "road maps" to assist women in their own breast cancer prevention plan. A small section at the end of the book is devoted to healthy cuisine and meal plans.

The problem is, he has intertwined facts and fiction so well that the unwary may believe that Arnot has the cure for breast cancer—when in fact he has no such thing. The book opens with a section citing numerous recognized medical ex-

perts, scientists, and research institutions. Yet when the American Council on Science and Health contacted many of the scientists cited, most were unaware of the book, and not one endorsed it. Arnot implies that the studies he cites were human studies, when most of them were done on animals. For example, he refers to the work of Dr. Lilian Thompson on flaxseed, and he says, "... what she has found is that breast cancer size actually decreased with a daily course of flaxseed." True, at least two of Dr. Thompson's studies have found that flaxseed supplementation reduces the size of mammary tumors—in rats, but not in women.

Throughout the book, Arnot often gives specific statistics without providing a supporting reference. Such omissions encourage readers to blindly accept some incredible claims.

Finally, Arnot's diet plan requires drastic lifestyle changes. Even if the book were more scientifically sound, it does not explain how women are supposed to achieve such dramatic alterations in lifestyle.

The sad fact is, there is no scientific evidence that a "breast cancer prevention diet" exists.

NOT RECOMMENDED

Fanciful Combinations

Susan Parry Mandel, MS, RD

The Complete Book of Food Combining: A New Approach to the Hay Diet and Healthy Eating by Jan Dries and Inge Dries (Rockport, MA: Element Books, 1998), 240 pp., \$15.95 paperback, ISBN 1-86204-239-X.

This volume describes in detail the authors' eccentric program of "food combining"—a supposed way to achieve better health by eating only certain foods specified by a rigid formula. It tells you which food combinations are good, which are poor, and which are "problematical." It provides examples of recipes and menus that are considered appropriate. And, though it promotes the increased consumption of fruits and vegetables, it is mostly just inaccurate, confusing, and downright difficult to follow.

The principles of food combining out-

lined here are based on the authors' own interpretation of digestive physiology. Supposedly, as each food is eaten, it forms a layer in the stomach, and each layer is then sequentially digested. The dominant nutrient in a food determines the type of digestive enzymes that will be secreted. To ensure adequate digestion, one must therefore consume foods of only one type of dominant nutrient. The authors contend that there are—contrary to basic nutrition textbooks—five different macronutrients in food: protein, fat, starch, sugar, and acid. To determine the dominant nutrient, one calculates the nutrient's weight as a percentage of a food's total weight rather than its caloric content. A food combining pentagon with the good and bad food combinations depicts which dominant nutrients are digested well together.

But the pentagon is based on a shaky foundation. In the opening chapter, the authors reject scientific evidence and offer anecdotal evidence—mostly their own—as the only information "that counts." For example, the authors note (incorrectly) that a fruit-only diet is well tolerated and nutritionally sound for cancer patients. The authors suggest that consumption of only one food in a diet would be the most appropriate for digestive problems, ignoring the fact that a variety of foods are required to ensure adequate micronutrient intake.

Although the book emphatically states that it is "up-to-date" in terms of modern physiology and nutrition, the majority of mechanisms described are inaccurate. Despite the authors' insistence, the pancreas does not secrete only one of three enzymes according to the dominant nutrient in a meal. Even the numbers used to illustrate how to calculate the dominant nutrient in a meal are incorrect. Behind the food-combining theory one will find elements of a calorie-restricted, low-fat, mostly vegetarian diet that is likely to account for any success it may have in aiding with digestion and weight control. The diet is complicated and unnecessarily restricted in macro- and micronutrients. Not one reference is in English. Not one referenced author can be found with a National Library of Medicine Medline search.

This is not a healthy combination. **NF**

NOT RECOMMENDED

**VITAMIN PRICE-FIXING
CONVICTION**

The Swiss pharmaceutical giant Hoffmann-La Roche Ltd agreed to plead guilty and pay a record \$500 million criminal fine for leading a worldwide conspiracy to raise and fix prices and allocate market shares for vitamins A, B2, B5, C, E, and beta-carotene sold in the United States and elsewhere, the Department of Justice announced. A German firm, BASF Aktiengesellschaft, also will plead guilty and pay a \$225 million fine for its role in the same antitrust conspiracy. The conspiracy, which lasted from January 1990 into February 1999, affected the vitamins most commonly used as nutritional supplements or to enrich human food and animal feed as well as in vitamin premixes used to enrich breakfast cereals and other processed foods.

**FTC INTERNET CAMPAIGN
UPDATE**

The FTC has secured consent agreements with four companies that were making unsubstantiated claims for health products marketed through the Internet. The Arthritis Pain Care Center had claimed that cetylmyristoleate (CMO), purportedly a fatty acid derived from beef tallow, cures most forms of arthritis by modifying the immune system and is effective against many other diseases. Body Systems Technology, Inc. had claimed shark cartilage capsules and a liquid containing Cat's Claw were effective against cancer and HIV/AIDS. Magnetic Therapeutic Technologies had claimed that its magnetic sleep pads or other products: (a) are effective against cancers, diabetic ulcers, arthritis, degenerative joint conditions, or high blood pressure; (b) could stabilize or increase the T-cell count of HIV patients; (c) could reduce muscle spasms in persons with multiple sclerosis; (d) could reduce nerve spasms associated with diabetic neuropathy; (e) could increase bone density, immunity, or circulation; and (f) are comparable or superior to prescription pain medicine. Pain Stops Here! Inc., had claimed that its "magnetized water" and other products are useful

'Cellulite Removers'

The whole truth about erasing fad fat

by Stephen Barrett, MD

Cellulite is a term coined in European salons and spas to describe deposits of dimpled fat found on the thighs and buttocks of many women. Widespread promotion of the concept in the United States followed the 1973 publication of *Cellulite: Those Lumps, Bumps and Bulges You Couldn't Lose Before*, by Nicole Ronsard, owner of a New York City beauty salon that specialized in skin and body care. Cellulite is alleged to be a special type of "fat gone wrong," a combination of fat, water, and "toxic wastes" that the body has failed to eliminate.

Alleged "anticellulite" products sold through retail outlets, by mail, and through the Internet have included loofah sponges, cactus fibers, special washcloths, horsehair mitts, creams and gels to "dissolve" cellulite, supplements containing vitamins, minerals and/or herbs, bath liquids, massagers, rubberized pants, exercise books, brushes, rollers, body wraps, and toning lotions. Many salons offer treatment with electrical muscle stimulation, vibrating machines, inflatable hip-high pressurized boots, "hormone" or "enzyme" injections, heating pads, and massage. Some operators claim that 5 to 15 inches can be lost in one hour. A series of treatments can cost hundreds of dollars.

Cellulite is not a medical term. Med-

ical authorities agree that cellulite is simply ordinary fatty tissue. Strands of fibrous tissue connect the skin to deeper tissue layers and also separate compartments that contain fat cells. When fat cells increase in size, these compartments bulge and produce a waffled appearance of the skin. Many years ago, Neil Solomon, MD, conducted a double-blind study of 100 people to see whether cellulite differed from ordinary fat. Specimens of regular fat and lumpy fat were obtained by a needle biopsy procedure and given to pathologists for analysis and comparison. No difference between the two was found.

More recently, researchers at the Rockefeller Institute used ultrasonography, microscopic examinations, and fat-metabolism studies to see how affected and unaffected skin areas differed in seven healthy adult subjects (five women, two men; four affected, three unaffected). The researchers concluded: (a) certain characteristics of skin make women more prone than men to develop cellulite, (b) the process is diffuse rather than localized, and (c) there are no significant differences in the appearance or function of the fatty tissue or the regional blood flow between affected and unaffected sites within individuals (*Plast Reconstr Surg* 101:1934-1939, 1998).

EMS and Iontophoresis Devices

Electrical muscle stimulators (EMS) are legitimate medical devices approved for certain conditions—to relax muscle spasms, increase blood circulation, prevent blood clots, and rehabilitate muscle function after a stroke. But many health spas and figure salons claim that muscle stimulators can remove wrinkles, perform face lifts, reduce breast size, reduce a “beer belly,” and remove cellulite. Iontophoresis devices are prescription devices that use direct electric current to introduce ions of soluble salts (i.e., medications) into body tissues for therapeutic or diagnostic purposes. The only FDA-approved use is for diagnosing cystic fibrosis.

The FDA considers promotion of muscle stimulators or iontophoresis devices for any type of body shaping or contouring to be fraudulent. The most infamous of these devices, the Relax-A-Cizor, was claimed to reduce girth by delivering electric shocks to the muscles. More than 400,000 units were sold for \$200 to \$400 each before the FDA obtained an injunction to stop its sale. At the trial, 40 witnesses testified that they had been injured while using the machine. In 1971, a federal judge concluded that the device could cause miscarriages and aggravate many preexisting medical conditions, including hernias, ulcers, varicose veins, and epilepsy.

Thigh Creams

Various products are being promoted in the skin care market as thigh and stomach slimmers. Many contain aminophylline, an asthma drug that the promoters claim will dissolve the fat and smooth the skin. Since some individuals are allergic to ethylenediamine, a component of aminophylline, the FDA is concerned about the use of this ingredient in cosmetic skin products.

Body Wrapping

Many salons and spas invite clients to trim inches off the waist, hips, thighs, and other areas of the body. These facilities use wraps or garments, with or without special lotions or creams, applied to the skin. The garments may be applied to

parts of the body or to the entire body. Clients are typically assured that fat will “melt away” and they can lose “up to 2 inches from those problem areas in just one hour.” Home-use systems are also being marketed through the Internet and through multilevel marketing. Many of the systems are claimed to “remove toxins,” which is absurd. Some marketers suggest measuring a large number of body areas before and afterward and adding up the differences to get “total inches lost.” Life Force International, for example, suggests adding the results of 17 measurements. This enables minor changes due to temporary effects or to measurement variations to appear to be large numbers.

Products based on similar notions have also been marketed by mail. Rubber sweatsuits have been claimed to cause weight loss by increasing the amount of water lost through perspiration. Heat belts have been marketed with similar claims. Some have chemical heat packs to increase the temperature around the waist and have elasticized waist cinchers to fit close to the body to keep sweat from evaporating.

Although wrapping or special garments may cause temporary water loss as a result of perspiration or compression, any fluid will soon be replaced by drinking or eating.

Cellasene

An herbal product called Cellasene is being vigorously promoted as a cellulite remedy. The product was developed by an Italian chemist named Gianfranco Merizzi. Its ingredients are evening primrose oil, dried fucus vesiculosus extract, gelatine, fish oil, glycerol, soya oil, grape seed, bioflavonoids, soya lecithin, fatty acids, dried sweet clover extract, dried ginkgo biloba extract, and iron oxide. The product, to be taken twice daily (or three times per day for an “intensive” program) for two months and then once daily for maintenance, costs \$1.50 to \$2.00 per capsule. Here’s what one Internet marketer says (followed by my comments in italics):

Resveratrol Hype

Is this red wine's secret to good health?

by Melissa Q. B. McElderry, MS, RD

Resveratrol (trans-3,5,4'-trihydroxy-stilbene), a compound found largely in the skins of red grapes, is a component of Ko-jo-kon, an oriental medicine used to treat diseases of the blood vessels, heart, and liver. It came to scientific attention only four years ago, however, as a possible explanation for the "French Paradox"—the low incidence of heart disease among the French people, who eat a relatively high-fat diet. Today, it is touted by manufacturers and being examined by scientific researchers as an antioxidant, an anticancer agent, and a phytoestrogen. It is also being advertised on the Internet as "The French Paradox in a bottle."

Sources

While present in other plants, such as eucalyptus, spruce, and lily, and in other foods such as mulberries and peanuts, resveratrol's most abundant natural sources are several species of grapes that are used to make wine. It occurs in the vines, roots, seeds, and stalks, but its highest concentration is in the skin, which contains 50-100 micrograms (μg) per gram. Resveratrol is a phytoalexin, a class of antibiotic compounds produced as a part of a plant's defense system against disease. Since fungal infections are more common in cooler climates, grapes grown in cooler climates have a higher concentration.

The resveratrol content of wine is related to the length of time the grape skins are present during the fermentation process. Thus the concentration is significantly higher in red wine than in white wine because the skins are removed earlier during white-wine production, lessening the amount that is extracted. Grape juice, which is not a fermented beverage, is not a significant source of resveratrol. A fluid ounce of red wine averages 160 μg of resveratrol, compared to peanuts, which average 73 μg per ounce. Since wine is the most notable dietary source, it

is the object of much speculation and research.

Cardiovascular Effects

Many studies suggest that consuming alcohol (especially red wine) may reduce the incidence of coronary heart disease (CHD). Several studies have demonstrated that resveratrol is an effective antioxidant. By inhibiting the oxidation of low-density lipoprotein (LDL), it protects cells against lipid peroxidation. It is thought to provide more effective protection than other well-known antioxidants, such as vitamins C and E. On the other hand, it is less effective than the antioxidants quercetin and epicatechin found in red wine. Reduced platelet aggregation has also been demonstrated, which can also help prevent atherosclerosis.

To date, most of the research on resveratrol's antioxidant and antiplatelet properties has been done in vitro (in an artificial environment using test-tube or tissue-culture preparations). Further studies in animals and humans are necessary to determine whether resveratrol supplementation makes sense.

Cancer-Related Effects

Resveratrol is being studied to see how it affects the initiation, promotion, and progression of cancer. With regard to tumor initiation, it has been shown to act as an antioxidant by inhibiting free radical formation, and as an antimutagen in rat models. Resveratrol appears to decrease tumor promotion activity by inhibiting cyclooxygenase-1 (COX-1), an enzyme that converts arachidonic acid to proinflammatory substances that stimulate tumor-cell growth. Studies related to progression have found that resveratrol induced human promyelocytic leukemia cell dif-

WORST

Nutrabalance (<http://www.nutrabalance.com>) is a bizarre computerized testing system that combines the results of a blood chemistry profile, a urinalysis, and other tests to classify patients according to 14 "metabolic types" and to recommend dietary changes and food supplements.

NutriSystem Direct (<http://www.nutrisystemdirect.com>), an offshoot of the weight-loss center chain, has begun marketing prepackaged foods through independent distributors. It is also offering its own line of supplement and herbal products, most of which are irrationally formulated.

The Good Doctor Web site (<http://www.thegooddoctor.com>), maintained by George Wolverton, MD, a family practitioner in Clarksville, Indiana, offers dubious advice about a variety of dubious diagnostic tests and invalid treatments. His section on "juicing" advocates eating "live foods" (those that still have their enabling enzymes in them) and avoiding "dead" foods (any food that does not spoil within 3 days if left out of the refrigerator).

- Dried ginkgo biloba extract assists in blood circulation and stimulates the metabolism of fats. *Although ginkgo can increase circulation, it does not stimulate fat metabolism. Even if it did, there is no reason it would exert a localized effect.*
- Dried sweet clover extract can increase blood circulation and assist in removing fluid build-up. *This ingredient may have mild diuretic action, but "fluid build-up" is not a factor in the appearance or composition of fatty tissue.*
- Grape seed bioflavonoids are powerful antioxidants that protect cells and blood vessels from damage. *Whether antioxidant supplements help protect tissues is not scientifically settled. Regardless, any such mechanism has nothing to do with the quantity or appearance of fatty tissues.*
- Dried fucus vesiculosus extract stimulates metabolism and can help reduce localized fats. *This herb contains significant amounts of iodine and could adversely effect the thyroid gland. The U.S. Recommended Daily Allowance for iodine is 150 micrograms. The average American woman ingests 170 micrograms per day from food (not including iodized salt). Each capsule of Cellasene contains 240 micrograms of iodine. If enough were taken to increase thyroid function, the result would be unhealthy.*
- Evening primrose oil and fish oil are rich in polyunsaturated fatty acids, a source of energy that increases metabolic levels and helps in diminishing saturated fatty acids. *The "energy" is simply the caloric value. Neither oil increases metabolism or reduces the amount of other fats one eats.*

- Soya lecithin helps to break down fats. *The body makes all the lecithin it needs. Lecithin supplements do not cause the body to shed fat.*

Rexall Sundown, Inc. is Cellasene's primary marketer in the United States. The company's Web site claims:

Cellasene works from within, nutritionally, to help fight cellulite at its source . . .

Cellasene is a safe, clinically studied formula that works over time at the source of the problem—below the surface of the skin. This unique formula of plant extracts and other beneficial dietary supplements nourishes connective tissue from within and helps reduce cellulite. The herbal ingredients in Cellasene work to increase blood circulation, reduce fluid buildup, stimulate metabolism and reduce localized fats. CONVENIENT AND EASY TO USE. . . .

You do not need to change your diet and exercise routine for Cellasene to work. It is simple and effortless to incorporate the easy-to-swallow Cellasene softgels into your daily regimen.

On March 15, 1999, during an interview on CNBC-TV, Rexall's chief executive officer claimed that three clinical trials sponsored by the company had demonstrated a 90% success rate, but the results would not be submitted to scientific journals because Rexall does not

want to reveal the amounts of each ingredient in its formula. This statement was preposterous because results could be published without revealing the exact amounts of each ingredient.

Near the end of May, apparently in response to criticism in the media, Rexall released various

details on two of the studies and posted them to its Science on Cellasene Web site. The first study was performed on 25 healthy female volunteers whose hip and thigh and ankle circumferences were measured before and after eight weeks of daily consumption of the product. Although differences between the initial and final measurements were reported,

no control group was used, so that it would not be possible to tell whether any changes were related to taking the products or to measurement variations. In addition, neither individual measurements nor weights were reported, so that it is not possible to judge from the data whether the reductions were related to weight loss, whether coincidental or otherwise.

The second study compared 25 people who took the product with 15 people who took a placebo for eight weeks. According to the report, the average weight of both groups varied little but average hip and thigh circumference and skin thickness (measured with an ultrasound test) decreased. However, the experimental design was so seriously flawed that the findings should not be regarded as valid. The participants were not told whether they were receiving Cellasene or the placebo, but the investigators knew who was in each group because only the Cellasene group had blood drawn for testing. This could have influenced the way the measurements were performed, as well as the participants' motivation. No data were given to demonstrate whether the measurement process was accurate or whether the appearance or feel of the women's skin had changed. In addition, although measurements were made at the experiment's beginning, midpoint, and end, the midpoint measurements were not reported on Rexall's Web site.

It seems to me that a valid test should involve: (a) more participants, (b) a longer initial investigative period plus monthly follow-up measurements for at least a year, (c) standardization of the measurement technique, (d) measurements taken by at least three investigators, (e) blinding of the investigators about who received the Cellasene and who did not, (f) measuring several times a week to see whether measurements tend to change or remain constant, (g) weekly ratings of the appearance of the skin by both the participants and the experimenters, and (h) release of the individual data in addition to the group averages.

A spokesperson for Cellasene's Italian manufacturer stated that a study involving 200 women will be done at the University of Miami with results expected by next fall.

**The simple truth
is that no product
or exercise
can cause
spot-reduction.**

Endodermologie

In 1998, the FDA approved a high-powered, handheld massage tool that consists of a treatment head and two motorized rollers, with a suction device that compresses the affected tissue between the rollers. The manufacturer is permitted to promote it for "temporarily improving the appearance of cellulite." The procedure—called Endodermologie—usually takes 10 to 20 treatments to get the best results, and one or two maintenance treatments per month are required to maintain them. Without the maintenance, the benefits are soon lost. The typical cost is \$45 to \$65 per session. A recently published study of 85 women between the ages of 21 to 61

found that 46 patients who completed seven sessions showed a mean index reduction in body circumference of 1.34 cm, while 39 patients who completed 14 sessions of treatments showed a mean index reduction in body circumference of 1.83 cm (*Aesthetic Plast Surg* 22:145–153, 1998).

The Bottom Line

The simple truth is that no product or exercise can cause spot-reduction. The amount of fat in the body is determined by the individual's eating and exercise habits, but the distribution of fat in the body is determined by heredity. In most

cases, reduction of particular parts can be accomplished only as part of an overall weight-reduction program. Exercise affects the amount of fat throughout the body, not just in the exercised parts. Endodermologie may temporarily improve the appearance of dimpled areas, but the procedure is time-consuming and expensive. Liposuction may permanently help in some cases. **NF**

FIBER INTAKE AND CHD IN WOMEN

An 10-year epidemiologic study supports the hypothesis that higher fiber intake from cereal sources reduces the risk of coronary heart disease (CHD) in women (*JAMA* 281:1998-2004, 1999). The study compared the incidence of heart attacks of death due to CHD to the amount of dietary fiber consumed by 68,682 women aged 37 to 64 years who had no previously diagnosed angina, heart attack, stroke, diabetes, or high

blood cholesterol when the study began. Women in the highest 20% of cereal fiber intake had a 34% lower risk of CHD than those in the lowest 20%. Reprints can be obtained from Alicja Wolk, DMSc., Dept. of Epidemiology, Karolinska Institutet, Box 281, SE-17177, Stockholm, Sweden (e-mail alicja.wolk@mep.ki.se).

CREATINE SIDE EFFECTS

A survey of athletes who took creatine (28 male baseball players and 24 male football players, ages 18 to 23) found that 16 (31%) experienced diarrhea, 13 (25%) experienced muscle cramps, 7 (13%) reported unwanted weight gain, 7 (13%) reported dehydration, and 12 reported various other adverse effects (*J Am Diet Assoc* 99:593-594, 1999).

HOMOCYSTEINE AND CARDIOVASCULAR RISK IN WOMEN

A prospective study has found that elevated homocysteine levels are associated with moderately increased risk of future heart disease among postmenopausal women (*JAMA* 281:1817-1821, 1999). The study compared homocysteine levels of 122 women who died or had a nonfatal heart attack, stroke, angioplasty, or bypass surgery with 244

matched women who remained disease-free during a 3-year follow-up period. It is not yet known whether lowering mildly elevated homocysteine levels reduces the incidence of adverse cardiovascular events, but many experts believe that clinical trials will demonstrate this. Reprints can be obtained from Paul M. Ridker, M.D., Division of Cardiovascular Diseases, Brigham and Women's Hospital, Boston, MA 02115.

CHITOSAN DEBUNKED

A controlled trial has found that the supplement chitosan does not affect weight or serum cholesterol levels (*Eur J Clin Nutr* 53:379-381, 1999). The study involved 30 overweight volunteers who received four capsules of either chitosan or a placebo for 28 consecutive days and were told to eat their normal diet. The chitosan and placebo groups showed no differences in weight or serum cholesterol levels. Chitosan is derived from chitin, a polysaccharide found in the exoskeleton of shellfish such as shrimp, lobster, and crabs. Many sellers falsely claim that chitosan causes weight loss by binding fats in the stomach and preventing them from being digested and absorbed. Some refer to it as a "fat magnet." **NF**

[continued from page 35]

ferentiation and inhibited ribonucleotide reductase, an enzyme needed for DNA synthesis in proliferating cells. One appealing characteristic of resveratrol's anticancer potential is its minimal toxicity to blood-forming cells. More studies using both cellular and animal models are needed before any such data would be applicable to human use.

The similarity in structure between resveratrol and diethylstilbestrol has prompted investigations into resveratrol's potential as a phytoestrogen (a plant compound that produces estrogen-like effects). However, these properties also stimulate the growth of human breast cancer cells. This finding seems contrary to its other anticancer activities, and is a cause for concern.

Final Analysis

Laboratory tests have clearly demonstrated that resveratrol may help prevent cardiovascular disease and cancer. However, there are several reasons why recommending a population-wide increase would be premature.

First, little is known about the absorption and clearance of resveratrol, the identities of its metabolic products, or its effects on the liver. Second, the research on resveratrol has focused on its short-term effects and has been dominated by in vitro studies. Third, its role as a potentiator of breast carcinomas may significantly limit its use, even for its "proven" benefits. Finally, its main dietary source is red wine. Not only is its concentration in wine extremely variable, but recommending increased consumption of red wine to boost resveratrol intake could certainly do more harm than good. In spite of any beneficial

aspects, red wine and other alcoholic beverages pose health risks that include liver damage and physical addiction.

The health-food industry is claiming that resveratrol is the wine component responsible for the "French Paradox." While taking resveratrol pills is certainly safer than heavy consumption of red wine, supplementing with unproven substances is generally unwise. At this point, occasional use of red wine seems far more prudent. **NF**

Mrs. McElderry is a dietitian who co-owns and operates several restaurants and theatre-pubs. Carolyn M. Klinge, Ph.D., Assistant Professor of Biochemistry and Molecular Biology, University of Louisville School of Medicine, reviewed this article before publication. Thomas J. Wheeler, Ph.D., and Manfred Kroger, Ph.D., helped edit it.

Book Reviews

Analysis and Ratings

The following reviews not only offer analyses but also rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to *Nutrition Forum Book Reviews*, P.O. Box 664, Amherst, NY 14226-0664.

Immoral Eating

Becky Chase, MS, RD

The Resolution Diet: Keeping the Promise of Permanent Weight Loss by David Heber, MD, PhD (Garden City Park, NY: Avery Publishing Group, 1999), 209 pp., \$21.95, hard cover, ISBN 0-89529-872-4.

David Heber, MD, Director of the UCLA Center for Human Nutrition, believes obesity can be blamed on four factors: food advertising, genetics, stress, and low physical activity. His antidote? Take responsibility for your lifestyle and stop being influenced by the food marketing industry. This book reveals the "secrets of success" that Heber claims are the key to permanent weight loss.

The Resolution Diet consists of using a meal replacement beverage, such as Ultra Slim•Fast, for two meals a day and adding other portion-controlled foods for a total intake of 1200 to 1500 calories per day. Other allowed foods include certain vegetables, fruits, whole grains, and lean proteins. No additional fats are included. When target weight is reached, meal replacements are used for one meal a day.

Heber claims that meal replacements offer the dieter better control over calorie intake, they ease the anxiety associated with dieting, and they assure nutritional adequacy since they are fortified with vitamins and minerals. He advocates the use of these products as a lifelong strategy for weight control. However, no clear and

concise guidelines for evaluating meal replacement products are given. The three scientific studies Heber cites to support his dieting strategy were funded, at least partially, by Slim•Fast Foods Company.

Heber also advocates avoiding what he calls "trigger" foods, such as nuts, cheese, pizza, salad dressings, butter, margarine, mayonnaise, red meat, fatty fish, frozen yogurt, ice cream, cookies, pastries, and cakes. He believes these that foods "turn you on and make you fat." His advice is to avoid these foods forever, including the low-fat or fat-free versions. He believes that by avoiding these foods one can learn to lose the desire for them. He also believes that no one can learn to eat smaller portions of his or her favorite foods.

One of the more outrageous claims in the book is that someone is morally superior if he or she can overcome the urge to eat certain foods. This just reinforces the myths that overweight people are morally inferior and that certain foods are "good" or "bad." Ideas like this only contribute to the fat-phobia and low self-esteem often found in individuals who are overweight or who have eating disorders.

The book does offer a potentially beneficial series of questions and exercises designed to help readers gain insight about their own eating behaviors. It would be more helpful, however, if the book provided information about how to use them to tailor the diet to meet individual needs.

One of the book's strong points is the discussion of exercise. Heber emphasizes the importance of both cardiovascular and muscle-building exercises in weight management. The information on relapse prevention, stress management, and social support, though brief, is on target. Unfortunately, Heber skims over many of the psychosocial issues involved with weight loss.

While some people may be successful in losing weight following this diet, the book reinforces much of what is problematic about dieting today—completely avoiding certain foods, eating only certain foods, and feeling guilty about enjoying food. **NF**

NOT RECOMMENDED

Finally. Science meets alternative medicine.

The Scientific Review of Alternative Medicine (SRAM) is the only peer-reviewed medical journal dedicated exclusively to carefully assessing the claims, treatments, and hypotheses of unconventional medicine.

HERBAL FOODS?

The Dietary Supplement and Health Education Act of 1994, which included herbs within its definition of supplements, has spurred herbal marketers to promote thousands of products with questionable claims and inadequate directions for use. Increasing numbers of ordinary foods are being spiked with herbs that can produce pharmacologic effects. For example, R.W. Knudsen's "Simply Nutritious" line includes Peach Berry St. John's Wort, a juice product fortified with St. John's wort extract, is advertised in *Vegetarian Times* as "a convenient, delicious way to reduce anxiety and depression." Other Simply Nutritious products include Lemon Ginger Echinacea, Ginseng Boost, and Ginkgo Alert.

FOODBORNE ILLNESS REPORT

The American Council on Science and Health has revised its booklet, *Eating Safely: Avoiding Foodborne Illness*, which describes how to prevent more than 40 illnesses. The 48-page report notes that disease-causing organisms are the primary cause and that poor sanitation and preparation practices are more common in the home than in food-processing establishments. The booklet can be downloaded from <http://www.acsh.org> or purchased for \$5 from the American Council on Science and Health, 1995 Broadway, New York, NY 10023.

WEIGHT-LOSS GUIDELINES FOR PROVIDERS

The FTC has issued guidelines primarily intended for commercial weight-loss clinics. The guidelines call for disclosure of staff qualifications, key program components, risks (if any), costs, outcome information, and the fact that the odds of keeping weight off can be improved through a lifelong commitment to regular physical activity and to healthful eating in accordance with the Dietary Guidelines for Americans. The text and advice on setting weight-loss goals can be accessed online by clicking "more info" at <http://www.consumer.gov/weightloss/>

The Juice Plus+® 'Miracle'

Can powdered, encapsulated foods save your health?

by Stephen Barrett, MD

National Safety Associates (NSA) president Jay Martin likes to turn simple ideas into megamillion-dollar sales. An NSA brochure states that by 1997 his company had generated over \$3 billion in sales by "developing and introducing innovative new products that are on the leading edge of whole new industries": home fire detectors in the 1970s, water filters in the early 1980s, and air filters in the late 1980s. But its "biggest hit yet" is a line of "natural food-based products designed to help prevent disease." Its flagship product—Juice Plus+®—was introduced in 1993 and hit \$6 million per month by the end of its first year.

The Juice Plus+® recipe for success is very simple: Fruits and vegetables are good for us. Capture their goodness in convenient products. Add endorsements, testimonials, a pinch of fear, a scientific veneer, and several dollops of deception. And harness the power of multilevel marketing (MLM) to spread the word. All of these ingredients have been around for many years. But NSA has developed a winning mix.

It is well established that dietary strategies can help prevent certain cancers and reduce the risk of cardiovascular disease. Popularization of the diet-cancer link began during the early 1980s when the National Academy of Sciences (NAS) reported that people who eat lots of

whole-grain cereals, fruits, and vegetables have a lower incidence of certain cancers. Since that time, research has shown that emphasizing these foods can also help prevent heart attacks and strokes. These ideas have been quantified in the Food Guide Pyramid System (1992), which recommends 6–11 servings of grain products, 2–4 servings of fruit, and 3–5 servings of vegetables per day, depending on the individual's caloric intake.

Since it was not known which dietary factors, if any, might be helpful, the NAS report specified that supplementation with individual nutrients was not advisable. Within a few months after the report was issued, however, several products containing dehydrated vegetables or various nutrients were marketed as though the report had supported their use for cancer prevention. Government regulatory actions drove some of the early products from the marketplace, but new studies (particularly of antioxidants), new marketing techniques, and lax federal enforcement have enabled many more to take their place.

Add endorsements, testimonials, a pinch of fear, a scientific veneer, and several dollops of deception.

The Power of MLM

MLM is a form of direct sales in which independent distributors can make money not only from their own sales but also

from those of the people they recruit. Its roots date back to the 1930s when a California businessman began offering friends a commission for selling a food supplement to their friends. The operation evolved into Nutrilite Products in 1939 and began significant interstate distribution in 1945. In 1959, two highly successful distributors formed a new company that evolved into the multibillion-dollar, international conglomerate now called Amway. Shaklee Corporation, another MLM giant, was founded in 1956 by a retired chiropractor. Since that time, hundreds of other companies and millions of "independent distributors" have joined the fray.

The "success" of network marketing lies in the enthusiasm of its participants. Most people who think something has helped their health enjoy sharing their success with their friends. Testimonial-givers are usually motivated by a sincere wish to help their fellow humans. Since people tend to believe what others tell them about personal experiences, testimonials can be powerful persuaders. An NSA distributor manual notes that "as people use the product, they begin to build their own Juice Plus+® story to share with others." Although NSA literature states, "We do not make any claims . . . involving the prevention, cure, mitigation of any disease," NSA distributors are circulating claims that Juice Plus+® products have relieved a wide variety of discomforts. In 1994, I even acquired a 69-page booklet of endorsements and testimonials.

Until the mid-1980s, claims made for health-related MLM products were conveyed mainly through direct personal contact in which the salesperson's personal success story (health or financial) played an important role. Since that time, however, many companies have added slick videotapes and audiotapes to spread their story, telephone conferences to train large groups of salespeople, scientific advisory boards to seem more authoritative, company-sponsored research to appear more authentic, and endorsements from prominent persons to lend prestige. Many companies use scare tactics and cite scientific research to suggest that their products will prevent disease. NSA does all of

these things. Its "Preferred Customers" who buy a four-month supply of Juice Plus+® capsules at a time, pay about \$500 per year.

What's in Juice Plus+®?

NSA's *Guide for New Distributors*, a 94-page loose-leaf manual dated October 1997, states that 17 foods are juiced to extract their nutritional essence and then reduced to powders using a proprietary process that avoids high temperatures. During the process, sugar, salt, and most of the calories and fiber are removed. "Orchard Blend" capsules are derived from acerola berries, apples, cranberries, oranges, papaya, peaches, and pineapple. "Garden Blend" capsules contain barley, beets, broccoli, cabbage, carrots, kale, oats, parsley, spinach, and tomato. Both products are also said to contain corresponding soluble and insoluble fibers, phytochemical "food actives," vitamins, minerals, and enzymes. Additional fiber and enzymes are added, and the products are encapsulated by a company called Natural Alternatives International.

Neither the product labels nor the product literature indicate the quantities of these ingredients in Juice Plus+® capsules. The manual advises taking Orchard Blend and Garden Blend at separate times because "fruits are digested differently from vegetables and your system can handle them more efficiently if they're dealt with separately." However, Juice Plus+® "Better Bars" combine both concentrates with "real fruits, oats, bran, and a host of other natural ingredients." NSA also markets a meal-replacement drink, Juice Plus+® Lite, each serving of which provides 110 calories, 4 grams of dietary fiber, and significant amounts of 12 vitamins and a few minerals.

Peculiar Claims

Pages 41 and 42 of the manual suggest that each food source offers a special health benefit. Apples, for example, are said to "contain boron, a trace mineral that affects the electrical activity of the brain, increasing mental alertness." Oranges are said to "contain every class of

[continued on page 44]

'Cures' for Multiple Sclerosis

Dozens of remedies are supposed to work— including nutritional therapies

Multiple sclerosis (MS) is a degenerative disease of the brain, spinal cord, and optic (eye) nerves, in which patches of inflammation and scarring interfere with the function of the brain, spinal cord, and/or the nerves to the eyes. The cause of MS is unknown, but the most attractive theory is that it is an immune reaction to the nervous system. Its symptoms include muscular weakness, loss of coordination, and difficulty with speech and vision. It occurs chiefly in young adults and, like arthritis, can have a very variable course. Some people have only a single attack. Others have only a few attacks in a lifetime, recover from these, and experience no disability except during attacks. Others have frequent attacks from which they don't recover completely, but which cause only partial disability. Still others have a slow progression of disability over a period of 10 to 25 years, which eventually leaves them helpless. When attacks occur, symptoms may come and go suddenly and may even vary from hour to hour.

MS's extreme variability makes it a perfect disease for quacks. The only way to know whether a treatment is effective is to follow a large number of patients for years to see whether those who receive the treatment do better than those who do not. Quacks don't bother with this kind of testing, however. They simply claim credit whenever anyone who consults them improves. And since the majority of attacks are followed by complete or partial recovery, persuasive quacks can acquire patients who swear by whatever they recommend.

The Therapeutic Claims Committee of the International Federation of Multiple Sclerosis Societies has analyzed more than a hundred alleged treatments and published the results in a book called *Therapeutic Claims in Multiple Sclerosis* by W. Sibley et al. (4th edition. New York: Demos Vernande, 1996). The volume is revised every few years. Each

analysis includes a description of the method, the proponents' rationale, a scientific evaluation, estimate of risks and/or costs, and the authors' conclusion. The methods are then classified according to plausibility, extent of study, risk, and cost.

No cure is known, but a few methods are useful in shortening the duration of attacks, reducing their severity, or helping to deal with the symptoms. Methods that have a plausible rationale but have not been sufficiently tested are considered "investigational." Investigational methods are not listed here because information about them should be obtained from a qualified neurologist who can thoroughly discuss them. Reliable information is also available from the National Multiple Sclerosis Society.

The committee noted that no nutritional deficiency is known to be a factor in MS, and that no special diet or the addition of vitamins or minerals has been proven to alter its course. Polyunsaturated fatty acids (PUFA) have slight immunosuppressive properties, but studies involving sunflower seed oil, evening primrose oil, safflower seed oil, and fish oils have produced conflicting results. The committee concluded that other than a possible benefit of PUFA-containing oils there is no evidence that any dietary change affects MS.

Methods to Avoid

The methods considered implausible or ineffective are listed below:

Adequately tested but ineffective in influencing the course of MS:

Aspirin and sodium salicylate; colchicine (for immune modulation); thymectomy (removal of the thymus gland); transfer factor; myelin basic protein; hyperbaric oxygen (HBO).

[continued on page 47]

WEB WATCH

This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc., which is working hard to improve the quality of health information on the Web. He now operates three Web sites: Quackwatch (<http://www.quackwatch.com>), Chirobase (<http://www.chirobase.org>), and MLM Watch (<http://www.mlmlwatch.org>).

BEST

GlobalMedic (<http://www.globalmedic.com>) offers interactive health quizzes for assessing eating habits, stress level, and heart health, and for preliminary evaluation of various symptoms. The site also includes health news, first-aid information, and a medical encyclopedia.

WORST

MotherNature.com (<http://www.mothernature.com>) offers "30,000 vitamins, herbs, and supplements. And expert advice. On everything from breast tenderness to gout. In complete and total privacy." The site features a "Health Encyclopedia" promoting products for more than 100 conditions. For cancer, it states: "Shark cartilage is also a popular alternative treatment for cancer, taken both to slow the growth of existing tumors and in smaller daily doses to prevent cancers."

HealthShop.com (<http://www.healthshop.com>) claims it is "the world's most complete natural food store." Its search box enables the browser to identify products alleged to be helpful for the problem selected. The site also has a "health planner" to "create a health and nutritional program tailored to your unique needs." The process is programmed to recommend supplements to everyone.

Doctor's Nutrition On Line (<http://doctorsnutrition.com>) operated by two Mississippi chiropractors, offers products for "optimal nutrition" and a toll-free number for individual consultations.

HealthWatchers System (<http://www.healthwatchers.com>) offers several worthless tests and other information intended to hawk its supplements. The site is operated by Gary Martin, former proprietor of the American College of Nutripathy, a nonaccredited correspondence school.

Global Health (<http://www.watercure.com>) is dedicated to the bizarre idea that dehydration is the primary cause of disease. The "doctor" responsible for this idea is not listed in the AMA's physician database.

MIXED

PlanetRx (<http://www.planetrx.com>) combines a huge amount of information with an online pharmacy and health food store. The medical information is valid, but sections dealing with dietary supplements and other alleged "alternative" treatments contain many inappropriate recommendations.

cancer inhibitor known." Acerola cherries are "a source of vitamin C, known to relieve symptoms of osteoarthritis." Carrots are said to lower cholesterol, parsley to be "good for the heart and immune system," kale to be a "powerful cancer fighter," and cabbage is "thought to block breast cancer." Even if these claims were true, there is no reason to conclude that taking Juice Plus+® capsules could provide the same benefit.

Page 43 states, "The food enzymes in Juice Plus+® will facilitate digestion of

your food, making it more useable to your body. This also conserves the body's own enzyme supply to do other important things like fighting off disease." This statement is false because: (a) most people have enough enzymes in their intestinal tract to digest their food; (b) most of the enzymes in food are destroyed during digestion; and (c) the body's production of metabolic enzymes does not depend upon the amounts of enzymes in the digestive tract.

The enzymatic nonsense reflects the ideas of Humbart "Smokey" Santillo, author of *Food Enzymes: The Missing Link*

to *Radiant Health*, to whom NSA attributes the Juice Plus+® concept. Santillo's credentials include a bachelor of science degree from Edinboro State Teacher's College, a doctor of naturopathy degree from a nonaccredited correspondence school, an iridology "certificate of merit," a master herbalist certificate from the School of Natural Healing, and eight years of study at the Concept Therapy Institute (which teaches a biotheistic chiropractic technique). One of NSA's audiotapes features Santillo claiming that whole fruits and vegetables should not be eaten closely together as foods but are

Does 'Juicing' Work?

According to the cover of his book *The Juiceman's Power of Juicing*, Jay "the Juiceman" Kordich offers a "revolutionary program for staying healthy, looking young, staying trim, and feeling great—all by taking advantage of the natural healing power of fresh fruit and vegetable juices." Kordich claims that at age 20, he became gravely ill with a cancer and was told he might not live. Inspired by literature about the Gerson diet, he began drinking 13 glasses of carrot-apple juice every day. "Two and a half years later," he says in the book, "I was a well man." After more than 20 years of hawking juice extractors from town to town, Kordich gradually harnessed the power of television to boost "juicing" into a nationwide fad with sales in the tens of millions annually. Health-food stores are profiting from the fad by selling juice extractors and "organic" foods.

Kordich's book is filled with fanciful physiologic tidbits and far-fetched claims that juices boost energy and are effective against scores of ailments. His recipes include "Pancreas Rejuvenator" (carrot-apple-lettuce-string bean-Brussels sprout juice), "Body Cleanser" (carrot-cucumber-beet juice), "Graying Hair Remedy" (cabbage-spinach-carrot juice), and other concoctions for anemia, anxiety, arthritis, gallstones, impotence, and heart disease. He claims that for the more serious diseases, "the right nutrients may retard or reverse the manifestations of some of these diseases by feeding the immune system and making the body healthier and stronger overall."

Kordich claims that "live foods" are superior to cooked or processed foods because they contain "active enzymes." These, he claims, help break down foods in the digestive tract, "thus sparing the body's valuable digestive enzymes. . . . This allows vital energy in the body to be shifted from digestion to other body functions such as repair and rejuvenation." Of course, "organic foods" are preferable because "the corporate giants use deadly chemicals." Further:

The abundance of live, uncooked foods flushes your body of toxins, leaving you refreshed, energized, and relaxed all at the same time. The pure foods make your skin glow, your hair shine, your breath fresh, and your entire system so regulated you will never have to give it another thought. Colds and flu become fewer and farther between; many people report that arthritic joints loosen with renewed flexibility; and gums and teeth become less prone to bleeding and cavities.

The above notions are nonsensical. Uncooked (or fresh-frozen) foods, alone or combined as Kordich suggests, can be a valuable component of a balanced diet. However, they do not "flush the body of toxins," "energize the body," or alleviate any of the diseases or conditions as Kordich claims. Nor is it correct that juices can strengthen the immune system or the body as a whole. The enzymes in plants help regulate the metabolic function of plants. When ingested, they do not act as enzymes within the human body, because they are digested rather than absorbed intact into the body. "Organically grown" foods cost more but are neither safer nor more nutritious than conventionally grown foods. And sensible eating, which is not difficult to do, furnishes an adequate nutrient supply.

Juice extractors cut food into tiny pieces that are then spun to separate the juice from the fiber-containing pulp. Ordinary juicer machines leave the pulp in the juice. Since the fiber in fruits and vegetables is an important part of a balanced diet, there is no reason to remove it while making juice. There's nothing wrong with including extracted juices in a diet that is adequate in fiber. But promoting them as alternatives to whole foods or as powerful healing agents is irresponsible.

safely combined in Juice Plus[®]. He also claims that Juice Plus[®] Lite helps people manage their weight because "it has so much food value and is so easy to digest. Once they start absorbing all that food, they just don't have the same hunger . . . and lose weight automatically."

The Scientific Veneer

Juice Plus[®] promoters also refer to science. NSA's most powerful sales aids are tape recordings by Richard DuBois, MD, a board-certified internist who is described as "one of the world's leading authorities on infectious disease." Citing scientific studies, DuBois correctly notes that (a) considerable research shows that diets high in grains, fruits, and vegetables are associated with lower rates of certain cancers, cardiovascular disease, and several other types of degenerative disease; (b) many Americans do not eat the recommended number of servings; (c) epidemiologic studies have found that these diseases are associated with low blood levels of certain phytonutrients; and (d) an NSA-sponsored study of 15 healthy individuals found that supplementation with Juice Plus[®] for 28 days raised the blood levels of five phytonutrients (*Current Therapeutic Research* 57:445-461, 1996). The study found, for example, that beta-carotene levels were 5 times as high, and lycopene levels were 20 times as high.

To further support his argument, DuBois correctly describes how clinical trials have found that supplementation with individual nutrients sometimes does more good than harm. But he then asserts that the Juice Plus[®] nutrients are safe and more effective, because the phytonutrient content of plants is "balanced." Based on all of the above assumptions, he concludes that everyone should take Juice Plus[®].

The above reasoning is not valid. Nearly all of the evidence relating disease rates to dietary composition is epidemiologic. Epidemiologic studies do not prove cause and effect. And even if causal connections are established, they do not prove that dietary supplements will remedy a poor diet or that Juice Plus[®] is an optimal supplement. Only well-designed, long-term clinical trials can determine whether taking it or any other pill or potion can actually prevent disease.

But that's not all. Much of the protective effect of fruits and vegetables is due to their fiber content. Juice Plus[®] pills have nearly all the fiber removed. Moreover, eating the recommended portions of grains, fruits, and vegetables does not merely provide high levels of phytochemicals. It usually means that the overall diet is low or moderate in fat. Nobody knows whether adding a product like Juice Plus[®] to a high-fat or low-fiber diet would provide much benefit. The bottom line is that if someone's diet is low in fruits, vegetables, or grains, the most prudent action is to fix the diet.

Curiously, DuBois himself has cast doubt on his claim that Juice Plus[®] provides "balanced nutrition." In the 1998 NSA videotape, "Homocysteine, Oxidative Stress, Pathogenesis and Prevention of Disease," he states extra carotenoids are stored in the skin and that his own skin has turned orange from the pills. Rather than seeing this as a problem (since beta-carotene supplements have been associated with increased cancer rates in a few studies), he claims that "When you turn orange,

you have neutralized your oxidative stress" (a purported measure of harmful free-radical activity) and therefore reduced your odds of getting certain diseases. He even describes how his patients say, "I want to look like you. I want that carotenoid gloss." How can he possibly know that years of living with orange skin will do more good than harm?

NSA sales aids acknowledge that taking Juice Plus[®] is not as good as eating the recommended amounts of grains, fruits, and vegetables. But they also state that everyone should take Juice Plus[®]. If every American did so, the total annual cost would exceed \$100 billion. Do you think this would be a wise allocation of our financial resources? **NF**

Dr. Barrett, a retired psychiatrist, is board chairman of Quackwatch, Inc., and a board member of the National Council Against Health Fraud. The Quackwatch Web site (<http://www.quackwatch.com>) contains additional information on nutrition and health fads.

Finally. Science meets alternative medicine.

The Scientific Review of Alternative Medicine (SRAM) is the only peer-reviewed medical journal dedicated exclusively to carefully assessing the claims, treatments, and hypotheses of unconventional medicine.

BRIEFS

[continued from page 41]

INTERNET HELPS SNAG MEDICAL IMPOSTOR

Gregory Earl Caplinger has pled guilty in North Carolina federal court to six counts of wire fraud in connection with a scheme that involved selling stock in a company set up to market his alleged cure for AIDS and cancer. The treatment, which is bogus, has been administered at Caplinger's clinic in the Dominican Republic. Caplinger represented himself for many years as a distinguished physician, researcher, and board-certified cancer specialist who has authored many scientific publications. However, testimony presented to the court by an FBI agent and Dr. Stephen Barrett indicate that: (a) Caplinger had never attended medical school; (b) his medical and doctor of science "degrees" were obtained from diploma mills; (c) various other "professional" credentials were acquired either by simply paying a fee or by printing them himself; and (d) nothing he has written has been published in a recognized scientific journal. The investigation was facilitated by victims who had read about Caplinger on Barrett's Web site. The full story can be accessed on [http://www. quack-watch.com](http://www.quack-watch.com) by searching for "David Weekley" and clicking on the topmost line of the results.

QUESTIONABLE MAIL-ORDER PRODUCTS

Gero Vita International has been vigorously advertising mail-order products in the United States and Canada for more

than five years. Some of the products may be effective (though overpriced), but many are promoted with misleading claims. Gero Vita's chairman, A. Glenn Braswell, marketed many health and beauty products during the late 1970s and early 1980s. During that period, the U.S. Postal Service filed 138 false representation complaints involving 50 products. The cases were settled through 32 false representation orders and 15 consent agreements. Braswell also pled guilty to mail-fraud charges involving the faking of before-and-after advertising photographs for bust developer, hair-growth, and cosmetic products, and was sentenced to five years' probation. In addition, he was sentenced to a three-year prison term for federal income tax evasion and perjury charges developed during the mail-fraud investigation. In March 1999, the FDA banned the importation of all Gero Vita products marketed with claims that they can prevent or treat disease. However, this action is unlikely to be effective because products are shipped from within the United States.

GNC MEGADEALS

Royal Numico, N.V., a Dutch manufacturer of nutrition products, has signed an agreement to acquire General Nutrition Companies, Inc., for \$2.5 billion. The parties state that the merger will create the world's largest company devoted to nutrition. GNC has also formed a ten-year partnership with Rite Aid Corporation and drugstore.com that will increase its prominence on the Internet.

RESEARCH SCANDAL

Mannatech Inc. has filed suit against Darryl See, MD, its former \$10,000-a-

month consultant, alleging that research he published contained false claims. The suit alleges that See also lied when he said that the study was funded by the National Institutes of Health and conducted under the auspices of the University of California Irvine Medical School. The misrepresentations were uncovered by David Evans, an investigative reporter for *Bloomberg News*. See's report, which ranked Mannatech's pills in the top five of 196 that were subjected to laboratory testing, has been a key document used by the company's 400,000-plus distributors to promote its products. However, See's former department chairman told Evans that mere lab tests are insufficient to show effectiveness or safety of such products in humans. The complete story is available on <http://www.mlmwatch.org>.

WARNING AGAINST RAW SPROUTS

The FDA has warned that raw sprouts can cause potentially dangerous salmonella and *E. coli* O157 infection, particularly in children, the elderly, and persons with weakened immune systems. (In healthy adults, these infections may cause diarrhea but usually run their course without causing serious illness.) In an advisory issued in July, the agency advised that (a) cooking can significantly reduce the risk of illness, (b) consumers should check that sandwiches and salads in restaurants are made without sprouts, and (c) sprouts grown under clean conditions in the home may still present a risk if bacteria are present in the seeds from which they are grown. **NF**

Statement of Ownership, Management, and Circulation (Required by 39 U.S.C. 3685)

Date of filing: September 16, 1999. Title: Nutrition Forum. Frequency of issue: bimonthly. Complete mailing address of known office of publication: 59 John Glenn Drive, Amherst, NY 14228-2197. Publisher: Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197. Editor, Managing Editor: Lewis Vaughn, 59 John Glenn Drive, Amherst, NY 14228-2197. Owner: Prometheus Books, 59 John Glenn Drive, Amherst, NY 14228-2197. Stockholder owning or holding 1 percent or more of total amount of stock: Paul Kurtz, 59 John Glenn Drive, Amherst, NY 14228-2197. Known bondholders, mortgagees, and other security holders: none. Average no. copies of each issue during preceding 12 months: A. Total no. copies printed (net press run) 917. B. Paid and/or requested circulation (1) Sales through dealers and carriers, street vendors and counter sales 0; (2) Mail subscriptions 640. C. Total paid and/or requested circulation 640. D. Free distribution by mail, samples, complimentary and other free copies, 51. E. Free distribution outside the mail, carriers or other means 0. F. Total free distribution 51. G. Total distribution (sum of C and F) 691. H. Copies not distributed (1) Office use, leftovers, spoiled 809; (2) Returns from news agents 0. I. Total (sum of G, H1 and H2) 917. Actual no. copies of single issue published nearest filing date: A. Total no. copies printed (net press run) 1,000. B. Paid and/or requested circulation (1) Sales through dealers and carriers, street vendors and counter sales 0; (2) Mail subscriptions 556. C. Total paid and/or requested circulation 556. D. Free distribution by mail, samples, complimentary and other free copies 46. E. Free distribution outside the mail, carriers or other means 0. F. Total free distribution 46. G. Total distribution (sum of C and F) 602. H. Copies not distributed (1) Office use, leftovers, spoiled 898; (2) Returns from news agents 0. I. Total (sum of G, H1 and H2) 1,000.

Implausible and untested or inadequately tested:

Various nonsteroidal antiinflammatory drugs (NSAIDs); thyrotropin-releasing hormone; cannabis (marijuana); Diltiazem; Nifedipine; Verapamil; low-fat diet; intravenous yeasts (Proper-myl); pancreatic extract (epropanex); honey-bee venom (safety is uncertain); octacosanol; superoxide dismutase (SOD); procaine hydrochloride; dimethyl sulfoxide (DMSO); Alphasal (formerly Chlororazone or Vitamin X); allergens; Rodilemid; alpha-fetoprotein; Proneut; immunobiological revitalization; proteolytic enzymes; injections of calcium orotate or calcium aminoethyl phosphate; oral calcium + magnesium + vitamin D; sodium bicarbonate or phosphate; hyperimmune colostrum ("immune milk"); Nystatin; transcutaneous nerve

stimulation (TNS); ultrasound treatment applied near the spinal column; magnet therapy; dental approaches such as correction of bad bite, TMJ treatments, or removal of mercury-amalgam fillings; hysterectomy; allergen-free diet; Kousmine diet; gluten-free diet; raw food diet (Evers diet); MacDougal diet; pectin- and fructose-restricted diet; sucrose- and tobacco-free diet; vitamin regimens; mineral supplements; cerebroside; aloe vera juice; various enzymes (Wobenzym, digestive enzymes, Vitafestal, Bilicomb, Panpur, Panzynorm).

Implausible and known to have significant risk or side effects:

ACTH or other corticosteroids administered into the spinal canal; chloroquine; x-ray treatment; immunosuppression with chlorambusil (Leukoran), Lumustine, or 5-Fluorouracil; immune

modulation with thymus hormones (Thymosin, Thymuline/Facteur Thymique Scribe, Thymopoetin 5, TFX-Polfa, THX, T-Activin); myelin basic protein; Interferon gamma; interferon inducers (Tilorone, Poly-ICLC, Staphage Lysate); Progabide (for spasticity); heart and pancreas extract (Pancorphen); snake venom (PROven, Venagen, Horvi MS9); cellular therapy; autogenous vaccines; chelation therapy; "metabolic therapy"; promazine hydrochloride (Sparine); Le Gac Therapy (antibiotics plus hot tubs); acupuncture; electrical stimulation of the dorsal column of the spinal cord; sympathectomy; ganglionectomy; surgical spinal cord relaxation (cervicolordodesis); vertebral artery surgery; surgical implantation of pig brain tissue; Cambridge or other very-low-calorie liquid diets; high dosage of vitamin C and various other high-dosage vitamin or mineral regimens. **NF**

Book Reviews

Analysis and Ratings

The following reviews not only offer analyses but also rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers. Readers who would like to see specific books reviewed may send their suggestions (or copies of books) to Nutrition Forum Book Reviews, P.O. Box 664, Amherst, NY 14226-0664.

Herbal Disaster

Varro E. Tyler

Herbal Medicine: The Use of Herbs for Health and Healing, by V. Pitman (Rockport, MA: Element Books, 1994), 161 pp., soft cover, ISBN 1-85230-591-6.

When I was in London recently, I visited the book stores on Charing Cross Road to see what was new in the herbal field. Foyles, the largest bookstore in the world, had little to offer. Blackwells across the street had nothing, but a clerk there referred me to Watkins Books and gave me the address. When I got there, the sign above the shop window indicated they were specialists in mystical and occult literature. On entering, I found an enormous selection of books devoted to herbal remedies, mostly by British authors.

This experience clearly denotes the status of herbal medicine as a non-science—even antiscience—in the U.K. Although the author of this volume is a native of the United States, she has clearly adapted to the British concept, and her book is a model of the nonscientific/antiscientific approach which I have long referred to as paraherbalism.

After reviewing the basic elements, earth, air, fire, and water (to which Ms. Pitman adds ether to the four Greek originals of Empedocles), she notes that these intermingle to create three energy patterns, or “humours,” that determine our constitutional type. All of this is based on Ayurvedic philosophy and not on that of

Hippocratic medicine which postulated four humors. She notes the similarity of the two systems. Apparently, one element or humor more or less is of relatively little consequence. She then goes on to assert that a knowledge of the activity of herbs combined with a knowledge of humoral constitution will allow the reader to form a successful “herbal strategy.”

This philosophic nonsense gives way to pure antiscience in some of the subsequent monographs on the individual herbs. Comfrey (*Symphytum* species) contains extremely toxic pyrrolizidine alkaloids proven to cause cancer of the liver in small animals and veno-occlusive disease in humans. Scientists everywhere condemn its internal use in unmodified form, and externally it should be applied only to intact tissue, not to open wounds. The author begins her discussion of this herb with a humour assessment noting that comfrey strengthens water essence and cools fire. She then asserts that its carcinogenicity is based on “flawed research” and that it is one of those “invaluable herbs.” One can only infer here that it may be invaluable to funeral directors. Many significant benefits are then cited, ranging from the treatment of bleeding ulcers and lungs to severe burns.

The potential toxicity of coltsfoot (*Tussilago farfara*) which contains the same type of carcinogenic alkaloids is not even mentioned in the discussion of that herb.

A publisher's note on the copyright page of this volume indicates that, contrary to its title, the book is not intended as a replacement for medical advice. I should hope not!

NOT RECOMMENDED

Herbal Details

Varro E. Tyler

Hypericum & Depression, by H. H. Bloomfield, M. Nordfors, and P. McWilliams (Los Angeles: Prelude Press, 1996), 203 pp., \$7.95, soft cover, ISBN 0-931580-36-6.

This book provides an excellent introduction in its initial 93 pages to the lay reader who wants to know the facts about St. John's wort (*hypericum*) and its safety

and utility in treating mild to moderate depression. The remainder of the volume is devoted to an analysis of the medical studies, complete with references, on which the first part of the volume is based. It will be of interest to the intellectually curious who want to know the details.

The first portion of the book consists of three logical divisions. Part one, “Depression,” covers definition and treatment of the condition. Part two, “Hypericum Perforatum,” discusses the herb itself. Part three, “Hypericum and Depression,” details the therapeutic use of the herb. The final part, “Medical Studies on Hypericum and Depression,” provides details on the pharmacological and clinical studies supporting use of the herb.

My main criticism of this otherwise useful volume deals with the listing on pages 82–84 of “research-grade” St. John's wort products. These are said to contain the “same exact formulation used in a majority of those [medical] studies.” Most of the controlled studies conducted on the herb since 1991 have used a Lichtwer product designated LI 160, and some of the products listed do not contain that particular extract. Instead, their status is based on “borrowed science”—the (false) assumption that if a product has a similar composition to the one tested, it must have the same chemical activity. Admittedly, the original producer of the herbal extract is not always listed on the label and is therefore difficult to identify, but the authors could have exercised more caution in preparing this listing.

Unfortunately, this book is printed on very poor, newsprint quality paper, probably to keep the price low. Still, a dollar more for quality paper would have resulted in a much nicer-appearing and longer-lasting book. Sadly, it is not indexed—a major deficiency in a work of this quality.

But the volume provides the facts about St. John's wort without excessive hyperbole or unreliable anecdotal reports. If you are curious about the herb and are looking for an easily understood, science-based, reliable reference, *Hypericum & Depression* will meet your needs. **NF**

FULL TEXT OF AMA JOURNALS ONLINE

All recent editorial material—including original research, review articles, editorials, letters, and book reviews—from *JAMA* and the *Archives Journals* is now available online. Users can view complete text versions of the articles and search the single or multiple journals using text words, author names, or related articles. Links to references and abstracts are also included. This collection is available free of charge for a limited time. Users also can receive a free e-mail alert of the journals' tables of contents. To access the online *JAMA* and *Archives Journals* articles, visit the AMA's publications Web site at <http://pubs.ama-assn.org>.

OBESITY INCREASING

Although attempts to lose weight are common in the United States, the prevalence of obesity has been steadily increasing during the past 20 years. On October 27, 1999, *JAMA* published a theme issue urging that this problem be given higher public health priority. The lead article noted that obesity, defined as a body mass index (BMI) equal to or greater than 30 kg/m², has increased from 12% in 1991 to 17.9% in 1998. Another article concluded that obesity was associated with higher prevalence of high blood cholesterol, high blood pressure, coronary heart disease, osteoporosis, and type 2 diabetes. Other articles dealt with exercise patterns, exercise equipment, the effect of television viewing by children, recent research advances, and physician counseling.

THE USE OF UNCONVENTIONAL TREATMENTS

Using data from the 1996 Medical Expenditure Panel Survey, researchers from Yale University estimated that in 1996, 6.5% of Americans had visits for both unconventional therapies and conventional medical care; 1.8% used only unconventional services; 59.5% used only conventional care; and 32.2% used neither (*JAMA* 282:651–656, 1999). Chiropractors topped the list of unconventional

The Bizarre Claims of Hulda Clark

Playing dangerously with people's health

by Stephen Barrett, MD

Hulda Regehr Clark, ND, PhD, author of *The Cure for All Cancers* and *The Cure for All Diseases*, is facing criminal and civil charges related to her activities. Clark, 70, claims to cure cancer, AIDS, and many other serious diseases. She describes herself as an "independent research scientist" with bachelor's and master's degrees from the University of Saskatchewan and a PhD degree in physiology from the University of Minnesota (1958). She also lists a naturopathic (ND) degree, but the source is not identified.

Clark's treatment is available at Century Nutrition, a clinic in Tijuana, Mexico, where the basic fee for two weeks of "treatment" is \$4,500 (plus 10% tax). This figure does not include the cost of a motel room (approximately \$210/week); meals (\$250/week); blood tests (\$70 each); standard diagnostic imaging tests (\$40 to \$400); dental x-rays (at least \$200); "individually tailored" supplements (\$400 to \$1,500 for a month's supply); equipment (about \$350); tooth extractions (\$80 each); and partial or full dentures (\$450).

Bizarre Claims

Clark claims that all cancers and many other diseases are caused by "parasites, toxins, and pollutants" and can be cured by killing the parasites and ridding the

body of environmental chemicals. Her book *The Cure for All Cancers* states:

All cancers are alike. They are all caused by a parasite. A single parasite! It is the human intestinal fluke. And if you kill this parasite, the cancer stops immediately. The tissue becomes normal again. In order to get cancer, you must have this parasite. . . .

This parasite typically lives in the intestine where it might do little harm, causing only colitis, Crohn's disease or irritable bowel syndrome, or perhaps nothing at all. But if it invades a different organ, like the uterus, kidneys or liver, it does a great deal of harm. If it establishes itself in the liver, it causes cancer! It only establishes itself in the liver of some people. These people have propyl alcohol in their body. All cancer patients (100%) have both propyl alcohol and the intestinal fluke in their livers. The solvent propyl alcohol is responsible for letting the fluke establish itself in the liver. In order to get cancer, you must have both the parasite and propyl alcohol in your body.

Clark further alleges:

- The adult fluke "stays stuck to our intestine, (or liver, causing cancer, or uterus, causing endometriosis, or thymus, causing AIDS, or kidney, causing Hodgkin's disease)." Or the pancreas, causing diabetes; the brain, causing Alzheimer's disease; the prostate,

Clark claims that all cancers and many other diseases are caused by "parasites, toxins, and pollutants."

causing prostatitis; or the skin, causing Kaposi's sarcoma.

- "As soon as there are adults in the liver . . . a growth factor, called ortho-phospho-tyrosine, appears. Growth factors make cells divide. Now YOUR cells will begin to divide too! Now you have cancer. . . Having propyl alcohol in your body allows the fluke to develop outside of the intestine."
- "When the fluke and all its stages have been killed, the ortho-phospho-tyrosine is gone! Your cancer is gone."
- "Clearly, you must do 3 things: (1) Kill the parasite and all its stages; (2) stop letting propyl alcohol into your body; and (3) flush out the metals and common toxins from your body so you can get well."
- "It is not unusual for someone to have a dozen (or more) of the parasites I have samples of. You can assume that you, too, have a dozen different parasites."
- Three herbs, used together, can rid you of over 100 types of parasites: black walnut hulls, wormwood, and common cloves. But the amino acids ornithine and arginine improve this recipe.
- Use of these five products will kill the cancer-causing fluke in the first five days and the remaining parasites in another two weeks.
- It takes 5 days to be cured of cancer regardless of the type you have. Surgery, radiation, or chemotherapy can be canceled, because after Clark's recipe cures the cancer it cannot come back.
- All metal (fillings, crowns, bridges, etc.) should be removed from the mouth, and all teeth with root canals should be extracted, because their presence damages the immune system.
- To prevent recurrence, stay on a maintenance program of killing parasites and give yourself a high-dose program at least twice a year. Also treat all family members and household pets.

Clark is also using and promoting three devices. Her Syncrometer is claimed to identify diseased organs and

toxic substances by noting whether the device makes various sounds when "test substances" are placed on a plate. The device is simply a galvanometer that measures skin resistance to a low-voltage current that passes from the device through a probe touched to the patient's hand. Various models for home use can either be commercially purchased or made by the patient. Clark's "Zapper" is a low-voltage device that supposedly kills parasites, bacteria, and viruses with electrical energy, but does not harm human tissue. Its use is based on Clark's notion that all living things broadcast a characteristic range of radio frequencies and that the device can issue counterfrequencies that kill unwanted organisms. The third device is a frequency generator, which Clark claims can electrocute individual organisms. None of these devices has any genuine medical value.

Clark's books, herbal products, and devices are marketed through many Web sites. Her ideas are also advocated by the Dr. Clark Research Association, a group founded in 1998 by David P. Amrein, a Scientologist who resides in Switzerland. The site also reports on Clark's activities and instructs her followers about what they can do to help her.

Case Histories

Pages 119-372 contain "case histories" of 138 cancer patients, of whom 103 were "cured" and 35 "did not carry out instructions or could not be followed." The standard way to determine whether a treatment is effective is to carefully record the nature of the patient's disease before treatment and to determine the patient's condition indefinitely. Clark's reports contain little information about the patient's history and no indication that Clark performed any physical examinations. The only follow-up reports are for a few patients who returned for further treatment—usually a few weeks later. Cancer

Clark's reports contain little information about the patient's history and no indication that Clark performed any physical examinations.

[continued on page 6]

High-Dose Vitamin C Against Cancer

Does it work—or is it a Linus Pauling dream?

The claim that vitamin C is useful in the treatment of cancer is largely attributable to Linus Pauling, PhD. In 1976 and 1978, he and a Scottish surgeon, Ewan Cameron, MB, ChB, reported that patients treated with high doses of vitamin C had survived three to four times longer than similar patients who did not receive vitamin C supplements. The study was conducted during the early 1970s at the Vale of Leven Hospital in Loch Lomonside, Scotland. Dr. Cameron treated 100 advanced cancer patients with 10,000 milligrams of vitamin C per day. The clinical course of these patients was then compared with that of 1,000 patients of other doctors whose records were obtained from the same hospital, but who had received no vitamin C. The findings were published in 1976, with Pauling as coauthor, in the *Proceedings of the National Academy of Sciences*.¹

The 1976 report emphasized that all of the patients had been “treated initially in a perfectly conventional way, by operation, use of radiotherapy, and administration of hormones or cytotoxic substances.” The vitamin C patients were reported to have a mean survival time 300 days longer than that of the controls. Moreover, the vitamin C patients were said to have shown an improvement in their quality of life. In response to doubts about the validity, reliability, and quality of the control population, Cameron and Pauling replaced some of the patients and controls and published another analysis in September 1978 in the same journal.² In 1979, two Japanese researchers affiliated with the Linus Pauling Institute claimed similar results in two studies totaling 130 cancer patients treated during the 1970s.³

Faulty Design

The Pauling/Cameron study was not a clinical trial in which patients were compared to carefully matched patients chosen at random and followed using a stan-

dardized protocol. Instead, Pauling and Cameron attempted to reconstruct what happened to the control group by examining their medical records. Most cancer specialists and journal editors are extremely reluctant to accept this type of study for evaluating the validity of contemporary cancer therapy, primarily because bias may occur in selecting controls.

In 1982, William D. DeWys, MD, chief of the clinical investigations branch of the National Cancer Institute’s cancer therapy program, pointed out that the vitamin C and control groups had not been properly matched.⁴ First he observed that no data had been published to demonstrate that the patients had been matched by stage of their disease, functional ability, weight loss, and sites of metastasis, all of which are important for judging the stage of the disease. Then he pointed out that Cameron’s patients began getting vitamin C when Cameron judged them “untreatable” and their subsequent survival was compared to that of the control patients from the time they had been labeled “untreatable.”

DeWys reasoned that if the two groups were comparable, the average time from the initial diagnosis to “untreatable” status should be similar for both groups. But they were not. He concluded that many of Cameron’s patients had been labeled untreatable earlier in the course of their disease and would therefore be expected to live longer. DeWys also noted that more than 20% of the patients in the control group had died within a few days of being labeled untreatable, whereas none of Cameron’s patients had died. This, too, suggested that Cameron’s patients had less advanced disease when they were labeled untreatable.

In the Japanese study, the treatment and control groups were treated with various doses and at different times, which made the conclusions even more questionable.⁵

WEB WATCH

This month’s ratings are by Stephen Barrett, M.D., board chairman of Quackwatch, Inc., which is working hard to improve the quality of health information on the Web. He now operates three Web sites: Quackwatch (<http://www.quackwatch.com>), Chirobase (<http://www.chirobase.org>), and MLM Watch (<http://www.mlmlwatch.org>).

BEST

CBS HealthWatch (<http://www.cbsmedcape.com>), Medscape’s new consumer site, has outstanding consumer information geared to three levels of understanding. Registration is necessary to access the “advanced” and “expert” levels. Registered users can monitor progress toward their health goals and can arrange for information on their favorite topics of interest to be available automatically.

The International Bibliographic Information on Dietary Supplements (IBIDS) database at <http://www.dietary-supplements.info.nih.gov> now has nearly 400,000 citations, some of which are not included in Medline. The database is a project of the NIH Office of Dietary Supplements in partnership with the U.S. Department of Agriculture’s Food and Nutrition Information Center.

WORST

Quixtar (<http://www.quixtar.com>), Amway Corporation’s new site, includes a 60-question online “health assessment” that provides “personalized product recommendations” for NUTRILITE® products. Respondents who indicate that they eat well may be congratulated for “an incredible job of meeting your nutritional needs in this specific area.” However, indicating concern about various body functions will trigger recommendations for products alleged to help those functions. Many such recommendations are inappropriate. To locate the health-assessment form, click “My Assessment” in the “Reference Desk” column on the site-map page.

VitalCast <http://www.vitalcast.com> provides a large amount of misinformation about “alternative” methods. Its offerings include an online magazine (*Vital Living*) and many syndicated radio broadcasts that can be downloaded.

Nutri-Kids.com (<http://www.nutri-kids.com>) promotes Rexall Showcase International’s Nutri-Kids School-Aid, “a protein and multivitamin- and mineral-enriched supplement drink mix to be used as an adjunct to your children’s breakfast.” Pediatrician William Sears, MD, who helped develop the product, claims it contains “many ingredients that have been scientifically shown to help children concentrate and maintain their focus.”

Mayo Study #1

In 1978, the Mayo Clinic embarked on a prospective, controlled, double-blind study designed to test Pauling and Cameron's claims. Each patient in this study had biopsy-proven cancer that was considered incurable and unsuitable for further chemotherapy, surgery, or radiation. The patients were randomized to receive 10,000 milligrams of vitamin C per day or a comparably flavored lactose placebo. All patients took a glycerin-coated capsule four times a day.

The patients were carefully selected so that the vitamin C and placebo groups were equally matched. There were 60 patients in the vitamin C group and 63 in the placebo group. The age distributions were similar. There was a slight predominance of males, but the ratio of males to females was virtually identical. Performance status was measured using the Eastern Cooperative Oncology Group Scale, a clinical scale well recognized by cancer researchers. Most study patients had some disability from their disease, but only a small proportion were bedridden. Most patients had advanced gastrointestinal or lung cancer. Almost all had received chemotherapy, and a smaller proportion had undergone radiation therapy.

The results were noteworthy. About 25% of patients in both groups showed some improvement in appetite. Forty-two percent of the patients on placebo alone experienced enhancement of their level of activity. About 40% of the patients experienced mild nausea and vomiting, but the two groups had no statistically significant differences in the number of episodes. There were no survival differences between patients receiving vitamin C and those receiving the placebo. The median survival time was approximately seven weeks from the onset of therapy. The longest surviving patient in this trial had received the placebo. Overall, the study showed no benefit from vitamin C.⁶

After the study was published, Pauling complained in a letter to the editor that most patients had had extensive prior chemotherapy and were therefore immunologically compromised—so no benefit from vitamin C in the patient population should be expected.⁷ In response, the

Mayo researchers pointed out that Pauling's own reports had said that all of his patients had undergone "perfectly conventional" therapy.⁸ But Pauling maintained that only 4 of Cameron's 100 patients had received prior chemotherapy.⁹ Curiously, at a meeting in February 1985 at the University of Arizona, Pauling stated that vitamin C therapy could be used along with all conventional forms of treatment.¹⁰

A 1975 study at the Mayo Clinic had demonstrated that patients with advanced cancer can mount an immunological response. The study involved forty patients who had undergone chemotherapy for a gastrointestinal malignancy. Many of these patients had immune responses to BCG vaccine, indicating that people with advanced cancer are not uniformly or inevitably immunologically compromised.¹¹ Nevertheless, the Mayo researcher decided to retest vitamin C.

Mayo Study #2

Patients in the second Mayo study of vitamin C and cancer had tissue-proven colorectal adenocarcinoma that was considered incurable. They were ambulatory and had not had chemotherapy. Most had no symptoms. The patients were carefully classified according to the interval between the diagnosis of inoperable disease and entry into the study, the sites of metastasis, and whether there was a measurable area of tumor. A total of 51 patients were randomly allocated to vitamin C, and 49 patients were assigned to receive a milk-sugar placebo.

There were no objective regressions from either placebo or vitamin C for the 19 patients in each group who had measurable tumors. Among the patients who had symptoms when the study began, 7 (64%) of the 11 vitamin C patients and 11 (65%) of the 17 placebo patients claimed some degree of symptomatic relief. To be sure that patients were following the experimental protocol, urine specimens from five patients selected randomly from the treatment group and six patients from the control group were analyzed for vitamin C. The vitamin C patients had significant levels, while the five of the six placebo patients had negligible levels of urinary vitamin C. (The other patient was taking medications that made it impossible to interpret the test.)

The median survival for all patients was approximately 10–11 months, while that from entry into the study until "progression" was declared was about four months. (Progression was declared when a tumor increased significantly in size, new metastases occurred, symptoms or performance worsened substantially, or weight decreased 10% or more.) No meaningful differences were found between patients on vitamin C and those on placebo. Thus, there was no apparent benefit from treatment with high-dose vitamin C.¹²

Mayo Study #3

Following publication of these results, some commentators suggested that the study patients might not have been representative of cancer patients as a whole—that perhaps there was a subtle selection or referral bias that may have skewed the results. So a third prospective, randomized, stratified study was conducted under the auspices of the North Central Cancer Treatment Group, an international, multi-institutional, collaborative oncology group. Based primarily at the Division of Oncology at the Mayo Clinic, the group also had input from community-based cancer specialists in the Upper Midwest, Louisiana, Montana, Pennsylvania, and Saskatchewan.

This study included 71 patients on vitamin C and 73 patients on placebo. The patients were carefully matched by age and gender. Performance scores indicated that most of them had some disability from their advanced cancer. The sites of the primary cancers were virtually identical to those of the original study—primarily lung and colorectal cancer—and the distribution between treatment groups showed no meaningful differences by diagnosis or site. All had advanced cancer that had progressed after standard treatment.

Most patients had had prior chemotherapy, and a smaller proportion had undergone radiation therapy. The study found that the vitamin C group survived no longer than the placebo group. The median survival time was approximately one month, which is fundamentally the same as in the initial vitamin C study. The data did show something that was somewhat intriguing. At two weeks after the onset of therapy, some patients receiving

vitamin C experienced substantial improvement in appetite, strength, and pain relief. However, these advantages quickly dissipated so that by 4–6 weeks no meaningful advantage from vitamin C remained. The researchers concluded that vitamin C had provided transient symptomatic improvement in appetite and strength for a small proportion of treated patients. However, survival was not enhanced by vitamin C.¹³

Thus, three prospectively randomized, placebo-controlled studies involving 367 patients documented no consistent benefit from vitamin C among cancer patients with advanced disease. Moreover, high doses of vitamin C can have significant adverse effects. High oral doses can cause diarrhea. High intravenous dosage has been reported to cause kidney failure

due to clogging of the kidney tubules by oxalate crystals.^{14,15}

Despite these hard facts, many individuals still claim that high doses of vitamin C are useful as a cancer treatment. It is important for responsible health professionals to clarify this issue so that patients neither forfeit scientific care nor put themselves at risk by using a product that has no merit.

Imaginative Claims for Bromelain ‘Diet Pills’ A case of fat delusions?

Bromelain (also spelled bromelin) is a mixture of protein-digesting and milk-clotting enzymes found in the juice and stem of the pineapple plant *Ananas comosus* (Linné) Merr (*Fam Bromeliaceae*). A leading textbook of pharmacognosy (plant medicine) states that bromelain is used to make protein hydrolysates, to tenderize meat, and in the leather industry.¹ There is no scientific evidence that bromelain digests fats or is effective as part of a weight-reduction regimen.

In 1995, the Pennsylvania attorney general obtained an injunction against Ananas, Inc., a Canadian company that was marketing bromelain products in Pennsylvania.² The company’s claims included:

- Users would lose up to 20 pounds in two weeks and never be hungry.
- No dietary changes or exercise would be necessary.
- Ananas bromelain was an astonishing discovery of German researchers who found an enzyme that digests 900 times its own weight in fat.
- Six to eight bromelain capsules per day will force your organism to dissolve all of its excess fats.
- In a controlled medical tests three peo-

ple lost their excess weight while eating more than usual.

- After being absorbed into your bloodstream, bromelain attacks surplus fat in your hips, thighs, stomach, buttocks, and calves, to uniformly reduce their size.
- Bromelain will drain fatty accumulations out of your body.

The attorney general charged that all of the above statements were fraudulent, false, or misleading. The complaint noted that the company had received approximately 11,000 orders totaling \$385,000. A medical consultant reported that:

- No nonprescription product can produce weight reduction without reducing caloric intake, nor can most people lose weight without increasing exercise.
- Weight loss is a matter of arithmetic. There are about 3500 calories stored in a pound of fat. The solicitation claims that 98% of people using the product lost an average of 1.8 pounds a day. That would require an average deficit of 6,300 calories per day. This claim is absurd. Most people who lead a moderately active life need about 15 calories per pound to maintain their weight. Such a person with

a steady weight of 200 pounds would consume about 3,000 calories per day. Even fasting (which would be very dangerous after a few days) would not result in loss of a pound of fat per day. (Starvation will trigger loss of body fluid, but that is unsafe and does not contribute to meaningful weight reduction.)

- Literature for the product claims that a controlled experiment demonstrated weight loss among people in Brussels who took bromelain capsules. But no reference for this alleged study is cited.
- Bromelain is not absorbed into the bloodstream and transported throughout the body. Bromelain is a protein. When eaten by humans, it is broken down into its component amino acids and is not absorbed intact into the body. Even if it were absorbed and could “attack surplus fat,” the breakdown products would be reassembled into fat and not “efficiently eliminated by your body’s natural functions.”

treatment results are normally expressed in terms of cancer-free status or survival over periods of years. Five-year survival rates are a common measure. Clark claims she can tell that patients are cured as soon as their ortho-phospho-tyrosine test is negative—within days or even a few hours after her treatment is begun. This claim is preposterous.

Thirty-eight of the 103 reports indicate that the patient had been medically diagnosed with cancer, and most of these 38 had received standard treatment. In 59 other cases, however, there was no indication that the patient had undergone any medical test or treatment that would indicate the presence of a cancer. (In 10 other cases, which Clark diagnosed as HIV infection, there was no history suggestive of AIDS. In the rest, it was not clear whether the patient had been medically diagnosed with cancer.)

Judging from the reports, Clark's judgments were based entirely on the results of her own peculiar diagnostic tests. If "ortho-phospho-tyrosine" was found in the blood, the patient had cancer. If a "protein 24 antigen" was found in the blood, the patient had AIDS. And, anywhere from a few hours to several weeks later, if these tests became negative, Clark considered the patient cured. The book describes how some of the patients who had consulted Clark for other problems were startled to hear they had cancer or AIDS.

None of the reports provides any basis for concluding that Clark's treatment has the slightest value. The majority of the people described in the 103 case reports did not have cancer. Of those that did, most had received standard medical treatment or their tumors were in their early stages. In these cases, Clark pronounced them cured but did not follow what happened after they left her clinic—so she could not possibly know how they did afterward. In some cases, she counted patients as cured, even though she noted

that they died within a few weeks after she treated them. Despite all this, hundreds of people appear to regard Clark as their savior.

Legal Difficulties

In September 1999, Clark was arrested in San Diego, California, based on a fugitive warrant from Indiana, where she faces charges of practicing medicine without a license. In November, a former patient filed suit accusing her of negligence and fraud.

The criminal case originated when Clark lived and practiced in Indiana. In 1993, after a former patient complained to the Indiana attorney general, a health department official visited her office and was diagnosed with AIDS and sent to a laboratory for a blood test. Clark—apparently tipped off by the lab—found out she was being investigated and left Indiana a few days later. After being returned to Indiana, she was released on \$10,000 bail. Her trial has been scheduled for February 2, 2000. Meanwhile, her supporters—who refer to her as a "medical pioneer"—are sending protest letters to press outlets and government officials.

The civil case was filed in September by Esther and Jose Figueroa of New York City against Clark, the Dr. Clark Research Association, Century Nutrition, and several associated individuals. Mrs. Figueroa, who had been medically diagnosed with breast cancer, sought treatment in September 1998. The court papers state that she was told that (a) dust from her apartment was responsible for her breast cancer; (b) returning to her apartment would place her at special risk to develop leukemia because of her blood type; (c) she had asbestos, lead, and a lot of copper in her system; (d) the Syncrometer detected a parasite called "rabbit fluke" inside her breast; (e) she also had *E. coli*, asbestosis, and salmonella, due to improper food sterilization; and (f) several teeth should be removed and "cavitations" in her lower jaw should be scraped out. Clark subsequently arranged for all

of Mrs. Figueroa's front and molar teeth to be removed, prescribed more than 30 dietary and herbal supplements to be taken during a 12-week period, and badly burned her breast while administering treatment with a "Zapper" device. During the 3-month period of treatment, the tumor increased from 1.5 cm to 14 cm. Despite this fact, Mrs. Figueroa was falsely told that she was getting better, that tests for "cancer markers" were negative, and that pain she was experiencing did not reflect persistence of her cancer.

Internet Help

The Internet provides an efficient way to help victims of quackery. I first learned of Clark through the healthfraud discusslist, several of whose members were familiar with her activities. When she was arrested, they kept the rest of us informed about the situation and how to access online news reports. I obtained further information about Clark by reading her books and accessing Web sites operated by her advocates. The Quackwatch Web site (<http://www.quackwatch.com>) asks quackery victims to contact me for help in getting redress. The site also lists attorneys who are interested in representing victims in court. The civil suit resulted from introducing the Figueroa family to one of our attorneys. **NF**

Dr. Barrett, a retired psychiatrist who resides in Allentown, Pennsylvania, is board chairman of Quackwatch, Inc. and a board member of the National Council Against Health Fraud. To join the health-fraud discusslist, send a blank message to healthfraud-subscribe@ssr.com and follow the instructions you receive.

None of the reports provides any basis for concluding that Clark's treatment has the slightest value.

providers (used by 3.3% of the survey population), followed by massage (2%), herbal remedies (1.8%), spiritual healing (1.8%), nutritional advice (1.1%), acupuncture (0.6%), meditation (0.5%), and homeopathic remedies (0.4%). The researchers concluded that the use of unconventional therapies was substantially lower than had been reported in previous national surveys and was associated with increased use of physician services. Reprints are available from Benjamin Druss, MD, MPH, 950 Campbell Ave., 116A, West Haven, CT 06516.

CANDY BAR PROTEST SUCCEEDS

Nestle USA has agreed to stop using the names "Psycho Sam," "Looney Jerry," and "Weird Wally" for its Tandy Taffy bars. For more than a year, officials of the National Alliance for the Mentally Ill (NAMI) had tried quietly to persuade Nestle that the names were stereotypes that promoted stigmatization of mental illness. The company maintained that the names were rooted in playful humor that amused children and gave personality to its cartoon characters. It backed down, however, after NAMI called on its network of Stigmabusters and others to protest. Former First Lady Rosalynn Carter also objected.

'NUTRACEUTICAL' BILL INTRODUCED

The Nutraceutical Research and Education Act (HR 3001), introduced by Rep. Frank Pallone (D-NJ), would reward those who do clinical research demonstrating that "natural" substances provide

specific health or medical benefit. The bill defines "nutraceutical" as a "dietary supplement, food, or medical food . . . that (1) possesses health benefits; and (2) is safe for human consumption in such quantity, and with such frequency, as required to realize such properties." The bill provides that if the FDA approves a petition for approval of a new health claim, the person or company that developed the supporting evidence would be entitled to exclusive use of that claim for ten years. The bill would also establish the Nutraceutical Advisory Council and periodic publication of a Nutraceutical Index listing the claims that have been approved or are still under consideration.

HERBAL GUIDES NOW IN PAPERBACK

The 4th edition of Tyler's *Honest Herbal* provides a referenced analysis of about 120 herbs and related substances, with each in a separate chapter. *Nutrition Forum* readers can obtain discounted copies for \$21 (\$24 Canada) postpaid from Quackwatch, P.O. Box 1747, Allentown, PA 18105. The 3rd edition of Tyler's *Herbs of Choice*, which discusses the clinical uses, costs \$17 (\$19 Canada) postpaid.

SOY PROTEIN AND CHD

On October 26, 1999, the FDA authorized the use of health claims about the role of soy protein in reducing the risk of coronary heart disease (CHD) on labeling of foods containing soy protein. The decision was based on evidence that including soy protein in a diet low in saturated fat and cholesterol may help to reduce the risk of CHD. Recent clinical trials have shown that consumption of soy protein compared to other proteins, such

as those from milk or meat, can lower total and LDL-cholesterol levels. Foods that carry the claim must also meet the requirements for low fat, low saturated fat, and low cholesterol content; the foods made with the whole soybean may also qualify for the health claim if they contain no fat in addition to that present in the whole soybean. Scientific studies show that 25 grams of soy protein daily in the diet is needed to show a significant cholesterol lowering effect. In order to qualify for this health claim, a food must contain at least 6.25 grams of soy protein per serving. Because soy protein can be added to a variety of foods, it is possible for consumers to eat foods containing it at all three meals and for snacks. The eligible foods include soy beverages, tofu, tempeh, soy-based meat alternatives, and some baked goods. An example of a health claim about the relationship between diet and the reduced risk of heart disease is: "Diets low in saturated fat and cholesterol that include 25 grams of soy protein a day may reduce the risk of heart disease. One serving of (name of food) provides ____ grams of soy protein."

MILK USE SUPPORTED

The American Council on Science and Health (ACSH) has issued a booklet debunking several criticisms of milk by vegetarian extremists. ACSH agrees with the American Academy of Pediatrics that the best foods for infants are human breast milk or infant formula. But after the age of one year, the use of unmodified cow milk is appropriate. The booklet can be downloaded from <http://www.acsh.org> or purchased for \$5 from the American Council on Science and Health, 1995 Broadway, New York, NY 10023. **NF**

Our reviews not only offer analyses but also rate each book as either RECOMMENDED, NOT RECOMMENDED, or RECOMMENDED WITH RESERVATIONS, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers.

Mismanaging Cancer

Manfred Kroger, PhD

Cancer: Your Guide to Complementary Therapies, Alternative Techniques, Conventional Treatments, by Philip Baron (Rockport, MA: Element Books, Inc.,

1998), 136 pp., \$5.95 paperback. ISBN 1-85230-799-4.

Published as one in a series called *The Natural Way*, this slender booklet steers the reader *away* from conventional mainstream medical practice. It is "approved by the British and American Holistic Medical Associations." Actually, it does a pretty good job in the first half explaining to the lay reader what cancer is and what the many causes may be. But even here, among the good, some outlandish statements appear. For example, to "eat against cancer" you should reduce sugar intake and eat organic foods as far as possible. Also, modern food-packaging materials are suspect and must be avoided.

The second half of the paperback is a subtle condemnation of modern medical practices in cancer treatment and an insis-

tent argument for "natural approaches," namely, the "gentle alternatives" in cancer therapy. The following are briefly discussed, with the (false) claim that they are helpful: acupuncture/acupressure, aromatherapy, Ayurvedic medicine, homeopathy, herbalism, massage, naturopathy/hydrotherapy, nutritional therapy, reflexology, yoga, tai chi, hypnotherapy, faith healing, meditation/relaxation, psychotherapy, visualization or imagery, counseling, art, music, and drama therapy.

All in all, the information provided is largely promotional for the emerging profession of natural therapists and a broadside against science-based medical approaches in cancer research and treatment. **NF**

NEW SUPPLEMENT REGULATIONS

A revised final rule on health claims for dietary supplements was published on January 6 and took effect on February 7 (*Federal Register* 65:999–1050, 2000). The Dietary Supplement Health and Education Act of 1994 (DSHEA) permits claims that products affect the structure or function of the body, provided the manufacturer has substantiating documents on file. Without prior FDA review, products may not bear a claim that they can prevent, treat, cure, mitigate, or diagnose disease. The final rule prohibits express disease claims (such as “prevents osteoporosis”) and implied disease claims (“prevents bone fragility in postmenopausal women”), including claims made through a product’s name (“CircuCure”) or through pictures or symbols. The rule permits health-maintenance claims (“maintains a healthy circulatory system”); other nondisease claims (“for muscle enhancement,” “helps you relax.”); and claims for common, minor symptoms associated with pregnancy, menopause, or other life stages (e.g., “for common symptoms of PMS,” “for hot flashes”).

SUPPLEMENT-PROMOTING LEGISLATION

The Food Stamp Vitamin and Mineral Improvement Act of 1999 (H.R.3304), introduced by Rep. Dan Burton (R-IN), would permit food stamps to be used to purchase “nutritional supplements providing a vitamin or mineral.” A similar bill (S. 1307) was introduced in the Senate by Tom Harkin (D-IA) last June. Burton asserts that these bills “would contribute substantially to improving the nutrition and health of a segment of our society that too often falls below recommended levels of nutrient consumption.” Though some people might benefit from such a program, a poor diet plus supplements can still be a poor diet. However, (a) it would be better to promote dietary improvement than to encourage supplement use; and (b) the bill’s wording does not appear to exclude irrationally formulated products.

How Quackery Sells

Why modern-day quacks are sneakier and more powerful than ever

by Stephen Barrett, MD & William T. Jarvis, PhD

Modern health quacks are supersalesmen. They play on fear. They cater to hope. And once they have you, they’ll try to keep you coming back for more. Seldom do their victims realize how often or how skillfully they are cheated. Does the mother who feels good as she hands her child a vitamin think to ask herself whether he really needs it? Do subscribers to “health food” publications realize that articles are slanted to stimulate business for their advertisers? Not usually.

Most people think that quackery is easy to spot. Often it is not. Its promoters wear the cloak of science. They use scientific terms and quote (or misquote) scientific references. Talk show hosts may refer to them as experts or as “scientists ahead of their time.” The very word “quack” helps their camouflage by making people think of an outlandish character selling snake oil from the back of a covered wagon—and, of course, no intelligent people would buy snake oil nowadays, would they?

Well, maybe snake oil isn’t selling so well, lately. But acupuncture? “Organic” foods? Hair analysis? The latest diet book? Megavitamins? “Stress formulas”? Nutritional “cures” for AIDS? Shots to pep you up? Business is booming for health quacks. Their annual take is in the billions. Spot reducers, “immune boosters,” water purifiers, “ergogenic aids,”

systems to “balance body chemistry,” special diets for arthritis. Their product list is endless.

What sells is not the quality of their products, but their ability to influence their audience. To those in pain, they promise relief. To the incurable, they offer hope. To the nutrition-conscious, they say, “Make sure you have enough.” To a public worried about pollution, they say, “Buy natural.” To one and all, they promise better health and a longer life. Modern quacks can reach people emotionally. Here is how they do it.

What sells is not the quality of their products, but their ability to influence their audience.

Appeals To Vanity

Many people mistakenly believe that vitamins make them feel energetic or have relieved various symptoms. The first step toward hooking people is commonly an appeal to curiosity, persuading the person to *try and see*. The next step is an appeal to disregard logic and scientific evidence in favor of personal experience—to *think for yourself*. Supplementation is encouraged by a distorted concept of *biochemical individuality*—that everyone is unique enough to disregard the Recommended Dietary Allowances (RDAs). Quacks won’t tell you that the RDAs are deliberately high enough to allow for individual differences. A more dangerous appeal of this type is the suggestion that although a remedy for a serious disease

has not been shown to work for other people, *it still might work for you. (You are extraordinary!)*

A more subtle appeal to your vanity underlies the message of the TV ad quack: *Do it yourself—be your own doctor.* “Anyone out there have ‘tired blood?’” he used to wonder. (Don’t bother to find out what’s wrong with you, however. Just try my tonic.) “Troubled with irregularity?” he asks. (Pay no attention to the doctors who say you don’t need a daily movement. Just use my laxative.) “Trouble sleeping?” (Don’t bother to solve the underlying problem. Just try my sedative.)

Turning Customers into Salespeople

Most people who think an unorthodox method has helped them enjoy sharing

their success story with their friends. People who give such *testimonials* are usually motivated by a sincere wish to help others. Rarely do they realize how difficult it is to evaluate a “health” product on the basis of personal experience. The average person who feels better after taking a product will not be able to rule out coincidence—or the placebo effect (feeling better for taking a supposedly positive step). Since we tend to believe what others tell us of personal experiences, testimonials can be powerful persuaders. Despite their unreliability, they are the cornerstone of the quack’s success.

Multilevel companies that sell nutritional products systematically turn their customers into salespeople. “When you share our products,” says the sales manual

[continued on page 12]

Vulnerability to Quackery

Victims of quackery usually have one or more of the following vulnerabilities:

Lack of suspicion. Many people believe that if something is printed or broadcast, it must be true or somehow its publication would not be allowed. People also tend to believe what others tell them about personal experience. Many people believe that any health-related claim in print or in a broadcast must be true, and many are attracted by promises of quick, painless, or drugless solutions to their problems.

Belief in magic. Some people are easily taken in by the promise of an easy solution to their problem. Those who buy one fad diet book after another fall into this category.

Overconfidence. Despite P.T. Barnum’s advice that one should “never try to beat a man at his own game,” some strong-willed people believe they are better equipped than scientific researchers and other experts to tell whether a method works and that if they look at “all sides” of a controversy they can figure out what is correct without expert help.

Desperation. Many people faced with a serious health problem that doctors cannot solve become desperate enough to try almost anything that arouses hope. Many people suffer from chronic aches, pains, or other discomforts for which medicine cannot offer clear-cut diagnoses or effective treatment. The more persistent the condition, the more susceptible the sufferer may be to promises of a “cure.” Fears of social unacceptability or growing old (wrinkles, loss of hair and sensory acuity, decreased sexual potency, and incontinence) can also lead people astray.

Alienation. Some people feel deeply antagonistic toward scientific medicine but are attracted to methods represented as “natural” or otherwise unconventional. They may also harbor extreme distrust of the medical profession, the food industry, drug companies, and government agencies.

Induced Hypoglycemic Treatment

A case of case histories leading to trouble

Induced Hypoglycemic Treatment (IHT) is one of several cancer-treatment methods offered by BioPulse International, which operates clinics in Mexico and Germany and plans to open additional facilities elsewhere. The company's Web site states that IHT uses a regulated level of insulin and other medications to induce a sleeping state during which the attending physician "regulates blood oxygen levels, body temperature, and pH levels to target the cancerous tumors." The sessions normally last about an hour.

The "BioPulse program with IHT" costs \$5,000 per week for the first four weeks and \$3,500 per week thereafter. The program usually includes "detoxification" with colonic irrigation; intravenous infusions of vitamin, minerals, amino acids, and enzymes; oral supplements; dietary strategies; and referral to "biological dentists" to remedy alleged problems caused by amalgam fillings and root canals. A four-week program that includes one session of whole-body hyperthermia (an unsubstantiated treatment in which the body's temperature is temporarily raised to 106°F) costs \$24,000. The sleep sessions are usually done once a day, five days a week, for three to seven weeks. Advance payment is required.

IHT is claimed to work by (a) starving cancer cells of glucose; (b) raising the blood pH to an alkaline state that is hostile to tumors; (c) increasing blood oxygen saturation, which prevents "anaerobic" tumor cells from thriving; (d) cleansing the body through sweating; and (e) restoring the body's energy levels and increasing appetite. However, this rationale is not logical.

(a) Cancer cells cannot be selectively "starved" by lowering blood sugar. If blood sugar is lowered far enough to damage cells, the body's brain cells would be among the first casualties. Hypoglycemic episodes are fairly common among diabetics who take insulin, including diabetics who have cancer. If hypo-

glycemia could selectively kill cancer cells, it stands to reason that diabetics would have a lower incidence of cancer as well as a higher recovery rate. But neither of these has been detected.

(b) The body's self-regulatory mechanisms keep blood pH within a narrow range. This range is not regulated by insulin. Even if insulin could raise the blood pH, it would have no effect on any cancer.

(c) Blood oxygen saturation is not regulated by insulin. Nor are tumors anaerobic. The theory that tumor cells thrive when oxygen-deprived was discredited more than fifty years ago. Growth requires both nutrients and oxygen. Solid tumors require more because they grow faster than the corresponding normal cells.

(d) The main substance excreted in sweat is sodium chloride (table salt), which is why sweat tastes salty. Most chemical waste products are excreted by the liver and kidneys. Increasing perspiration does not "detoxify" the body. Nor is there any valid reason to believe that "accumulated toxins" are responsible for the majority of cancers or that removing such alleged chemicals would be therapeutic.

(e) Hypoglycemic episodes are usually followed by several hours of depressed functioning. Many factors can influence how energetic people feel. Giving seriously ill cancer patients new hope, for example, may make them feel better—and more energetic. But if the hope proves false, the good feeling will quickly disappear.

The BioPulse site includes skimpy case histories of four people who apparently believe that IHT was highly effective against their cancers, but the reports were made only a few months after the treatment was administered. Three of the patients have also had standard treatment. Three of the reports state that the patients still have evidence of cancer but claim to have improved or stabilized. The standard

WEB WATCH

• This month's ratings are by Stephen Barrett, M.D., board chairman of Quackwatch, Inc., which is working hard to improve the quality of health information on the Web. He now operates four Web sites: Quackwatch (<http://www.quackwatch.com>), Chirobase (<http://www.chirobase.org>), MLM Watch (<http://www.mlmlwatch.org>), and NutriWatch (<http://www.nutriwatch.org>).

BEST

The Institute of Food Technologists' redesigned Web site (<http://www.ift.org>) provides ready access to its scientific status summaries and monthly "Communicators Alert" newsletter, which is also available by e-mail.

The Council for Agricultural Science and Technology (CAST) Web site (<http://www.cast-science.org/castpubs.htm>) provides publications on food, nutrition, and agricultural issues.

FoodSafety.gov (<http://www.foodsafety.gov>) provides a gateway to government information on food safety.

WORST

Healthexcel (<http://www.healthexcel.com>) offers "customized nutrition through metabolic typing." Its proprietor, "Ecological Lifestyle Advisor" William Linz Wolcott, is promoted as "the world's leading authority on the modern clinical science of metabolic typing." His book *The Metabolic Typing Diet* includes a questionnaire to determine whether you are the "protein type," "carbo type," or "mixed type" and other self-tests "to identify a diet tailored to your body chemistry, and yours alone." His theories are also expounded on <http://www.metabolictyping.com>. A "self-test" can be obtained by mail by sending a blood sample to Wolcott's partner, "nutritional pioneer" Dr. Harold Krystal, D.D.S. (<http://www.bloodph.com>). The \$156 fee includes an instructional video and enough material for two "blood pH tests" that supposedly indicate what diet and supplements should be used.

Nutri-West's online catalog (<http://www.nutriwest.com/index/products>) makes unsubstantiated claims for a huge line of supplement concoctions marketed primarily through chiropractors. To access the catalog, readers must agree not to hold the company or any of its contributors responsible for "any injury, loss or damage caused or alleged to be caused by any information within the entire Product Catalog."

of one such company, "you're not just selling. You're passing on news about products you believe in to people you care about. Make a list of people you know; you'll be surprised how long it will be. This list is your first source of potential customers." A sales leader from another company suggests, "Answer all objections with testimonials. That's the secret to motivating people!"

Millions of Americans have signed up as multilevel distributors. Like many drug addicts, they become suppliers to support their habit. A typical sales pitch goes like this: "How would you like to look better, feel better and have more energy? Try my vitamins for a few weeks." People normally have ups and downs, and a friend's interest or suggestion, or the thought of taking a positive step, may actually make a person feel better. Many who try the vitamins will mistakenly think they have been helped—and continue to buy them, usually at inflated prices.

False hope for the seriously ill is quackery's cruelest form because it can lure victims away from effective treatment.

plify. To promote "organic" foods, they lump all additives into one class and attack them as "poisonous." They never mention that natural toxicants are prevented or destroyed by modern food technology. Nor do they let on that many additives are naturally occurring substances.

Sugar has been subject to particularly vicious attack, being (falsely) blamed for most of the world's ailments. But quacks do more than warn about imaginary ailments. They sell "antidotes" for real ones. Care for some vitamin C to reduce the danger of smoking? Or some vitamin E to combat air pollutants? See your local salesperson.

Quackery's most serious form of fear-mongering has been its attack on water fluoridation. Although fluoridation's safety is established beyond scientific doubt, well-planned scare campaigns have persuaded thousands of communities not to adjust the fluoride content of their water to prevent cavities. Millions of innocent children have suffered as a result.

Hope for Sale

Since ancient times, people have sought at least four different magic potions: the love potion, the fountain of youth, the cure-all, and the athletic superpill. Quackery has always been willing to cater to these desires. Yesteryear's products were unicorn horn, special elixirs, amulets, and magical brews. Today's products are vitamins, bee pollen, ginseng, Gerovital, "glandular extracts," special diets, and many more.

False hope for the seriously ill is quackery's cruelest form because it can lure victims away from effective treatment. Even when death is inevitable, however, false hope can do great damage. People who accept the reality of their fate not only die psychologically prepared, but also can put their affairs in order. Those who buy false hope can waste not only financial resources but what little remaining time they have left.

Clinical Tricks

The most important factor in quacks' success is probably their ability to exude *self-confidence*, which can be contagious and spread to patients and their loved ones. Even when admitting that a method is unproven, they can attempt to minimize this by mentioning how difficult and expensive it is to get something proven to the satisfaction of the FDA these days.

Because people like to make choices, quacks often refer to their methods as *alternative*. However, methods that are unsafe, ineffective, or unproven are not genuine alternatives to proven ones.

Quacks don't always limit themselves to phony treatment. Sometimes they offer legitimate treatment as well—the quackery is promoted as *something extra*. One example is the "orthomolecular" treatment of mental disorders with high dosages of vitamins in addition to standard forms of treatment. Patients who receive the "extra" treatment often become convinced that they need to take vitamins for the rest of their life. Such an outcome is inconsistent with the goal of good medical care, which should be to discourage unnecessary treatment. Another clever trick is to include the product or procedure in a list of otherwise commonly accepted practices in order to promote it by *association*. They may say, for example, that their method works best when combined with lifestyle changes (which, quite often, will produce tangible benefits).

The *one-sided coin* is a related ploy. When patients on combined (standard and quack) treatment improve, the quack remedy gets the credit. If things go badly, patients are told they arrived too late, and standard treatment is faulted. Many quacks who mix proven and unproven treatment call their approach *complementary* or *integrative* therapy.

Quacks also capitalize on the natural healing powers of the body by *taking credit* whenever possible for improvement in a patient's condition. One multilevel company—anxious to avoid legal difficulty in marketing its herbal concoction—makes no health claims whatsoever. "You take the product," a spokesperson suggests on the company's introductory videotape, "and tell me what it does for you." An opposite tack—*shifting*

blame—is used by many cancer quacks. If their treatment doesn't work, it's because radiation and/or chemotherapy have "knocked out the immune system."

Another selling trick is the use of *weasel words*. Quacks often use this technique in suggesting that one or more items on a list is reason to suspect that you may have a vitamin deficiency, a yeast infection, or whatever else they are offering to fix.

Disclaimers are a related tactic. Instead of promising to cure your specific disease, some quacks will offer to "cleanse" or "detoxify" your body, balance its chemistry, bring it in harmony with nature, or do other things to "help the body to heal itself." This type of disclaimer serves two purposes. Since it is impossible to measure these processes, it is difficult to prove the quack wrong. In addition, if the quack is not a physician, the use of nonmedical terminology may help to avoid prosecution for practicing medicine without a license.

Books espousing unscientific practices typically suggest that the reader consult a doctor before following their advice. This disclaimer is intended to protect the author and publisher from legal responsibility for any dangerous ideas contained in the book. Both author and publisher know full well, however, that most people won't ask their doctor. If they wanted their doctor's advice, they probably wouldn't be reading the book in the first place.

Sometimes the quack will say, "You may have come to me too late, but I will try my best to help you." That way, if the treatment fails, you have only yourself to blame. Patients who see the light and abandon quack treatment may also be blamed for stopping too soon.

The *money-back guarantee* is a favorite trick of mail-order quacks. Most have no intention of returning any money—but even those who are willing know that few people will bother to return the product.

Another powerful persuader—*something for nothing*—is standard in ads promising effortless weight loss. It is also the hook of the telemarketer who promises a "valuable free prize" as a bonus for buying a water purifier, a six-

month supply of vitamins, or some other health or nutrition product. Those who bite receive either nothing or items worth far less than their cost. Credit card customers may also find unauthorized charges to their account.

Another potent technique is *cultural association*, in which promoters ally themselves with religious or other cultural beliefs by associating their product or service with an article of faith or prejudice of their target audience.

In a contest for patient satisfaction, art will beat science nearly every time. Quacks are masters at the art of delivering health care. The secret to this art is to make patients believe they are cared about as people. To do this, quacks *lather love lavishly*. One way this is done is by having receptionists make notes on the patients' interests and concerns in order to mention them during future visits. This makes each patient feel special in a very personal sort of way. Some quacks even send birthday cards to every patient. Although seductive tactics may give patients a powerful psychological lift, they may also encourage overreliance on an inappropriate therapy.

Handling the Opposition

Quacks are involved in a constant struggle with legitimate health care providers, mainstream scientists, government regulatory agencies, and consumer protection groups. Despite the strength of this science-based opposition, quackery manages to flourish. To maintain their credibility, quacks use a variety of clever ploys. Here are some favorites:

"*They persecuted Galileo!*" The history of science is laced with instances where great pioneers and their discoveries were met with resistance. Harvey (nature of blood circulation), Lister (antiseptic technique), and Pasteur (germ theory) are notable examples. Today's quack boldly asserts that he is another example of someone ahead of his time. Close examination, however, will show how unlikely this is. First of all, the early pioneers who were persecuted lived during times that were much less scientific. In some cases, opposition to their ideas stemmed from religious forces. Secondly, it is a basic

principle of the scientific method that the burden of proof belongs to the proponent of a claim. The ideas of Galileo, Harvey, Lister, and Pasteur overcame their opposition because their soundness can be demonstrated.

A related ploy, which is a favorite with cancer quacks, is the charge of *conspiracy*. How can we be sure that the AMA, the FDA, the American Cancer Society, drug companies, and others are not involved in some monstrous plot to withhold a cancer cure from the public? To begin with, history reveals no such practice. The elimination of serious diseases is not a threat to the medical profession—doctors prosper by curing diseases, not by keeping people sick. It should also be apparent that modern medical technology has not altered the zeal of scientists to eliminate disease. When polio was conquered, iron lungs became virtually obsolete, but nobody resisted this advancement because it would force hospitals to change. Neither will medical scientists mourn the eventual defeat of cancer. Moreover, how could a conspiracy to withhold a cancer cure be hoped to succeed? Many physicians die of cancer each year. Do you believe that the vast majority of doctors would conspire to withhold a cure for a disease which affects them, their colleagues and their loved ones? To be effective, a conspiracy would have to be worldwide. If laetrile, for example, really worked, many other nations' scientists would soon realize it.

Claims of *suppression* are used to market publications as well as treatments. Many authors and publishers purport to offer information that your doctor, the AMA, and/or government agencies "don't want you to know about."

Organized quackery poses its opposition to medical science as a *philosophical conflict* or *paradigm shift*, rather than a clash between proven versus unproven or fraudulent methods. This creates the illusion of a "holy war" rather than a conflict that could be resolved by examining the facts. Another diversionary tactic is to charge that quackery's critics are *biased* or have been *bought off* by drug companies.

Quacks like to charge that "*science doesn't have all the answers.*" That's true, but it doesn't claim to have them. Rather,

it is a rational and responsible process that can answer many questions—including whether procedures are safe and effective for their intended purposes. It is quackery that constantly claims to have answers for incurable diseases. The idea that people should turn to quack remedies when frustrated by science's inability to control a disease is irrational. Science may not have all the answers, but quackery has no answers at all! It will take your money and break your heart. Medicine's shortcomings do not justify what quacks do.

Many treatments advanced by the scientific community are later shown to be unsafe or worthless. Doctors also make mistakes. Such failures become grist for organized quackery's public relations mill in its ongoing attack on science. Actually, "failures" reflect a key element of science: its willingness to test its methods and beliefs and abandon those shown to be in-

valid. True medical scientists have no philosophical commitment to particular treatment approaches, only a commitment to develop and use methods that are safe and effective for an intended purpose. When a quack remedy flunks a scientific test, its proponents merely reject the test.

Each of these ploys represents a basic technique called *misdirection*—analogous to what magicians do to shift the audience's attention away from what is important in order to deceive them. When faced with criticism, quacks deftly change the subject.

How to Avoid Being Tricked

The best way to avoid being tricked is to stay away from tricksters. Unfortunately, in health matters, this is no simple task. Quackery is not sold with a warning label. Moreover, the dividing line between what

is quackery and what is not is by no means sharp. A product that is effective in one situation may be part of a quack scheme in another. (Quackery lies in the promise, not the product.) Practitioners who use effective methods may also use ineffective ones. Even outright quacks may relieve some psychosomatic ailments with their reassuring manner.

This article illustrates how adept quacks are at selling themselves. Sad to say, in most contests between quacks and ordinary people, the quacks still are likely to win. **NF**

Dr. Barrett, a retired psychiatrist who resides in Allentown, Pennsylvania, is board chairman of Quackwatch, Inc., and a board member of the National Council Against Health Fraud. Dr. Jarvis, the council's founder and executive director, is professor of public health and preventive medicine at Loma Linda University.

BRIEFS

[continued from page 9]

NATUROPATHIC ACCREDITATION AGENCY IN JEOPARDY

The Council on Naturopathic Medical Education (CNME), the accrediting agency for U.S. naturopathic medical colleges, may have its federal recognition withdrawn. The U.S. Department of Education staff and the National Advisory Committee on Institutional Quality and Integrity have asked U.S. Secretary of Education Richard W. Riley to reject CNME's petition for renewal. According to a report in *Probe* magazine, the recommendation was based on CNME's failure to respond appropriately to misconduct at one of the three American schools it accredits. Riley is expected to decide early this spring. CNME has indicated that it will appeal if its recognition is withdrawn.

LABELING OF TRANS FATTY ACIDS PROPOSED

The FDA has published a proposed rule that would require the amount of trans fatty acids in foods, including dietary supplements, to be included in the amount and percentage Daily Value declared in the nutritional labeling of saturated fats

(*Federal Register* 64: 62745–62825, 1999). When trans fatty acids are present, the declaration of saturated fatty acids would be required to contain a symbol that refers to a footnote stating the number of grams of trans fatty acids per serving. Trans fatty acids would be subject to the same limits as saturated fats for the purposes of nutrient content claims, health claims, or disclosure and disqualifying levels. The FDA also proposed to define the nutrient content claim for "trans fat free." The proposal is at <http://vm.cfsan.fda.gov/~lrd/fr991117.html>

GENETICALLY ENGINEERED FOOD LABELING

On November 16, Rep. Dennis Kucinich, D-OH, and 20 cosponsors introduced the Genetically Engineered Food Right to Know Act (H.R. 3377). The bill would require labels on food that contains or is produced with genetically engineered material, which it defines as material derived from any part of a genetically engineered organism, without regard to whether the altered molecular or cellular characteristics of the organism are detectable in the material. The Institute of Food Technologists has concluded that genetic modification is safe, will increase world food production, and can improve plant characteristics that will

benefit farmers, consumers, and the environment. The FDA has stated that special labeling would be inappropriate unless a technique significantly changes the composition of a food. Proponents of labeling claim that legislation is needed to enable consumers to exercise their "right to choose." Some who advocate labeling perceive it as an efficient way to undermine public confidence in genetically modified foods. Forty-eight congressional representatives have asked the FDA to require labels.

SECRETIN INEFFECTIVE FOR AUTISM

Three recently published studies have found no evidence that the hormone secretin is an effective treatment for autism. Questions have also been raised about its safety. In a letter published in the *Wall Street Journal* (4/16/99), seven professionals warned that: (a) since injectable secretin is extracted from pig intestines, repeated doses might cause the body to make antibodies to secretin; (b) smaller protein fragments in secretin preparations might trigger immune reactions; (c) the amino acid cysteine, which is used to stabilize the preparations, could cause other adverse effects. Information about the studies is available on [Quackwatch.com](http://www.Quackwatch.com). **NF**

Book Reviews

Analysis and Ratings

Our reviews not only offer analyses but also rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers.

Bitter Medicine

Manfred Kroger, PhD

The Complete Book of Symptoms & Treatments, by Roland Bettschart, Gerd Glaeske, Kurt Langbein, Reinhard Saller, and Christian Skalnik; edited by Edzard Ernst (Boston, MA: Element Books, 1998), 953 pp., \$24.95 paperback. ISBN 1-86204-424-4.

Research at Yale University revealed that in 1996, use of unconventional therapists was substantially lower in the United States than had been reported in earlier surveys. Chiropractors topped the list, with 3.3% of Americans seeking treatments from them, followed by massage (2%), herbal remedies (1.8%), spiritual healing (1.8%), nutritional advice (1.1%), acupuncture (0.6%), meditation (0.5%), and homeopathic remedies (0.4%). Overall, 6.5% of Americans had visited both conventional and complementary therapists, and 1.8% had sought unconventional services only.

Let's face it, unconventional treatments have always been around, are here to stay, and will most likely grow larger in proportion and visibility, as has already happened to vegetarianism and organic foods. The conflict between its staunchest adherents and science-based medicine will continue unabated. This tug of war is observed and reported with great interest by the popular media. That's where this book, subtitled "Your Comprehensive Guide to the Safety and Effectiveness of Alternative and Complementary Medicine for Common Ailments," comes in. We most certainly do need an impartial, knowledgeable, and comprehensive source to guide us, consumers and profes-

sionals alike, through this hodgepodge of dozens of choices available in an often bizarre bazaar of therapies.

To date this is the best and most comprehensive overview I have seen on the subject. And it seems to be impartial too. *Consumer Reports* couldn't have done it better. I proudly state that it is a German book, first published in 1995, and in 1998 translated for Element Books in England. In the past, that publisher has been overly partial to authors of alternative medical therapies. Many of its titles have received negative ratings by *Nutrition Forum*. One might even say that Element Books is not a proponent of mainstream medicine and what science stands for. As with most Element books, this one features an appendix of "useful addresses" (93 on 8 pages), which most certainly were not in the original German edition. I wonder whether Europeans are interested in the California School of Herbal Studies or the Australian Federation of Homoeopathy. I found it rather telling that the book's German title, *Bitter Natural Medicine, Effectiveness and Evaluation of Alternative Treatments, Diagnostic Procedures, and Medications*, had not been correctly translated into English (the text, however, is an admirable achievement by translator D. Wood and editor Professor Edzard Ernst). Bitter medicine is a pejorative term, something unpleasant, something forced on an unwilling ailing person, and possibly something that is quite out of the ordinary.

Indeed, the book shows again and again that most alternative therapies are out of the ordinary and do not deliver at all what their proponents all over the world claim. Some forty therapies (from acupressure/shiatsu to vitamins) are evaluated for about eighty different maladies (from AIDS to worms). These labels are provided to readers: *useful, may be of some use, of little use, inappropriate, and not advised*. The latter ratings show up more often than the former. That's no surprise when you consider that osteoporosis is pounced upon by twenty different therapists with many healing promises. For each ill-health condition, causes, symptoms and orthodox treatment are given, and then the authors cover all the known alternative therapies. So we learn that for osteoporosis, aromatherapy is inappropriate, cell

therapy is not advised, magnetic field therapy is of little use, physical therapies may be useful as bone strengthening measures, and willow bark herbal remedy may be of some use if pain alleviation is sought (it contains salicin, which may be more readily available as acetyl salicylate in aspirin, but that would be crossing over into orthodox drug treatment). The book's twelve diagnostic techniques, running the gamut from dowsing to hair mineral analysis to pendulum diagnosis, are all rated "not advised as the sole method of diagnosis."

The five authors, overall, come across as thorough, authoritative, and objective. In this exhaustive overview they deal largely negative blows to alternative treatment, which should not sit too well with the alternative (the politically correct term nowadays is "complementary") health and healing establishment. And it was courageous for Element Books to publish this information, in view of the loyalty they have shown for the alternative side in the past. Three of the authors are freelance writers with impressive health writing backgrounds; the other two are medical doctors and educators, albeit in the complementary medical area. The book's editor is the Director of the Centre for Complementary Health Studies at the University of Exeter, England.

This book is a valuable piece of literature—consumer intelligence, if you wish. It provides a rational overview of a confusing field for laypersons and professionals alike. There are no references in this work; nevertheless, I will call it a scholarly, encyclopedic contribution.

Love of Tea

Manfred Kroger, PhD

The Herb Tea Book: Blending, Brewing, and Serving Teas for Every Mood and Occasion, by Susan Clotfelter (Loveland, CO: Interweave Press, 1998), 128 pp., \$12.95 paperback. ISBN 1-883010-60-8.

Here is a slender and pretty booklet, a good reference and a fun read. Along with sections on basic nomenclature, history, and tea processing technology, the volume offers information on home tea

brewing and all the tools needed to do it right. Most of it is a collection of forty recipes (with instructions) supplied by fifteen tea scholars and other cognoscenti. All of these recipes involve herbs and spices to produce beverages under such rubrics as "energizing," "relaxing," "comforting," "festive," and "seasonal," plus two others entitled "green teas" and "chai," the latter a home-blended spicy tea by and for true tea aficionados.

Some thirty herbal ingredients are described in the first chapter, including remarks on their safety. The author challenges her readers to grow and gather a few of these to make the final result a totally integrated soothing experience.

The writing is excellent, no medical claims are made, and some interesting facts are presented. All in all, it's a no-nonsense book that can be made to work for the production of satisfaction at several levels—culinary, creative, social, and intellectual.

RECOMMENDED

Silly Nutrition

Manfred Kroger, PhD

Vitamins & Minerals: A Step-by-Step Guide, by Karen Sullivan (Rockport, MA: Element Books, 1997), 58 pp., \$ 7.95 hardback. ISBN 1-86204-011-7.

Have you ever been attracted to a chic, good-looking, well-groomed individual? And then he/she utters a few words and you are repulsed by what you hear. This book is like that. I read, I was dazzled, I shuddered. Under the cute veneer of packaging and layout, I found some of the goofiest utterances I've ever encountered. The whole product is nothing but a motley thirty-page compilation of twelve vitamins and eighteen minerals lifted from various standard and unreliable sources, plus twenty-three more pages describing what they are, what roles they play, where they are in nature, and how to take them as supplements.

There is also a list of thirty-four common ailments that might be alleviated by taking these micronutrients. For arthritis,

you're advised to increase intake of vitamins A,C,E, D, and B-complex, especially B-5, as well as calcium, magnesium, and copper (worn as a bracelet). The nonsense of mostly unsubstantiated claims is repeated over and over again.

The following quotations, half-baked, inane, and irrational, are samples of why this booklet should be rejected by the public:

"In the body, proteins, carbohydrates, and fats combine with other substances to yield energy and build bones and tissue."

"Ideally, vitamins and minerals are found in all organic foods, but in reality, processing and other modern methods of food production may deplete them. Organic food is generally more nutritious."

"Eat the skins of fruits and vegetables whenever possible (I do admire the folks who utilize citrus and banana peels!)."

Enough already! **NF**

way to report cancer-treatment outcome is to collect detailed data for at least five years and to follow enough patients to determine whether the outcome is better than would be expected from other treatment or from the natural course of the disease. Treatment effectiveness cannot be judged from anecdotes, testimonials, skimpy case reports, or short-term follow-up. BioPulse began doing IHT in June 1999 and re-

ported "outstanding results" less than three months later. The results were announced at the annual convention of the Cancer Control Society and in a cover story in *Alternative Medicine Digest*.

Insulin-coma treatment (also called "insulin shock") was legitimately used to treat schizophrenia beginning in the 1930s. Its use declined after electroconvulsive treatment was developed, and it was abandoned, beginning in the 1950s, as a potent antipsychotic drugs became

available. Permanent measurable complications are rare but have included memory impairment, reduced intelligence, strokes, abnormal heart rhythms, and even death. The *Alternative Medicine Digest* report states that BioPulse's sleep treatment is aimed to lower the patient's blood-sugar levels to "20 mg/dL or below," which is extremely low. Although BioPulse reports no complications so far, insulin coma should not be regarded as risk-free. **NF**

FTC ATTACKS INTERNET FRAUDS

The FTC has obtained consent agreements involving three Internet marketers, one that had been selling Essiac tea as a cancer cure and two that had been selling cetylmristoleate (CMO) for arthritis and several other serious diseases. To help boost their traffic, two of the companies used metatags (keywords embedded in the source code for a Web page that are invisible to an average consumer but are used by some search engines to respond to search requests). One also used hyperlinks to direct visitors to other purportedly independent Web sites that it actually had created to promote its product deceptively.

DIETARY GUIDELINES DRAFTED

The HHS/USDA Dietary Guidelines Committee has drafted the fifth (2000) edition of *Dietary Guidelines for Americans*, which is intended serve as the basis of federal nutrition policy and provide advice to consumers about food choices that promote health and decrease the risk of chronic disease. The proposed guidelines—three more than in previous versions—are: (1) aim for a healthy weight; (2) be physically active each day; (3) let the pyramid guide your food choices; (4) choose a variety of grains daily, especially whole grains; (5) choose a variety of fruits and vegetables each day; (6) keep foods safe to eat; (7) choose a diet that is low in saturated fat and cholesterol and moderate in total fat; (8) choose beverages and foods that limit your intake of sugars; (9) choose and prepare foods with less salt; and (10) if you drink alcoholic beverages, do so in moderation. The draft report is accessible at www.ars.usda.gov/dgac and can be read using Adobe Acrobat. The final version is expected later this year.

The Truth About Network Marketing

Turning ordinary people into quacks

by Stephen Barrett, MD

Don't be surprised if a friend or acquaintance tries to sell you vitamins, herbs, homeopathic remedies, magnets, or weight-loss powders with claims that they can benefit your health. Millions of Americans have signed up as distributors for companies that market such products from person to person. Often they have tried the products, concluded that they work, and become suppliers to support their habit.

Multilevel marketing (MLM)—also called network marketing—is a form of direct sales in which independent distributors sell products, usually in their customers' homes, by telephone, or through the Internet. In theory, distributors can make money not only from their own sales but also from those of the people they recruit.

Becoming an MLM distributor is simple and requires no special knowledge of health or nutrition. Many people do so initially in order to buy their own products at a discount. For a small sum of money—usually between \$35 and \$100—a company sells a distributor kit that includes product literature, sales aids (such as a videotape or audiotape), price lists, order forms, and a detailed instruction manual. The application form is usu-

ally a single page that asks only for identifying information.

Many MLM companies publish a magazine or newsletter containing company news, philosophical essays, product information, success stories, and photographs of top salespeople. Most companies, and tens of thousands of indi-

vidual distributors, also maintain Web sites. During a

recent search using google.com, "MLM" yielded more than fifty-three thousand links and the phrase "network marketing" yielded more than twenty thousand.

A pyramid scheme is an illegal promotion in which many people at the bottom of the pyramid pay money to a few at the top.

Questionable Financial Opportunity

Network marketers can buy products "wholesale," sell them "retail," and recruit other distributors who can do the same. When enough distributors have been enrolled, the recruiter is eligible to collect a percentage of their sales. Companies suggest that this process provides a great money-making opportunity. However, it is unlikely that people who don't join during the first few months of operation or become one of the early distributors in their community can build enough of a sales pyramid to do well. And many who stock up on prod-

ucts to meet sales goals get stuck with unsold products that cost thousands of dollars. Some companies permit direct ordering of their products, which avoids this problem.

An Amway Corporation report indicates that the vast majority of its distributors make very little money. Amway's 1998 *Business Review* tabulates figures gathered from April 1994 through March 1995 from distributors who attempted to

make a retail sale, presented the Sales and Marketing Plan, received bonus money, or attended a company or distributor meeting in the month surveyed. The average gross income for these "active distributors" was \$88 per month. The report defines "gross income" as the amount received from retail sales minus the cost of

[continued on page 20]

Recent MLM Regulatory Actions

Body Wise International, of Carlsbad, California, markets "fitness" products and weight-management products. In 1995, the FTC charged the company with making unsubstantiated claims that Cardio Wise was "designed to give an extra margin of insurance against heart disease" and that its weight-management products would foster weight loss without dieting. The company signed an agreement prohibiting it from making unsubstantiated health-related claims in the future.

Nu Skin International, Inc., of Provo, Utah, sells body-care products and dietary supplements. Nu Skin's Interior Design division markets expensive antioxidant, phytochemical, and "active enzyme" products. In 1993, the company and three of its distributors agreed to pay a total of \$1,225,000 to settle FTC charges that they made unsubstantiated claims for Nutriol Hair Fitness Preparation and two skin-care products. In 1997, the company agreed to pay \$1.5 million to settle charges that it had made unsubstantiated claims for five more of its products. The products, which contained chromium picolinate and L-carnitine, were falsely claimed to reduce fat, increase metabolism, and preserve or build muscle.

Morinda, Inc., of Linden, Utah, has alleged that its Tahitian Noni juice can treat, cure, or prevent numerous diseases, including diabetes, depression, hemorrhoids, and arthritis. In 1998, the attorneys general of Arizona, California, New Jersey, and Texas announced a settlement under which the company would no longer make disease-related claims that are unsubstantiated or lack FDA approval. The agreement also called for consumer refunds and payment of \$100,000 for investigative costs.

In 1998, the FDA ordered **Reliv International, Inc.**, of Chesterfield, Missouri, to stop making unsubstantiated claims that its Arthaeffect is effective against degenerative joint conditions.

In 1998, **New Vision International, Inc.**, of Scottsdale, Arizona, and a leading distributor agreed to settle FTC charges that they made unsubstantiated claims in their advertisements for a dietary supplement combination called "God's Recipe." Ads for the recipe had claimed that it could cure Attention Deficit Disorder (ADD) or Attention Deficit Hyperactivity Disorder (ADHD).

Quest IV Health Products, of Arlington, Texas, has claimed that its Restores+ is effective against ADD, ADHD, and specific symptoms related to these diseases. The company also marketed Caucasicum+ as a treatment for alcoholism and heart disease. In 1999, the Texas attorney general secured a consent agreement under which the company was required to pay \$15,000 and to stop claiming that the products are effective against these conditions or against any other disease.

Managing Irritable Bowel Syndrome

The role of diet, eating habits, stress, and more

Irritable bowel syndrome (IBS)—also called irritable or spastic colon—is a common functional intestinal disorder characterized by recurrent abdominal discomfort and abnormal bowel function. The discomfort often begins after eating and goes away after a bowel movement. The symptoms can include cramps, bloating, constipation, diarrhea, and a feeling of incomplete emptying.

IBS occurs in about one in five Americans, more commonly in women, and more often at times of emotional stress. It usually begins in late adolescence or early adult life and rarely starts after the age of fifty. In severe cases, it can result in missed work days and curtailment of social activities. Although effective help is available, many people with IBS are too embarrassed, pessimistic, or afraid to seek medical care. Even worse, some people who consult a doctor receive insufficient guidance and conclude that nothing further can be done for them.

Why Symptoms Occur

During normal digestion, foods are broken down in the stomach and small intestine so that their nutrients can be absorbed into the body. Undigested or partially digested portions—mostly in liquid form—then enter the large intestine (colon), where most of the water is reabsorbed. Movement through the intestines results from peristalsis, a wavelike contraction of muscles in the intestinal walls that propel their contents forward. When all is well, the end result is stool that is solid but soft enough to be excreted easily.

Diet, eating habits, stress, and various environmental factors can disrupt the normal function of the intestines. If the intestines squeeze too hard or not enough, the partially digested food can travel too rapidly or too slowly through the digestive system. Movement that is too fast will result in diarrhea, because not

enough water is reabsorbed. Movement that is too slow can result in constipation, because too much water is absorbed. Overly hard squeezing (spasm) can result in cramps. However, the diarrhea of IBS can also occur without pain.

IBS symptoms occur after eating because of the gastrocolic reflex—increased movement of the intestinal contents in response to food entering the stomach. The strength of this reflex can be influenced by the volume and temperature of the food and the number of calories it contains. Large meals (particularly high-fat meals) and large numbers of cold beverages can trigger IBS attacks.

Medical Evaluation

A thorough history and physical examination should be obtained. The extent of further evaluation depends on the patient's age, general health, and symptoms. If symptoms have been present for a long time and have a typical pattern, the doctor may rely mainly on the patient's description to diagnose IBS. If symptoms are recent in origin, testing may be needed to be certain that an infection, inflammation, or tumor is not responsible for the symptoms. The tests may include blood tests, stool tests, x-ray examinations, and endoscopy (examination of the colon with a hollow tubular instrument inserted from below).

Management Tips

The first step in managing IBS should be to identify what triggers the symptoms. The factors to consider include food intolerances, eating habits, dietary factors, emotional stress, exercise habits, use of laxatives, and vitamin C intake. It may help to keep a diary that relates symptoms to daily activities.

Many people with IBS are have difficulty digesting lactose (milk sugar). This

WEB WATCH

This month's ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc., which is working hard to improve the quality of health information on the Web. He now operates four Web sites: Quackwatch (www.quackwatch.com), Chirobase (www.chirobase.org), MLM Watch (www.mlmlwatch.org), and NutriWatch (www.nutriwatch.org).

BEST

The FDA Center for Food Safety and Applied Nutrition dietary supplement page (vm.cfsan.fda.gov/~dms/supplmnt.html) links to a wealth of news and other information pertaining to dietary supplements.

The Diet Debunker section of Phys.com contains brief analyses of many fad diets (www.phys.com/b_nutrition/02_solutions/diet_debunker/diet_debunker.html).

Google (www.google.com) is an extraordinarily fast and powerful search tool that can display up to one hundred links at a time and can access many pages that are no longer posted. Google automatically adds "and" between words that are entered so it returns only pages that include all the search terms. To search for an exact phrase, place the entire phrase in quotation marks. The first search will display up to ten links, but a pull-down menu enables the user to get more.

WORST

Nutritionaltest.com (www.nutritionaltest.com) offers interactive tests that supposedly identify supplements useful for treating a variety of health conditions. A detailed investigative report is available at www.quackwatch.com/12Web/drbbob.html.

Biomedx (www.biomedx.com) promotes live-cell analysis, body wrapping, and a variety of other dubious tests, products, and theories. The site claims, for example: "There is a genetic connection between the food you eat, your blood type, the look of your blood under the microscope, and your state of health. Food can be medicine if chosen correctly, or it can be like poison. Blood typing can give indications to food compatibility and related health issues."

Chiropractor David Wheeler (www.davidwheeler.com) markets the "ultimate natural supplement program for the immune system." The site relates products to about one hundred diseases and conditions but claims that the "the dosage level of the natural supplements Dr. Wheeler recommends are not for a specific disease but for the level of severity of a health condition."

products, plus any bonus. It does not take any business expenses into account. If this figure includes purchases for personal use, the potential profit would, of course, be less. The report also notes that “approximately 41% of all distributors of record were found to be active.”

A pyramid scheme is an illegal promotion in which many people at the bottom of the pyramid pay money to a few at the top. To maintain the process, however, the number of new participants must keep multiplying—which is impossible. When the supply of recruits dries up, the pyramid will collapse, leaving almost everyone but the earliest participants as losers.

To avoid being classified as pyramid schemes, multilevel companies must pay commissions for retail sales but not for recruiting new distributors. However, retail sales are difficult to sustain because most steady customers will become distributors in order to purchase their products “wholesale.” In 1999, the National Association of Attorneys General announced that complaints about multilevel marketing and pyramid schemes were tenth on their list of consumer complaints.

Dubious Health Claims

More than a hundred multilevel companies are marketing health-related products. Most claim that their products are effective for preventing or treating disease. Many falsely claim that their products strengthen the immune system. Some merely suggest that people will feel better, look better, or have more energy if they supplement their diet with extra nutrients. These suggestions are typically accompanied by warnings about faulty diet, food additives, soil depletion, “over-processed” foods, air and water pollution, rising cancer rates, or other alarming issues. A few companies make no claims in their literature but rely on testimonials,

encouraging people to try their products and credit them for any improvement that occurs. Most claim that their products are superior to those of their competitors.

Most multilevel companies tell distributors not to make claims for the products except for those found in company literature. (That way the company can deny responsibility for what distributors do.) However, many companies (or their distributors) hold sales meetings at which people are encouraged to tell their stories to the others in attendance. Some companies sponsor telephone conference calls during which leading distributors describe their financial success, give sales tips, and describe their personal experiences with the products. Testimonials also may be published in company magazines, audiotapes, or videotapes. Testimonial claims can trigger

enforcement action, but since it is time-consuming to collect evidence of their use, government agencies seldom bother to do so.

Government enforcement action against multilevel companies has not been vigorous. These companies are usually left alone unless their promotions become so conspicuous and their sales volume so great that an agency feels compelled to intervene. Even then, few interventions have substantial impact once a company is well established.

Misguided Motivation

The “success” of network marketing lies in the enthusiasm of its participants. Most people who think they have been helped by an unorthodox method enjoy sharing their success stories with their friends. People who give such testimonials are usually motivated by a sincere wish to help their fellow humans. Since people tend to believe what others tell them about personal experiences, testimonials can be powerful persuaders.

Since people tend to believe what others tell them about personal experiences, testimonials can be powerful persuaders.

medscape.com

Medscape

Perhaps the trickiest misconception about quackery is that personal experience is the best way to tell whether something works. When someone feels better after having used a product or procedure, it is natural to give credit to it. However, this is unwise. Most ailments are self-limiting, and even incurable conditions can have sufficient day-to-day variation to enable bogus methods to gain large followings. In addition, taking any action often produces temporary relief of symptoms (a placebo effect). For these reasons, scientific experimentation is almost always necessary to establish whether health methods are really effective. Instead of testing their products, multilevel companies urge customers to try them and credit them if they feel better. Some products are popular because they contain caffeine, ephedrine (a stimulant), valerian (a tranquilizer), or other substances that produce mood-altering effects.

Another factor in gaining devotees is the emotional impact of group activities. Imagine, for example, that you have been feeling lonely, bored, depressed, or tired. One day a friend tells you that "improving your nutrition" can help you feel better. After selling you some products, the friend inquires regularly to find out how you are doing. You seem to feel somewhat better. From time to time you are invited to interesting lectures where you meet people like yourself. Then you are asked to become a distributor. This keeps you busy, raises your income, and provides an easy way to approach old friends and make new ones—all in an atmosphere of enthusiasm. Some of your customers express gratitude, giving you a feeling of accomplishment. People who increase their income, their social horizons, or their self-esteem can get a psychological boost that not only can improve their mood but may also alleviate emotionally based symptoms.

Multilevel companies refer to this

process as "sharing" and suggest that everyone involved is a "winner." That simply isn't true. The entire process is built on a foundation of deception. The main winners are the company's owners and the small percentage of distributors who become sales leaders. The losers are millions of Americans who waste money and absorb the misinformation.

Laypersons are rarely qualified to judge whether prospective customers need supplements—or medical care. Even though curative claims are forbidden by the written policies of each company, the sales process encourages customers to experiment with self-treatment. It may also promote distrust of legitimate health professionals and their treatment methods. Former National Council Against Health Fraud president William T. Jarvis, PhD, calls MLM "the most effective system ever devised to turn ordinary people into quacks."

Physician Involvement

During the past few years, thousands of physicians have begun selling health-related MLM products to patients in their offices. The companies most involved appear to be Amway, Nu Skin Interior Design, and Rexall Showcase International. Doctors are typically recruited with promises that the extra income will replace income lost to managed care. The products usually cost much more than similar products marketed through drugstores or health-food stores.

In June 1999, the AMA House of Delegates approved ethical guidelines emphasizing that physicians should not coerce patients to purchase health-related products or recruit them to participate in marketing programs in which the physicians personally benefit, financially or otherwise, from the efforts of their patients. The guidelines clearly frown on doctors profiting from the sale of health-related nonprescription

products such as dietary supplements. However, many will continue to do so.

Recommendations

Consumers would be wise to avoid health-related multilevel products altogether. Those that do have nutritional value (such as vitamins and low-cholesterol foods) are invariably overpriced and may be unnecessary. Those promoted as remedies are generally either unproven, bogus, or intended for conditions that are unsuitable for self-medication. I do not believe it is possible to make an honest living selling health-related products through network marketing.

Government agencies should police the multilevel marketplace aggressively, using undercover investigators and filing criminal charges when wrongdoing is detected. People who feel they have been defrauded by MLM companies should file complaints with their state attorney general and with local FDA and FTC offices. A letter detailing the events may be sufficient to trigger an investigation. The more complaints these agencies receive, the more likely that corrective action will be taken. **NF**

Dr. Barrett, a retired psychiatrist who resides in Allentown, Pennsylvania, is board chairman of Quackwatch, Inc., and a board member of the National Council Against Health Fraud. His MLM Watch Web site (www.mlmwatch.org) provides a skeptical view of multilevel marketing.

[continued from page 19]

results from a shortage of lactase, an enzyme normally produced by cells lining the small intestine. Lactase breaks down milk sugar into simpler substances that are absorbed into the bloodstream. When there is not enough lactase, undigested lactose can ferment in the large intestine and cause nausea, cramps, bloating, flatulence, and diarrhea that begin between thirty minutes and two hours after consuming lactose-containing foods. The severity of symptoms varies with the amount of lactose the individual can tolerate. To determine whether lactose intolerance is a factor in IBS, the patient can experiment to see whether symptoms are related to milk intake. Laboratory testing may also be useful. If lactose intolerance is significant, lactase drops or tablets can be added to ordinary milk, low-lactose products can be substituted, or dairy products can be avoided (in which case the patient should take calcium supplements).

Bloating or excessive gas can also be

related to eating habits and diet. Drinking carbonated beverages can introduce gas into the intestines and cause abdominal pain. Eating or drinking rapidly, chewing gum, smoking, nervously gulping air, or wearing loose dentures can cause some people to swallow large amounts of air, some of which reaches the large intestine. Gas can also be produced by such foods as beans, onions, broccoli, and cabbage. Eating more slowly and minimizing gas-forming foods may help.

Since caffeine can increase intestinal motility, people with IBS should avoid or minimize the use of caffeine-containing beverages such as coffee and caffeinated colas. Fructose or sorbitol (a sugar substitute) can induce diarrhea in some people. Since vitamin C supplements of one gram per day or more can cause diarrhea, patients with chronically loose stools should be advised to stop taking them.

Unnecessary delay in defecation should be avoided. When an urge is felt, leaving the stool in the colon may contribute to constipation because the longer

the contents remain, the more fluid may be absorbed. Use of certain laxatives can perpetuate constipation because the large intestine can become dependent on them. People with IBS should not take strong laxatives.

Increasing the fiber content of the diet or taking a stool softener such as methylcellulose or psyllium may help regulate bowel movements and reduce both constipation and diarrhea. Dietary fiber should be increased gradually to give the body time to adjust. Prescription drugs are available to slow the movement of food through the intestines or to relieve intestinal spasms.

Medication, a hot bath, or a hot water bottle applied to the abdomen may relieve an acute attack of abdominal pain. Antispasmodics can also prevent attacks. If a certain type of activity is known to trigger an attack, taking an antispasmodic drug beforehand may prevent trouble. If modifiable sources of stress can be discovered, resolving them may help. Regular exercise can also help to normalize bowel action. **NF**

BRIEFS

[continued from page 17]

tion exists between the health and environmental risks posed by plants genetically engineered through modern molecular techniques and those modified by conventional breeding practices. However, it recommended increased government monitoring to ensure that such plants would not cause allergies or harm the environment. The report—*Genetically Modified Pest-Protected Plants: Science and Regulation*—can be viewed or purchased at the National Academy Press Web site (www.nap.com).

EPHEDRA RULE DELAYED

In 1997, the FDA proposed to establish a dosing regimen, require warning statements, and affect other aspects of labeling for "dietary supplement" products containing ephedrine alkaloids. (Such products have been marketed for weight control, despite a lack of evidence that they are effective.) In July 1999, the U.S. General Accounting Office (GAO) concluded that the FDA's concern about

ephedra-containing products was justified, but that the agency had relied too heavily on adverse-event reports that had not been sufficiently investigated. On April 4, 2000, the FDA announced that it was withdrawing its proposed regulations about dosage and length of use and would not implement other provisions until it has completed further review as recommended by the GAO report (*Federal Register* 65:17474-17477, 2000). The seventy-nine-page GAO report—*Dietary Supplements: Uncertainties in Analyses Underlying FDA's Proposed Rule on Ephedrine Alkaloids* [GAO/HEHS/GGD-99-90]—is available free of charge from the General Accounting Office, P.O. Box 37050, Washington, DC 20013. It can also be viewed online by searching for "ephedra" in the GAO Archives at www.gao.gov/audit.htm.

IRRADIATED MEAT UPDATE

The U.S. Department of Food Safety and Inspection Service has issued a final rule on meat and poultry irradiation. The rule, published in February 1999, permits the use of ionizing radiation for

treating refrigerated or frozen uncooked meat, meat by-products, poultry, and certain other meat food products to reduce levels of foodborne pathogens and to extend shelf life (*Federal Register* 72149-72166, 1999). Use of the maximum permissible dose of irradiation could result in significant reduction or elimination of pathogenic microorganisms, including various species of *Salmonella*; *E. coli* O157:H7; *Clostridium perfringens*; *Staphylococcus aureus*; *Listeria monocytogenes*; *Campylobacter jejuni*; and the protozoan parasite *Toxoplasma gondii*. The packaging of retail products that have been irradiated must note this and bear the radura symbol.

ZINC LOZENGES AND COLDS

The Quigley Corporation and QVC (a cable TV "home shopping" network) have agreed to halt unsubstantiated claims that Quigley's Cold-Eezer or Cold-Eeze zinc lozenges can prevent colds, relieve allergy symptoms, reduce the risk of contracting pneumonia, and reduce the severity of cold symptoms in children. **NF**

Book Reviews

Analysis and Ratings

Our reviews not only offer analyses but also rate each book as either **RECOMMENDED**, **NOT RECOMMENDED**, or **RECOMMENDED WITH RESERVATIONS**, depending on the book's factual accuracy, reliance on scientific research methods, and usefulness to readers.

Risking Kids

Manfred Kroger, PhD

Dr Hoffer's ABC of Natural Nutrition for Children, by Abram Hoffer (Kingston, ON: Quarry Press, 1999), 318 pp., \$14.95 paperback. ISBN 1-55082-185-7.

As a parent of three children I have always enthusiastically shopped for all kinds information that might benefit me and my offspring. I soon realized there are three genres of nutrition information: sales literature, scientific literature, and self-promotional literature. Dr. Hoffer's book is of the third kind. Under the mantle of science and adorned with academic degrees, he attempts to induce in his readers a distrust of conventional medicine and nutrition (including your supermarket and the food industry in general) and to sway them to sign on to orthomolecular treatments. This long word, coined by Linus Pauling, deals with the treatment of medical conditions by administering "heroic" doses of various nutrients or supplements.

Kurt Butler's *A Consumer's Guide to "Alternative Medicine"* (Amherst, NY: Prometheus Books, 1992) states that Abram Hoffer is the Prophet of Niacin, just as Linus Pauling was the Prophet of Vitamin C. Niacin can cause all kinds of unpleasant symptoms, from itching to stomach bleeding to liver toxicity, and slow-release niacin products are even more toxic. Butler points out that it is ironic that in light of the claim that niacin can cure schizophrenia, there is evidence it may actually activate a psychosis. (Also see J. Freed, *Vitamin Politics* [Amherst, NY: Prometheus Books, 1984]).

What I see in this book is lots of self-

promotion. About one-third of it is case histories of successful treatments. The reader is told that some two thousand children have been relieved of learning and behavioral disorders and chronic illnesses by adjusting nutrient intake. This book details the author's beliefs and observations with children's nutritional therapy. There are chapters on diagnosis and treatment of physical and mental illnesses. Invariably, the recommendations are vitamin and mineral supplements, and not psychotherapy, surgery, or pharmaceutical intervention (down with Ritalin!). Many parents probably like to hear what Dr. Hoffer says. He is a great salesman.

But I read dubious assertions like "chemical flavor additives . . . over the long haul will be found to be toxic" or "modern high-tech foods . . . produce a state of chronic ill health" or "overly processed food is both dead and stale." His contempt for what you find in today's supermarkets is naively belligerent, but it does form the underpinning to his hypotheses and the diets he prescribes: "No food which contains added sugars can be part of the diet."

Parents are advised, before acting on this book's recommendations to seek two more opinions, preferably from experts who base their treatments on science.

NOT RECOMMENDED

Theory without a Clue

Manfred Kroger, PhD

Vitamin B-3 & Schizophrenia: Discovery, Recovery and Controversy, by Abram Hoffer (Kingston, ON: Quarry Press, 1998), 167 pp., \$14.95 paperback. ISBN 1-55082-079-6.

The author was born in 1917, underwent a medical education in Canada, and spent his career there practicing medicine and collecting patient observations in psychiatry. He has published numerous articles and ten books, invariably and tenaciously focusing on hypotheses and therapies that have never entered the mainstream of the healing profession; all along, his proposals have been highly controversial.

This book tells the story of Dr. Hof-

fer's fanatical, almost quixotic, attempts to see his work on vitamin B-3 and schizophrenia acknowledged, accepted, and put into practice by the "establishment." As it is well known, antipsychotic drugs have been proven effective in the control of mental illness and are now the main components of current therapy—not megavitamin/orthomolecular treatment, which has been relegated to what is today euphemistically called "alternative medicine" by those who believe quackery to be too harsh a term.

If the book has any merit at all, it is its reporting of the persistent efforts of one practitioner and one idea that never found justification. One can almost taste the author's bitterness oozing from the pages. Dr. Hoffer comes across as a self-promoting, energetic, embattled, yet caring person. But his "research" and findings do not convince the critical reader.

The book may serve as an example, a teaching tool, if you wish, showing a medical direction taken by a well-meaning professional who propelled himself to the outside of the playing field. Reading this book should remind the impartial observer of the ten Red Flags of Junk Science, which are a test for accuracy of information. It was proposed by the Food and Nutrition Science Alliance (FANSA). The book raises several of these flags:

- (1) Recommendations that promise a quick fix.
- (2) Dire warnings of danger from a single product or regimen.
- (3) Claims that sound too good to be true.
- (4) Simplistic conclusions drawn from a complex study.
- (5) Recommendations based on a single study.
- (6) Dramatic statements that are refuted by reputable scientific organizations.
- (7) Lists of "good" and "bad" foods.
- (8) Recommendations made to help sell a product.
- (9) Recommendations based on studies published without peer review.
- (10) Recommendations from studies that ignore the difference among individuals or groups. **NF**

'FAT TRAPPER' GETS TRAPPED

Marketers of the Enforma System have agreed to settle FTC charges of deceptively advertising that the user could "eat what you want and never, ever, ever have to diet again." The system consists of "Fat Trapper," a chitosan-based product purported to prevent the absorption of dietary fat, and "Exercise in a Bottle," a pyruvate product that supposedly increases the body's capacity to burn fat. The system was promoted chiefly through televised 30-minute infomercials, featuring former baseball player Steve Garvey, as well as through the company's Web site. The settlement prohibits the marketers from making unsubstantiated claims that any product, service, or program: provides weight control without dieting or exercise; prevents fat absorption; increases metabolism; burns fat; or allows weight loss even if users eat high-fat foods. The company must also pay \$10 million to be used for refunds or distributed to the U.S. Treasury.

FIBER/COLON CANCER LINK DISPUTED

Evidence is mounting that no link exists between dietary fiber intake and colon cancer. Last year, researchers reported that a 16-year prospective study of 88,757 women found no significant relationship between fiber intake and the occurrence of precancerous polyps (colorectal adenomas) (*N Eng J Med* 340:169-176, 1999). This year, researchers reported on a clinical trial involving 1429 men and women ages 40 to 80 who had had one or more colorectal adenomas removed within three months before the study began. The participants entered a supervised program of dietary supplementation with either high amounts (13.5 g per day) or low amounts (2 g per day) of wheat bran fiber. Of the 1303 subjects who completed the study, 719 had been randomly assigned to the high-fiber group and 584 to the low-fiber group. By the time of the last follow-up colonoscopy, at least one adenoma had been identified in 338 subjects (47%) in the high-fiber

Antioxidant RDIs Fill in Some of the Blanks

The latest on vitamins C and E, selenium, and antioxidants

by Stephen Barrett, MD

The third installment of the Dietary Reference Intakes (DRIs) has raised the Recommended Dietary Allowances (RDA) for vitamins C and E, lowered the RDA for selenium for adult males, and set no RDA for beta-carotene or other carotenoids. The report also concludes: (a) insufficient evidence exists to support claims that taking megadoses of these antioxidants can prevent chronic diseases; (b) most North American adults get enough vitamin C, vitamin E, and selenium from their normal diet; and (c) those who don't can get enough simply by improving their diet.

Dietary antioxidants are nutrients that help protect cells from a normal—but damaging—physiological process sometimes referred to as "oxidative stress." Such nutrients are found naturally in many foods, particularly fruits and vegetables. They are also added to some foods and are available as dietary supplements. For many years, researchers have sought to determine the extent to which these antioxidants may lower the risk of various chronic diseases. But many unanswered questions remain.

The DRIs are nutrient-based reference values for use in planning and as-

sessing diets and for other purposes. They are intended to replace the RDAs that the National Academy of Sciences has been publishing since 1941.

The DRIs are being determined by the Standing Committee on the Scientific Evaluation of Dietary Reference Intakes of the Food and Nutrition Board, Institute of Medicine (IOM), National Academy of Sciences, with help from Health Canada. (The IOM is a private, non-profit organization that provides health policy advice under a congressional charter granted to the National Academy of Sciences.)

The values are being released in a series of seven reports that discuss how each nutrient functions in the body, the best way to determine its requirement, which factors may affect how it works, how the nutrient may be related to developmental abnormalities or chronic disease, whether supplementation may be beneficial, and recommendations for research. The first report, published in 1997, covered nutrients related to bone health (calcium, phosphorus, magnesium, vitamin D, and fluoride). The second report (1999), covered the B vitamins and choline. The current report covers vitamins C and E, selenium, and carotenoids. The remaining

The Food and Nutrition Board has responded by changing its basic approach to setting nutrient reference values.

four reports will cover macronutrients (e.g., proteins, fats, carbohydrates); (b) trace elements (e.g., iron, zinc); electrolytes and water; and other food components (e.g., fiber, phytoestrogens).

A New Approach

More than 20 years ago, the RDAs were defined as: "The levels of intake of essential nutrients that, on the basis of scientific knowledge, are judged by the Food and Nutrition Board to be adequate to meet the known nutrient needs of practically all healthy persons." Since that time, scientific knowledge about the roles of nutrients has expanded dramatically and many studies have examined relationships between diet and chronic disease. The Food and Nutrition Board has responded to these developments by changing its basic approach to setting nutrient reference values. While the RDAs were based on the amounts needed to protect against deficiency diseases, the DRIs reflect a shift in emphasis from preventing deficiency to decreasing the risk of chronic disease. Where adequate scientific data exist, the DRIs will include levels that can help prevent diseases that are diet related. Instead of a single category, the DRIs will encompass four:

- (1) *Recommended Dietary Allowance (RDA)*: The dietary intake that meets the nutrient need of nearly all (97-98%) of the healthy individuals in a particular age and gender group. The RDA should be used in guiding individuals to achieve adequate nutrient intake aimed at decreasing the risk of chronic disease. It is based on estimating an average requirement plus an increase to account for the variation within a particular group. The available evidence allowed the DRI committee to calculate RDAs for vitamin C, vitamin E, and selenium.
- (2) *Adequate Intake (AI)*: A recommended intake value based on observed or experimentally determined approximations of estimates of nutrient intake by a

group (or groups) of healthy people that are assumed to be adequate—used when an RDA cannot be determined.

- (3) *Tolerable Upper Intake Level (UL)*: The highest level of nutrient intake that is likely to pose no risk of adverse health effects for almost all individuals in the general population. As intake increases above the UL, the risk of adverse effect increases. The UL is not intended to be a recommended level of intake, and there is no established benefit for individuals to consume nutrients at levels above the RDA or AI. The term "tolerable upper intake level" was chosen to avoid implying a possible beneficial effect. For most nutrients, it refers to total intake from food, fortified food, and supplements.
- (4) *Estimated Average Requirement (EAR)*: A nutrient value that is estimated to meet the requirements of half the healthy individuals in a life-stage or gender group. Nutrition policymakers can use this figure to evaluate the adequacy of nutrient intakes for population groups.

The RDAs were developed when food was usually the only source of nutrients. The need for setting ULs arose because food fortification was increased and dietary supplements are being used by more people and in larger doses.

Interpretation

The DRIs are intended to apply to the healthy general population. RDAs and AIs are dietary intake values that should minimize the risk of developing a condition or sign associated with the nutrient in question that has a negative functional outcome. They refer to average daily intake over one or more weeks. They should not necessarily be expected to replenish individuals who are already malnourished and may not be adequate for disease states marked by increased requirements. Individuals known to have

[continued on page 28]

When Promoting Fruit Consumption Goes Sour

Misleading ads from the Florida Department of Citrus

For many years, the Florida Department of Citrus has produced ads that exaggerate the value of citrus products. The most recent example, appearing both on television and on its Web site, suggests that drinking a single glass of orange juice per day can greatly reduce the odds of having a stroke. According to a press release on its Web site:

A study published in the October 6 edition of the *Journal of the American Medical Association (JAMA)* found that drinking a glass of orange or grapefruit juice every day may lower the risk of stroke by 25 percent. . . .

[The researchers] found that increasing overall vegetable consumption reduced the risk of stroke by just four percent, but increased consumption of cruciferous vegetables (broccoli, Brussels sprouts, cauliflower, etc.) cut the risk by 32 percent. As for fruit, increasing overall consumption lowered stroke risk by 11 percent, but simply drinking a glass of orange juice every day reduced the risk of stroke by 25 percent.

This study, which was well designed, was supported by grants from the U.S. Office of Dietary Supplements and by the Florida Department of Citrus. The researchers examined data on 75,596 women, ages 34 to 59, who were followed for a 14-year period, and on 38,683 men, ages 40 to 75, who were followed for eight years. All of the participants were free of cardiovascular disease when the studies began. The study found that those with the highest intake of fruits and vegetables—particularly cruciferous vegetables, green leafy vegetables, and citrus fruit and juice—had the lowest incidence of strokes caused by obstruction of blood supply to the brain. The researchers noted, however, that “the analyses of individual fruit and vegetable items did not

show any single fruit or vegetable that was strikingly more protective than others” (*JAMA* 282:1233–1239, 1998). The Citrus Department’s “25 percent reduction” figure was derived from a table showing that the people reporting consumption of one serving per day of citrus juice had 20% fewer ischemic strokes than the 20% of people who consumed the fewest number of servings of fruits and vegetables. The study provides strong support for the prevailing scientific recommendation to consume at least five servings of fruits and vegetables a day. But it cannot predict the effect of adding citrus juice to your current diet—as the ad suggests.

In 1986, the department advertised that people who exercised couldn’t get enough potassium in their diet and that the potassium in grapefruit juice not only would provide enough, but would “balance sodium levels to regulate blood pressure and fight off fatigue.” When the National Advertising Division (NAD) of the Council of Better Business Bureaus investigated, a department spokesperson said that the potassium deficiency claims were based on an opinion survey of athletes conducted by a nutrition consultant, plus a study of the effects of intense conditioning in young men undergoing basic military training. In addition, a literature survey was provided as substantiation of the roles of sodium and potassium as nutritional factors in controlling blood pressure. NAD’s investigator replied that the data obtained from the studies could not support broadly stated claims and that the ad had overstated the benefits of drinking normal quantities of grapefruit juice. The spokesperson informed NAD that the claims had been discontinued and that a new campaign would promote grapefruit

[continued on page 31]

This month’s ratings are by Stephen Barrett, MD, board chairman of Quackwatch, Inc., which is working hard to improve the quality of health information on the Web. He now operates four Web sites: Quackwatch (www.quackwatch.com), Chirobase (www.chirobase.org), MLM Watch (www.mlmwatch.org), and NutriWatch (www.nutriwatch.org).

Full-text versions of *JAMA* and all ten of the AMA’s specialty journals are accessible online, free of charge, at jama.ama-assn.org/. All issues since December 1998 are retrievable.

The full text of *Nutrition Perspectives*, a quarterly newsletter published by the University of California Extension Division, is available at nutrition.ucdavis.edu/perspectives/

MEDLINEplus (www.nlm.nih.gov/medlineplus/), a pathway to the more than 11 million scientific articles in the National Library of Medicine’s database, has greatly improved its interface. The site also provides a medical encyclopedia and information on 9,000 prescription and over-the-counter drugs.

WORST

Nutricom (www.nutricom.cnhost.com) markets “software for the professional” that provides supplement recommendations in response to various tests. Its “Symptom Survey”—available online—asks about the frequency of 197 questions about symptoms, most of which have little or nothing to do with diet or nutrition. Other tests interpret (or misinterpret) the significance of various laboratory blood tests. The recommended “nutrition support protocols” are composed of products made by Standard Process Laboratories, a company with a long history of questionable marketing tactics. Nutricom claims that the products “facilitate healing and cell regeneration.”

Emethy® Medicinals (www.emethy.com), which sells “energy medicine products,” claims that (a) its combinations of herbs and other natural ingredients “transfer a wireless ‘Electrical Charge’ from the glass vial to the user within moments of use!” (b) Emethy “easily and safely enters the body via the nerve endings which in turn affect the entire electrical centers or pathways throughout the body”; (c) “when these electrical centers are balanced they produce a positive- harmonious flow to one’s entire system”; and (d) for people with memory loss, indigestion, arthritis, stress, hormonal imbalances, trauma, immune problems, pain, heart problems, addictions, low vitality, chronic fatigue, etc., Emethy allegedly helps to “balance mental, emotional and physical energies associated with these problems within just moments of use.”

[continued from page 26]

diseases that greatly increase requirements, or who have increased sensitivity to developing adverse effects associated with higher intakes, should be guided by qualified medical and nutrition personnel.

Nutrient intake less than the RDA does not necessarily mean that a given individual is not getting enough of that nutrient. Healthy individuals who meet the AI have a low risk of inadequate intake. However, an intake well below the RDA or AI would be a reason to assess the individual's nutritional status through laboratory testing or clinical examination. The IOM expects future publications to provide more detailed advice on how the DRIs should be interpreted and used.

In many cases, various levels of intake can have different benefits. One level may be related to the risk of deficiency, for example, while another level can influence the risk of chronic disease for that nutrient. For this reason, "nutrient adequacy" should be expressed in terms of "adequate for what?" For this reason, the DRIs are far more elaborate than the RDAs and cannot be expressed in a simple table of values.

Vitamin C

Vitamin C functions as a water-soluble antioxidant, which means that it neutralizes oxidizing agents before they can damage cells in the body. In addition, it is required for synthesis of collagen, carnitine, and neurotransmitters, such as serotonin, in humans. Scurvy is the severe deficiency disease caused by a lack of vitamin C in a person's diet. Because humans, guinea pigs, and a few other mammals cannot make their own vitamin C, they must meet their vitamin C needs through dietary sources.

The recommended intakes of vitamin C were increased to achieve maximum saturation in the body and antioxidant protection. The new RDAs are 75 mg per day for women, 90 mg daily for men, and an additional 35 mg per day for smokers. During pregnancy and lactation, the recommended amounts were 80 and 115, respectively, for women up to 18 years of age, and 85 and 120 after age 18. These

intakes are easily obtainable without taking supplements. The best sources include citrus fruits, strawberries, broccoli, tomatoes, potatoes, peppers, and leafy green vegetables. An eight-ounce glass of orange juice (from frozen concentrate) supplies about 100 mg of vitamin C. The other fruits and vegetables that are sources of vitamin C average about 40 mg of vitamin C per serving.

The report sets the upper intake level for vitamin C, from both food and supplements, at 2,000 mg per day for adults. Intakes above this amount can cause diarrhea in some people. Any intake above the RDA is likely to be excreted by the body unused. Although several studies have reported an inverse correlation between vitamin C intake and cardiovascular disease, some types of cancer, and cataracts, others have failed to do so. For this reason, the DRI committee concluded that there was not sufficient evidence to estimate a vitamin C requirement based on preventing any of these conditions.

With respect to the common cold, the report concluded that large doses of vitamin C (500–1,000 mg/day) have no significant effect on the incidence of the common cold, but may provide a moderate reduction in duration and severity—possibly because of an antihistaminic action.

Since vitamin C increases the absorption of iron, the committee recommended that further research be done to evaluate the extent to which vitamin C may increase the incidence of hemochromatosis (iron overload disease).

The DRI committee did not say as much, but based on current evidence, there is no good

reason to take more than the RDA of vitamin C. Also missing was a comment that although smokers who ingest RDA amounts of vitamin C might be slightly better off than those who ingest 35 mg less, this "benefit" is trivial when compared to the devastating effects of smoking.

Vitamin E

Chemists define vitamin E in eight naturally occurring forms found in food: four tocopherols (alpha-, beta-, gamma-, and delta-tocopherol) and four tocotrienols (alpha-, beta-, gamma-, and delta-tocotrienol). The only form of vitamin E that can be fully utilized by the body is alpha-tocopherol. Vitamin E's major function is as a chain-breaking antioxidant that is soluble in fatty substances. Unlike most nutrients, no specific role in a required metabolic function has been found for it.

Recommended daily intake levels were increased for this nutrient; both

medscape.com

Medscape

women and men should consume 15 mg from food. This is equivalent to 22 international units (IU) of natural-source vitamin E or 33 IU of the synthetic form.

The upper level, achievable only with supplements, is 1,000 mg of alpha-tocopherol per day for adults. This amount is equivalent to roughly 1,500 IU of d-alpha-tocopherol, sometimes labeled as natural-source vitamin E, or 1,100 IU of dl-alpha-tocopherol, a synthetic version of vitamin E. Consuming greater amounts increases the risk of bleeding, since high levels of vitamin E act as an anticoagulant.

The main dietary sources of vitamin E are edible vegetable oils. At least half of the tocopherol content of wheat germ oil, sunflower oil, cottonseed oil, safflower oil, canola oil, and olive oil is in the form of alpha-tocopherol. Soybean and corn oils contain about 10 times as much gamma-tocopherol as alpha-tocopherol. Other foods providing vitamin E include unprocessed cereal grains, nuts, fruits, vegetables, and meats (especially the fatty parts).

Overt vitamin E deficiency is rare in the United States and Canada. It is seen only in individuals unable to absorb the vitamin because of malabsorption of fat, or in people with rare, inherited abnormalities that prevent the maintenance of normal blood concentrations. Thus, current dietary patterns appear to provide enough vitamin E to prevent deficiency symptoms.

Much speculation exists about whether large doses of vitamin E can prevent coronary heart disease. The DRI committee stated that only one of the four double-blind, placebo-controlled trials that have been reported had positive results. For this reason, it considers it premature to recommend high intakes of vitamin E for the general population. The committee also felt that it is unknown whether raising vitamin E intake will benefit people who smoke or are routinely exposed to cigarette smoke.

Selenium

Selenium functions largely through selenoproteins, several of which are enzymes that help prevent cell damage by oxidants from the environment or from normal metabolic processes. The RDA is set to maximize the activity of these enzymes. Both women

and men should get 55 µg per day of selenium. Food sources include seafood, liver, meat, and grains. The upper limit for selenium is set at 400 µg per day, including amounts consumed from both foods and supplements. Greater amounts can cause selenosis, a toxic reaction marked by hair loss and nail sloughing.

Selenium intake varies according to geographic location, but there is no indication of average intakes below the RDA in the United States and Canada. Dietary intakes depend on the selenium content of the soil where plants are grown or where animals are raised. Food animals in the United States and Canada usually have controlled diets to which selenium is added when the local soil is lacking. Thus, the amounts found in muscle meats, milk, and eggs are more consistent than those amounts found in plant foods. While the food distribution systems in the United States and Canada ensure a mix of plant and animal foods from the broad range of soil conditions, the selenium content of local foods (e.g., from farmers' markets) may vary considerably from the average values given in food composition databases. However, the variation in selenium content of food sources does not appear to exceed that for many other nutrients; and the fact that people obtain their food from many sources helps ensure an adequate supply.

Although two studies have found that the incidence of certain cancers was lower among people with above-RDA intakes of selenium, this evidence should be considered preliminary without confirmation by a large clinical trial.

Beta-Carotene and Other Carotenoids

Carotenoids consist of more than 600 compounds that are found in some species of living organisms, including animals, plants, and microorganisms. The most prevalent carotenoids in North American diets include beta-carotene, alpha-carotene, lycopene, lutein, zeaxanthin, and beta-cryptoxanthin. Beta-carotene, alpha-carotene, and beta-cryptoxanthin, which are converted to vitamin A, are referred to as provitamin A carotenoids. Beta-carotene is abundant in carrots and is also found in cantaloupe, broccoli, spinach, and collard greens. The other five are found in carrots, orange juice, tomatoes, spinach, and collard greens.

In laboratory tests, carotenoids act as antioxidants, but the results have not been consistently duplicated in humans. In addition, data on the adverse effects of carotenoid overconsumption are contradictory. For these reasons, the report does not recommend a daily intake level or an upper intake level for carotenoid consumption.

Many epidemiologic studies suggest that higher blood concentrations of beta-carotene and other carotenoids obtained from foods are associated with lower risk of macular degeneration of the eye, cataracts, some cancers, and coronary heart disease. Although consistent, this evidence is not enough to establish a requirement for beta-carotene or total carotenoid intake because the observed effects may stem from other substances

found in fruits and vegetables or may be related to other behavior correlated with fruit and vegetable consumption. Three major double-blind, randomized clinical trials using high-dose beta-carotene supplements have found no evidence that beta-carotene supplements protect against any cancer; and two of these reported a higher incidence of lung cancer. Thus the DRI committee supports existing recommendations for increased fruit and vegetable consumption and advises against

beta-carotene supplementation except to help prevent or control vitamin A deficiency in populations at risk.

For Further Information

The full report—*Dietary Reference Intakes for Vitamin C, Vitamin E, Selenium, and Carotenoids*—costs \$45 for the pre-publication version, \$59.95 for the final hardcover version, and \$39.95 for the final softcover version. It can be pur-

chased by calling (800) 624-6242; writing to the National Academy Press, 201 Constitution Ave. NW, Washington, DC 20418; or ordered at a 20% discount online at www.nap.edu. The full text can also be read online, although the process is cumbersome. **NF**

group and 299 subjects (51%) in the low-fiber group. The authors concluded that "as used in this study, a dietary supplement of wheat-bran fiber does not protect against recurrent colorectal adenomas (*N Eng J Med* 342:1156-1162, 2000).

TAX STATUS OF WEIGHT-CONTROL PROGRAMS

In 1999, the American Obesity Association and ten other groups petitioned the Internal Revenue Service to permit the cost of weight-loss treatment (surgery, drug therapy, behavioral counseling, and weight-control programs) to be tax-deductible. The agency responded that such a ruling would require evidence either that obesity itself is a disease or that weight loss by an obese person prevents the onset of disease. The association submitted substantiating information to the IRS on March 17, 2000. IRS Revenue Ruling 99-28 allows taxpayers a medical deduction and approves the use of medical savings accounts for smoking cessation programs and medicines. Weight-control groups are also mobilizing their members to ask Congress to give weight-control programs the same tax status.

NEW WEB SITE FOR CONTACTING COMPANIES

PlanetFeedback has launched a Web site (www.planetfeedback.com) for channeling consumer complaints, praise, and suggestions and for promoting responses from the companies to

which they are directed. The site provides templates to provide an efficient way to generate messages that are forwarded to the appropriate company officials. To increase impact, letters can be copied to government agencies, consumer associations, friends, and family. The site also provides a utility for organizing and monitoring their communications to companies, an online community, shared information on companies and a "BuyersBuzz" news service for consumer-specific reports information.

PROPAGANDA TACTIC

Daniel E. Shaughnessey, vice president for governmental and public affairs for the Council for Responsible Nutrition, has urged supplement-industry spokespeople to vigorously deny allegations that supplements are unsafe and that the industry is "largely unregulated." In the May 2000 issue of *Whole Foods*, a trade magazine, he advises: "Always tell reporters that the FDA sets the format for supplemental label content, requires approval for nutrient content claims, and can declare products misbranded or adulterated." Although these statements are literally true, the FDA cannot adequately protect consumers because: (a) its enforcement power was greatly weakened by the Dietary Supplement Health and Education Act of 1994; (b) it lacks the resources to test whether products contain what their labels say; and (c) it lacks the resources to attack the enormous number of false and misleading claims made for supplement products.

PRODUCT LABELS INACCURATE

Researchers at the University of Arkansas who tested 20 supplement

products containing ephedra (*ma huang*) found many differences in alkaloid content from product to product and between two lots of the same product. Half the products exhibited discrepancies of 20% or more between the label claim and the actual content, and one product contained no ephedra alkaloids (*Am J Health Syst Pharm* 57:963-969, 2000). Ephedra products are marketed as "energy boosters" and/or "thermogenic" diet aids, even though no published clinical trials substantiate that they are safe or effective for these purposes. The researchers also noted that hundreds of such products are marketed and that their number exceeds that of conventional prescription and nonprescription ephedra products (which are FDA-approved as decongestants). The April issue of *D* magazine (Dallas, Texas) reported that—at its request—a leading laboratory had tested five brands of DHEA, ginger, ginkgo biloba, ginseng, melatonin, saw palmetto, St. John's wort, and milk thistle. The ginger and melatonin products contained the stated amounts, but 10 of the other 30 products did not, and a few products had capsules that easily fell apart.

PIZZA WARS

In line with a jury verdict, a federal court judge has ruled that Papa John's Pizza's claim to have "Better Ingredients. Better Pizza" was false and misleading. The slogan had been the centerpiece of the company's \$300-million marketing campaign. The ruling bars Papa John's from claiming in future promotions that its pizzas are superior unless the claim can be scientifically substantiated. The judge also concluded that claims of superior

sauce and superior dough and other attacks on Pizza Hut's quality were false and deceptive. In addition to issuing an injunction, the judge assessed damages of \$467,619.75. Papa John is appealing the verdict and has filed a suit questioning Pizza Hut's slogan: "Best Pizza Under One Roof" and contending that Pizza Hut unlawfully appropriated images of the Papa John's founder in its own attack ads.

'VITAMIN O' SNUFFED

Rose Creek Health Products, Inc., The Staff of Life, Inc., and their president Donald L. Smyth have agreed to pay \$375,000 in redress to settle Federal Trade Commission charges that they made false and unsubstantiated health claims in advertising a purported nutritional supplement called "Vitamin O." The ads claimed that "Vitamin O" could treat or prevent serious diseases such as cancer, heart disease, and lung disease by enriching the bloodstream with supplemental oxygen. As part

of the settlement, the defendants are prohibited from making unsubstantiated claims that that "Vitamin O" or any food, drug, or dietary supplement they market has any health benefit.

ADS FOR CHILDREN'S SUPPLEMENTS

The Federal Trade Commission has warned against misleading claims in ads for supplement products intended for children. Regarding claims that the product is a "scientific breakthrough," "miraculous cure," "exclusive product," "secret ingredient," or "ancient remedy," an agency official suggested that parents ask themselves, "If a product is so amazing, why would I be reading about it for the first time in an ad?"

HERBAL CIGARETTES NOT SAFER

Santa Fe Natural Tobacco Company, Inc., and Alternative Cigarettes, Inc., based in Buffalo, New York, have agreed

to settle FTC charges that ads for their cigarettes were deceptive. Santa Fe markets Natural American Spirit tobacco cigarettes and has also sold tobacco-free herbal cigarettes. Alternative Cigarettes markets Pure and Gold tobacco cigarettes, as well as Herbal Gold and Magic herbal cigarettes. Both companies alleged that their tobacco-containing cigarettes were safer than other cigarettes because they contained no additives. Alternative Cigarettes implied that smoking its herbal cigarettes did not pose the health risks associated with tobacco cigarettes. The companies have agreed to disclose prominently in future ads that make a "no additives" claim: "No additives in our tobacco does *not* mean a safer cigarette." Both companies have also agreed to disclose prominently on packages and in ads for herbal cigarettes: "Herbal cigarettes are dangerous to your health. They produce tar and carbon monoxide." **NF**

[continued from page 27]

as a significant source of potassium when part of a healthy regimen, including proper diet and exercise. However, a subsequent ad stated that grapefruit juice was "high in potassium with no sodium: a combination that, along with proper diet and exercise, can help control blood pressure." This was still misleading because drinking normal quantities of grapefruit juice is unlikely to lower blood pressure.

In 1993, the department distributed a

booklet containing several pages of misleading information about vitamin C. Among other things, the booklet suggested that vitamin C "may offer remarkable protection against heart disease" and "can help prevent tuberculosis." (The latter claim was attributed to "Dr. Irwin Stone," but did not indicate that Stone's doctoral credential was a Ph.D. from nonaccredited Donsbach University.) The booklet also claimed that vitamin C must be ingested daily because it cannot be stored in the body. This claim was false,

because the body normally stores about a month's supply.

FDA regulations state that health claims on food labels must be "complete, truthful, and not misleading." The Federal Trade Commission has a similar policy for advertising. The Florida Citrus Commission's claims about orange and grapefruit juice have certainly not met this standard. But the remarkable thing about them is not their content but the fact the Florida Department of Citrus is a government agency! **NF**

Labeling Trans Fatty Acids

The FDA tries to sort it all out

On November 17, 1999, the FDA published a proposed rule that would require the amount of trans fatty acids in food, including dietary supplements, to be included in the amount and percentage Daily Value declared in the nutritional labeling of saturated fats. When trans fatty acids are present, the declaration of saturated fatty acids would be required to contain a symbol that refers to a footnote stating the number of grams of trans fatty acids per serving. Trans fatty acids would be subject to the same limits as saturated fats for the purposes of nutrient content claims, health claims, or disclosure and disqualifying levels. The FDA also proposed to define the nutrient content claim for "trans fat free."

The Basics

Dietary fats are composed of fatty acids and glycerol. Dietary fatty acids consist of carbon chains of various lengths and a terminal carboxyl group. The carbon atoms in these chains are connected by single or double bonds. Hydrogen atoms are attached to the noncarboxyl carbons. A saturated fatty acid has no double bonds between the carbon atoms in the chain. An unsaturated fatty acid may contain one or more double bonds between carbon atoms and, therefore, two fewer hydrogen atoms per double bond. A fatty acid with a single double bond is called a monounsaturated fatty acid. A fatty acid with two or more double bonds is called a polyunsaturated fatty acid. Most naturally occurring dietary unsaturated fatty acids are in a "cis" configuration (i.e., the two hydrogen bonds attached to two carbons are on the same side of the molecule at the double bond which gives the molecule a "bend" at the site of the double bond). These bent molecules cannot pack easily together, so fats of these molecules are more often in a liquid form. In a trans configuration, the hydrogen atoms attached to the carbon atoms at a double bond are not on the same side of the double bond. ("Trans"

means "across" in Latin.) This arrangement stabilizes the molecule in a relatively straight contour. The FDA is proposing to define trans fatty acids as "unsaturated fatty acids that contain one or more . . . double bonds in a trans configuration."

Trans fatty acids are primarily the result of hydrogenation, a process by which hydrogen atoms are added to unsaturated sites on the carbon chains, thereby reducing the number of double bonds. In partial hydrogenation, some double bonds remain but may be moved in their positions on the carbon chain and changed from a cis to trans configuration. Hydrogenation increases the melting point, shelf life, and flavor stability of unsaturated fatty acids. Through hydrogenation, oils (fats in liquid form), such as soybean, safflower, and cottonseed, which are rich in unsaturated fatty acids, are converted to semisolids and solids that are useful in margarines and vegetable shortenings. Hydrogenation also occurs in the digestive tract of ruminant animals, but the resultant trans fatty acids comprise only a small percentage of the total fatty acids of such products.

The partial hydrogenation process was developed in the 1930s and has been in widespread commercial use since the 1940s. Dietary fats containing hydrogenated fatty acids, such as those used in margarine, have gradually greatly displaced animal fats, such as butter and lard, in the average American diet. About two-thirds of the dietary fat consumed in the 1940s was of animal origin. The balance was reversed by the 1960s, with two-thirds coming from fats of vegetable origin. This trend resulted in a decrease in the intake of saturated fat and an increase in the intake of polyunsaturated and trans fatty acids.

The American Heart Association has recommended that naturally occurring unhydrogenated oil should be used when possible. Attempts should be made to substitute unhydrogenated oil for hydrogenated or saturated fat in processed foods. Softer margarines should be substituted for harder margarines and cooking fats.

ASCN/AIN Labeling Recommendations

In 1996, a task force of the American Society for Clinical Nutrition/American Institute of Nutrition (ASCN/AIN) recommended that:

- Trans fatty acids should be added to or included with saturated fatty acids on labels.
- Trans fatty acids should be a separate class on labels.
- There should be a threshold proportion of trans fatty acids for health claims. This proportion (g/portion), if exceeded, will preclude use of a low-fat, low-saturated fat descriptor or health claim on the label.
- Fatty acids should be classified as cholesterol-raising and cholesterol-lowering. The task force indicated that its proposal ignored differences in individual responsiveness to each fatty acid as well as their possible effects on risk factors in chronic diseases other than cardiovascular ones. The FDA's proposed rule noted that more recent studies have strengthened the link between trans fatty acids and coronary heart disease (CHD).

FDA Analysis

The FDA has concluded that consuming trans fatty acids (rather than cis-monounsaturated or polyunsaturated fat) can raise the level of low-density lipoproteins (LDL), which is a major risk factor for CHD. Although interventional studies are too short in duration to provide direct evidence of the incidence of CHD, they provide evidence for an effect of dietary trans fatty acids on LDL. Epidemiologic studies have consistently found associations between estimated dietary intake of trans fatty acids and the incidence of CHD. The available studies do not provide a definitive answer to the question of whether trans fatty acids have an effect on LDL and CHD risk equivalent to saturated fats on a gram-for-gram basis. They also do not provide information about mechanisms responsible for the observed increases in LDL. However, the repeated and consistent findings under a variety of conditions are strong evidence of a relationship between consumption of higher levels of trans fatty acids and increased risk of CHD. **NF**
