The Strange Case of Quackery and the FDA

Stephen Barrett, M.D.

Popular wisdom states that health products marketed with unproven claims should be reported to the FDA. Having personally reported hundreds of such products, I can assure you that doing so is rarely effective.

When the FDA learns that a misbranded food supplement is being marketed, it can issue a warning, seize the product, seek a civil injunction, press criminal charges, or do nothing. Each year the agency issues a few warning letters, seizes a few such products, and obtains a few injunctions. Most often, however, no enforcement action is taken.

Because civil actions are slow and almost never result in a net loss to the sellers, they have little or no deterrent value. *Criminal* prosecutions—which involve the possibility of imprisonment—have great deterrent value. Yet between 1963 and 1983, the agency launched only one criminal prosecution for food supplement misbranding.

In September 1983, as part of an extensive 4-year investigation of frauds against the elderly, Congressman Claude Pepper sent detailed questionnaires to federal agencies, asking what they are doing about quackery. The FDA indicated that 40 staff years and \$1.8 million (0.5%) of its \$362.7 million budget for 1983 were allocated to the control of quackery, but that these figures included educational activities and publications in addition to enforcement actions. Mr. Pepper was also informed that no specific office within the agency was designated to handle health frauds, and that the FDA actually had no organized program to deal with them—or even to detect them!

The health food industry is keenly aware of the FDA's apathy toward quackery. Hundreds of misbranded food supplement products are currently being sold with suggestions that are effective in preventing and/or treating a wide variety of diseases. Hardly a month goes by without some "miraculous" substance being re-discovered or newly marketed with unproven claims. Users of these products are engaged in what Dr. Victor Herbert calls "nutrition roulette."

This situation could easily be corrected by a systematic program of detection and *criminal* prosecution. But the FDA claims that it lacks the resources needed

for such a program because priority must be given to regulation of prescription drugs. That is simply untrue. Detecting violations is quite easy, and the resources being used for civil prosecution could simply be shifted to criminal prosecution.

About a year ago, I mailed a series of penetrating questions designed to explore this issue to Joseph P. Hile, Associate FDA Commissioner for Regulatory Affairs, the agency's top enforcement official. Among other things, I asked him to compare the cost in dollars and man-hours of warning letters, seizures, civil injunctive procedures and criminal prosecutions. I also asked how many complaints the agency had received about misbranded food supplements during the previous five years and how many of them had led to regulatory action. Mr. Hile did not reply.

In July 1984, an FDA official named Paul Sage filed a petition—as a private citizen—asking the agency to adopt a new enforcement policy. As a senior member of the FDA's litigation and recall staff, Mr. Sage has investigated quackery and observed the effects of enforcement actions for almost 20 years. His petition notes the following:

- Persons who violate the labeling provisions of the Food, Drug and Cosmetic Act by marketing products without FDA approval create a threat to the public health. For example, use of an unapproved vitamin E preparation may have been responsible for the recent deaths of more than 30 infants.
- Because the marketplace is flooded with unapproved drugs, civil action on a case-by-case basis is not practical. But if criminal sanctions were used routinely to deal with violations of this kind, future violations would be deterred.
- Criminal cases would require less of the agency's resources than civil cases because they are simpler to carry out.

Along similar lines, Congressman Pepper has recommended that the FDA should: 1) significantly increase its public educational efforts regarding quackery; 2) set up a systematic method of detecting labeling violations; 3) enforce its laws quickly and vigorously; and 4) unite with the FTC and Postal Service to develop a concerted effort against repeat offenders.

Mr. Pepper also wants Congress to increase the maximum penalties for crimes related to the promotion of unproven remedies to at least five years in jail and a \$5,000 fine, five times the current levels under the Food, Drug and Cosmetic Act.

Responding to Mr. Pepper, the FDA promised to develop new programs to deal with health quackery and has already set up a health fraud branch. It has also been reported that the agency is developing a regulatory policy for "medical foods." But Mr. Sage suggests that unless the FDA Commissioner watches closely and presses for effective action as requested in his petition, new programs may be blocked by the entrenched apathy of FDA bureaucrats responsible for the current mess.

The "starch blocker" situation illustrates further why criminal prosecution is essential. Beginning in 1981, these products were widely heralded as a new type of effortless weight-reduction remedy. As promotion mushroomed, reports of nausea, vomiting, diarrhea, cramps and bloating surfaced among users, but the number of manufacturers still rose dramatically to more than 300. When the FDA asked companies to voluntarily halt marketing of the products, many refused, and the agency took civil action against a few of them. By the time court orders prohibiting their sale were won, starch blockers had been profitably manufactured for over a year; and they remained available in many health food stores months after the court orders were issued.

Commenting further in his petition, Mr. Sage said, "The public can thank its lucky stars that the adverse effects of starch blockers were not disastrous. People should not have to depend upon such luck for

assurance that products . . . are safe and effective. That is why we have a Food, Drug and Cosmetic Act."

I certainly agree, but without criminal prosecution, the Act cannot be enforced effectively. If you would like the FDA to become more aggressive against quackery, there are three things you can do:

1. Send a brief letter to FDA Commissioner Frank E. Young, M.D., Ph.D., stating why you think quackery enforcement should be given higher priority.

2. Report misbranded or unapproved supplements to your congressional representatives, asking that they request the appropriate government agency to take action. This is potentially more potent than complaining directly to the FDA because communications from Congress are likely to receive more attention.

3. Send a statement supporting Mr. Sage's petition to the Documents Management Branch, U.S. Food and Drug Administration, 5600 Fishers Lane, Rockville, MD 20857. Your statement should be identified with Docket #84P-0242CP and submitted in four copies.

Everyone knows that people who cheat on their income tax may wind up in jail. Unlike tax evasion, food supplement misbranding cannot be concealed. If the FDA makes it clear that cheating on a label can result in imprisonment, do you think it will remain a problem?

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author [with Dr. Victor Herbert] of Vitamins and "Health" Foods: The Great American Hustle. In June 1984, they both received FDA Commissioner's Special Citation Awards for Public Service in combatting nutrition quackery.

PERSPECTIVE ON ASPARTAME

Manfred Kroger, Ph.D.,
J. Lynne Brown, Ph.D.

Aspartame, also known by its trade name, NutraSweet, was approved by the FDA for use in soft drinks in July 1983. It had been approved in 1981 for use as a tabletop sweetener (Equal) and in dry beverage mixes, cold breakfast cereals, chewing gum, gelatins, puddings, fillings, and dry mixes for dessert toppings.

Aspartame was discovered in 1965 by scientists at G. D. Searle & Company and has been the subject of more than 100 studies to test its safety and potential uses in foods. As a result, scientists generally agree that aspartame is one of the most thoroughly tested food additives ever approved. It is being used in more than 30 countries. According to Searle, total sales of NutraSweet were \$336 million worldwide in 1983.

Aspartame is made from two commercially produced amino acids, phenylalanine (as the methyl ester) and aspartic acid, and can therefore be considered protein-like. It is about 180 times as sweet as sucrose (table

sugar). One gram of aspartame, which has the sweetening power of almost half a pound of sugar, supplies only 4 calories. Because of this intense sweetness, the amounts ingested are small enough for aspartame to be considered virtually noncaloric. While saccharin can have a bitter aftertaste, aspartame does not. But aspartame's higher price (\$90 vs \$4/pound), as well as formulation considerations, has led most soft drink manufacturers to combine the two.

Since aspartame is completely hydrolyzed within the intestine, it does not enter the blood stream as such. Therefore many of the safety studies have also explored whether aspartame's components or their metabolic by-products cause any difficulty. Concerns about aspartame's safety have revolved primarily around six issues:

1. *Methanol production.* Aspartame, whether digested, heated, or temperature-abused in improperly stored products, ultimately breaks down into its original

components: aspartic acid and phenylalanine, plus a small amount of methanol (methyl alcohol) from the methyl ester. Methyl alcohol, among other things, is used to denature ethyl alcohol for industrial use, making it unfit to drink. However, the amounts of methanol resulting from aspartame breakdown are harmless. Small amounts of methanol are normally found in foods such as tomato juice, bananas, cherries, wines, and other fermented products.

Woodrow Monte, Ph.D., R.D., Director of the Food Science and Nutrition Laboratories, Arizona State University, has voiced much concern about the level of methyl alcohol which he believes can result from aspartame use. Together with the Arizona Dietetic Association and the Central Arizona District Dietetic Association, he petitioned the Arizona Department of Health Services to ban aspartame use in carbonated beverages within the state; and he has expressed his views on nationwide television and elsewhere. The petition alleged that breakdown of aspartame to methyl alcohol, which would be accelerated by high storage temperatures, would create a health hazard.

In March 1984, the petition was denied by the Arizona health department, based on a 25-page, point-by-point analysis. The state agency concluded that the issues raised in the petition had all been adequately addressed by the FDA during the investigations leading to approval of aspartame as a food additive. Among other things, the agency correctly pointed out that methanol released during storage is metabolized the same way as methanol released from intact aspartame digested in the body—and that the amounts in either case are not large enough to be significant.

If all the aspartame in a carbonated soft drink were to break down into its components, the maximum amount of methanol produced would be about 56 milligrams (mg) per liter of beverage, about a third the amount normally derived from a similar quantity of fruit juice. The estimated threshold for toxicity is about 35,000 mg for a 150-lb individual. Clinical studies with aspartame have shown no adverse effects in people who ingested up to 20 mg of methanol per kilogram (kg) of body weight in a single dose. This is about 1,400 mg of methanol per individual, the amount that would be produced by drinking 25 liters of diet soft drinks at once with all of their aspartame degraded. Of course, people don't drink this much in a day.

The toxicity of methanol actually results from its metabolism to formic acid. But no increased formate has been detected in blood even after high ("abuse") levels of aspartame ingestion.

2. *Changes in brain neurotransmitter levels.* Phenylalanine is a precursor of dopamine (DA) and norepinephrine (NE), two of several neurotransmitters

known to be involved in brain function. There has been speculation that large amounts of aspartame consumed with carbohydrate (which releases insulin into the blood stream) may affect the levels of DA and NE in relation to other neurotransmitters and thereby alter behavior—even though no unusual behavior has been reported among aspartame consumers in countries where the sweetener has been used for years, or in clinical tests of aspartame where unusually high doses were consumed.

Amino acids cross the blood-brain barrier through an active transport mechanism for which they compete. Phenylalanine shares the same pathway as tryptophan (precursor of the neurotransmitter serotonin) and other large neutral amino acids. Since insulin accelerates the metabolism of amino acids as well as carbohydrates, it lowers blood levels of these competing amino acids and thus makes entry of phenylalanine easier.

Dr. Richard Wurtman of M.I.T. has shown that brain phenylalanine levels are increased and tryptophan levels decreased in rats given glucose plus aspartame. Other experiments, not involving aspartame, have led him to believe that these altered amino acid levels lead to higher ratios of DA and NE to serotonin in the brain, and to speculate that very large intakes of aspartame-containing beverages (well above consumption levels expected by the FDA) could lead to behavioral changes or convulsions.

However, Dr. John Fernstrom and others at the University of Pittsburgh have shown that aspartame doses large enough to significantly increase brain phenylalanine do not alter levels of DA, NE or serotonin. This led the FDA to state in its final rule (published in the July 8, 1983 *Federal Register*): "The data supplied . . . do not provide support for the hypothesis that the ingestion of aspartame and carbohydrates will alter brain levels of neurotransmitters and thereby produce behavioral modification."

3. *Diketopiperazine (DKP) production.* Concern has been expressed that DKP, another chemical produced when aspartame decomposes, can react with nitrite to produce nitrosamines, which are carcinogens. Storage tests at 30°C (86°F) for 8 weeks have shown that 38 percent of the aspartame in a cola beverage was degraded, with 12 percent remaining as DKP. At higher temperatures, aspartame stability drops off markedly, but the FDA believes that simple precautions during the handling and storage of soft drinks can prevent this. Although aspartame is not generally intended for use in baking or in heated foods because it breaks down and loses its sweetening power, it must be assumed that some individuals will use the tabletop product in cooking. Proper labeling of aspartame should minimize such

EDITORIAL BOARD

EDITOR: Stephen Barrett, M.D. **ASSOCIATE EDITORS:** Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; Manfred Kroger, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.

misuse. The FDA believes that DKP has been adequately tested, and that the heating of aspartame would not create a health hazard but merely result in loss of sweetness. Further, tests on DKP have demonstrated that no formation of nitrosamines occurs with DKP or aspartame.

4. *Phenylketonuria (PKU)*. One in 15,000 babies is born with an inherited inability to metabolize phenylalanine to tyrosine due to lack of the enzyme, phenylalanine hydroxylase. This metabolic disorder is now routinely detected at birth so that PKU babies can be put on a phenylalanine-restricted diet. If this is not done, phenylalanine blood levels rise very high and cause brain damage with severe mental retardation. Products containing aspartame are labeled to indicate they contain phenylalanine so that they will not be given to children with PKU.

Problems with phenylalanine metabolism do not occur in normal individuals. Nevertheless, to test the hypothesis that aspartame could cause a dangerous rise in plasma phenylalanine, extensive studies have been conducted by giving normal adults 34, 50, 100, or 200 mg/kg of aspartame. Even with single doses of 200 mg/kg—six times the maximum of estimated use—blood phenylalanine levels stayed well below the concentration associated with neurotoxicity. It has also been determined that children metabolize aspartame at the same rate as adults. Thus, even with abuse, phenylalanine will not reach toxic blood levels; and in all cases, normal levels are reestablished within 24 hours after ingestion. It has also been determined that parents

and siblings of PKU children can safely consume aspartame.

5. *Tooth decay*. Studies at the National Institute of Dental Research indicate that aspartame does not promote tooth decay. It contains no fermentable carbohydrate and therefore does not support the bacteria which produce acids that attack tooth enamel.

6. *Diabetes*. The American Diabetes Association states that aspartame is an acceptable sugar substitute as a sweetener for products that may be included in diabetic meal plans. Recently reported research by Dr. D.L. Horwitz of the University of Illinois, reaffirmed that aspartame is safe for diabetics.

Thus aspartame, as currently known and used, appears to be a perfectly safe component in the human diet.

Perhaps the most aggressive adversaries of aspartame use are the Community Nutrition Institute (CNI) of Washington, D.C., and its attorney, James Turner. (Turner, principal author of *The Chemical Feast*, has been a relentless critic of the FDA, and served in the late 1970s as "Washington Representative" of the National Health Federation.) Though rebuffed twice since the FDA approvals in 1981 and 1983, CNI has continued to press through the federal courts for a temporary restraining order against aspartame use. But so far the courts have ruled that no evidence exists to justify such a request.

Dr. Kroger is Professor of Food Science and Dr. Brown is Assistant Professor of Food Science Extension at The Pennsylvania State University.

Inexpensive Publications

Single copies of 23 government publications on food and nutrition, most of them reprints of articles from *FDA Consumer*, are available at nominal cost from the Consumer Information Center, Department N (Attn: S. James), Pueblo, CO 81009:

- 151M Cholesterol and Your Health
- 155M Exercise and Weight Control
- 516M A Compendium of Fats
- 517M The Confusing World of Health Foods
- 518M Consumer's Guide to Food Labels
- 519M Food Additives
- 520M A Primer on Dietary Minerals
- 521M RDAs: Key to Nutrition
- 522M Roughage
- 523M Saccharin, Cyclamate, and Aspartame
- 524M Sodium
- 525M Some Facts and Myths About Vitamins
- 526M Sugar
- 527M That Lite Stuff
- 528M Vegetarian Diets
- 529M What About Nutrients in Fast Foods?
- 530M Can Your Kitchen Pass the Food Storage Test?
- 532M Microwave Oven Radiation
- 556M About Body Wraps, Pills, and Other Magic Wands
- 557M Cellulite
- 558M Weight Loss
- 597M Food Safety for the Family
- 599M Toxic Herbs

Articles should be requested by order number. Any single title is free, but a \$1 per order handling fee applies if more than one title is requested. (Up to 20 titles can be requested for the same dollar.) The check should be payable to Superintendent of Documents.

At Your Own Risk, an accurate and comprehensive book about chiropractic, was published in 1969 and is out of print. However, paperback copies are still available for \$2 each plus \$1 postage from LVCAHF, P.O. Box 1602, Allentown, PA 18105.

Booklets on the following topics are available for \$2 each from the American Council on Science and Health, 47 Maple St., Summit, NJ 07901. Bulk rates are available on request.

- Alcohol Use During Pregnancy: Its Effect on the Unborn Child (1981)
- "Vitamin B-15": Anatomy of a Health Fraud (1981)
- U.S. Food Safety Laws: Time for a Change? (1982)
- Food Additives and Hyperactivity (1982)
- Irradiated Foods (1982)
- The Health Effects of Caffeine (1983)
- Fast Food and the American Diet (1983)
- Breast or Bottle? (1983)
- Fluoridation (1983)
- Cancer in the U.S.: Is There an Epidemic? (1983)
- Antibiotics in Animal Feed: A Threat to Human Health? (1983)
- Pesticides in your Home and Garden (1984)
- Ethylene Dibromide (1984)

Health Food Store Sales Drop

Describing 1983 as "the year the bubble burst," *Health Foods Business* reported that its annual survey of health food stores indicated a 17.6% drop of total sales for the industry compared to 1982. Total sales of \$2 billion in 7,700 stores included \$747 million for vitamins and supplements (+1.8%), \$138.6 million for herbs (-22.2%), \$54.2 million for herbal teas (+11.1%), and \$46.2 million for books (-17.8%). However, the magazine cautioned that since fewer than 10% of questionnaires were returned, the survey should be considered indicative of trends rather than taken too literally.

Natural Foods Merchandiser's annual report noted that vitamin sales had risen 5.2%, the smallest increase in five years, but that overall retail sales had declined. "The runaway favorite for best growth category" was amino acids, whose popularity was attributed to media coverage of amino acids and the book, *Life Extension*, by Dirk Pearson and Sandy Shaw.

General Nutrition, Inc. (GNC) with about 1,200 health food stores—reported 1983 gross sales of \$374.9 million, up 5.5% from 1982, but profits remained virtually unchanged at \$24.9 million. GNC founder David Shakarian said that, "Every supermarket, every health and beauty aid chain, every department store is putting in a nutrition department, and this competitive pressure has caused a strain on our earnings."

Other industry officials blame part of the 1983 decline on criticism. In *Health Foods Business*, one company president said that "there appears to be a carefully orchestrated, multimedia, nationwide campaign intended to impair, impede, if not to destroy the health food industry." Another official, referring to Drs. Victor Herbert, Fredrick Stare and Elizabeth Whelan, stated, "When these people do a radio show or get on television in our area, it hurts! A local newspaper article featuring one of these attacks can cause us no end of problems."

Shaklee Corporation bucking the trend, had record U.S. sales of \$398.1 million to its distributors in the year ending September 30, 1983, up 11% from the previous year.

QUESTION BOX

Q. Is there a reliable magazine that covers general health topics for laypersons?

A. *Rx Being Well*, published bimonthly by the Biomedical Information Corporation, 800 Second Ave., New York, NY 10017, offers authoritative health and medical information in clear, easy-to-read language. It is unique among health magazines because its staff is headed by two medical school professors who are highly respected medical editors. Every article is either written or carefully reviewed by at least one additional health authority. The magazine is distributed free to 100,000 doctors for placement in their waiting rooms, but it can also be obtained by subscription for \$9/year.

Briefs

Health promotion. Representatives of more than 60 government, professional, public health and business organizations gathered recently in Washington, D.C., for a 2-day conference sponsored by the Department of Health and Human Services on Prospects for A Healthy America: Achieving the National Health Promotion Objective. Anita Owen, R.D., who represented the nutrition community, reported general agreement that: 1) prevention through healthier lifestyles must be the key objective; 2) national organizations should issue formal policy statements, set and implement long-range goals, and help their members increase communication and behavioral change skills.

Antiquackery group goes national. Reflecting the fact that hundreds of its 1000+ members live in other states, the California Council Against Health Fraud was recently renamed the National Council Against Health Fraud. Chapters have already been organized in several states. Membership information can be obtained from NCAHF, P.O. Box 1276, Loma Linda, CA 92354.

Megavitamin classic updated. John Fried's 1975 classic, *The Vitamin Conspiracy*, has been updated in paperback as *Vitamin Politics*. Thoroughly researched, the book includes interviews with leading megavitamin proponents and the author's profound analysis of their lack of credibility. Copies can be ordered for \$9.95 each plus \$2.00 postage from Prometheus Books, 700 E. Amherst St., Buffalo, NY 14215.

The Stokes Report, a monthly newsletter for food service managers, is now in its fourth year of publication. Its topics include computers, cost management, labor/productivity, energy conservation, equipment selection, and government regulations. Its publisher, Judy Ford Stokes, R.D., also conducts seminars and is a consultant to schools, health care facilities and correctional institutions. Subscription information can be obtained c/o P.O. Box 27595, Atlanta, GA 30327.

Librarians Beware! *Trace Elements, Hair Analysis and Nutrition*, by Richard Passwater, Ph.D., and Elmer M. Cranton, M.D., has been selected by *Library Journal* as one of the top six health books of 1983 despite its espousal of unproven methods. Dr. Cranton is a former president of the American Holistic Medical Association, a group that promotes unscientific practices. Passwater is research director for a food supplement company. His "Ph.D." is from Bernadean University, an unaccredited correspondence school which was not legally authorized to grant degrees.

Charges filed in herb tea case. Five individuals are being prosecuted by the District Attorney of Los Angeles County for promoting ADS, an herbal tea imported from Japan. The five are charged with violating California's cancer quackery laws and with conspiracy and grand theft by false pretenses. ADS, also known as RD-7, Excel and Forte, was touted by defendants as a cure for everything from cancer to arthritis, according to DA investigators. Defendants allegedly used video tapes showing patient testimony and claiming a 98% cancer cure rate. Laboratory investigation revealed the substance to be water and nondescript vegetable matter with no medicinal properties. [*California v. Middleton, Yamagishi, Dix, Sanford, Halstead*, No. A399111, Municipal Court of Los Angeles, 1984.]

Possible lecithin toxicity. Studies conducted by Joanne Bell, Ph.D., pharmacology research associate at Duke University, suggest that pregnant women who use a diet aid containing lecithin may expose their unborn children to neurological damage. Dr. Bell found that pregnant rats given 5% lecithin in their regular diet produced offspring with abnormally slow reflexes and abnormalities in brain enzymes important to early development.

Zap a diploma mill? The Federal Trade Commission is investigating schools that issue nutrition degrees by mail. Information should be sent to Attorney Walter Gross, Federal Trade Commission, Sixth St. and Pennsylvania Ave., N.W., Washington, DC 20580.

Zap a quack? Legislators considering nutritionist licensure often ask for examples of individuals harmed by advice from diploma mill "graduates" or other nonprofessional "nutrition counselors." *Nutrition Forum* is interested in receiving reports of such cases.

Dubious claims. Ads by General Nutrition Centers (GNC) claim that its "Life Expander G.H. Releaser" provides "weight control and reduction without dieting." Composed of "precisely measured amounts" of the amino acids, 1-ornithine, 1-arginine and 1-tryptophan, it is claimed to "stimulate the release of growth hormone that directs your body to burn fat for needed energy." If the product actually did this, it would be an unapproved and misbranded new drug that would be illegal to sell. Moreover, above-normal production of growth hormone in adults causes acromegaly, a disease characterized by abnormal growth and deformity of many parts of the body!

Fat profits. The American Dietetic Association estimates that weight loss centers have grown into a \$500 million-a-year national market. Using demographic studies and high-powered advertising, they have taken aim at some 75 million Americans regarded as overweight. *Physicians Financial News* reports that Weight Watchers, with about 10,000 centers, is no longer selling franchises. Diet Center, with 1,850 units and still growing rapidly, had 1983 sales of \$30.2 million. Nutri-System which had 690 units by year's end, is also expanding rapidly. According to Nutri-System's director of investor relations, its typical franchise recovers the initial investment in 6 to 18 months and is likely to gross \$350,000 annually after a year.

Media setback. The National News Council, an independent body formed 11 years ago to hear complaints about the press, voted recently to cease operations. The organization was formed with the belief that a channel through which complaints about unfair reporting could be investigated would contribute to higher journalistic standards. But, as noted by former NNC vice-chairman, Elie Abel, "Remarkably few captains of the news industry saw it that way. They knew the council had no power to punish or compel. Its only sanction was exposure. And as we have sadly learned, even that hypothetical power comes to naught when major newspapers, magazines, and networks treat the council's existence and its findings as a dirty little secret." Although the number of cases involved was not large, the council was effective in countering nutrition misinformation. Thus its closing is a serious setback for the scientific nutrition community.

"Health freedom." The National Health Federation, the militant lobbying arm of the health food industry, has announced that its top priority for 1984 is passage of federal legislation to permit "holistic doctors" to use drugs or other therapy not approved by the FDA. Dr. William Jarvis, President of the National Council Against Health Fraud, calls this type of law "a hunting license for quacks." Although no bill was identified, NHF recently asked members to mail form letters to Congress supporting this type of legislation.

Heavy penalty. A London school district has been ordered to pay \$13,000 in damages to a 16-year-old girl whose weight rose from 140 to 210 during a 2-month hospital stay after she broke her leg in school. The gain was attributed to inactivity plus access to large amounts of candy.

"Organic" legislation advances. The Agricultural Productivity Act (H.R. 2714), which would earmark \$2 million annually for research into "organic farming," was passed by the U.S. House of Representatives in January 1984 and is now under consideration (as S.B. 1128) in the Senate. The bill calls for study of 12 farms to see the effects of "transition from (A) farm practices which rely on synthetically compounded fertilizers, pesticides, growth regulators, livestock feed additives, and tillage practices which control erosion; to (B) farm systems which rely on legume and other sod-based crop rotations, the efficient use of crop residues, green manures, animal manures, off-farm organic wastes and mineral-bearing rocks . . . efficient conservation practices . . . and nonchemical or biological methods of weed and pest control." The bill is being heavily promoted by health food stores under the leadership of Friends of the Earth.

Mushroom warning. A report on four cases of mushroom poisoning in the February 24, 1984 *Journal of the American Association* notes that 1 to 2 percent of an estimated 5,000 species of wild mushrooms are toxic. "Despite popular myths," the authors conclude, "there is no simple and reliable way to determine whether mushrooms are safe or dangerous. Poisonings often occur in persons supposedly experienced in foraging for and identifying wild mushrooms . . . Consumption of wild mushrooms carries an inherent danger that is sometimes life-threatening."

Top book award. *Vitamins and Minerals: Help or Harm?* [George F. Stickley Co., \$14.95] has been selected as the best trade book of 1983 by the American Medical Writers Association. Biochemist Charles W. Marshall, Ph.D., the book's author, invested more than five years in full-time study of the scientific literature and correspondence with leading nutrition authorities.

A company to watch. An article in *Forbes* magazine notes that Bernard Cornfeld, who built a worldwide \$3 billion mutual fund empire whose investors lost hundreds of millions of dollars when it collapsed in the early 1970s, has become chairman of Orthomolecular Nutrition Institute, Inc. The company's products will include "health foods," food supplements, metabolic tests, hair analysis, diet programs, cooking courses, exercise classes, and even a health spa that offers cosmetic surgery. According to the article, the sales force will be composed mostly of housewives managed by some of those involved in the mutual fund venture.

Free fluoridation newsletter. Professionals involved in promoting fluoridation can request placement on the mailing list for *Dear Colleague*, published quarterly by the U.S. Centers for Disease Control (CDC). Its purpose is to enable fluoridation promoters to exchange information about their activities and educational materials. Requests (specifying your involvement) should be sent to William B. Bock, D.D.S., Chief, Dental Disease Prevention Activity, Center for Prevention Services, Centers for Disease Control, Atlanta, GA 30333.

New threat to fluoridation. Antifluoridation crusader John Yiamouyiannis, Ph.D., has organized the Center for Health Action to coordinate antifluoridation activity worldwide. This organization appears to involve merging of the assets of two other groups founded in 1980 by Yiamouyiannis—the Safe Water Foundation and the National Health Action Committee—neither of which appears to be solidly funded. Headquartered in Delaware, Ohio, the new group describes itself as “a union of virtually every effective antifluoridation group in the country.” Its brochure, which claims that more than 100 million Americans suffer from fluorosis, projects an annual budget rising from \$750,000 its first year to \$5,625,000 by 1987.

More vitamin statistics. A telephone survey recently reported by the FDA found that 43% of those questioned take daily vitamin or mineral supplements. There were 2,991 respondents, aged 16-95. Based on this study, the FDA estimates that 39.9 percent of the U.S. population aged 16 or over takes supplements. Eleven percent of those surveyed were taking five or more different ones, and about 4 percent were taking 25,000 I.U. or more vitamin A. According to a report in the *Chicago Tribune*, during 1983 the regional poison control center at Rush-Presbyterian-St. Luke's Medical Center received more than 800 calls from parents of children who took overdoses of flavored vitamins. About 90 percent of the children were less than three years old.

Dangerous enemas. “High colonic” enemas given by chiropractors, naturopaths, “nutritional counselors” and misguided physicians often involve the use of 20 or more gallons of water which may contain herbs, coffee, enzymes and other additives. Advocates claim erroneously that this procedure can heal a wide variety of ailments by washing out accumulated “toxins” from the large intestine. Reported complications include severe infections (resulting from inadequately sterilized equipment), perforation of the bowel (mainly in elderly individuals), fluid overload, and electrolyte imbalance.

Selenium overdose. The U.S. Centers for Disease Control (CDC) recently reported a case of selenium intoxication in a 57-year-old woman who suffered fingernail abnormalities and hair loss. The case is considered unusual because it appears to involve a product that contained 182 times the amount of selenium indicated on its label. The mislabeled product—only 250 bottles of which are believed to have been distributed—has been recalled by its manufacturer.

Botulism from honey. CDC has also issued a warning that honey should not be fed to infants under one year of age because of the possibility of infant botulism. In this condition, which is rare, *C. botulinum* toxin is produced in and absorbed from the infant's gastrointestinal tract. This differs from food-borne botulism, a more dangerous problem resulting from ingestion of toxins present in improperly prepared foods.

Restaurants and smoking. Complaints by restaurant patrons about smoking have been increasing. A recent nationwide survey by the trade publication *Restaurants and Institutions* found that over one-third of respondents said smoking was a source of irritation. The National Restaurant Association, whose own study found that over one-third of respondents considered a no-smoking section important, has issued a guide on this subject for restaurateurs. Yet only 10 out of 81 New York restaurants and chains surveyed by the New York Heart Association provided no-smoking areas. And a poll of 70 Chicago restaurant managers reported by Ann Landers found that 87% of them would permit smoking, but only 34% would permit breast-feeding!

Naturopath's conviction upheld. A Kentucky court recently upheld the conviction of naturopath Kenneth May for practicing medicine without a license. May failed to diagnose a 3-year-old boy's leukemia and treated him instead with natural diets and vitamins during the three months prior to his death. According to expert testimony, had the leukemia been diagnosed and treated in time, the child's chances of recovery would have been 80%. [*May v. Commonwealth of Kentucky*, Fayette Circuit Court, No. 83-X-034, Feb. 14, 1984.]

Guinea pig doctors. Some 27,000 physician volunteers are still enrolled in a 5-year double-blind study to determine whether taking beta-carotene capsules every other day lessens the incidence of cancer. According to the project's director, Charles H. Hennekens, M.D., of Harvard University, fewer than 2 percent of the original participants dropped out during the first six months.

What's behind the name? The National Institute of Health [not a government agency], P.O. Box 536, Staten Island, NY 10310, sells Shaklee products by mail. Although its brochure says, “We won't promise you the moon,” it also suggests that supplements can provide “energy, vitality, body and figure, mental capacity, zing and zest, youthfulness, physical fitness, stamina, well being and longer life . . . There's no better way of keeping your optimum health than with SHAKLEE nutritional supplements.”

Profile bread. The Federal Trade Commission has denied a petition from ITT Continental Baking Co. to modify a 1971 consent order regarding Profile bread. The order had settled charges that ads for the bread had falsely claimed that it had special value in helping people lose weight. In denying the request, the Commission said that ITT may truthfully advertise the bread's caloric content, but that the information submitted by the company in support of its petition “does not provide a reasonable basis for any weight reduction or control claims.”

Lower telephone bills. Most people who spend \$10/month or more for long distance calls can save money with a discount service. SPRINT is ideal because it has no monthly service fee. Calls may be made from any pushbutton phone in hundreds of calling areas (even when you are traveling) to any number in the United States. Per call discounts range up to 50% of Bell rates with additional discounts if total calls exceed \$75/month. For complete information, call 1-800-521-4949.

1984 IOWA TITLE BOUT ENDS WITH TECHNICAL KNOCKOUT

Judith D. Klopfenstein, M.S., R.D.

Just when it appeared that Iowa would become the first state to require licensure of dietitians and nutritionists, a series of unforeseen events delayed the legislation another year. The preliminary rounds of the licensure battle were fought in December 1983 before the Commission of Professional and Occupational Regulation (COPOR), a regulatory body that rules on the merits of all proposed licensure statutes before they can be considered by the Iowa Legislature. Following subcommittee and public hearings on the issue, COPOR voted 6-4 to recommend that the scope of practice in the fields of dietetics and nutrition be defined, and that individuals practicing as dietitians or nutritionists be required to obtain a state license. The minority opposition was led by House Representative Darrell Hanson, COPOR chairman, who remained a formidable adversary.

Following COPOR approval, the proposed act was drafted into an official legislative bill and assigned to both House and Senate subcommittees. Many bills die at this point, but skillful action by the lobbyist for the Iowa Dietetic Association (IDA) helped ours gain approval by the house subcommittee and subsequently the House State Government Committee.

So far, the only opposition voiced had been that of individual Representatives opposed to any additional professional licensing. However, immediately prior to debate by the full House of Representatives, several Diet Center establishments became aware of the bill and hired two lobbyists and an attorney to oppose it on grounds that it would require them to hire dietitians to do weight control counseling. Because of the support this group was able to generate, the bill was amended to allow commercial weight control centers to provide counseling if their program had been approved by the Iowa State Department of Health. The Iowa Dietetic Association readily accepted this provision.

During debate in the House, Representative Hanson persuaded most of his colleagues that a title act defining "dietitian" and "nutritionist" but not limiting who could practice in these fields would offer sufficient public protection. A title bill was then passed 94-6 and sent to the Senate for consideration.

After a Senate subcommittee and full committee approved the title bill for full Senate debate, national representatives from Shaklee Corporation and the National Nutritional Foods Association (NNFA) voiced opposition. Shaklee's representatives wanted the bill to specify that the sale of food supplements would not be restricted, and that individuals marketing such products could continue to advise customers regarding their use. NNFA's attorney claimed in a letter to the Senate leadership that first amendment rights were being restricted by the bill.

IDA representatives struggled to retain the essence of the bill while seeking to accommodate these objections. An amendment finally evolved that did not restrict the sale of food and nutritional products but did limit the claims that could be made by individuals marketing such products. The limitation read, "Individuals who do not hold themselves out to be dietitians or nutritionists and who market or distribute food products as defined by the federal Food and Drug Administration may engage in explanation and education of customers regarding the use of such products for normal nutritional needs."

During the full Senate debate, the bill was amended to return it to a full licensure act rather than a title act, and this bill was sent to the House of Representatives for final consideration. However, time ran out. Anxious to adjourn before the Easter holiday and weary of debating into the small hours of the night, the House set a time limit. This enabled Representative Hanson to prevent further consideration of our bill by announcing that he would filibuster it to death.

IDA members who had worked so arduously for passage of a licensure act were very disappointed, but our mood is not one of despair. The opponents are now clearly identified, so it should be easier to develop strategies to contain them. Most important, perhaps, we gained visibility and recognition in the eyes of the legislators and "learned the ropes" of the legislative process.

Ms. Klopfenstein is Assistant Director of Food and Nutrition Services at Iowa Lutheran Hospital, Des Moines, Iowa.

Vitamin Victims Sue Harold Manner

Stephen Barrett, M.D.

In 1977, Harold W. Manner, Ph.D., achieved considerable notoriety by claiming to have cured cancer in mice with injections of laetrile, enzymes and vitamin A. What he actually did was *digest* the tumors by injecting digestive enzymes (the equivalent of sticking a red-hot poker into them), but this does not cure cancer. Since that time he has developed and promoted "metabolic" approaches which he claims can help cancer, arthritis, multiple sclerosis and genital herpes.

Manner became chairman of the biology department at Loyola University of Chicago in 1972. During a speech last year, he stated that his controversial beliefs led the school's administration to ask him to give up "metabolic research" or to resign. He resigned and is now president of the Metabolic Research Foundation of Glenview, Illinois.

Manner's methods are taught at "metabolic health seminars," held four times a year at various locations in the United States. He estimates that "200 physicians" are trained to use his methods, but about half are apparently chiropractors. In 1982, a reporter from WBBM-TV, Chicago, became "Metabolic Doctor #219" by attending a seminar in Los Angeles and donating \$200 to the Metabolic Research Foundation. (To indicate his professional background, the reporter used the initials "D.N.," which, he later explained, stood for "Doctor of Nothing.") Manner promised to refer 10 patients a year to him. Foundation doctors are supposed to report their treatment results to Dr. Manner after 21 days, 3 months, 1 year, 3 years and 5 years, but as far as I know, no summary has been published so far.

In 1983, Manner opened the Emerald Isle Clinic in Montserrat, West Indies, where treatment costing several thousand dollars is administered by a local medical doctor under Manner's supervision. The clinic has 40 beds, but Manner hopes it will eventually expand to 400.

During a recent telecast, Manner said that cancer is basically a disease of the immune system. He theorizes that every day "embryonic cells" become cancerous when they encounter carcinogens from such

sources as polluted air or "junk foods." If the body's immune system is working properly, these cancer cells are quickly destroyed; but if it is not, clinical cancer results. He also said that the immune system is the only thing that is going to eliminate the cancer, and that radiation and chemotherapy are bad because they destroy the immune system. His treatment is designed "to build up the immune system so it can restore the body's health."

Asked about his results, he stated that 85% of the cancer patients coming to the Emerald Isle Clinic have been told by their medical doctors that no more could be done for them. Of these "70% leave the clinic without cancer or with cancer no longer life-threatening—on its way down." He said that 85% of arthritis patients and over 90% of those with multiple sclerosis were similarly helped. However, he contradicted himself during the interview by saying, "We are not eliminating a cancer in 21 days, but are putting people on the right path." Patients are then referred to a local metabolic physician for follow-up care.

Manner, still based in Chicago, visits the Emerald Isle Clinic every three weeks and personally greets and helps plan treatment for each patient. During the 21-day stay, cancer patients receive enemas, herbal diets to produce twice daily bowel movements, and enzymes to supposedly make sure the stomach has the correct degree of acidity and the intestines the right degree of alkalinity. Patients also receive "massive doses of vitamin A and thymosine" plus daily "Manner cocktails" of dextrose, laetrile, vitamin C and DMSO given intravenously over 2-3-hour periods. Manner claims that even patients with rampaging cancer usually "feel like a new person within 1, 2, or 3 days." He also states that insurance companies pay for this treatment.

In 1982, *The New England Journal of Medicine* published the results of a clinical test of laetrile and metabolic therapy done at the Mayo Clinic and three other major cancer centers under the direction of the National Cancer Institute. Not one of the 156 patients studied was cured or improved in any way. However, a rebuttal statement issued by Manner claimed that the

treatment regimen was incomplete and that the dosages used were too low. His method, he said, involved daily dosages of vitamin C up to 85 grams and of emulsified vitamin A close to 1 million International Units.

Manner claims that such massive doses of vitamin A have no significant side effects. But Paulette Peters of Midlothian, Illinois, knows otherwise. According to suit papers filed in November 1983, her son Chuckie almost died as a result of intoxication from vitamin A administered with encouragement and reassurance from Dr. Manner.

In 1978, at the age of 7, Chuckie was diagnosed as having leukemia and began chemotherapy. In the hope of finding a nutritional method to counter side effects of the chemotherapy, the Peters' contacted "nutritional consultants" Gerry and Betty Phillips. After taking several "tests" and consulting with Robert Baldwin, M.D., of Carlsbad, Texas, the Phillips' recommended that daily dosages of laetrile plus 120,000 International Units of a vitamin A emulsion (said to bypass the liver) be administered to Chuckie. Encouraged by the Phillips' to consult Dr. Manner, Chuckie's mother heard him speak at a health convention, spoke to him afterwards, and was told that the vitamin A treatment was both effective and safe. At the meeting, she also purchased his book, *The Death of Cancer*, which contains similar claims. Manner advised her to discontinue Chuckie's chemotherapy. She didn't do this or use laetrile, but she did administer the recommended amounts of vitamin A.

About a year later, Chuckie developed headaches, extreme sensitivity to light, severe bone pain, mental confusion, and a 10-pound weight loss. According to the suit papers, he became unable to walk and touching his arms caused him to scream in pain. After thorough examination, doctors at the University of Chicago diagnosed vitamin A poisoning, and the vitamin A was stopped. Chuckie stayed in the hospital for about 15 days so his bone pain could be relieved with narcotics. Although he eventually recovered completely from the effects of vitamin A, it took two more months before he was strong enough to return to school.

Today, at age 12, Chuckie appears to have been cured of his leukemia and is determined to do his part "to stop other kids from being hurt as I was." He and his parents are suing Dr. Manner, the Metabolic Foundation, the Phillips' and Dr. Baldwin, and recently presented their story at the quackery hearings held by Representative Claude Pepper's House Subcommittee on Aging. The Peters' attorney is Steven Handler of Chicago. Dr. Manner and his Foundation are represented by Dilling, Dilling and Groneck, a law firm frequently involved in the defense of unorthodox practitioners.

Stephen Barrett, M.D., a practicing psychiatrist and consumer advocate, is author/editor of 12 books, including *The Health Robbers* (a comprehensive exposé of quackery), *Vitamins and "Health" Foods—The Great American Hustle*, *The Tooth Robbers: A Pro-Fluoridation Handbook*, *Shopping for Health Care*, and the college textbook *Consumer Health—A Guide to Intelligent Decisions*. An expert in medical communications, he is medical consultant to WFMZ-TV, Allentown, Pa., and Consumer Health Editor of *Nautilus Magazine* and of *Our Age*. He is also a scientific advisor to the American Council on Science and Health.

"CHELATION THERAPY" SUITS

Mrs. Joyce B. Haller of Allentown, Pa., has filed suit against an osteopathic physician who treated her with chelation therapy. According to Mrs. Haller, Conrad Mulfair, D.O., of Mertztown, Pa., failed to properly diagnose and treat her for arteriosclerosis (hardening of the arteries) of the legs. The suit papers state that Dr. Mulfair administered intravenous injections of ethylene diamine tetra-acetic acid (EDTA) every 3 or 4 days for 3 months. Before treatment started, Mrs. Haller was able to walk normally, but as time went on, her feet became discolored, her legs became cold, walking became so painful that she needed crutches. She decided to consult a vascular surgeon but fell on the way to his office, fracturing both legs. The suit also charges that bone repair could not be accomplished because "the EDTA had washed away the calcium of the bones of the lower legs and feet," that the bones had broken with little provocation, and that circulation of blood to the legs had become so inadequate that amputation of both legs was required. Chelation therapy is not approved by the FDA for the treatment of arteriosclerosis. Mrs. Haller states that she was not warned of the risks, consequences and possible complications of chelation therapy. Her attorney is James F. McBride of Philadelphia.

Suits are pending against two other doctors who use chelation therapy. In Kansas City, Missouri, a man whose right leg was amputated following chelation therapy has charged an osteopath with negligence and malpractice. And in Detroit, another osteopath is accused of contributing to a heart attack of a chelation patient.

QUESTION BOX

Q. What is the Food Institute?

A. The American Institute of Food Distribution, Inc.—more commonly referred to as the Food Institute—is a nonprofit group formed in 1928 to gather and report information on food marketing. Its 2,775 current members include growers, processors, brokers, wholesalers, retailers, food industry suppliers, food service buyers, advertising and banking executives, schools, publications, government agencies, and others concerned with the distribution of food products. Membership, which costs \$275/year, includes the weekly 24-page *Food Institute Report*, special reports, and access to the Institute's extensive library. The Institute's address is 28-12 Broadway, Fair Lawn, NJ 07410.

Q. Will Nutrition Forum focus primarily on food faddism, quackery and their promoters?

A. Many of our editors have a special interest in these topics; but we do plan to cover a wide variety of other subjects.

PERSPECTIVE ON HERBAL MEDICINE

Varro E. Tyler, Ph.D.

It seems surprising that in this era of high technology and wonder drugs, interest in herbal medicine is reawakening. This phenomenon is usually attributed to 1) disillusionment with the medical establishment—related to inaccessibility, high cost, and the failure to cure everything; and 2) the “back-to-nature” philosophy which is enormously popular throughout the world.

Unfortunately, science has not kept pace with public interest. Because of economic considerations, relatively little pharmacologic and practically no therapeutic research with herbs is presently being done in the United States.

Chain Drug Review has reported that in 1981, herbs accounted for \$360 million in sales, an amazing 10 percent of total sales of various natural products (or 20 percent if vitamins are eliminated from consideration). Literature, much of it devoted to the use of herbs, accounted for another \$145 million in sales (4% of the market). Since that time, herbs have increased in popularity, so these figures are quite conservative. It is a rare “health food” outlet which does not stock at least 20 single herbs, 20 combination formulas, and several creams, ointments, extracts, and the like. In some of the larger outlets, 100 to 200 different herbs are commonly available. The profit margin on herbal products in these outlets is 44 percent, a figure exceeded only by that for vitamins and supplements (48 percent). Thus there is considerable incentive to promote and sell herbs.

Americans are not alone in their interest in herbs. Recent surveys in Germany revealed that nearly 76 percent of the women interviewed drank herbal teas for supposed medicinal and health-producing effects. An amazing 52 percent of German adults turned first to self-treatment with a natural product (herbs, extracts, or derivatives) for their illnesses.

When sold as foods or food additives, herbs cannot bear any indication on the label that they are “good” for any disease or condition. Doing so would place them in the category of drugs under the control of the Food and Drug Administration and therefore illegal to market unless approved by the agency as safe and effective. Consequently, to inform people about their uses, their promoters have made available a wide variety of litera-

ture ranging from one-page flyers and paperbacks to large, well illustrated, expensively bound books. Much of this is a rehash of the writings of 16th and 17th century authorities such as Nicholas Culpeper and John Gerard.

These old claims are not only extremely unreliable; they also fail to take into account the extensive chemical and toxicological data about plant drugs which have accumulated in the intervening centuries. Such studies have shown that plant materials contain a wide variety of toxic constituents, including carcinogens, cocarcinogens, teratogens, photosensitizers, allergens, cellular respiratory inhibitors, abortifacients, irritants, and the like, some of which are quite insidious in their actions. Uninformed use of herbs and herbal products is therefore best avoided.

That is not to say, however, that all herbs are harmful or even nonhelpful; many are quite useful when properly employed. Three categories of utility are generally recognized:

1. *Safe and effective for self-treatment under appropriate circumstances.* Examples include chamomile as an anti-inflammatory agent, fresh aloe gel for minor abrasions and burns, and valerian for its tranquilizing properties.

2. *Potentially harmful.* These include comfrey and coltsfoot with their content of carcinogenic pyrrolizidine alkaloids, sassafras containing safrole, also a carcinogen, and pokeroor with its toxic saponins and other constituents.

3. *Neither specifically helpful nor harmful.* These include such plants as alfalfa for arthritis, burdock for skin disorders, and chaparral as an anticancer agent. However, the use of herbs in the last category may prevent an ill person from seeking competent medical treatment and thereby cause even more serious illness. In addition, they are always harmful to the pocketbook.

Dr. Tyler, Dean of Purdue University's Schools of Pharmacy, Nursing, and Health Sciences, is an expert in pharmacognosy (the science of medicines from natural sources) and author of *The Honest Herbal*, an evaluation of popular herbs.

HAIR ANALYSIS SCHEME HALTED BY FTC

A & A Laboratory, the largest advertiser of hair analysis to the American public, is being prosecuted by the Federal Trade Commission for making false claims about the procedure. Based in Ft. Washington, Maryland, the company has operated for more than three years as Holistic Hair Analysis, Micro Trace Minerals, New Age Nutritional Supplement Co., and Unique Concepts Advertising. On August 8, 1984, a federal judge for the Eastern District of Virginia issued a temporary restraining order against the company, its subdivisions, and its principals, Arthur F. Furman, his wife Ethel Furman, and their son Alan Furman. The judge also froze the assets of the parties involved to provide for possible consumer redress.

Since 1981, defendants have been offering hair analysis for \$36.95 through ads in various magazines and at "holistic" health fairs around the country. The ads promise information to help "balance body chemistry" and to "clearly recommend which supplements to take and when to take them." Those who submitted specimens would receive a 3-page computer printout purporting to indicate hair levels of 18 minerals as well as deficiencies and excesses for which supplementation is needed. The reports also contain "mineral ratios" which, if "high" or "low," are supposedly associated with disorders such as diabetes, arteriosclerosis, hypothyroidism, infertility and mental problems. The reports and recommendations were ascribed to "Dr. Arthur F. Furman, Director of Medical Services."

The lab's services were also advertised to health food retailers and chiropractors who could collect specimens and obtain the tests for \$25. A company letter to retailers called hair analysis "an ideal way to aid your customers and increase your profits."

In support of its complaint, the FTC filed affidavits from experts stating that: 1) hair analysis tests do not provide a basis for determining the mineral levels in consumers' bodies; 2) even if multi-elemental spectroscopic analysis of hair is conducted accurately, it does not provide a reliable basis for identifying an individual's mineral deficiencies or excesses; 3) hair analysis does not provide a reliable basis for recommending dietary supplements; and 4) reports of multi-elemental hair analysis can mislead people into getting treatment that is unnecessary, inappropriate and unsafe. Documents collected by the FTC during its lengthy investigation also note:

- Arthur Furman is not a medical doctor but a former dentist who permanently surrendered his license to practice dentistry in Maryland following a 1982 conviction for mail fraud. In that case, Dr. Furman was charged

with scheming with several patients to obtain money from insurance companies by submitting false reports of dental repairs following nonexistent accidents. After pleading guilty to one count of mail fraud, Furman was fined \$1,000, placed on 5 years' probation, and ordered to perform 1,000 hours of community service.

- A & A Laboratory was never licensed by the State of Maryland to operate a clinical laboratory and thus could not legally perform hair analyses or any other type of clinical laboratory tests.

- A survey of defendants' testing services was conducted by the FTC with the help of Dr. Richard M. Jacobs, Chief of the Nutrient Toxicity Section, Division of Nutrition, of the FDA Center for Food Safety and Applied Nutrition. For this study, six identical 1-gram samples were prepared from a large hair specimen and submitted under different names to Trace Mineral Systems for analysis. The results were widely inconsistent. "From report to report," said Dr. Jacobs, "test values for the same elements varied by an average of 830%, and from a minimum of 39% to as much as 5,860% for individual elements . . . Moreover, eight of the elements tested should not have been reported at all because they were not found by the FDA in quantities that are accurately and reliably reportable." Dr. Jacobs also called Trace Mineral Systems' practice of relating mineral ratios to serious disease "totally devoid of scientific merit."

- The recommendations for supplementation were also quite varied. Each of the six reports recommended a supplement of either molybdenum, zinc or chromium. Three reports recommended silicon, two recommended iron and two recommended potassium. Three suggested a supplement regimen "for removal of toxic metals," and all six recommended that a variety of vitamin and non-vitamin substances be consumed to "enhance optimal health." Order forms were sent separately to enable customers to purchase the recommended supplements from the New Age Nutritional Supplement Company. Repeat analyses were suggested to measure progress in four months.

According to an FTC staff attorney, the defendants ceased operations following issuance of the temporary court order. The agency still intends to pursue a permanent injunction. However, it is not clear whether action will be taken against the many commercial laboratories which do not advertise directly to the public but perform hair analyses at the request of licensed health practitioners.

REDRESS FOR FOOD SUPPLEMENT CUSTOMERS

The Direct Selling Association (DSA), represents some 150 firms whose goods and services are marketed by independent salespeople through person-to-person contacts. At least ten of the companies sell nutritional supplements: Amway Corporation, Better Living Products, Inc., Care Free International Inc., Chambre' Cosmetic Corporation, Fortunate Corporation, Heritage Corporation of America, Multiway Associates, Neo-Life Corporation of America, and Shaklee Corporation. DSA's Code of Ethics forbids deceptive or unlawful practices and states that any offer of products for sale shall be truthful as to value.

Distributor agreements for food supplement companies typically state that the company is not responsi-

ble for any claims made by a distributor which are not authorized by the company. (This clause is intended to protect the company if a distributor makes illegal therapeutic claims.) But DSA's Code requires its member companies to take responsibility for their independent salespeople for purposes of Code complaints. According to a recent DSA news release, dissatisfied customers can receive prompt attention by complaining to the DSA Code Administrator, Direct Selling Association, 1730 M St., N.W., Washington, DC 20036. [Nutrition Forum would appreciate a copy.] Pending final resolution of the complaint, the Administrator can even reimburse the complainant out of a special fund.

WEIDER FIRM CHARGED BY FTC

The Federal Trade Commission has filed an administrative complaint against Weider Health and Fitness Inc., and its president, Joseph Weider, of Woodland Hills, California. Ads for Weider products have claimed that its *Anabolic Mega-Pak* is "scientifically created," produces "faster-than-ever-before muscle growth" and is a "Natural Steroid Replacement Kit You Can Live With." Ads for its *Dynamic Life Essence* have claimed that it is superior to "conventional protein sources to muscle up," is "unlike any other amino acid source in the world," and that "Life Essence Builds Bigger Muscles—Faster!"

The *Anabolic Mega-Pak* contains five pills or capsules containing various amino acids, minerals, vitamins and herbs. A 30-day supply costs \$24.95. *Dynamic Life Essence* consists of capsules or powders of amino acids, which can cost up to \$60 for a 30-day supply.

Weider has been advertising these products primarily to bodybuilders and weight trainers, many of whom believe anabolic steroids increase muscularity and strength. These drugs have been banned by the international sports community because they give users an unfair competitive advantage and have many dangerous side effects. Weider claims its products produce results similar to those of anabolic steroids without their dangerous side effects. The company advertises in two major bodybuilding magazines it publishes through subsidiaries, *Muscle and Fitness* and *Flex*.

According to the FTC complaint, Weider misrepresented that:

- a typical user would achieve greater muscular development over the course of a few months of a weight training program than a non-user of these products;
- a typical user would achieve at least the muscular

development of a non-user, but in a shorter period of time;

- a typical user would achieve results equivalent to those bodybuilders generally believe are achievable through use of anabolic steroids—rapid and substantial muscular development;
- the products would stimulate greater than normal production or release of human growth hormones, resulting in faster or greater muscular development;
- *Dynamic Life Essence* is unlike any other amino acid source in the world;
- the *Anabolic Mega-Pak* was developed by a team of the world's most renowned nutritional biochemists, exercise physiologists and trainers.

The Federal Trade Commission issues a complaint when it has reason to believe that the law has been or is being violated. Such action marks the beginning of a proceeding in which the allegations will be ruled upon by an administrative law judge after a formal hearing. The Commission noted that it might seek a court order for consumer redress or refunds in this case.

Years ago, Mr. Weider had several brushes with the Postal Service as a result of false representation of weight reduction plans sold by mail. His current food supplement line includes other questionable products: *Dynamic Super Stress-End*, *Dynamic Power Source*, *Dynamic Driving Force*, *Dynamic Fat Burners*, *Dynamic Liver Concentrate Energizer*, *Dynamic Sustained Endurance*, *Dynamic Recupe*, *Dynamic Body Shaper* and *Dynamic Muscle Builder*. None of these seems capable of doing what their names suggest, and none contains any nutrients not readily obtainable from a balanced diet.

Book Reviews

Title: *Your Personal Vitamin Profile* (1982)

Author: Dr. Michael Colgan

Publisher: Quill, New York

Price: \$7.95, softcover

Reviewed by: Stephen Barrett, M.D.

The book's jacket claims that the author's work "has been recognized throughout the world," but it doesn't say by whom. The book's foreword indicates that the author has had training in engineering, psychology and physiology, but it doesn't tell what field his doctoral degree is in. The table of contents suggests that vitamin supplements can inhibit aging and prevent heart disease, cancer, diabetes—and even herpes.

The warning on the copyright page is even more curious: "Any application of the advice herein is at the reader's sole discretion and risk. Readers are urged to consult the medical references given to decide for themselves the adequacy of the conclusions reached in the book." Actually it would be easier to ask any sane doctor or registered dietitian. They'll tell you that the conclusions are bunk. The author cites hundreds of reputable reports, but the scientists who wrote them would certainly disagree with his advice!

To determine your "individual biochemical equation," the author suggests starting with a basic 28-nutrient formula and adding various amounts of these and other nutrients for each positive answer to more than 50 questions. For example, a 125-lb. woman who lives in a big city, takes the Pill, and gets colds is advised to take 1500+1000+500+1000 mg of vitamin C and 300+0+100+100 mg of vitamin E daily. The author seems unaware that 4000 mg daily of vitamin C can cause diarrhea or that 500 mg daily of vitamin E can cause fatigue. Most readers who follow the prescribed schedule exactly for each nutrient would waste hundreds of dollars per year.

Title: *Recalled by Life* (1982)

Author: Anthony J. Sattilaro, M.D.

Publisher: Avon Books, New York

Price: \$3.50, paperback

Reviewed by: William T. Jarvis, Ph.D.

This very readable book details the fortunate recovery from cancer of 47-year-old physician Anthony Sattilaro. It is controversial because of the degree of credit given to "macrobiotic" eating. Sattilaro underwent extensive orthodox treatment but concluded that his dietary practices were more effective.

Sattilaro states that his story "is not meant to serve the interests of any single group or so-called movement," but he strongly endorses both the diet and the philosophy of Michio Kushi, America's leading macrobiotic proponent.

Only an insensitive reader would fail to empathize with Dr. Sattilaro as he simultaneously faces his father's death from prostatic cancer and his own poor prognosis

from the same disease. However, anyone familiar with quackery will also be concerned about the story's potential for abuse. Although Sattilaro is explicit that "anecdotal evidence such as my own story is not regarded as scientific proof of anything," it is well known that patients facing life-threatening illnesses tend to listen selectively and grasp for anything offering even a remote chance for recovery. Moreover, the book's jacket says flatly that the diet worked after surgery and chemotherapy failed.

Macrobiotic zealots are bound to make the most of Sattilaro's experience in their promotions. Sattilaro himself reports that after his story appeared in the August 1980 *Saturday Evening Post*, Kushi's East West Foundation received over 35,000 letters. Additional thousands have flocked to hear him lecture, and television publicity for his book has reached millions more.

Recalled by Life provides a fascinating account of the conversion process at work. Those desiring deeper insight into how people come to believe in incredible things should read William Sargant's *Battle for the Mind: The Physiology of Conversion and Brainwashing* [Harper & Row, 1959] and see how well Sattilaro's story fits the mold. His psychologically shattering experience combines with feelings of guilt and low self-esteem to set him up for macrobiotics with its metaphysics, its simplistic explanations, its social support system, and the symbolism of its dietary regimen. Bad-tasting food provides an opportunity both for penance and a sacrament. Ritual chanting and meditation do their part to touch deep emotional chords. Sattilaro finally accepts a system poles apart from his medical beliefs—the reaction Sargant describes whereby vulnerable converts come to love what they would previously have rejected. Sattilaro reveals much inner conflict between his emotional and rational selves as he analyzes his feelings as a patient spared a terrible fate and as a physician familiar with the uncertainties of clinical medicine. It is clear that his experience was as much religious as medical.

Sattilaro's stated purpose for publicizing his story is to stimulate research into macrobiotic eating as a cancer treatment. But no responsible researcher would permit patients with a chance of recovery through conventional therapy to be treated with diet alone or to serve as a no-treatment control group, as Sattilaro proposes. Moreover, he exhibits only superficial knowledge of the epidemiological literature on diet and cancer.

What will the future bring? Will Sattilaro eschew conventional therapy altogether? Will he eventually rebuke the irresponsible use of his story? Will his enthusiasm stimulate a scientific test of macrobiotics? And if such a test fails, will he accept its results? At least one thing seems certain: Dr. Sattilaro's remarkable case will reverberate through the media for years to come.

Dr. Jarvis is Professor of Health Education at Loma Linda University and President of the National Council Against Health Fraud, Inc.

Briefs

Dangerous new strategy! James R. Johnson, Ph.D., head of the National Nutritional Foods Association's "Certified Nutritionist" program, has suggested a new strategy to undercut the drive for laws to protect the public against unqualified "nutritionists." Writing in the October 1984 *Health Store News*, he has advised members of the natural foods industry to "go to the county seat, the same place where you got your retail occupational license and tell them you want to take out a license as a Nutritionist. They won't know anything about it and there are usually no prerequisites. It amounts to filling out some forms, and paying some money. Make sure the license states 'Nutritionist' or 'Nutritional Counselor.' If it happens, you will be 'grandfathered' in under the law, or if it doesn't happen, you will have built a little more prestige." He also advises retailers to teach courses in their stores or through adult education programs at local school systems.

Possible FTC reversal. The Federal Trade Commission is reconsidering its 1971 regulation that retail food stores have adequate amounts of advertised items in stock or readily available. The rule was adopted to prevent unfair "come-ons," but an FTC staff report has speculated that in the long run, compliance with the rule may cost consumers more than it saves. Public comments should be addressed to the Secretary, Federal Trade Commission, Washington, DC 20580.

Sugar-hyperactivity link unsupported. Twenty-one boys considered by their parents to have adverse behavioral reactions to dietary sugar were challenged with glucose, sucrose and a placebo (saccharin) in a series of double-blind tests. Neither sugar appeared to produce behavioral excitation. Trained observers found no consistent or significant changes in behavior, attention span or memory. For the group as a whole, sugar ingestion actually produced a slight but significant decrease in motor activity as measured with a belt-worn device during the first three hours after ingestion. The researchers believe that these data cast doubt on the significance of sugar intake in causing behavioral disturbance. Reprints of the study can be obtained by writing to Dr. Judith L. Rapoport at the National Institute of Mental Health, Building 10, Room 3N204, 9000 Rockville Pike, Bethesda, MD 20205.

Textbook series changes publishers. *Contemporary Issues in Clinical Nutrition* is a series of textbooks for clinical nutrition professionals, produced under the supervision of Richard S. Rivlin, M.D., Chief of the Nutrition Service at Memorial Sloan-Kettering Cancer Center. The first 7 volumes were published over the past four years by Churchill Livingstone Inc., 1560 Broadway, New York, NY 10036. Beginning this year with Volume 8, *Nutrition and Diabetes*, the publisher will be Alan R. Liss, Inc., 150 Fifth Ave., New York, NY 10011.

Milk for missing kids. More than 100 dairies have agreed to display photographs of abducted children on millions of milk cartons. A major manufacturer will display a total of 24 pictures of these children on millions of cartons distributed to dairies around the country. The program is an offshoot of local efforts by dairies in Iowa, Illinois and California. In California, a 13-year-old girl returned home after seeing publicity about her photo on cartons of milk from the Alta-Dena dairy [NF 2:1-4].

Fluoridation law upheld. The Illinois Supreme Court has upheld a state law mandating fluoridation of public water supplies, apparently ending a challenge begun 16 years ago by the Illinois Pure Water Committee. Two years ago a circuit court judge ruled the law unconstitutional on the theory that the state had not studied fluoridation's long-range effects adequately. However, the law remained in force while state officials appealed this decision. The state supreme court said that plaintiffs had failed to prove the law so unreasonable that it exceeded the government's power to establish public health regulations. No court of last resort has ever ruled against fluoridation regardless of the issues involved.

Shaklee income drops. Reversing a long record of uninterrupted growth, Shaklee Corporation reported sales of \$459.1 million for the year ending September 30, 1984, a 15% drop from fiscal year 1983. Gross sales of nutritional products were \$343.9 million. Net income was \$13.2 million, but \$10 million of this came from international sales. The company attributed the drop to increased competition and reduced public interest in doing part-time sales work. To remedy the situation, the company has been trying to increase its visibility by: 1) establishing a scientific advisory board; 2) advertising to medical doctors; and 3) supporting the U.S. Ski Team. According to the company's annual report, "These activities are helping the public to more closely associate Shaklee with nutrition, fitness and well-being." Distributor incentives have also been increased.

Free publication. *Contemporary Nutrition*, which provides an excellent referenced analysis of one topic each month, is available free-of-charge to food and nutrition professionals. Back issues cost \$4.00/set. Requests should be sent to Gloria T. Florey, Production Manager, General Mills, P.O. Box 1113, Dept. 65, Minneapolis, MN 55440.

New board. The American Society for Parenteral and Enteral Nutrition has established an independent National Board of Nutrition Support Certification to certify health professionals in the field of intravenous and tube feeding of patients. The first examination will be offered to nurses in January, 1986.

Cancer quack convicted. A 77-year-old, self-styled "healer" who administered colored light therapy, vigorous abdominal massage, and a diet restricted to lemonade, salt water and herb tea to a 24-year-old leukemia victim has been convicted of felony practicing medicine without a license. Evidence at the trial suggested that the patient had died as a result of abdominal bleeding caused by the massage. Upholding the verdict, the California Supreme Court noted that conviction for involuntary manslaughter could properly have been considered, but the trial judge had not suggested it in his instructions to the jury. The defendant had been convicted in 1960 of practicing medicine without a license. [People v. Burroughs, Crim. 23141 (Super. Ct. No. 58541), Supreme Court, Calif., April 19, 1984.]

Alcohol's effect on the fetus. A study of 31,604 pregnancies published in the October 12, 1984 *Journal of the American Medical Association* has found that the number of drinks a pregnant woman takes daily is inversely related to her infant's birth weight. After adjustment for other risks (such as cigarette smoking), the data showed that "consuming at least one to two drinks per day had a substantially increased risk of producing a growth-retarded infant." Offspring of women who had 3 to 5 drinks daily averaged about 6 ounces lighter than those of complete abstainers, while offspring of mothers who had less than one drink daily were about half an ounce lighter. While speculating that "an occasional drink has only a trivial effect on intrauterine growth," the authors caution that a "safe" level has not actually been established. An editorial in the same issue suggested that, "Women who are pregnant and wish to have healthy babies should not drink alcohol at all."

Measures to reduce drunk driving. The Allentown *Call-Chronicle* reports that public pressure and lawsuits holding tavern owners responsible for injuries and deaths caused by intoxicated patrons are changing tavern policies throughout Pennsylvania. Fewer visibly intoxicated persons are being served. At many establishments, free food has replaced free drinks and "two-for-one" specials at "happy hours." One bar is serving high-protein and high-fat foods (which slow down alcohol absorption into the body). Another offers free soft drinks to "designated drivers" to encourage one person in each group to remain sober. Liquor liability insurance premiums have been rising rapidly and many companies have stopped writing them.

"Pill" prevents anemia. Oral contraceptives improve menstrual regularity and lighten blood flow for many users. The National Institute of Child Health and Human Development estimates that use of the pill prevents 27,000 cases of iron deficiency each year. [Source: *Facts About Oral Contraceptives*, 1984.]

Spotting the excessive drinker. A 4-question test appears to offer a simple way to detect alcoholism. The questions are: 1) Have you ever felt you ought to cut down on your drinking? 2) Have people annoyed you by criticizing your drinking? 3) Have you ever felt bad or guilty about your drinking? 4) Have you ever had a drink first thing in the morning to steady your nerves or get rid of a hangover? A controlled study of acknowledged alcoholics and heavy drinkers found that almost all answered two or more questions affirmatively. [JAMA 252:1905-1907, Oct. 12, 1984]

Poisoned Easter eggs. Hard-boiled eggs cooled in water and not kept refrigerated were the source of staphylococcal food poisoning in more than 300 children who participated in an Easter egg hunt. A report in the August 24/31, 1984 *Journal of the American Medical Association* indicates that disease-causing bacteria were transmitted to water used to cool the eggs by a cook, and the eggs were then stored at room temperature for 3 to 5 days. Researchers who conducted laboratory studies following the outbreak concluded that although unbroken and uncooked eggs are quite resistant to bacterial invasion, cooked eggs provide an ideal growth medium. Therefore cooked eggs should be handled as cleanly as possible and kept refrigerated until they are consumed.

Aspartame update. After interviewing more than 500 aspartame users who had complained to the FDA, the U.S. Centers for Disease Control (CDC) has concluded that no specific pattern of symptoms was clearly related to aspartame use. Of the many different symptoms reported, CDC found that "the great majority were mild and are common in the general populace." Symptoms occurring after aspartame consumption could be coincidences, the results of suggestibility, or some as yet unidentified individual sensitivity. Aspartame's manufacturer, G.D. Searle and Co., is designing protocols for clinical studies to make further checks between the reported symptoms and use of its product.

Swimming and weight control. According to Grant W. Gwinup, M.D., professor of medicine at the University of California (Irvine) College of Medicine, swimming will not help obese patients lose weight, but at least 30 minutes of "huffing and puffing" from aerobic exercise will. He said this recently at the annual meeting of the California Academy of Family Physicians after studying obese patients randomly assigned to daily swimming, cycling or walking without any consideration of dietary intake. Only the swimmers did not lose weight. Dr. Gwinup also noted that weight loss is difficult to maintain, possibly because the hypothalamus monitors body fat and tries to keep the amount constant. "Inside every thin man is a fat man wanting to come back," he said.

THE SCIENCE AND POLITICS OF RAW MILK Odom Fanning

Slogans vied with science at an informal FDA hearing on raw vs. pasteurized milk held in Washington, D.C., on October 11th and 12th. The hearing's purpose was to help the Secretary of Health and Human Services (HHS) decide whether new rule-making is needed.

Pasteurization is accomplished by heating milk for specified time/temperature combinations, most commonly 161°F (71.6°C) for 15 seconds. This kills microorganisms that can transmit disease to humans through milk, and also kills almost all spoilage bacteria. The process does not sterilize milk, but does make it safe to drink and extends shelf life.

Unpasteurized (raw) milk may be certified or uncertified. Certified raw milk (CRM) is the trademark designation of milk produced according to standards set by the American Association of Medical Milk Commissions, an industry organization. CRM is produced by three large dairies and can be sold through retail food stores in 24 states. In 6 other states, sale is limited to direct farm sales, while in 20 it is prohibited. Uncertified raw milk is typically produced in small quantities by individual dairy farmers and sold on the farm or by home delivery.

Even though a final regulation mandating pasteurization was proposed by the FDA 11 years ago, it was never issued. Last April, Public Citizen's Health Research Group (HRG), an organization founded by Ralph Nader, petitioned HHS to ban all raw milk sales in the United States. Then in September, joined by the American Public Health Association, HRG filed suit in U.S. District Court for the District of Columbia to force the agency to respond.

The hearing was held before FDA Commissioner Frank E. Young, M.D., Ph.D., Walton B. Read, M.D., of the FDA Bureau of Foods, and HHS attorney Fred Degman. Witnesses were not allowed to question the panel or one another—but were interrogated by the panel after giving testimony of two pre-announced questions:

- Is the consumption of raw milk, including certified raw milk (CRM) and raw milk products, of public health concern?

- Would requiring pasteurization of raw milk, including CRM and such products, be the most reasonable regulatory option?

The Commissioner also asked witnesses whether labeling CRM as to its risks would provide adequate protection for the public. Should he make a finding of fact that consumption of raw milk is of public health concern, he would then make a recommendation to the HHS Secretary—presumably for either compulsory pasteurization or mandatory labeling of milk in interstate commerce. Before a proposed regulation could be published, it would have to be approved by the Office of Management and Budget—and presumably the President. A final regulation is unlikely to be developed and take effect within the next year.

The political strength of raw milk advocates can be judged by the string of witnesses produced for the FDA hearing by Alta-Dena Certified Dairy, of City of Industry, California. According to a press kit distributed by the company, it is the largest producer-dairy in the world. It spans 600 acres and has 8,000 milking cows, 7,000 stock cows, 800 employees, and annual sales of \$100 million. Twenty percent of its production is sold as raw milk or raw milk products. About 90% of all raw milk sold in California comes from Alta-Dena, which also funds the Los Angeles County Milk Commission, a certifying body.

Press reports assign to Alta-Dena a high political profile in California, where between 100,000 and 200,000 residents are said to drink certified raw milk or feed it to their children daily. The dairy and its supporters once marshalled 17,000 letters to the governor, against only a handful opposing its position.

One witness at the hearing was Harold Stueve, Alta-Dena's founder and co-owner. More than 60 members of the Stueve family are said to work for the company. Another witness was Rep. William E. Dannemeyer (R-Calif.), who was an attorney for Alta-Dena from the early 1960s until he entered Congress in 1978. Last Spring Dannemeyer got 36 of the other 44 Congressional representatives from California to join him in signing a

letter to HHS urging FDA to back off from regulating certified raw milk. (Some have since withdrawn their support.)

"This ostensibly is a battle over public health," he testified at the hearing. "Disabuse yourself. It's a battle over the politics of public health. We are in this controversy because the medical profession for decades has produced doctors who are taught that all milk should be pasteurized. They don't get into the whys. It is only natural that people who achieve positions of responsibility then base their actions on what they were taught. These are dedicated people who believe that milk should be pasteurized."

Dannemeyer traced the history of opposition to Alta-Dena and CRM from 1966 and said that the public has lost respect for public health authorities in California in regard to this issue. He claimed that health department records show that 3.6 million human cases of salmonellosis were reported between 1971 and 1982 in California, and that almost half of them were attributed to food service establishments, most of the remainder to meat and poultry, and only 103 to certified raw milk. He asked, "If it is the intention of public health authorities to eliminate *Salmonellas* from humans in the United States, how is it they ignore all except CRM?"

Another witness for Alta-Dena was Joseph L. Fleiss, Ph.D., head of the Division of Biostatistics at Columbia University's School of Public Health. He described an "odds ratio" scheme for controlled retrospective studies, with relative risks from 1 to 15. A value of 1 means "no associated risk." A value of 5 means "important public health risks," while 6 to 15 mean "probable cause and effect." Asked to rate certified raw milk on that scale, Dr. Fleiss responded: "My experience is that, if all things were known, it would not come down to 1, it would come down to 5."

Another Alta-Dena witness was John M. Douglass, M.D., an internist from Los Angeles. "Isn't it better to maintain control in the marketing of certified raw milk than to lose control?" he asked. "We might want to label it with some of the pros and some of the cons. That gives people freedom of choice. The label should be informative. Some people tolerate raw milk better than others. It may contain deleterious antigens."

Also testifying was William Campbell Douglass, M.D. (no relation to John Douglass), president of the Douglass Center for Nutrition and Preventive Medicine and author of *The Milk of Human Kindness—Is Not Pasteurized*. "For rapid, healthy growth in young children, there is no substitute for raw, certified milk," he asserted. "Pasteurized milk is dead milk, which will rot on standing. One of nature's most perfect foods has been murdered. At the turn of the century, 5,000 babies died annually from drinking raw milk, but instead of requiring dairymen to clean up their act they required pasteurization. Today, milk producers are clinging to outdated methods such as heat treatment to cover up sloppy production methods." [Editor's note: Pasteurization is not the only public health measure opposed by

Dr. Douglass. A recent article by him in the National Health Federation's monthly magazine states that chlorinated-fluoridated water causes cancer, chronic fatigue, atherosclerosis, allergy, heart attacks and strokes. Clinton Ray Miller, NHF's Washington lobbyist, also testified.]

Paul M. Fleiss, M.D. (a cousin of Joseph L. Fleiss), a pediatrician from Hollywood, California, admitted that he had been "repelled" to discover that in Hollywood there was a large group of consumers of raw milk. For a number of years, he said, he tried to dissuade mothers from feeding their infants and children a product with such a bad reputation. Finally, he investigated for himself, read the literature, visited dairies, "became a convert," and now heads the Los Angeles County Milk Commission.

"I have a very busy pediatrics practice, and many mothers tell me that their children do better on raw milk," he said. "Some dairies are heating milk far beyond the heating required for pasteurization—they're sterilizing it. This destroys some important nutrients. And you can taste the difference."

He also claimed that immunoglobulins and enzymes such as lactases and lipases are destroyed by sterilization. "Raw milk contains lipase, free fatty acids, which when absorbed help the body utilize fat better," he explained. "This is why some allergies might be due to pasteurized milk."

Another witness at the hearing was Mrs. Sandy Gooch, author of the book *If You Love Me, Don't Feed Me Junk*. She identified herself as the proprietor of a California health food store which in June sold 5,319 gallons of raw milk, and as vice president of the Natural Foods Network [NF 1:16], which she said has three million customers nationwide. She asserted that she knew of no report of illness ever attributed to raw milk consumption.

Other supporters of raw milk marketing said repeatedly that mandatory pasteurization would threaten consumers' "freedom of choice." One contended that everybody knows that cigarettes cause cancer, but government has not banned them, and everybody knows that passive restraints in automobiles save lives, but government has not mandated them. Another said, "We tried prohibition (of liquor) once, and it didn't work. Is raw milk next?"

The witnesses against raw milk were equally outspoken. One was public health veterinarian Morris E. Potter who, with three others from the U.S. Centers for Disease Control (CDC), published a state-of-the-art report on the hazards of unpasteurized milk in the October 19th *Journal of the American Medical Association*. The report lists seven supposed benefits claimed by raw milk advocates, including higher nutritive value, reduced incidence of tooth decay, enhanced resistance to disease, and enhanced fertility. Citing 65 references, however, Potter et al. conclude that no significant nutritional difference has been found between raw and pasteurized milk in numerous studies in both animals and humans.

The report explains that pasteurization affects six milk constituents with known nutritional benefits. Three vitamins for which milk is a minor source (thiamine, B₁₂, and C) are reduced about 10%. About 6% of the calcium in milk is rendered insoluble, about 1% of milk protein is coagulated, and some fat globules are dispersed; but these changes have no effect on the bio-availability of these three nutrients.

On the public health issues, the CDC group states that, "Abundant evidence has shown that raw milk serves as the source of bacteria that cause outbreaks of disease in humans: in recent years, most frequently salmonellosis and campylobacteriosis. In the investigations of such outbreaks, the epidemiologic evidence, combined with knowledge about the occurrence of specific pathogens in cattle and the isolation of some of these pathogens from raw milk, leaves no doubt that raw milk is a vehicle for disease in humans."

The main symptoms of these infections are cramps, diarrhea and fever, but *Salmonella dublin* presents a special problem. This relatively rare organism is known to be host-adapted to cattle and is more likely to be identified as being derived from raw milk than are the more commonly isolated types of *Salmonellae*. The authors note that, "Numerous studies in multiple locations have confirmed the role of raw milk in the transmission of *S. dublin* to humans . . . *S. Dublin* infections are of particular concern because the associated illness tends to be severe"—and is not limited to the digestive tract.

At the FDA hearings, Dr. Potter added that, "From 1980 to 1983, 53% of the foodborne outbreaks of *Campylobacter* reported to CDC were associated with drinking unpasteurized milk. The reported rate of isolates identified is 20 times greater in states that permit the sale of unpasteurized milk."

According to CDC, outbreaks of campylobacteriosis associated with raw milk consumption have been reported recently in Arizona, California, Colorado, Georgia, Kansas, Maine, Oregon and Pennsylvania.

Michael Osterholm, M.D., Minnesota Department of Health epidemiologist, described the investigation of a current mysterious disease outbreak in that state. After months of investigation, in which 94 families have been contacted, the investigators know only this: The causative agent has not been identified, but the method of transmission is undisputed. Unpasteurized milk produced by one dairy had been drunk by all 122 victims during the three weeks before onset. Some have been sick for months. For those under age 18, the median is 76 days' duration. Children have recovered more

quickly than adults, but only 11 (9%) have fully recovered. The producing dairy has voluntarily stopped selling raw milk products.

"All cases of which we are aware are associated with raw milk consumption, and there have been no new cases since the implicated milk product was withdrawn," said Dr. Osterholm. "This is no *S. campylobacter*. It is not a virus or a fungus. It stumps the best experts."

Raw milk's growing popularity as a "supposed health food" is of concern to the American Academy of Pediatrics, said another witness, John Bolton, M.D., a San Francisco pediatrician.

The Academy "has reviewed both the nutritional properties and the safety records of raw milk and has found that the risks outweigh the benefits," he declared. "There are no benefits of raw milk that would outweigh the extreme risk of infection that sometimes follows feeding raw milk products to infants, children with malignancies, and children with problems involving the immune system."

He said that, since 1977, 192 isolates of *Salmonella* have been made in certified raw milk in California. This milk is also transported across state lines by distributors. According to Dr. Bolton, "The most recent finding on September 28, 1984, involved 4,000 gallons of certified raw milk distributed to consumers and retail outlets." Press reports prior to the hearing indicate that California health officials had recalled Alta-Dena's raw milk products 17 times since 1977 because state tests found *S. dublin* in samples. The incident referred to by Dr. Bolton occurred just hours before Gov. George Deukmejian vetoed a controversial bill that would have freed the dairy from control by state regulatory agencies. The bill would have allowed the sale of CRM shown by state labs to harbor salmonellae. Another recall involving Alta-Dena and two other California dairies has occurred since the FDA hearing.

Dr. Bolton exhibited a chart which analyzed the 123 cases of *S. dublin* reported in California in 1983. It showed 51 patients who used raw milk including 44 who used it from Alta-Dena. Only 10 of the 51 had been exposed to such other possible sources of *S. dublin* infection as raw eggs or raw or rare meat. The list of pre-existing diseases in these patients "reads like the index to a pathology textbook: cancer, leukemia, lymphoma, cirrhosis, lupus, AIDS, etc.," he said. "This points out one of the most tragic aspects of this problem. Seriously ill patients purchase a so-called 'health food' only to be exposed to *S. dublin*. Raw milk is even advertised as a basic food for invalids."

EDITORIAL BOARD

EDITOR: Stephen Barrett, M.D. **ASSOCIATE EDITORS:** Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; Manfred Kroger, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.

In response to certified raw milk producers' claim that the product is made safe by the practice of spraying the udders of the cattle with an antiseptic solution and then using two clean towels to wipe off, Dr. Bolton stated categorically that, "Potentially harmful bacteria still reside on the udders and inside some of the cattle as well."

Advocates of raw milk consumption point to other foods such as poultry which are frequently contaminated with *Salmonellae*. "What they fail to point out," said Dr. Bolton, "is that these foods are intended to be cooked before consumption. Heat destroys *Salmonellae*. Pasteurization, heat treatment of milk, is the only way to assure safe milk supplies."

Referring to the statistical analysis of *Salmonella* illnesses cited by Congressman Dannemeyer, Dr. Bolton called it "creative." Literature distributed by Alta-Dena shows that the figure of "3.6 million cases between 1971 and 1982" was derived by multiplying the number of all types of *Salmonella* infections reported annually (3,000) by 12 years and again by 100, "since some say that only 1 out of 100 *Salmonella* cases are ever detected/reported." However, the number of *S. dublin* cases connected with raw milk consumption was given as the actual number reported (103), not the 10,300 which would result from multiplying this figure by 100.

According to state health officials, the fact that the number of *S. dublin* cases in California is not larger "relates to the fact that the population that drinks CRM is very small and that contamination of CRM appears to

be intermittent." In its March 30, 1984 morbidity report, the Infectious Disease Section of the California Department of Health Services estimates that *S. dublin* infections are 158 times more likely in CRM users than in non-CRM users.

Others testifying in favor of a federal rule regarding raw milk included representatives of the Association of Food and Drug Officials; International Association of Milk, Food, and Environmental Sanitarians; Interstate Milk Shippers; and National Milk Producers Federation.

The FDA hearing was but a skirmish in what *The Los Angeles Times* [Aug. 31] called "a holy war over milk" in California. "Each time the state laboratories have found salmonella in Alta-Dena's milk," the writer noted, "another recall notice has been issued, warnings have appeared in newspaper articles and the raw milk has been pulled off supermarket shelves. In this war of attrition, the state seems to be slowly winning." Although Alta-Dena's total sales have increased steadily in recent years, raw milk sales have declined from almost 20,000 gallons a day in 1977 to about half of that amount today. Yet, the article points out, "after all the recalls and all the press releases, an estimated 200,000 people a day still drink raw milk in California."

Mr. Fanning, formerly a science writer for *The Atlanta Journal* and director of information for the Centers for Disease Control, is editor and publisher of *Consumer Newsweekly*.

Briefs

Low-calorie liquor? Responding to a petition from the Heublein Spirits Group, the Bureau of Alcohol, Tobacco and Firearms (BATF) has requested public comment on whether to set up a new class of distilled spirits bottled at lower proof than currently permitted. It also wants ideas on what such products should be called ("mild" or "light," for example). A standard does exist for less-than-full-proof distilled spirits, but Heublein feels that the required term ("diluted") has a negative connotation to consumers. In its petition, the company noted that "consumers are seeking foods and beverages with less sugar, salt and fewer calories [including] low calorie wines and beer." Comments, due by January 31, 1985, should be sent to: Chief, FAA, Wine and Beer Branch, BATF, P.O. Box 85, Washington, DC 20044. Attn: Notice No. 491. For additional information, see page 44921 of the November 13th *Federal Register*, or contact Charles N. Bacon at the above address (telephone 202-566-7626).

Chelation doctors challenged. Concluding that no scientific documentation shows that chelation therapy is effective against cardiovascular disease, atherosclerosis, rheumatoid arthritis or cancer, the AMA House of Delegates recently voted to call upon proponents of this method to conduct properly controlled studies to test their claims.

More vitamin C. The Swiss-based Roche Pharmaceuticals Group has opened its largest single production facility in Scotland. According to *Health Foods Business*, the plant took five years to build, cost \$210 million, and can produce up to 20 metric tons of vitamin C daily.

Experts available. The National Council Against Health Fraud operates a speakers bureau and can also help injured plaintiffs and government agencies secure expert witnesses to testify in court cases involving quack methods. Its telephone number is 714-796-3067.

Nutrition Forum ISSN 0748 8165 is published monthly by the George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106. Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES: \$30/yr., \$57/2 yrs., \$81/3 yrs., prepaid; VISA and Master

card acceptable; foreign postage by airmail add \$10.00. Manuscripts, books for review, and other editorial correspondence should be sent to Dr. Stephen Barrett, P.O. Box 1602, Allentown, PA 18105. Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

Health food industry priorities. Pat Heydlauff, newly appointed executive director of the National Nutritional Foods Association (NNFA) has announced four priorities facing the Association: 1) meeting the threat of dietitian's licensure to take away store owners' rights to give nutritional advice; 2) countering negative media attacks by individuals like Drs. Victor Herbert and Elizabeth Whelan; 3) enhancement of NNFA's program for product standards; and 4) increased public relations to create a positive image for the natural foods industry. The organization has revived its Health Freedom Victory Fund with a goal of raising \$250,000 to fight dietitian licensing. Health Resources Group (a Kurt Donsbach enterprise) donated \$2,000 to the fund. General Nutrition has donated \$5,000, and Shaklee Corporation and Diet Centers have also contributed.

Push for veggie burgers. American Vegetarians, a Maryland-based group, is campaigning to pressure McDonald's into offering a meatless version of its burgers. According to the *East/West Journal* (a publication of macrobiotic proponent Michio Kushi), the organization has been picketing selected restaurants in 25 cities and claims to have assembled 300 citizens' groups to help with a boycott endorsed by Dick Gregory and United Farm Workers president Cesar Chavez. McDonald's has responded that it tested a soy burger several years ago but found it lacked mass appeal. The chain recently celebrated the sale of its 50 billionth burger.

New "holistic" coalition. The Coalition of Holistic Health Organizations (CHHO) was founded in March 1984 by 26 organizations including the American Holistic Medical Association, the East/West Institute (a promoter of macrobiotic eating), the National Center for Homeopathy, the National Colon Hygiene Association, the National Health Federation, and the People's Medical Society (a Rodale Press offshoot). CHHO's planned activities include: 1) a database on research into holistic practice; 2) a database on holistic practitioners and their services; 3) keeping current on legislative and regulatory information; 4) a national "bulletin board" of meetings and other events of interest; 5) coordination of a national speakers bureau which could respond to holistic health issues in the media. Voting membership, which costs \$250/year, is open to professional associations or membership organizations with at least three years of experience or 100 members, and also to suitable educational institutions. It is expected that communication between members will be done largely through a computer network.

Pepsi, Coke and corn syrup. PepsiCo., Inc. and The Coca-Cola Company have raised to 100% the amount of corn syrup their bottlers may use for sweetening their cola drinks—a change that will affect per capita sucrose consumption figures.

Historical tidbit. In 1958 the American Medical Association gave a special citation to the General Electric Company for sponsoring a television show on the dangers of cancer quacks. The award, for "one of the best examples of the value of television in public information," was accepted on behalf of the company by the show's director: Ronald Reagan.

Boon for gourmets? Predicting that the number of Americans between 15 and 29 years old will decline 7 million by 1991, a Food Institute report suggests that full menu restaurants may benefit at the expense of the fast food industry. According to the report, there "will be an increase of almost 16 million in the ranks of adults aged 30-49, an affluent group, usually associated with more sophisticated tastes." The likely result: more menu diversification at fast food outlets.

Chiropractors and nutrition. In 1982, the Iowa Supreme Court ruled that chiropractors could not provide nutrition advice to their clients because this service was not specified in the chiropractic licensing law. In 1983, the Iowa Chiropractic Society sponsored a bill to change this. The Iowa Dietetic Association (IDA) objected on grounds that chiropractors had insufficient training to provide nutrition counseling. When it became clear that the bill would pass, IDA succeeded in amending it to require that chiropractors pass a competency exam before engaging in the practice of nutrition. An additional amendment prohibits chiropractors from selling supplements at a profit in their offices. The amended bill passed and took effect July 1, 1983. Subsequently, a spokesperson for the Iowa Board of Chiropractic Examiners said that since chiropractic licensing exams already include a section on nutrition, no procedural changes are needed. [Source: Judith D. Klopfenstein, M.S., R.D.]

QUESTION BOX

Q. I have been reading about "dead" (cooked) versus "live" (uncooked) foods. Is it true that cooking destroys the enzymes in food, therefore making it less nutritious?

A. It is true that cooking can destroy enzymes in foods, but this has no significant effect on nutritional value. Enzymes are present in the tissues of plants and animals to serve their own biochemical needs. Claims that these enzymes are important to humans are based on the mistaken belief that they enter the body intact and function usefully as enzymes to aid metabolic processes. This is untrue. Enzymes are proteins, and like other proteins, are digested and enter the body as their component amino acids. The enzymes the body needs for digestion are produced by the gastrointestinal tract and other organs such as the pancreas and liver. The digestive enzymes are not the same as those found in food.

SOME FACTORS AFFECTING THE NUTRIENT CONTENT OF FOODS

Eleanor N. Whitney, Ph.D., R.D.

Linda K. DeBruyne, M.S., R.D.

The food industry has increased its attention to the nutritional quality of products—a desirable trend, considering that almost two-thirds of the food we consume has been commercially processed. Processing often involves a trade-off: it makes foods widely available at reasonable prices, makes them safer, and extends their usable lifetime, but it does cause some vitamin and mineral losses. Overall, however, the benefits outweigh the losses.

In some instances processed food has the edge over its unprocessed counterpart, even in terms of nutritional quality. For example, foods frozen and stored under proper conditions will often contain more nutrients when served than fresh fruits and vegetables that have stayed in the grocery store even for a day.

How do store-bought vegetables and garden-fresh vegetables compare nutritionally? Chemical analysis would find slight nutrient differences. The nutrient content of fresh foods varies with how the food is grown (for example, iodine content of plants depends on the mineral content of the soil), when the food is harvested (ripe or unripe), and how the food is treated after harvest. As a rule, the sooner after harvest the food is eaten, the better.

Vine-ripening maximizes vitamin content, but many fruits and vegetables stay attractive for only a day or so after picking and then begin to spoil. Vegetables such as tomatoes have to be harvested while still unripe, to facilitate shipping. Then they are ripened just before going to market. In this case, a fraction of the vitamin content is sacrificed in exchange for increased availability.

The ideal nutrient-conserving process for produce was suggested by Colonel Potter of the TV series *M.A.S.H.* He would take a hot plate out to his corn field and boil a pot of water. Then he'd bend cornstalks over the pot and dip the ears of corn in the water while they were still attached to the stalks. When they were barely cooked, he'd eat them right there in the field. This "recipe" would provide both maximum flavor and minimum nutrient loss due to storage.

Which is better—canned or frozen food? Canning is a good method for preserving food against microbes (bacteria, fungi, and yeasts) that might otherwise spoil it, but canning does diminish nutrient retention. The canning process is based on time and temperature. Each small increase in temperature has a major effect on the killing of microbes but only a minor effect on nutrients. In contrast, long treatment times cause greater nutrient

losses. Therefore high-temperature, short-time (HTST) treatment is used. This greatly reduces the content of several vitamins, notably thiamin and folacin. But HTST treatment actually helps preserve vitamin C by destroying its special enemy, ascorbic acid oxidase, an enzyme present in fruits and vegetables.

Freezing is an excellent way to preserve food. Some losses may occur during the steps preparatory to freezing, such as blanching, washing, trimming or grinding, but the freezing itself does not destroy nutrients. Because oxygen destroys vitamin C, some is lost whenever tissues are broken and exposed to air.

How should frozen foods be stored? Generally the lower the temperature, the longer the storage life and the greater the nutrient retention. To maximize the nutritive value of foods at home, use a thermometer to monitor the temperature of the freezer. Frozen food should be kept at a temperature colder than 32°F (0°C). Although food may seem frozen at 2°C, much of it is not—and enzyme-mediated changes can cause total loss of vitamin C in as little as two months.

What about mineral losses in processed foods? Unlike vitamins, minerals are unaffected by heat processing. However, they can be lost when they leach into water that is thrown away. A bit of Southern folk wisdom related to the cooking of "greens" (dark green vegetables) is to pour off the liquid ("pot liquor") and drink it. And the "liquor" from canned vegetables can be used to make soups, cook rice, or moisten casseroles. Nutrient losses are closely related to the extent to which food tissues have been broken, cut or chopped, and to the length of time the food is in the water.

How can I tell whether a food has lost nutritional value? The feeling that a food "doesn't look quite right" can be a valuable clue. As nutrient content deteriorates, there is often a corresponding deterioration in food quality (appearance, taste, and texture). For example, when a food smells bad, oxidative or enzymatic changes have occurred—the same kinds of changes that adversely affect nutrients. Thus, unprocessed "natural" foods sold in health food stores may be a poor choice since no measures have been taken to prevent vitamin loss from oxidative and enzymatic changes.

Does it matter which type of bread is eaten? The wheat kernel loses valuable nutrients during the milling process. Improvements in milling machinery made in the early 1900s resulted in a white, smooth-textured flour that people considered more desirable than the crunchy, dark brown, "old fashioned" flour. But while

"old fashioned" whole wheat flour includes the entire wheat kernel with its germ and bran (rich in vitamin E, niacin, thiamin, other nutrients and fiber), refined white flour contains only the starchy part of the kernel (starch and protein).

After refining became standard procedure for bread, people in the United States began to suffer from deficiencies of the nutrients iron, thiamin, riboflavin and niacin, which they had formerly received from whole-grain bread. To correct this situation, the Enrichment Act of 1942 requires that iron, thiamin, niacin and riboflavin be returned to refined products. This doesn't make a single slice of bread "rich" in these nutrients, but several slices of enriched bread provide significantly more of them than comparable amounts of bread made from unenriched refined flour.

Enrichment of grain products restores only four of the lost nutrients, however. Today, there is increasing evidence that whole-grain products should be used in order to restore trace minerals and fiber to our diet. Whole-grain items contribute significantly more magnesium, zinc, folacin and vitamin B₆ than enriched bread and cereals—and these are all necessary nutrients.

How can foods be stored and prepared at home to minimize vitamin losses? Vitamin loss in home cooking at home can be 100 percent, and it is not unusual for losses to be in the 60 to 75 percent range. In contrast, vitamin losses seldom exceed 25 percent in modern commercial processing. Thus, while the kinds of foods we buy certainly make a difference, what is done to them in the kitchen is also important.

Many enzymes work best at the temperatures at which the plants grow, normally about 70°F (25°C), which is also the room temperature in most homes.

After a fruit or vegetable has been picked, vitamin production largely stops, but degradation continues. Chilling a fruit or vegetable slows down degradation. To maximize and protect vitamin content, fruits and vegetables ideally should be vine-ripened, chilled immediately after picking, and kept cold until eaten.

Because vitamin C is an acid and an antioxidant, it is most stable in an acid solution, away from air. As long as the skin of citrus fruits or tomatoes is uncut, or the can of fruit juice is unopened, this vitamin is protected. Cut vegetables or fruits and open containers of juice should be covered tightly and refrigerated.

How should vegetables be prepared to minimize nutrient losses? Water-soluble vitamins and minerals readily dissolve into the water in which vegetables are washed or boiled. If this water is discarded, the nutrients go down the drain with it. Three things can be done to minimize losses: 1) wash the vegetables before cutting them; 2) steam or boil them in a small amount of water; and 3) avoid high temperatures and long cooking times.

How important is it to minimize nutrient losses during home preparation of foods? Vitamin losses under reasonable conditions are not catastrophic. It certainly isn't necessary to fret or worry over every little episode that might cause small nutrient losses. Eating a wide variety of foods daily, including some uncooked fruits and vegetables, ensures an adequate supply of nutrients.

Dr. Whitney is president of The Nutrition Company, Tallahassee, Florida, a professional group which develops educational materials and presents workshops on nutrition and health topics. She is also co-author of *Understanding Nutrition*, the leading college textbook of basic nutrition. Ms. DeBruyne is an associate of The Nutrition Company.

MORE TROUBLE FOR GENERAL NUTRITION

In September 1984, the United States Postal Service filed 13 civil complaints charging General Nutrition Corporation (GNC) with conducting schemes for obtaining money through the mail by means of false representations in advertisements.

The products involved were: *Risk Modifier*, a nutrient mixture claimed to decrease cancer risk; *Life Expander Choline Chloride*, claimed to improve memory power; *Mental Acuity Formula*, a nutrient mixture supposedly capable of preventing or retarding memory loss due to aging; *Life Expander Fat Fighter*, containing DHEA, claimed to cause weight loss without dietary modification; *Challenge Maximum Body Builder*, a nutrient mixture claimed to have special muscle-building properties; *L-Glutamine* tablets, claimed to "keep you mentally and emotionally in balance"; *Lipotropic Fat Fighter Tablets*, a nutrient mixture which supposedly can reduce body fat; *Spirulina*, which supposedly will "turn off your brain's appetite control center"; the *24-Hour Diet Plan* and the *Practical Diet Plan*, both "guar-

anteed" to produce weight loss of "up to 10 pounds in two weeks"; *Life Expander Growth Hormone Releaser*, claimed to cause weight loss without dieting; *Herbal Diet Formula*, supposedly capable, by itself, of causing weight loss; and *Inches Be Gone*, a body-wrapping cream claimed to reduce any area where you want to lose inches.

After the complaints were filed, a U.S. Attorney asked the U.S. District Court in Pittsburgh to temporarily restrict sales of these products. In December, GNC signed a consent agreement promising not to advertise or sell them by mail until the case has been resolved through administrative proceedings which judge whether the products can live up to the advertised claims. But sales through the company's 1,200 stores are still permitted. This case is separate from the criminal case involving evening primrose oil, filed in November in the U.S. District Court at Buffalo, New York. [NF 1:20]. In 1983, GNC also lost a civil court case involving sales of "starch blocker" tablets.

PAU D'ARCO

Varro E. Tyler, Ph.D.

Perhaps the most popular herbal cancer "cure" that has appeared in recent times is pau d'arco tea—also known as ipe roxo or taheebo tea. This beverage is prepared from the bark of various species of *Tabebuia*, a genus of about 100 broad-leaved, mostly evergreen trees of the family Bignoniaceae, native to the West Indies and Central and South America. Referred to in Brazil as ipe or pau d'arco, these plants have an extremely hard wood that is most attractive and practically indestructible. Its resistance to decay probably attracted the attention of the natives to the medicinal potential of the species.

Popular reports state that Indian tribal doctors in Brazil brew a tea from the inner bark of *Tabebuia avellanedae* or *Tabebuia altissima*, known respectively as lapacho colorado and lapacho morado, which is used to treat cancer as well as ulcers, diabetes and rheumatism. Proponents also claim that pau d'arco is "a powerful tonic and blood builder" and is effective against rheumatism, cystitis, prostatitis, bronchitis, gastritis, ulcers, liver ailments, asthma, gonorrhea, ringworm, and even hernias. The drug is claimed to have been popular in the old Inca Empire, long before the Spanish invaded the New World. *T. avellanedae* is native to the warmer parts of South America, but *T. altissima* supposedly grows high in the Andes Mountains where "not even the worst winter storms can blow it down."

Such popular reporting leaves much to be desired. There is no plant with the scientific name *Tabebuia altissima*; further, no species of *Tabebuia* grows high in the Andes. This remote habitat was apparently the creation of some advertising copywriter to make the drug sound more exotic. While *Tabebuia avellanedae* is a name found in the literature, the correct botanical designation of the species is *Tabebuia impetiginosa* (Mart.) Standl.

Complicating the matter of origin even further is the fact that some of the pau d'arco herbal teas marketed in this country do not derive from the *Tabebuia* species at all, even though they are labeled as lapacho

colorado or lapacho morado. Instead, they are stated to represent the bark of *Tecoma curialis* Solhanha da Gama, another closely related member of the same plant family. This probably makes little difference because the useful constituents and therapeutic activities, if any, are undoubtedly similar. It nevertheless leaves the botanical source of pau d'arco products unclear. The outstanding American botanical authority on this group of plants, Dr. A. H. Gentry, speculates that probably all of the bark in question is being obtained from some lowland *Tabebuia* species.

Because of their commercial significance in the construction industry, *Tabebuia* woods have been examined in detail. In addition to such therapeutically uninteresting constituents as volatile oils, resins, bitter principles, and the like, they contain from 2 to 7 percent of a naphthoquinone derivative known as lapachol. Although few detailed studies of the chemical constituents of *Tabebuia* barks have been conducted, it is reasonable to assume that most of these barks contain lapachol as their principal active ingredient.

Lapachol does possess some anticancer properties. In 1968 it was shown to have significant activity against Walker 256 carcinosarcoma, particularly when administered orally to animals in which this tumor had been implanted. In later studies, lapachol was found to be active against other kinds of animal cancers, including Yoshida sarcoma and Murphy-Sturm lymphosarcoma. In trials with human cancer patients, however, as soon as effective plasma levels were attained, undesirable side effects were severe enough to require that the drug be stopped. These included moderate to severe nausea, vomiting, anemia and a tendency to bleed. Animal and other laboratory studies have demonstrated that lapachol also possesses antibiotic, antimalarial and antischistosomal properties, but scientific studies have not been done in humans because of the problem of toxicity.

Pau d'arco is marketed in the United States as a tea or "dietary supplement" with no therapeutic claims made on product labels. Its lack of proven effectiveness, its potential toxicity, and its relatively high cost (about \$12 to \$50 per package) all render its use both unwise and extravagant.

GOVERNMENT ANTIQUACKERY ACTIVITIES MORE VISIBLE

Stephen Barrett, M.D.

In November 1983, Congress passed the Mail Order Consumer Protection Amendments of 1983 (Public Law 98-186) to give postal authorities greater power to stop mail-order schemes. The new law enables postal inspectors to investigate faster by going to an advertiser's place of business to purchase the product instead of having to gather evidence through the mails. Cease-and-desist orders to stop false representations can be obtained through administrative procedures. If such orders are violated, civil penalties can be sought in federal court for up to \$10,000 per day.

In December 1983, the FDA announced a 1-year pilot project directed against selected medical devices and other health care products for which deceptive or fraudulent claims are made. Call "Tipped Off or Ripped Off," its goal is to warn consumers not to waste money on such products. The program is restricted to products that pose no direct health risk; those which are inherently dangerous will be handled through traditional FDA mechanisms. When a questionable product is detected, promoters will be told that if steps are not taken within 30 days to comply with the law, the FDA will initiate a nationwide information campaign to inform consumers of false and misleading labeling, unsubstantiated claims, or other law violations. The agency's first action under the program was taken in December 1984 against three companies which had ignored FDA requests to stop misrepresenting that waist wraps, vibrating belts or sauna suits are effective for weight reduction or spot reduction.

In May 1984, the FDA and the Council of Better Business Bureaus sent information packets to the advertising managers of 9,500 newspapers and magazines, asking them to check ad copy more carefully before accepting it for publication. Citing common characteristics of misleading health ads, the agencies offered to evaluate questionable claims. In November, a similar mailing was sent to the sales managers of 10,000 television and radio stations.

On May 4th, an FDA Field Management Directive was issued "to create a mechanism that will identify and

generate a limited number of legal actions against health fraud not associated with direct health hazard." Health fraud products are defined as "either generally harmless and ineffective products to which people with serious disease conditions may turn instead of seeking or continuing proper medical treatment, or harmless or worthless articles promoted to improve general health, well-being, or appearance." The memo directs each region/district office "to nominate as candidate(s) for enforcement action the firm and/or products they believe represent the most significant health frauds for agency action." If the cases are not approved for action by the FDA center to which they are submitted, the agency's Compliance Policy Council is to review them and make a final decision.

On September 21st, Commissioner Frank E. Young, M.D., Ph.D., approved the creation of a 6-person Drug Health Fraud Compliance Branch (DHFCB). This unit, headed by Richard Chastonay, will be responsible for coordinating the review of actions recommended by the FDA field offices. It is setting up a new surveillance system and may also initiate and coordinate investigations.

At his first major conference on October 9th, Commissioner Young promised that antiquackery activities would receive high agency priority. The conference was called to announce "a massive public education campaign . . . spearheaded by the FDA and the Pharmaceutical Advertising Council." However, the campaign has not yet been designed. Some 4,500 advertising agencies and 1,000 health care companies are being invited to enter a competition to design actual messages. The campaign is to be financed through a \$55,000 grant from the FDA plus \$105,000 from pharmaceutical and health care companies. Consultants who reviewed the grant proposal have warned that some of the major contributors (Hoffmann-La Roche, Inc., Lederle Laboratories, and A.H. Robins) have engaged in misleading advertising of vitamin products. But agency officials have promised to retain tight control over what is released to the public.

Three Congressional subcommittees have shown considerable interest in the issue of government action against quackery. In May 1984, the House Select Committee on Aging's Subcommittee on Health and Long-Term Care (Claude Pepper, D-FL, chairman) issued a lengthy report containing sharp criticism of the FDA for not enforcing the criminal laws against unapproved new drugs [NF 1:1-2, 1:21]. In July, Congressman Pepper introduced three bills designed to increase public protection against health frauds. One would increase criminal penalties against "those who willfully sell or offer for sale drugs, devices, or medical treatment knowing that it is unsafe or ineffective or unproven for safety or efficacy." Another would establish a Strike Force on Health Quackery to coordinate the efforts of the Department of Justice, the FDA, the FTC and the U.S. Postal Service to curb the sale and promotion of fraudulent health products. The third bill would create within the National Library of Medicine a clearinghouse "to serve as an information center to provide a data base for consumers on the efficacy, comparative cost and possible side effects of drugs, medical devices, and medical treatment procedures, including [those] which have not been proven safe and effective."

In October, the Senate Commerce Committee's Consumer Subcommittee (Robert Packwood, R-OR, chairman), which has oversight jurisdiction over the Federal Trade Commission, held a public hearing as part of an investigation to determine whether that agency is doing enough to combat health frauds.

In November, the House Government Operations Subcommittee on Intergovernmental Relations (Ted Weiss, D-NY, chairman) announced that more than 5,000 prescription drugs are being unlawfully marketed without FDA approval in addition to thousands of unapproved nonprescription products (food supplements).

In November, criminal prosecution was begun against General Nutrition, Inc., for marketing evening primrose oil with claims that it is effective against arthritis, high blood pressure, multiple sclerosis and other ailments [see NF 1:20]. This action is unusual because only one criminal prosecution for food supplement misbranding was initiated by the agency between 1963 and 1983. *Health Foods Business* quotes an FDA spokesman as saying that the reason for criminal rather than civil action against General Nutrition was to raise the stakes, since in the past, GNC had established a pattern of behavior that indicated they would not change their way of doing business. "With starch blockers," said the unnamed FDA official, "we went after the product. Here we are trying to send a message to the entire health foods community that the promotion of health foods for therapeutic purposes by off-label claims is illegal and must stop. We believe that by winning this case we will change the way the entire industry does business."

This, of course, is exactly the policy advocated in the petition of FDA official Paul Sage and by the editors of *Nutrition Forum* [see NF 1:1-2]. Whether FDA policy is actually changing remains to be seen. The decision to

prosecute General Nutrition was actually made more than a year ago; and so far as we know, FDA headquarters has made no policy decision to permit additional criminal prosecutions. Moreover, the Commissioner has not responded to Mr. Sage's petition within the 180-day period required by FDA regulations.

On January 11, 1985, the FDA sent a mailing to radio talk show producers suggesting how to identify quacks so they have less chance of being selected as guests.

On January 15th, the agency proposed to remove from the market all lotions, creams and other topical nonprescription products claiming to grow hair or prevent baldness. This action was based on review of an expert advisory panel's recommendation that no such nonprescription product is effective. Public comments on this proposal, which will be accepted until May 15th, should be sent to the Dockets Management Branch, FDA, 5600 Fishers Lane, Rockville, MD 20857. *Nutrition Forum* has suggested that the ban be extended to food supplement products claimed to provide special nourishment to the hair.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 20 books including *Vitamins and "Health" Foods: The Great American Hustle*. In 1984, he received an FDA Commissioner's Special Citation Award for Public Service in combatting nutrition quackery.

QUESTION BOX

Q. Several vitamin manufacturers advertise that strenuous physical activity increases the need for vitamins and minerals, and therefore that people who engage in vigorous exercise or athletics should take supplements. Is there any truth to these claims?

A. Strenuous exercise increases the need for calories, water and a few nutrients. However, such increased nutrient needs are unlikely to rise above RDA amounts consumed by persons eating a balanced diet. Even if more than RDA amounts were needed, they would be supplied by the increases in food intake normally associated with exercising. The belief that extra vitamins are useful to athletes is also tied to the misconception that extra vitamins provide extra energy.

Q. Is palm oil a polyunsaturated fat?

A. No. Palm oil, a common oil in processed foods, is high in saturated fats. About 52% of its fatty acids are saturated, 39% are monounsaturated, and 9% are polyunsaturated. These proportions are similar to those of coconut oil, another oil used extensively by the food industry. Most other vegetable oils are highest either in monounsaturated fatty acids (e.g., olive oil) or polyunsaturated fatty acids (e.g., soybean, corn, and sunflower oils).

DIET AND BEHAVIOR: A STATE-OF-THE-ART REPORT

Kathleen A. Meister, M.S.

Many food faddists and members of the general public espouse the idea that food affects behavior. However, this concept has not been popular with the scientific community—and for good reason. Although anecdotal links between diet and behavior have been reported for thousands of years, the first scientific evidence for such a connection was not developed until 15 years ago.

The extent to which this field has grown since that time was clearly indicated by the symposium on "Diet and Behavior: A Multidisciplinary Evaluation," held November 27-29, 1984, in Arlington, Virginia. Those who follow this subject closely may have been disappointed because little new information was presented. The event was significant, however, because of its size, its distinguished sponsorship, and the tone of the presentations.

Few scientists would have imagined 15 years ago that the subject of diet and behavior would ever warrant a symposium with 37 speakers and 300 attendees, held under the joint auspices of the American Medical Association, the International Life Sciences Institute, and The Nutrition Foundation, Inc. But despite the substantial progress that a conference of this magnitude indicates, the overall theme was one of caution. Throughout the meeting, speaker after speaker warned against overgeneralization of experimental results, emphasized the distinction between anecdotal information and rigorous scientific studies, called for improvements in methodology, and urged that public policy not be based on unsubstantiated hypotheses or preliminary data.

Richard J. Wurtman, M.D., Professor of Neuroendocrine Regulation at the Massachusetts Institute of Technology and one of the pioneers in the study of diet and behavior, noted that, "It is now an established fact that diet can influence brain function. But this does not legitimize all of the anecdotes about how diet affects behavior."

Robert L. Sprague, Ph.D., Director of the Institute for Child Behavior and Development at the University of Illinois said that, "Testimonials may be the best way of influencing people, but they are the worst way to get information."

G. Harvey Anderson, Ph.D., Professor and Chairman of the Department of Nutrition Sciences at the University of Toronto, warned that, "It is important to be critical of scientific claims regarding the dietary component of behavior. If you find, for example, that dietary intake is associated with a certain behavior, it may well be that the behavior—or the circumstances that evoked the behavior—is actually the cause of the dietary intake. . . Reporters—and scientists—should be cautious about disturbing the public with messages about diet and behavior before the data are reasonably evaluated."

Alfred E. Harper, Ph.D., Professor of Nutritional Sciences and Biochemistry, University of Wisconsin said that, "Despite observations that certain nutrients can alter the concentrations of neurotransmitters in the brain, evidence supporting claims of associations between diet and behavior is weak. . . The ability to measure behavioral changes accurately and quantitatively is limited; also, it is extremely difficult to insure that the many factors that can influence behavior are effectively controlled. Nutritional control can be accomplished reasonably well in animal experiments, but comparable control is rarely possible in human experiments."

Robin B. Kanarek, Ph.D., Associate Professor of Psychology and Adjunct Associate Professor of Nutrition, Tufts University, said that, "Caution must be exercised in interpreting the results of experimental studies examining the relationship between diet and behavior. . . Proper experimental design, which includes such factors as double-blinding, placebo controls, matching of subjects and controls, and appropriate use of statistics, is crucial."

The data presented at the symposium amply justified these calls for caution. Much of the research in this field does not attempt to link dietary factors directly with human behavior. Rather, it is concerned with the impact of dietary factors on neurotransmitters—chemicals involved in brain function which are known to affect behavior. Much research has been done on the effects of psychopharmacologic drugs on these chemicals. But even with these studies where the tremendous difficulties involved in measuring behavior are avoided, few results can be generalized from the laboratory to

EDITORIAL BOARD

EDITOR: Stephen Barrett, M.D. **ASSOCIATE EDITORS:** Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; Manfred Kroger, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Linda K. DeBruyne, M.S., R.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Suzanne Pelican, M.S., R.D.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.

real-life situations. Information presented at the symposium showed that the impact of dietary factors on neurotransmitters and behavior can vary in different species, in acute vs. chronic situations, at different times of day, in people of different ages, and for slightly different dietary components (e.g. proteins from different sources).

Even the well-known model linking the consumption of carbohydrates vs. protein with a chain of biochemical events that leads to an increase or decrease in the level of the neurotransmitter serotonin in the brain (a model so well-established that a slide outlining it was shown by five different symposium speakers) was questioned. John D. Fernstrom, Ph.D., Associate Professor of Psychiatry and Pharmacology at the University of Pittsburgh, who originated the model in collaboration with Dr. Wurtman more than ten years ago, presented data indicating that the model does not hold up under all circumstances. In his experiments, the biochemical changes known to occur when a single dose of carbohydrate or protein is fed to an experimental animal after an overnight fast did not take place in more life-like circumstances in which diets varying in protein and carbohydrate content were fed to test animals over a longer period of time.

The difference between popular belief and scientific fact was illustrated most dramatically by the several speakers who commented on the impact of sugar on hyperactive behavior in children. Although many parents claim that sugar consumption has drastic negative effects on their children's behavior, no evidence for this Jekyll/Hyde syndrome has been found in double-blind studies involving more than 100 children. The Wurtman/Fernstrom model, incidentally, predicts that sugar or any other carbohydrate would decrease rather than increase activity.

Many studies of hyperactive children have used aspartame-sweetened foods or beverages as placebo controls and have included assessments of behavior in baseline periods in which no sweetener was consumed. No evidence presented at the symposium supported the contention that aspartame or sucrose (table sugar) has adverse effects on the behavior of children.

The conception that dietary factors have profound impact on aggressive and criminal behavior also came under severe attack. Both Craig T. Love, Ph.D., Chief of Research, Federal Correctional Institute, Butner, North Carolina and Gregory E. Gray, M.D., Ph.D., Postdoctoral Associate, Department of Psychiatry and the Behavioral Sciences, University of Southern California Medical Center, severely criticized most of the studies of diet and behavior in criminal populations that have been conducted to date.

Dr. Love noted that the research in this field was so bad that after reviewing and assessing the scientific literature, his institution gave up the idea of participating in a project. Many of the methodological and interpretation problems in these studies "arise from the naivete of the researcher about corrections, nutrition,

social science research methodology, or a combination thereof," Love said. However, both Love and Hardy Rauch, Project Director, American Correctional Association, indicated that correctional facilities would be likely to cooperate in well-designed studies of diet and behavior.

Dr. Gray noted that advocates of a link between diet and crime do not agree upon a single mechanism by which diet influences behavior—reactive hypoglycemia, food allergies, vitamin and mineral deficiencies and toxicities, and other adverse reactions to food additives, sugar and milk have all been blamed. He then listed the following flaws in the existing studies of diet and criminal behavior: use of unreliable diagnostic techniques, failure to study comparable control groups, failure to use double blind methodology, failure to present quantitative dietary data, improper statistical analysis, and selective presentation of experimental results.

"Because dietary intervention programs are being implemented in correctional facilities despite . . . lack of scientific evidence of their effectiveness," warned Dr. Gray, "there is increasing concern that food faddism is becoming the official policy of correctional facilities. Of particular concern are the social implications of theories of diet and crime . . . such theories imply that diet, rather than the individual, is responsible for aberrant behavior, a concept that has already made its way into the courtroom. In addition, dietary intervention programs may at times divert resources away from more effective treatment programs. Finally, poorly designed dietary changes may lead to nutritional deficiencies, and overzealous vitamin and mineral supplementation may lead to toxicity."

Some members of the audience objected to the fact that researchers who conducted the heavily criticized studies of diet and crime were not included among the speakers at the symposium. It is easy to understand, however, why they were not invited. The tightly scheduled program was already crowded with speakers who had done valid research, and the organizers of the symposium were undoubtedly concerned about the possibility of conferring credibility on truly appalling research by allowing the people who had conducted it to speak at such a prestigious conference. In any event, the symposium attendees were not deprived of information about these studies. The researcher who has conducted most of them, Stephen J. Schoenthaler, Ph.D., Coordinator, Criminal Justice at California State University at Stanislaus, participated

actively in the question-and-answer period, and copies of an issue of the *International Journal of Biosocial Research* which featured five of his studies were made available at the meeting.

Although criticism of poor research and calls for scientific rigor were prominent features of the diet and behavior conference, several questionable studies were presented there, too. Perhaps the most seriously flawed were those of Matti Virkkunen, M.D., Senior Lecturer, Psychiatric Clinic, Helsinki University Central Hospital in Finland. Dr. Virkkunen presented data indicating that glucose metabolism and insulin secretion in two groups of habitually violent offenders with different patterns of violence differed from that of normal controls, and to a lesser extent, from each other. He reported that the offenders had committed their crimes under the influence of alcohol and that most of them had had lengthy drinking binges during which they did not eat. But he did not take the subjects' alcoholism into account in interpreting his data or compare them to a control group of nonviolent alcoholics.

Simon N. Young, Ph.D., Associate Professor in the Department of Psychiatry at McGill University, also appeared to ignore an important factor in interpreting the data he presented. He reported that the amino acid tryptophan, a precursor of the neurotransmitter serotonin, did not affect aggression in a group of normal men. In a study of pathologically aggressive schizophrenics, however, large doses of this amino acid appeared to decrease aggressive behavior. Young concluded that "the dietary component tryptophan may be useful in modulating aggressive behavior when other factors are present in the brain to make a patient pathologically aggressive." Unfortunately, until a member of the audience raised the issue, he did not mention an important confounding variable—11 of the 12 schizophrenic subjects were taking antipsychotic medication.

Two symposium speakers reported studies in which measurable changes in human mood and behavior appeared to result from dietary manipulations. But they neglected to point out that neither of these studies could be carried out in a double-blind fashion. Angus Craig, Ph.D., M.R.C., of the University of Sussex, England, reported on several experiments in which people's performance on tests of sustained attention varied with whether they ate lunch or were deprived of food, and with the size of the lunch consumed. Bonnie Spring, Ph.D., Professor of Psychology at Texas Tech University, reported that subjects in two studies showed subtle differences in tests of performance after eating a carbohydrate meal (sherbet or pita bread) as opposed to a protein meal (turkey breast).

Not all results in the field of diet and behavior are tentative, however. David E. Barrett, Ph.D., Assistant Professor of Pediatrics, Children's Hospital Medical Center, Boston, noted that chronic undernutrition in early childhood can lead to reduced social involvement, poor attention and persistence, and decreased affect. And Ernest L. Hartmann, M.D., Professor of Psychiatry at

Tufts University, reported that it has been solidly established in placebo-controlled studies that administration of the amino acid tryptophan in pure form decreases the amount of time between going to bed and falling asleep for individuals who customarily have difficulty falling asleep.

Several other speakers reported other effects of tryptophan on mood and behavior. There was some controversy, however, about the use of this amino acid in the treatment of human insomnia and other problems. Questioners from the audience suggested that tryptophan, when administered in amounts greater than normally found in the diet, should be regarded as a drug, and that its safety should be proven. Studies to establish that tryptophan is safe as a drug have never been performed. (My own belief is that pure amino acids should be regarded as drugs no matter what the dose, and that their safety should be proven rather than assumed, since pure amino acids do not occur in nature. But this point was not raised at the symposium.)

A psychiatrist in the audience said that he had observed side effects when using tryptophan in his clinical practice. Other people noted that placebos also elicit side effects. Dr. Wurtman observed, however, that physicians (or laypersons) who recommend the use of tryptophan are on shaky legal ground since this substance is not a legal drug in the United States. Other scientists participating in the symposium appeared to be less concerned about the unproven safety of isolated amino acids. For instance, Michael W. Yogman, M.D., Assistant Professor of Pediatrics at Harvard Medical School, reported on studies in which various amounts of tryptophan and valine were administered to newborn infants.

Perhaps these criticisms are excessively severe. The field of diet and behavior is very young, and study of this subject is unusually difficult because it requires expertise in both nutrition and psychometrics and in many cases, in neurochemistry as well. Good research in this field involves cooperation by scientists from several disciplines. One purpose of the symposium was to improve communication among the relevant disciplines. The symposium's participants deserve commendation for this and for the effort most of them made to avoid overgeneralizing their findings.

Mrs. Meister is a research associate with the American Council on Science and Health.

Food Safety:
What are the Real Issues?

QUESTIONABLE ADVERTISING DISCONTINUED

Since 1971, the National Advertising Division (NAD) of the National Council of Better Business Bureaus has maintained an active program to investigate and adjudicate claims that advertising is misleading. Most cases involving nutrition are resolved with a promise that the advertising being questioned has been discontinued or will be modified. For example:

- Magazine ads headed "Improve stamina and endurance with Viobin Wheat Germ Oil" have included the claims: "More than 18 years of university research show positive evidence that Viobin Wheat Germ Oil can help athletes increase stamina and endurance plus help them overcome fatigue more quickly"; and, "One teaspoon of Viobin Wheat Germ Oil contains all the raw, unrefined wheat germ oil from 5 pounds of whole wheat . . . one of the world's richest natural sources of vitamin E and octacosanol. Studies indicate that octacosanol has a beneficial effect on oxygen intake, net oxygen debt and total body reaction time." According to the NAD, these claims were recently discontinued following a request by NAD for substantiation. The December 17, 1984 NAD Case Report states that "the advertiser . . . felt the advertising in question could be scientifically supported but in a spirit of cooperation had terminated the claims." [Viobin Corporation has been a subsidiary of the A.H. Robins Company since 1973. A few days before the acquisition, the Pennsylvania Department of Health embargoed a quantity of Viobin Wheat Germ Oil until the manufacturer promised to stop advertising that the product could "relieve heart stress."]

- The Purdue-Frederick Company has discontinued magazine advertising which stated that ". . . 4 out of 5 gastroenterologists surveyed recommend Fibermed. And nearly half of these doctors were taking it them-

selves" and that, "Two tasty Fibermed supplements provide more natural dietary fiber than even a serving of the so-called high fiber cereal . . . and with less salt, too." According to the company, the statistical claims were based on the first 364 respondents of 439 completed questionnaires received from a mailing to 3,300 office-based gastroenterologists. NAD had questioned: 1) whether the returns were representative of the total population surveyed; 2) the assumption that doctors who requested complimentary samples for "personal use" were actually taking Fibermed themselves; and 3) whether the doctors' recommendations had been influenced by the recent marketing efforts. Based on the labels of two cereals, NAD agreed that Fibermed provided somewhat more fiber than either one, but questioned whether it contained less salt. The advertiser responded that future advertising incorporating similar claims would be modified to meet NAD's concerns.

- In response to an NAD inquiry, Gold Medal Hair Products admitted that recent advertising of its Head Strong Vitamins had overstated the link between the use of dietary supplements and the health of hair. The company's ads had claimed that, "Your hair may be starving for proper vitamins it needs to grow . . . stronger, get thicker and shining" and said that its supplements would: "Stimulate hair growth. Diminish hair loss. Make your hair stronger. Add to your own nourishment."

NAD is well equipped to handle nutrition issues. Its director, Ronald H. Smithies, Ph.D., J.D., is an attorney with a doctoral degree in biochemistry. The investigative staff also includes a registered dietitian. The agency's address is 845 Third Avenue, New York, NY 10022.

STUDY FINDS HYPERACTIVITY UNRELATED TO FOOD ALLERGY

Using exclusion diets and double-blind provocative tests, British investigators were unable to find any evidence that food hypersensitivity played a role in the mood disturbances or other psychological symptoms of 23 consecutive patients seeking treatment at the allergy clinic of the University Hospital of South Manchester. Nineteen of these patients, who believed that their mental symptoms were related to food hypersensitivity, turned out to have no allergies at all—and their symptoms closely resembled a comparison group of 20 consecutive patients referred to the hospital's psychiatric clinic. The other 4 patients had genuine food allergies as well as psychological symptoms but had not considered them related to each other. In these patients,

tests showed that ingestion of the offending foods did not trigger the psychological symptoms.

The outcome of treatment appeared to depend on the degree of belief that symptoms had an allergic basis. The majority of patients in whom food allergy was excluded accepted the physician's findings and improved with supportive counseling. However, some patients insisted that they must have hidden food allergies and engaged in dangerous dietary restriction which they hoped would enable them to identify foods they needed to evade. The researchers believe that this study casts serious doubt on many of the claims of those attempting to link food allergy and mental symptoms. [*British Journal of Psychiatry* 145:121-126, Aug. 1984]

Briefs

Nutrition councils. More than 40 professionals met recently in Hershey, Pennsylvania to reactivate the Pennsylvania Nutrition Council, dormant since the early 1970s. The meeting was organized by Helen Guthrie, Ph.D., Professor of Nutrition at Pennsylvania State University. One speaker noted that nutrition councils exist in 42 states.

Food bill. The Food Institute reports that total food sales in the United States during the first six months of 1984 were \$133.8 billion.

Public entitled to price information. Smitty's Super Markets Inc., of Springfield, Mo., which had been charged with conspiring with other grocers to interfere with price surveys, has signed a proposed consent order from the FTC. Under the agreement, Smitty's may not: 1) take or threaten action to force price checkers to purchase surveyed products; 2) deny checkers the same access as is given to customers; or 3) coerce any checker, publisher or broadcaster into refraining from price reporting. A similar agreement was signed in October 1983 by Dillon Companies Inc. A third case has not yet been adjudicated.

Laetrile ineffective against pain. In July 1980, in response to political pressure, a clinical test of laetrile and "metabolic therapy" was begun at the Mayo Clinic and three other major cancer centers. The patients involved had cancers for which no standard treatment was known, but the great majority were in good general condition. The study found that no patient was cured or stabilized by laetrile treatment. By the end of the first year, almost all of the core group of 156 patients had died, a result expected with no treatment at all. A recently completed review of the records found that 16 (19%) of 83 patients with pretreatment pain reported some degree of pain relief. However, since other studies have shown that 17-23% of patients with advanced cancer experience pain relief in response to placebos, it is clear that laetrile exerts no pharmacological effect against pain.

Vitamin C complication. Intravenous administration of 2.5 grams of vitamin C is reported to have caused complete kidney failure in a 70-year-old man with impaired kidney function [*Journal of the American Medical Association* 252:1684, Oct. 5, 1984]. Biopsy in the case showed numerous calcium oxalate crystals clogging the kidney tubules. (Oxalate is a metabolite of vitamin C.) The patient, who was being prepared for "chelation therapy," must now use an artificial kidney for the rest of his life. A lawsuit was filed, but the chelation doctor—who carried no malpractice insurance—closed his office in Clearwater, Florida, and may have fled the state.

Just desserts! Newspapers which accept advertising for "miraculous" health products sold by mail sometimes become the victims of their own greed. Apparently it is not unusual for the U.S. Postal Service to receive complaints from newspapers which extended credit for the ads but did not receive payment.

Back door to laetrile reopened. Despite an adverse ruling by the U.S. Supreme Court five years ago, 81-year-old federal judge Luther Bohanon is still permitting individuals to import "personal supplies" of laetrile provided they obtain a physician's affidavit that they have had cancer and understand that the FDA disapproves of the drug's use. Bohanon's policy is a response to a class action suit brought against the FDA in 1975 by Glenn Rutherford, a Kansas seed salesman who claims that laetrile cured him of cancer and is keeping him alive. In March 1984, Bohanon finally acceded to a higher court order to dissolve the injunction supporting the affidavit system. But in May he restored the injunction in response to a motion by Rutherford's attorney to file an apparently groundless amended complaint. Bohanon, who sympathizes completely with the plaintiffs, will probably use any excuse he can to defy the higher courts until the case is reassigned to another judge. An estimated 25,000 patients have used the affidavit system.

Latest antifluoridation ploy. "Keeping up with the times," antifluoridation propagandists have been suggesting that fluoridation is a causative factor in AIDS. In September 1984, apparently inspired by a visit from the antifluoridation guru, Dr. John Yiamouyiannis [See *Nutrition Forum* 1:7], San Francisco Board of Supervisors' President Wendy Nelder called for an investigation to see whether fluoridation is responsible for the high incidence of AIDS among homosexuals in her city. Supervisor Harry Britt replied that the city's gays do not take Ms. Nelder's views seriously. Mayor Dianne Feinstein denounced these views as "off the wall." The *San Francisco Chronicle* called Nelder's request "an exercise in needless and unfounded fearmongering." And an astute *Chronicle* reader pointed out that if fluoridation (begun in SF in 1952) were a causative factor in AIDS, it would be rampant among middle-aged native San Franciscans and rare among gay immigrants to the city—not vice versa.

Sears "health food" concessions to close. Vitality Unlimited, which operated "health food" concessions in more than 100 Sears stores, has announced that it lost \$2.7 million during the first six months of 1984 and is closing all its Sears units.

Twin studies. The International Twin Study, USC School of Medicine, Los Angeles, CA 90033, is interested in learning about cases of cancer that have occurred in (one or both) twins. Participants will merely be asked certain questions. Further information can be obtained by writing to Dr. Thomas Mack at the above address or by calling 1-800-421-9631 toll-free (or 213-224-7420 collect from California).

Pills for everyone? Catalogs collected by the Lehigh Valley Committee Against Health Fraud list more than 3,000 vitamin, vitamin/mineral and other "food supplement" preparations marketed by some 100 companies aligned with the health food industry.

Risks of zinc supplementation. Adverse findings were demonstrated in healthy male volunteers who ingested 150 mg of elemental zinc as zinc sulfate twice daily for 6 weeks. This amount is 10 times the Recommended Dietary Allowance (RDA). Although the men experienced no symptoms, blood tests revealed decreased immune system responses as well as unfavorable changes in lipoprotein ratios associated with an increased risk of heart disease. [*Journal of the American Medical Association* 252:1443-1446, Sept. 21, 1984.]

Free reprints. Single copies of "Food Preservatives: A Fresh Report" and "Bee Pollen As A Health Food" may be obtained from the Food and Drug Administration, HFE-88, 5600 Fishers Lane, Rockville, MD 20857. Multiple copies are available from the FDA, HFW-40, at the same address, and from the agency's consumer affairs offices in 30 cities.

Starch blocker update. On September 11th, the U.S. Court of Appeals affirmed a U.S. District Court decision that starch blockers are illegal new drugs within the meaning of the federal Food, Drug and Cosmetic Act. The court also upheld the District Court's permanent injunction against the manufacture, sale and distribution of these products. The appeal had been filed by General Nutrition Corporation and two other companies. According to the FDA, starch blockers still available in some health food stores [see NF 1:2] are leftover stock or are not under federal jurisdiction because they were manufactured within the states in which they are being sold.

Diet, Nutrition and Cancer. The controversial 496-page report of the National Academy of Sciences can be ordered for \$19.95 from the National Academy Press, 2101 Constitution Avenue, N.W., Washington, DC 20418.

Diarrhea caused by sorbitol. Excessive intake of sorbitol from dietetic candy is believed responsible for an outbreak of diarrhea in a small group of children in New Hampshire. Those most severely affected had consumed 16 pieces of hard candy which each contained about 3 grams of this sweetener (a sugar-alcohol). Large amounts evidently act as an osmotic laxative, causing retention of water in the intestines.

Low-calorie sweeteners. An excellent 48-page booklet on the current status of aspartame, saccharin, cyclamate and several other low-calorie sweeteners is available for \$2 from the American Council on Science and Health, 1995 Broadway, New York, NY 10023.

Fake weight-loss gadget seized. Newspaper ads for 2-toned eyeglasses called the "Vision Dieter" claimed users could control their appetites and lose weight just by wearing them two hours a day. The inventor—optometrist John A. Miller of Little Rock, Arkansas—said the glasses were developed after he observed how food companies use colors to attract shoppers to their products. He reasoned that if color could control consumers, it could also decontrol them. The glasses, which sold for \$19.95, were to be worn in the morning and afternoon—but not during meals. The FDA said that the Vision Dieters did not work as claimed and were unapproved medical devices. U.S. marshals subsequently seized 652 pairs, and a U.S. District Court ordered destruction of all but 75 which the FDA will use for education on quackery.

"Natural food" retailers form new group. In June 1984 the Natural Foods Network was launched by representatives of 12 of the nation's largest natural food retail stores. Voting membership will be limited to retailers, but others will be invited to join as associate members. The group's aims include: 1) informing members of relevant scientific, economic, legal and political developments; 2) developing testing programs to promote accurate labeling of natural foods; 3) development of computerized consumer, professional and business data bases; and 4) conducting seminars and other presentations to educate members and the general public.

"Health food" clearinghouse. Another new health food industry organization is the National Foundation for Nutritional Research. Its purposes include: 1) exploring new concepts relating to the links between diet and disease and between adequate nutrition and optimum health; 2) stimulating and funding new research; and 3) developing computerized access to "literature supporting nutritional approaches to the prevention and treatment of disease." The Foundation's directors and advisors include Jeffrey Bland, Linus Pauling, Lendon Smith, Carlton Fredericks, Beatrice Trum Hunter, Rosemary West (past-president of the National Nutritional Foods Association), and several "orthomolecular" physicians. The information service is being marketed to retailers for \$200/year, but manufacturers will undoubtedly provide additional support.

Mushroom poisoning registry. The North American Mycological Association, Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI 48109, is interested in receiving reports of mushroom poisoning, whether slight or severe.

CYTOTOXIC TESTING

Stephen Barrett, M.D.
Grace P. Monaco, J.D.

Franchised storefront clinics, laboratories, "nutrition consultants," chiropractors and a few medical doctors are promoting cytotoxic testing. Derived from cyto- (Latin for cell) and toxic (poisoning), the procedure is also called cytotoxicity testing, leukocyte antigen sensitivity testing, Bryan's test, the Metabolic Intolerance Test, or just food sensitivity testing. The conditions supposedly related to food intake and diagnosable by the test include acne, anxiety, arthritis, asthma, back pain, baldness, bedwetting, conjunctivitis, constipation, depression, diarrhea, eczema, excessive sweating, fatigue, headaches, hearing loss, hoarseness, hypertension, hyperactivity, insomnia, learning disorders, nosebleeds, obesity, rashes, sinus trouble, stomach disorders, and susceptibility to cancer.

To perform the test, about 10 cubic centimeters of a patient's blood are placed in a test tube and centrifuged to separate the white cells (leukocytes). These are mixed with plasma and sterile water and applied to a large number of microscope slides, each of which has been coated with a dried food extract like that used by allergists for skin testing. The cells are then examined under a microscope at various intervals over a 2-hour period to see whether they have changed their shape or disintegrated—supposedly signs of allergy to the particular food. A slide with the patient's cells, serum and water is used as a control. Typically, the test results are used to explain the patient's symptoms and to design a "personalized diet program" that includes vitamins and minerals—sold by those administering the test.

Literature from Bio-Metabolic Laboratories, of Los Angeles, California, says that the cytotoxic test "is rapidly becoming the common method of detection for hidden food allergies." The company charges \$255.00 to do a cytotoxic analysis of 150 foods—or \$215.00 without the initial cassette tape consultation and personalized 4-day rotation diet.

American Biologics, of San Francisco, advertises that, "Millions of Americans have unsuspected or undiagnosed sensitivities to what they eat . . . which may express themselves in many subtle ways or may contrib-

ute to or be a major cause of more serious pathological conditions." Its version of cytotoxic testing is called the Metabolic Intolerance Test (M.I.T.) Ads for the M.I.T. program state that professionals who buy it are "in effect handed a functioning business" whose entire investment can be recovered by performing as few as two tests a month. The complete system for testing responses to 200 foods sells for \$9,750, while supplies for each test under this system cost \$70.

The Ecology Laboratory, Inc., of Pasadena, California, run by chiropractor Gerard Stavish, thinks that "the testing time to examine 150-250 foods is ridiculous." This lab charges doctors \$125 for a 25-food test and warns that positive findings must be confirmed by a food challenge test before a diagnosis of allergy can properly be made. However, each test report is accompanied by an "impressive package" containing a cassette tape and rotation diet for the patient to implement. Public lectures offered by the Ecology Health Center include such topics as "How Allergies Poison Your Body" and "Basics of Food Allergy: How it makes you sick and upsets your metabolism." Literature from the Center states that "studies reveal that 62% of all patients seen in private practice have allergic-related diseases or manifestations." (In contrast, the Asthma and Allergy Foundation of America estimates that about 35 million Americans are allergic, but only 5-10% of this number show food sensitivity.)

The Beverly Hills Health Center offers testing for "over 400 foods, chemicals and additives" for \$195.

Bio-Health Centers of Huntington Beach, California, charges \$350 to test for 186 common foods and additives. One of its recent ads—headlined "DISASTER LINKED TO THE FOOD YOU EAT!"—claims that "if you currently suffer from any health difficulties, this test is worth taking." A brochure from the company suggests that cytotoxic testing can be useful in solving the problems of overweight, headaches, stomach and intestinal problems, depression, stress, confusion, sinus problems, asthma, arthritis and hypoglycemia. Bio-Health Center teams composed of a "nutritionist" and a nurse travel

around the country, holding evening meetings during which they can test about 30 people per night—for a gross intake of about \$10,000. Clients are told that after their test results arrive, they can call the lab's toll-free number as often as needed for further dietary advice. Testing can also be obtained by mailing a blood specimen to the lab.

The National Allergy Clinics, of Beverly Hills, California, has advertised in *The Wall Street Journal* that a \$30,000 investment will enable prospects to "GET RICH! Be the first in your area to open up a lucrative allergy testing center—an ALL-CASH-UP-FRONT money-maker which uses a scientific breakthrough—a blood test that charts 245 food allergies simply and efficiently."

How reliable is cytotoxic testing? The official position statement of the American Academy of Allergy and Immunology (AAAI), the nation's largest group of allergists, was published in 1981 in the *Journal of Allergy and Clinical Immunology* [67:333-338] and reaffirmed this year. It notes the following:

- One study found that white cells from allergic patients reacted no differently when exposed to substances known to produce symptoms than when exposed to substances to which the patients were not sensitive [*Journal of Allergy* 29:93, 1958].
- Another study [*JAMA* 231:728, 1974] found that cytotoxic test results did not correlate with allergic and other untoward reactions to foods and that the results were inconsistent when repeated in the same patient.
- In a double-blind controlled study, positive cytotoxic tests were frequently obtained to foods that produced no clinical symptoms and negative reactions were obtained to foods that did produce symptoms [*Journal of Allergy and Clinical Immunology* 58:471, 1976].
- Another double-blind study found the test ineffective for diagnosis of food allergy [*Annals of Allergy* 45:150, 1980].

Based on these and other data, AAAI concluded that: 1) cytotoxic testing has never been proved effective by controlled studies; 2) that controlled studies have indicated that the test is ineffective for diagnosing food or inhalant allergy; and 3) that the test should be reserved for experimental use only in well-designed trials. These conclusions have been endorsed by the American Academy of Otolaryngology-Head and Neck Surgery, the American Academy of Otolaryngic Allergy and several other prominent professional societies. Although some well-credentialed allergists use cytotoxic testing, the vast majority do not.

A few months ago, a Bio-Health Centers program was attended by Raymond G. Slavin, M.D., AAAI's immediate past-president, and his wife, Alberta, who is a consumer editor with CBS television in St. Louis. After slides were shown, a lecture was given by a young man who said he had undergone two years of special nutrition training. Among other things, he advised the assembled group that inhalant sensitivities are not important—so that someone allergic to cats would no

longer have this problem if offending foods are no longer eaten. Mrs. Slavin actually has no allergies. But her test report, which arrived three weeks later, said that she is allergic to 25 foods—including wheat, cane sugar, corn, potato, beef and milk—and should avoid all of them for an 8-week period.

The Health Care Financing Administration (HCFA), which administers Medicare, proposed in 1983 that cytotoxic testing be excluded from Medicare coverage because it "lacks an acceptable rationale based on current knowledge of allergy and immunology. While the procedure may yield reproducible results, the validity of these results has not been supported in controlled, double-blind studies and there is a lack of correlation with clinical evidence of food allergy. The test is plagued with a number of false negative and false positive results indicating that it lacks specificity and sensitivity. The test is time consuming, requires well-trained and supervised technicians, and is dependent on subjective interpretation." [48 Fed. Register 37718]

In response to HCFA's proposal, one clinic wrote to its patients to tell HCFA how they have been helped by this procedure. "Dear patient," the letter urged. "You should explain (if it is true) that your chronic illness was of months (or of years) duration for which you have sought help from doctors who did not use these techniques with repeated laboratory tests, examinations of x-rays that failed to solve your problem. The total cost of the cytotoxic food test and the provocative neutralization tests done in our office finally solving your problem was less than all the previous tests, examinations and x-rays put together. In view of your personal experience you urge that these useful techniques (cytotoxic and provocative neutralization testing for food and chemical allergies) be paid for the same as for the other diagnostic laboratory tests . . . You might conclude your letter with your belief that medical progress by reputable physicians, which actually reduces the cost of medical care for an illness, should never be opposed."

At least one recipient of the above letter thought otherwise: "Of all the medical testing that has been done to me in the last five years CYTOTOXIC blood tests were probably the worst waste of time, money and health . . . After my first series of cytotoxic tests, the technician upon my questioning actually admitted that the results were practically useless. But did that keep the doctor from ordering another series of these tests? You bet not. The second test results turned out differently than the first, making the whole regime ambiguous, and again I was told that the tests were 'not really THAT reliable.'"

Providers of cytotoxic testing often suggest that it is covered by health insurance. However, patients are required to pay in advance and may have trouble collecting from insurance companies who question the procedure. The FDA advises consumers who believe that they may have a food allergy to see a properly trained medical doctor specializing in allergy for a complete physical exam, medical history, diagnosis and proven therapy.

Many cytotoxic tests are being done illegally. About 300 food extracts prepared by licensed suppliers are approved by the FDA for allergy skin tests and allergy shots. Use of such extracts in cytotoxic testing violates federal law.

If cytotoxic testing is directed by a licensed health professional, it is under the control of state licensing authorities. If no doctor is involved, the testing is illegal but subject to control by local and state authorities as practicing medicine without a license. Clinics compounding their own allergenic extracts or obtaining them from sources within their own state are not readily subject to federal regulation.

The FDA has been investigating cytotoxic testing under the direction of its Office of Regulatory Affairs—which usually moves quite slowly. Meanwhile the agency has been trying to protect the public through press releases and an article in the October *FDA Consumer*.

But Mrs. Slavin's investigation makes it clear that advice through the media will not overcome the appeal of this simple test in our nutrition-conscious society. After broadcasting a 3-part series exposing cytotoxic testing as a fraud, she received several calls from people asking where they could get the test!

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author of *Vitamins and "Health" Foods: The Great American Hustle*.

Mrs. Monaco, a partner of White, Fine and Verville, of Washington, D.C., specializes in health law as it applies to unproven methods of medical management. She is also a founder and current president of Candlelighters Foundation for Childhood Cancer, an international peer support group for parents of children with cancer.

MORE MAIL-ORDER BUNKUM

Full-page ads in newspapers and magazines called Metabolite 2050 "the ultimate cure for fat." "Eat as much as you want and still lose weight," the ads promised, "Metabolite 2050 literally pulls & destroys excess fat from hard to reach storage sites—waist, hips, thighs and buttocks . . . and prevents the further conversion and storage of excess fat all over your body." The ads also claimed that, "Demand for this new product has been so overwhelming that this revolutionary new weight loss compound will not be available at your local pharmacy until February 15, 1985."

Metabolite 2050 is one of many products marketed by mail during the past two years by the Robertson-Taylor Company, 1110 West Sunrise Blvd., Fort Lauderdale, Florida. Others include Actavin-917 (for mental alertness), Anabolin-ATF (for weight loss), Arthrex (for arthritis), Calor-Bloc 30 (starch blocker), Cellulase-EFX ("cellulite" dissolver), Derma-Tec (wrinkle remover), Intercal-SX (for weight loss), L-2000 (aphrodisiac), Libutol 1500 (sexual stimulant), Lipogene GHX (diet aid), Medi-Tec 90 (for baldness), Mamralin-BX (bust augmentation cream), Orafirm-ACS (body shaping compound), Revitalin SL 90 (multivitamin), Synertrim No. 9 (spot reducer), Testorex-35 (for sexual dysfunction and impotence), and Tranquinol (nerve relaxer).

According to FDA and Better Business Bureau reports, Robertson-Taylor is a division of Intra-Medic

Formulations, Inc. (same address), which was incorporated in July 1981. Robertson-Taylor began operations in south Florida in November 1981, became incorporated in July 1982, and has operated mail drops under the names of W.G. Charles, Co., of Chicago, and J.F. Pharmaceuticals, of Westport, Connecticut. In November 1982, at the request of the FDA, a supply of Calor-Bloc was seized and destroyed under court order. During 1984, postal authorities secured mail-stop orders enabling them to return to the sender orders for six of the other products. The Federal Trade Commission has also been investigating the company's activities.

Most advertisers of bogus mail-order solutions to health or beauty problems are fly-by-night operators. Possibly concerned about this image, Robertson-Taylor offered the following reassurance in some of its ads:

"When ordering by mail, know who you are dealing with. The Robertson-Taylor Co. is a solid *established retail and mail-order firm you can count on*. We are members of the Fort Lauderdale Chamber of Commerce and the Prestigious Direct-Mail Marketing Association. The address you mail your check to is our *real* address—not some post office box or rented mailing address. It is the address of our order processing center, corporate offices and central retail outlet . . . The Robertson-Taylor Co. delivers exactly what we promise and we stand 100% behind our guarantee. We won't let you down."

CRIMINAL CHARGES FILED AGAINST GENERAL NUTRITION!

On November 14, 1984, a U.S. Grand Jury returned a 7-count indictment against General Nutrition, Inc., plus three of its officers and two of its retail store managers. Headquartered in Pittsburgh, the company operates more than 1200 retail stores throughout the United States and Canada, doing business under the names General Nutrition Center and GNC. The defendants are charged with conspiring to defraud the FDA and violating provisions of the Food, Drug and Cosmetic Act which require that drug products be approved by the FDA as safe and effective prior to marketing. Court papers in the case allege:

- Between 1980 and 1981, the company, its president (Gary Daum), and two vice-presidents conspired to purchase evening primrose oil from Efamol Limited in London, England and to promote and sell it under the name Gammaprim for the prevention and treatment of high blood pressure, arthritis, multiple sclerosis and other ailments.

- In 1980, one of the defendants received a letter from David Horrobin, M.D., Ph.D., suggesting that Efamol be marketed without FDA approval. Referring to its supposed beneficial effects, the letter stated, "Obviously you could not advertise Efamol for these purposes but equally obviously there are ways of getting the information across." [Health food industry publications identify Dr. Horrobin as a former professor of medicine at the University of Montreal who is now affiliated with Efamol Research Inc., of Kentville, Nova Scotia. A recent article in *Whole Foods* states that he is the person responsible for initiating and encouraging much of the research on the effects of evening primrose oil.]

- Subsequent company memos describe an elaborate promotional scheme that included newspaper articles, radio talk shows, and publications for use in General Nutrition's retail stores.

- In addition, oral claims were made by retail employees to prospective customers. FDA investigators posing as customers at various stores in western New York State were told that Gammaprim would be better for treatment of high blood pressure than the prescription drugs Nitrostat or Diuril, and that it was good for arthritis as well.

- By virtue of these various claims, Gammaprim became a drug within the meaning of the law. However, rather than submitting the product to the FDA for premarket evaluation, defendants sought to disguise it as a food supplement, thereby attempting to defraud the FDA.

General Nutrition, Inc., operates the largest chain of health food stores in the United States and sells supplements by mail through its subsidiary, Natural Sales Company. According to a recent article in *Health Foods Business*, General Nutrition, Inc., netted \$4.25 million on sales of \$95.2 million during the first three months of 1984. The company was founded by David Shakarian who opened a store named Lackzoom in Pittsburgh in 1935 and added five more stores by 1941. In 1959, the name Lackzoom was changed to General Nutrition Centers. The first 12 stores outside the Pittsburgh area were opened during 1963. Gary A. Daum began working for the company that year and became its president in 1979.

NHF SPINS OFF FOUNDATION

The National Health Federation (NHF) has set up the Foundation for Health Research (FHR) to enable its supporters to make tax-deductible contributions. FHR's purpose is to fund "research in the areas of nutrition, preventive medicine and life extension—all fields neglected by the orthodox medical-industrial, governmental axis."

NHF a membership organization, was founded in 1955 by Fred J. Hart soon after a U.S. District Court ordered him to stop distributing 13 electrical devices with false claims that they could diagnose and treat hundreds of diseases and conditions. Many other NHF leaders have been in legal difficulty for questionable health activities. Over the years, the organization has supported a broad spectrum of unorthodox and unproven treatment methods in the name of "freedom of choice." Since its primary purpose and thrust have been political, direct contributions to it have never been tax-deductible.

However, according to NHF president Maureen Salaman, "The function of the FHR is exclusively scientific and educational. It will scrupulously avoid any political activity that would void its tax deductible status. Henceforth, our two separate organizations . . . while operating independently . . . will share overhead and staff, where legally possible . . ."

This is the third time NHF has announced that tax-deductible contributions can be made toward its work. During the early 1970s, NHF simply announced that dues and contributions were tax-deductible—until the Internal Revenue Service ordered this practice stopped. During late 1970s, NHF set up its Memorial Library as a separate corporation to which donations would be tax-deductible. However, this status was revoked by the IRS following a fundraising appeal which stated that the library's #1 priority was legalization of laetrile.

Grapefruit Diet Pills

Head Start Vitamin Products, of Fort Lauderdale, Florida, has notified retailers that "massive direct response television promotion . . . which will continue through next Spring, is building a tremendous consumer demand" for the company's Grapefruit 60/"Fat Burner" Diet Plan. The pills are said to act as a "fat-burning catalyst" and to contain "pure grapefruit extract in a base of tri-calcium phosphate with citrus bio-flavonoid complex . . . all the nutritive value of half of a fresh grapefruit, yet without the expense and inconvenience of eating grapefruit three times a day." The accompanying diet is claimed to combine food groups for "synergistic metabolism within your own system, to speed weight loss." Other items marketed by this company include: Head Start (a multivitamin formula claimed to improve hair condition as well as "virtually all body cellular development"); The Cellulite Program (Cellulite Eliminator Tablets and Creme); and VitaMan—The Man's Vitamin (claimed to help restore energy and eliminate any "marginal nutrient deficiency" which may be affecting work, sports or sex performance).

Head Start products were originally marketed by Braswell, Inc., of Atlanta, Georgia, whose various subsidiaries were subjected to more than 30 enforcement actions by the Postal Service during the early 1980s. In 1983, the Federal Trade Commission secured a consent judgment ordering Braswell, Inc. and its director, A. Glenn Braswell, to pay a civil penalty of \$610,000 and to stop false advertising of their products. A few months later, Mr. Braswell was sentenced in U.S. District Court to concurrent 3-year prison terms for perjury and income tax evasion and to 5 years' probation for mail fraud. [He was released from prison after serving a few months.] In 1981, an NBC television report estimated that Braswell, Inc., was grossing \$20 million per year.

Literature from Head Start Vitamin Products indicates that the Head Start name and product line were sold in 1983 to Sales/Services, Inc., an Atlanta-based company whose owners, Bob Wirt and Bettye Frye Keaton, had been involved in marketing the products to pharmacies and health food stores since 1976.

Briefs

Be a talk show guest? Nutrition professionals interested in telephone interviews can be listed free in a directory that will be sent in the Spring of 1985 to over 500 radio talk show station directors. To apply, send curriculum vitae and information about areas of special interest to *Nutrition Forum*, P.O. Box 1602, Allentown, PA 18105.

Caffeine/PPA drug combinations banned. The FDA has banned the marketing of all nonprescription drug products containing combinations of caffeine and phenylpropanolamine (PPA) as their sole active ingredients. Prior to October 29, 1984, such products were legally marketed if labeled as appetite suppressants, diet aids or diet aids/stimulants.

Chiropractic and nutrition. A recently reported mail survey of California chiropractors conducted in 1980 found that 84% of 2,715 respondents prescribed food supplements to their patients. To the question, "Do you believe that a chiropractor must examine each patient and arrive at a diagnosis?" 13% of respondents said "no" because they believed that "a chiropractor's only role in determining the condition of a patient is to analyze sub-luxations [spinal misalignments]."

GNC founder dies. David Shakarian, founder of General Nutrition, Inc., the nation's largest chain of health food stores, died of cancer on September 11th. He was 70 years old.

Quackery report available. *Quackery: A \$10 Billion Scandal*, the excellent 250-page report on Representative Claude Pepper's 4-year investigation into this subject, is available for \$6 from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. The order number is S/N052-071-00679-6.

Health food industry award. The National Nutritional Foods Administration (NNFA) has given its 1984 Rachel Carson Memorial Award to Michael F. Jacobson, Ph.D., Executive Director of the Center for Science in the Public Interest. NNFA is a trade association representing some 2,500 health food retailers, distributors and producers. Although Jacobson does not endorse most of the unorthodox practices promoted by the health food industry, his widely publicized criticisms of our food supply lend credibility to faddists who say government and the food industry shouldn't be trusted. Past Carson award winners include Emanuel Cheraskin, Linus Pauling, Gloria Swanson, Lendon Smith and Carlton Fredericks.

Price reduction. The price of *FDA Consumer* has been reduced from \$19 to \$17 for 10 yearly issues. Most articles in this excellent magazine are about food, nutrition or food safety. Orders should be sent to the Superintendent of Documents, Government Printing Office, Washington, DC 20402.

TOOTH DECAY: A DELICATE BALANCE

Sheldon Rovin, D.D.S., M.S.

Dental caries (tooth decay) affects over 95 percent of the United States population. Mainly because of water fluoridation, there has been a marked reduction in caries over the past quarter century which has been estimated to be as much as 30 percent. Nonetheless, dental caries is still one of the three most prevalent diseases in the U.S.—the others being periodontal disease and the common cold.

The tooth decay process has three basic participants: 1) *tooth enamel*, which is susceptible to the action of acid; 2) *dental plaque*, the not-readily-visible thin film of *bacteria* that accumulate on the tooth surfaces; and 3) *foods* (fermentable carbohydrates) which the bacteria act upon to form acid. Dental caries occurs because bacteria break down carbohydrates to form acids within the plaque which then demineralize (dissolve) the adjacent tooth enamel.

Tooth enamel becomes more resistant to acid penetration when adequate amounts of fluoride are available during the years that the teeth are forming (before they erupt). This is accomplished most efficiently through water fluoridation, but topical applications of fluoride to erupted teeth are also helpful. Individuals exposed to fluoridated water from birth onward develop about a third as many cavities as those in nonfluoridated communities.

Dental caries is reversible in its early stages; that is, the demineralized tooth surface can remineralize. This is facilitated by the natural properties of saliva which can neutralize the acid and cause calcium and phosphate to precipitate directly into demineralized enamel, causing it to remineralize and harden. Fluoride is also important to remineralization because it accelerates the deposit of calcium and phosphate and inhibits the production of acid.

Episodes of demineralization and remineralization alternate with each other. It is the balance between the two that determines how much decay takes place. Demineralization does not always lead to cavity formation. If the carbohydrates used by the bacteria to form acid are depleted, acid production stops and the pH of the plaque returns to its normal slightly alkaline state. At this pH, calcium and phosphate are deposited from the saliva through the plaque into the demineralized enamel, thereby repairing the affected area. Complete remineralization (healing) of the enamel can occur in this way.

Cavitation is the progression of dental caries to the point where a tooth's structure is sufficiently damaged to cause irreversible defects. It results when

the factors promoting dental decay consistently exceed the opposing factors. As indicated above, the promoting factors are bacteria and carbohydrates. The opposing factors are fluoride and proper oral hygiene. The balance between these factors is illustrated below.

The extent to which caries occurs depends on the carbohydrate content of one's food. However, all carbohydrates do not contribute equally. What counts is the type of carbohydrate, the frequency with which it is consumed, and the length of time it is permitted to remain adjacent to the tooth enamel.

The significance of the amount of carbohydrate ingested is probably less understood than the other aspects of the role of carbohydrates in causing caries. While animal studies readily show a correlation between carbohydrate consumption and caries activity, human studies are less clear. However, it appears that a certain minimum consumption level of carbohydrate (principally sucrose) is necessary for caries formation; and that below this level, caries occurs minimally if at all. As more carbohydrates are consumed, the caries level increases until it becomes rampant or very high. When caries becomes rampant, further carbohydrate consumption is apparently not influential.

Caries formation is also related to the type of ingested carbohydrate. Carbohydrates exist mainly as starches or sugars. The main culprits are the sugars in our diet, sucrose, glucose, fructose, lactose and maltose. Sucrose (table sugar) is by far the most common sugar eaten in the United States. Average sucrose intake is estimated to be about 100 pounds per person per year. Starches are less readily broken down into acids by bacteria than are sugars, and hence are less cariogenic.

The stickiness of the carbohydrate and the frequency of its ingestion both play important roles in caries formation. When dental plaque becomes sufficiently acid to dissolve the enamel, the length of time this acidity remains is crucial. Generally, each time a person eats

carbohydrates, the acid produced in the plaque is retained for about 10 minutes. This means that with each meal or snack, there is at least a 20-minute period when the acidity is sufficient for demineralization of the enamel. If these periods are prolonged or more frequent, demineralization and caries formation will increase. Thus, sticky carbohydrates which are retained on the teeth enable acid production to be prolonged. Examples of sticky foods include caramels, sugar-containing chewing gum, chocolate, raisins and other dried fruits. Products such as hard candies, lollipops, cough drops and mints are less sticky, but they are usually kept in the mouth for long periods and thus can prolong acid formation.

Soft drinks are commonly believed to be highly cariogenic because of their high sugar content, but they are actually less significant than these other types of carbohydrates because they are cleared from the mouth more rapidly. Carbohydrates in liquid form are retained for less time than are those in solid form, and consequently, tend not to prolong acid production in plaque. By the same principle, the drinking of water during and immediately after eating dilutes the acids being formed and helps decrease the acid retention time. Water also washes off some of the food.

The frequency that carbohydrate-containing foods are eaten probably is the most significant factor in caries formation, especially if the carbohydrates are of the sticky variety. Each time carbohydrates are eaten, acids are produced by the bacteria. If an individual eats carbohydrate-containing foods three times a day, caries-

causing acids will be produced and attack the teeth each time; since each episode is about 20 minutes long, the teeth are exposed to caries-causing acid approximately one hour a day. If an individual consumes the same foods five times a day—including snack times—the teeth will be attacked twice more for a total exposure of 1 hour and 40 minutes. The more frequently a person eats between meals, regardless of the quantity of carbohydrate involved, the greater the number of times during the day the teeth are subjected to the demineralizing effects of the acid.

When carbohydrates are eaten only at mealtimes, the teeth are subjected to less demineralization than when carbohydrates are consumed between meals as well. Thus tooth decay can be markedly reduced or even prevented by simply confining sugar intake to mealtimes; and it can be still further prevented by cleaning or at least rinsing the teeth after eating. The goal is to minimize the number and length of times the teeth are subjected to the acids produced by the bacteria in dental plaque. When the exposure time to acids is low, the balance between demineralization and remineralization is maintained and caries either does not occur or occurs only minimally. This, of course, is something that individuals can control.

Dr. Rovin is Professor and Chairman, Department of Dental Care Systems, University of Pennsylvania School of Dental Medicine, and co-editor of *The Tooth Robbers—A Pro-Fluoridation Handbook*.

READER FORUM

I'm surprised that your otherwise well-written first issue carried a brief on lowering telephone bills [NF 1:7] which looks like an ad. What does this have to do with nutrition?

Simone O. Adams, Dr.PH., R.D.
Storrs, CT

A few of our editors had feelings similar to yours, but the compulsive do-gooders among us prevailed. We reasoned that the possibility of helping readers save a lot of money outweighed the issue of relevance to nutrition. Incidentally, Consumer Reports has a complete analysis of this subject in its September issue.—Ed.

Congratulations. I just got the first issue and it's excellent! My partner and I wrote to the FDA in support of Paul Sage's petition [NF 1:2]. Would you like an article on nutrition quackery in dentistry?

John E. Dodes, D.D.S.
Woodhaven, NY

Yes, we are interested in articles on any practical aspect of nutrition.—Ed.

Thanks for your brief report on our study to determine whether beta carotene supplements can lessen the incidence of cancer [NF 1:7]. The actual number of randomized participants is not 27,000 but 21,991. We have been deeply impressed with their dedication.

Charles H. Hennekens, M.D.

“GROWTH HORMONE RELEASERS” DON’T CAUSE WEIGHT LOSS

James Lowell, Ph.D.

No More Fat! No More Flab! No More Cellulite. No More Dieting!
An effortless aid for “hard-to-lose” groups or dieters

LOSE WEIGHT EVEN AS YOU SLEEP

So claim ads for a new generation of questionable weight-loss products, the “growth hormone releasers.”

The theory behind them seems to have come from the best-selling book, *Life Extension*. The authors, Durk Pearson and Sandy Shaw, claim that: 1) most teenagers can eat like horses without becoming obese, even if they are sedentary; 2) blood levels of human growth hormone (HGH) decrease as people age; 3) this decrease is responsible for weight gain; 4) when the amino acids arginine (5 to 10 grams) and/or ornithine (2.5 to 5 grams) and/or tryptophan (1 to 2 grams) are eaten on an empty stomach at bedtime, growth hormone is released from the pituitary gland; and 5) this burns fat and results in weight loss.

Soon after the book’s publication, products based on these ideas were marketed. Ads for Lipogene-GH, Nite Diet, P.M., Dream Away, Nite Time Diet, Super-Amino Night, G.H. Releaser, Nutri-Diet PM, Amino FB and HGH-3X all suggest that bedtime use will cause overnight weight loss due to increased release of growth hormone.

What are the facts?

Some years ago, scientists noted that blood levels of HGH increase after a meal rich in proteins. Although various amino acids contained in the proteins could cause this release, arginine had the greatest effect. In fact, some doctors have used it as a drug to try to help slow-growing children attain normal stature. Currently, however, growth hormone itself is administered to children lacking adequate amounts of it.

Although the above products contain arginine, the quantities are far below those necessary to cause HGH release. One brand, for example, taken as directed, provides 1 gram of arginine daily—the amount found in about 2½ ounces of beef. But tests reported in the June 26, 1969 *New England Journal of Medicine* show that a 150-pound woman requires some 13 grams to have any effect at all, and this has to be injected, not taken orally. The effective dose for men is twice as high. In practice, doctors used even more.

Even if 1 gram of arginine could produce growth hormone release, other lines of evidence repudiate the claims of the promoters. People vary in the amounts of HGH produced at different times in their lives. For example, even though adults are no longer growing, they produce more HGH than young children do; and premenopausal women produce more than men. There is also a spurt during adolescence. But these times of high hormone production do not correlate well with periods of either growth or weight loss.

Moreover, Pearson and Shaw’s idea that HGH plasma levels decrease with age is simply wrong. Extra HGH is metabolized so rapidly that plasma levels—relatively high during the few weeks after birth—remain fairly constant after that [*NEJM* 288:1384.1973].

Pearson and Shaw note correctly that some obese people produce lower than normal amounts of growth hormone when given releasers such as arginine. This indicates a difference in the way people’s bodies work, but it also means that if these authors are correct, the weight-loss pills would be least likely to work in the people who need them most.

Does the amount of HGH produced actually affect a person’s weight? If the Pearson/Shaw theory were correct, adults with below-normal HGH levels would be fat. But they are not. Nor are those who produce too much growth hormone especially thin. Instead, they develop acromegaly, a disease in which their hands, feet and faces become abnormally large and deformed. When Dr. Raymond Hintz, a leading authority on HGH, administered very high doses of growth hormone to normal adults in order to test its safety [*Lancet* 1:1276, 1982 and personal communication], weight loss did not occur! Thus, even if amino acid pills could cause a release of HGH, weight loss would not result.

Dr. Lowell, a board member of the National Council Against Health Fraud, is Professor of Life Sciences at Pima Community College, Tucson, Arizona and a columnist for *The Arizona Daily Star*.

FOOD SAFETY: WHAT ARE THE REAL ISSUES?

Manfred Kroger, Ph.D.

The American food supply is abundant, affordable and appealing. And contrary to pop-nutritionist claims, it's nutritious when the right dietary choices are made. As things stand now, Americans certainly enjoy the safest and most wholesome food in the history of mankind. We should be proud of that achievement and have faith in our food system. Yet many are worried that our food supply is dangerous.

Actually, unsafe food has bothered people since time immemorial. It took thousands of years to understand how contamination and spoilage can cause discomfort, illness or death. These insights developed slowly through a process of trial and error. Today's scientists are trying to determine what relationships—if any—exist between diet or specific foods and such problems as cancer, heart disease, allergy, and disorders of mood and behavior. As a modern technological society, it behooves us to address food safety as thoroughly as we address military efforts, space research and other endeavors of science—but it also behooves us to maintain a realistic perspective.

In 1979, a committee of the U.S. Department of Agriculture set out to identify and rank areas of food safety and nutrition that deserve further research. After two years of study that included input from 134 food research administrators from industry, government and universities nationwide, the committee listed the following food hazards in the order of their importance. Note that this ranking is quite different from that generated by the media and held by much of the public.

1. *Mycotoxins*. Little is known about fungal toxins since only about two decades have passed since the discovery that aflatoxins (produced by the common mold *Aspergillus flavus* and other molds) can kill and are carcinogenic. Since both human food and animal feed tend to become moldy, consumption of mold toxins is almost inevitable. Even livestock can pass them on in modified form to consumers. History tells us much about ergotism (once called "St. Anthony's Fire"), alimentary toxic aleukia and other problems related to fungal contamination. Are naturally occurring mold toxins in our

diet actually making people ill? We don't know, but it seems prudent to be cautious about molds and moldy foods. Agricultural practices are now closely monitored to minimize mold contamination. And products such as peanuts, tree nuts, corn and oilseeds are closely monitored to detect aflatoxins. Not all molds are harmful. Most people clean up or throw out mold-contaminated food. The less affluent seem to be the ones most exposed to mold toxins because they cannot afford to throw spoiled food away. History shows that ergotism often appears when there are food shortages.

2. *Bacterial toxins*. These include the death-dealing neurotoxins produced by *Clostridium botulinum* and the debilitating enterotoxins of several other species. There is reason to believe that many unrecognized toxin-producing bacteria exist and contribute to food hazards. Most of our efforts with home and restaurant hygiene are directed at preventing food poisoning due to bacterial toxins. Sanitation procedures and proper food treatment have helped keep populations healthy. Understanding the principles, food handler education, and respect for hygiene will continue to be the major factors in reducing disease and death from food poisoning.

3. *Food-borne bacterial infections*. Salmonellosis is the best known, with thousands of cases reported annually in the United States. This is only the tip of the iceberg, since most cases of food poisoning are not reported to the Centers for Disease Control. There is still much to be learned about how people get sick from bacteria in food. All of us are familiar with "stomach upsets," "intestinal flu" and "travelers' diarrhea," but relatively little is known about the actual disease mechanisms. Experts would probably agree that of all human misery in the world, now and before us, there has never been a cause bigger than the wrong kind of tiny bacteria within us. (It would be a mistake, however, to conclude that all bacteria are bad. Those used in food fermentation are safe and useful, and various bacteria normally living within the human intestinal tract are essential for life.)

4. *Chemical residues.* This category includes pest control substances, biologicals used in animal agriculture, and industrial chemicals appearing as chronic or sporadic environmental pollutants. Modern technology is blamed for the presence of all of these unwanted chemicals in our food; so it is important to fully understand the risks and benefits of the substances that human ingenuity has conjured up to work for us.

The risk-benefit balance of agricultural chemicals tilts heavily towards benefit. Some countries that don't use pesticides lose up to half their food to insects and other pests. Washing fruits and vegetables removes most of the surface contaminants; the tiny amounts that may remain represent no threat to human health. Those who speak of the "chemicalization of our food" do not fully understand the realities of agriculture. Nor do they have proper appreciation of our technological heritage. "Technological" and "chemical" have come to define modern life, mankind and progress. We merely require the wisdom to effectively harness technology and chemistry. Food became "technological" and "chemical" centuries ago because more of it was needed to feed ever increasing populations. At the same time concern was generated to keep unhealthy chemicals out of our diet. Continuing awareness will assure us of a "clean" food supply.

5. *Naturally occurring toxicants and allergens.* Many people believe that anything coming from Mother Nature must be benign. That simply isn't so. If man's actions leave some chemicals in our foods, nature contributes the rest. *Every bit of every piece of food is composed of chemicals.* A cup of milk contains thousands of chemicals and so does a bite of bread or a whiff of coffee. Nutrients are chemicals. Most of the hundreds of thousands of chemicals are neutral in character, some (quite a few) are toxic. Of course, we know about poisonous mushrooms, but to what extent are toxic alkaloids in potatoes or sulfur compounds in onions hazardous to consumers? Questions of this type should be explored further but kept in perspective.

6. *Process-induced toxicants.* The value of technology—including such developments as refrigeration, pasteurization, and canning—is obvious. There is still cause for concern about possible chemical interactions and toxic products formed during food processing—such things as nonenzymatic browning reaction products, or the secondary effects of chlorine in meat processing, and unique radiolytic chemicals created during food irradiation, to name only a few.

7. *Viral infections.* About 25% of the reported outbreaks of food-borne disease cannot be attributed to known bacterial agents and may be due to undetected viruses. Food animals are susceptible to a wide variety of viruses—which may be transmittable to humans. These areas are not well understood. Our knowledge about the significance of virus-induced cancers is slimmer still.

8. *Food additives.* Promoters of "organic" foods and a number of so-called consumer advocates have suc-

ceeded in making this the number one food safety issue in the mind of the general public. Although vigilance is in order, the fact is that food additives have been extensively studied—probably more so than the other categories listed here.

9. *Toxicants formed in the body.* This is a remarkable new area. The fact that cancer-causing nitrosamines can form in the human digestive tract should certainly be studied further. What else is going on inside us that is food-related and might precipitate harm? Do we harbor a diet-related "self-destruct" mechanism?

10. *Parasitic infections.* This was a big problem in Europe and North America until 50 years ago, and it still is a problem in many other parts of the world. Food is a major vector for human parasites, particularly the organism that causes trichinosis. In 1940, some 16% of the U.S. population was infected with trichinae, generally from meat products. Today there are fewer than 100 cases per year. New technologies, such as food irradiation, may reduce this number further.

Other subjects worthy of study include food interactions, foods that prevent toxicity, and even foods that prevent cancer.

Totally synthetic food restricted to the 40 to 50 nutrients essential for life might eliminate all the hazards mentioned above and provide perfect food safety. Can you imagine eating such a diet?

Dr. Kroger is Professor of Food Science at The Pennsylvania State University.

QUESTION BOX

Q. What does "low sodium" mean on food labels?

A. Currently, there is no legal definition of the term "low sodium." However, beginning July 1, 1985, sodium labeling will be required for foods that already carry nutritional labeling or that make a claim about sodium. At that time the labeling regulations will include the following definitions: *sodium free*—less than 5 mg sodium per serving; *very low sodium*—35 mg or less/serving; and *low sodium*—140 mg or less/serving. In addition, *reduced sodium* will mean that a food has been processed to reduce the usual sodium level by 75% per serving; and *unsalted* will mean that the food has been processed without the normally used salt.

Q. Is carotene a different name for vitamin A?

A. Vitamin A is found almost exclusively in foods of animal origin. Carotene refers to a group of compounds of plant origin that the body uses to make vitamin A. Thus, carotene is said to be a precursor of vitamin A.

WHO TOOK THE FUN OUT OF FOOD?

Virginia Aronson, R.D., M.S.

Remember when most of us could lick an ice cream cone without guilt? Or munch on a handful of chips without thinking about sodium? Or order a nice thick steak without considering the possible advantages of vegetarianism? Whatever happened to good old-fashioned (yes, hedonistic) pleasures of the palate?

"Junk-food" junkies hunger within all of us. Yet in modern-day America where almost anything goes, eating has become the sinful practice we commit and deny. Millions are alternating self-indulgence with on-the-wagon diet pledges and Spartan eating behavior. While committing crime in the sweets, they loudly deny guilt and chomp on tofu as "health food" devotees.

Why has the simple act of eating become such a complex issue? Why must our foods and overall diets be classified as "good" or "bad," "healthful" or "junky"?

Who took the fun out of food?

- **Mothers.** Sorry, Mom, but this is where many of our dietary hang-ups began. The stereotypically big, warm matron, bustling around the heavily laden dinner table, cajoling and encouraging everyone to eat, eat, eat, started most of us down the path to Foodproblemland. When food is equated with love and security, rejection of proffered goodies may be considered insulting. Much lifelong dietary guilt stems from parental derision of food waste and the belief that food left on your plate is somehow related to starving children in other countries.

- **Doctors.** Many unfortunate individuals receive an embarrassing reminder each year by the family physician that fat loss is in order. The accompanying "diet sheet" is usually as dry as the cottage-cheese-and-melba-toast menu it advises. Other dietary foibles (besides flab) are sternly addressed by physicians who pressure us to believe that eating is more a medical issue than a gustatory pleasure. Though most medical meetings are fueled on coffee and donuts, doctors cite dietary risks that threaten our eating enjoyment.

- **Dietitians.** Also distressing are the small number of militant dietitians who seem to regard diet as something to be swallowed like medicine (but without a spoonful of sugar to help it go down, because we eat too much of that already). Admonishing us to eat less of

everything we like and to substitute broiled liver and boiled greens, they suggest that good health requires daily tabulation of both caloric content and RDA percentages per serving for the limited food choices that remain.

- **Pop "nutritionists."** Many "health food" gurus seem to believe that personal experience in eating qualifies them as preachers for the religion of diet. Touting nutrition as curative for all ills, they claim that our food supply is nutrientless and the cause of aging and death. They are helped by naive consumer advocates to alarm Americans about supposed dangers lurking at the dinner table.

- **News outlets.** The media will publicize anything sensational—that is, saleable. Research reports are often distorted or exaggerated to concoct revolutionary nutrition "breakthroughs" and "deadly" dietary scares.

- **Advertising industry.** Fashion dictates that "thin is in." The mass media urge us to look like Victoria Principal or John Travolta, to stay young forever, and to have boundless vitality. But at the same time, mouth-watering ads are everywhere—telling us that we deserve a break and beckoning us toward oral indulgence.

- **Diet industry.** According to the diet mentality, bathroom scales can predict the future as accurately as the local palm reader. Consumers are being lured by magical diets, exercise gimmickry, guarantees of overnight fat melt-off, and other "effortless" weight-loss plans. All promise happiness ever-after—for an up-front fee, of course.

Today's society is robbing food not of essential nutrients but of fun. Eating *should* be one of life's great pleasures. As with most things in life, *moderation* is the key. In lifestyles balanced with good old-fashioned common sense, food can indeed be a fun part of healthful living. More voices are needed for moderation!

Ms. Aronson, a nutritionist/writer at Harvard University's School of Public Health, is the author of *Thirty Days to Better Nutrition*. She is also co-author (with Dr. Fredrick J. Stare) of *Dear Dr. Stare: What Should I Eat?* and *Your Basic Guide to Nutrition* (G.F. Stickley, Phila.).

Briefs

Gayelord Hauser dies. On December 16, 1984, Benjamin Gayelord Hauser, author of *Look Younger, Live Longer* and 13 other books, died at age 89 of complications from pneumonia. He considered blackstrap molasses, brewer's yeast, yogurt, powdered skim milk and wheat germ to be wonder foods. He lectured frequently and was a partner in Modern Food Products of Milwaukee, a company that produces products bearing his name. According to an article in the *The Los Angeles Times*, his books sold almost 50 million copies.

Diet/cancer research. The National Cancer Institute has awarded \$453,971 to Nikolay Dimitrov, M.D., and colleagues at Michigan State University to explore whether vitamin E, beta-carotene and selenium can help prevent cancer. The study will involve both dietary analysis and long-term supplementation with selenium and vitamin E.

Fluoridation update. Surveys by the National Institute of Dental Research have found that the proportion of 9-year-olds with decay-free teeth rose from 29% in 1973 to 51% in 1979-1980. The U.S. Centers for Disease Control attributes most of this improvement to the availability of fluoride in community water supplies and in dental care. But it notes that 150 cities of 100,000—including Los Angeles and 8 more of the nation's 50 largest cities—are still not fluoridated. A free information kit for use in promoting community fluoridation can be obtained by writing to Paul Turner, Dental Disease Prevention Activity, Centers for Disease Control, Atlanta, GA 30333.

Food industry hotline. FoodCom, Inc., and The Food Institute are now operating an electronic mailbox and daily news hotline covering such areas as crop estimates, grower pricing, price changes, food sales, product recalls, and government agency actions. Access to the system, available by dialing a local phone number in any of more than 500 cities, requires a computer, word processor, communicating typewriter or other information terminal. There is no minimum charge; users are billed \$25/hour for actual use. Additional information can be obtained from Mr. Anthony DeBello, FoodCom, Inc., Main Line Industrial Park, Lee Boulevard, Frazer, PA 19355.

Less effort against quackery? In the March/April 1985 *Food and Nutrition News* Kristen W. McNutt, Ph.D., J.D., writes that the print and electronic media are the main forces shaping food decisions, and that most media information originates from unreliable sources. To counter this, she suggests that qualified nutritionists "take the offensive with a positive message" and "forget about fighting charlatans." She feels that "people who take the charlatan's bait" will not be swayed by scientific facts because "they believe what they want to hear." Dr. McNutt, who is Director of Scientific and Public Affairs for the Good Housekeeping Institute and a former president of the Society of Nutrition Education, urges more interaction with local writers and broadcasters. She suggests that "quotable quotes" and other useful source material should be offered, and that congratulatory letters should be sent whenever media presentations are good. A copy of the newsletter can be obtained from: F&NN Editor, National Live Stock and Meat Board, 444 N. Michigan Ave., Chicago, IL 60611. [Editor's note: Dr. McNutt's article contains excellent suggestions for media penetration. However, I believe her perspective on quackery is too pessimistic. Most victims of quackery are unsuspecting rather than gullible and can be influenced by facts encountered often enough.]

Judge orders FDA action on raw milk. U.S. District Judge Gerhard A. Gesell has ordered the Department of Health and Human Services to respond by March 15th to the Health Research Group's petition that the sale of unpasteurized milk be banned [see NF 2:1-4]. "The facts here speak for themselves," the judge noted. "Officials at the highest levels of the Department of Health and Human Services have concluded that certified raw milk poses a serious threat to the public health . . . The Food and Drug Administration has twice proposed, in 1973 and 1983, that all milk in interstate commerce be pasteurized. Hundreds of cases of serious gastrointestinal infections have been reported since . . . The only issue here is the reasonableness of the agency's delay, and the only remedy sought is a judicially established schedule for agency action. The Department's justification for its continued delay is lame at best and irresponsible at worst."

Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

Allergy testing for animals? According to *East West Journal*, Physicians Laboratories in Los Angeles offers a \$55 blood test it claims can indicate the presence of food sensitivity in animals. At the lab, processed blood serum is inoculated onto 46 slides containing common pet food ingredients. Elimination of supposedly troublesome foods from the diet is then recommended.

Updated text attacks food faddism. A 440-page third edition of the college textbook, *Consumer Health—A Guide to Intelligent Decisions*, by Harold A. Cornacchia, Ed.D., and Stephen Barrett, M.D., has just been published by Times Mirror/Mosby, 11830 Westline Industrial Drive, St. Louis, MO 63146. Three of its 22 chapters give thorough coverage to basic nutrition concepts, nutrition fads and fallacies, and weight control issues. Copies are available for \$26 postpaid from the Lehigh Valley Committee Against Health Fraud, P.O. Box 1602, Allentown, PA 18105. Requests for desk copies should be sent to the publisher.

Pritikin commits suicide. According to press reports, Nathan Pritikin killed himself on February 21st by slitting the veins in his forearms with a razor. During the previous ten days, he had been undergoing chemotherapy for leukemia at a hospital. The condition was diagnosed in 1958 but was in remission until recently, when it became terminal. Pritikin, an inventor with more than 25 patents in chemistry, physics and electronics, attracted nationwide attention through his controversial diet and exercise books. According to *People Magazine*, 18,000 people have gone through the program at the Pritikin Longevity Center in Santa Barbara since it opened in 1976. Following Pritikin's death, telephone calls and reservations for treatment at the Center were reported to have risen sharply despite its cost of up to \$6,800. Pritikin's son Robert is expected to continue his father's work.

Recalls hurt consumer confidence. Food Marketing Institute President Robert O. Aders has expressed concern about the timing of food product recalls: "We receive the news at the same time as the media. And it seems to happen a lot at 5 p.m. on Friday. The system does not leave us nearly enough time to spread the word to our 1,300 members, who must in turn notify some 17,000 supermarkets. An unfortunate consequence of this is awkward confrontations with the news media. They learn about recalls before most food retailers; in fact, that is the way the recall system is designed, although most reporters don't know this. As a result, they come into our stores and seeing the recalled products still on our shelves, they focus on the fact that consumers are at risk." Speaking last September at the National Consumer Product Safety Conference for Retailers, Mr. Aders suggested that recall procedures take into account the need to protect consumer confidence in the food system. He said that either retailers should be informed ahead of the news media or the media should be made aware that

they are the principal messengers of recalls. Except in life-or-death situations, manufacturers could be given a 24-hour lead for voluntary recalls, and supermarkets could be given a few hours to clean the shelves off before the media are told.

FTC Chairman opposes alcohol advertising ban. Testifying before a Senate subcommittee, FTC Chairman James C. Miller III, said that "most alcohol advertising appears as carefully packaged image promotion directed at brand recall in association with certain images of taste and style." But he asserted that while this advertising has considerable effect on the choice of brands or beverage types, it has "no effect on overall alcohol consumption, much less abuse. He also said that his agency, which is considering this issue, has found little evidence demonstrating that an advertising-related remedy would be effective in reducing alcohol abuse.

Herbalife. An article in the February *Forbes Magazine* states that Herbalife's gross sales were \$488 million in the year ending January 31, 1985. According to company founder and chief executive, Mark Hughes, more than 700,000 distributors are selling his products in the United States, Canada, Australia and the United Kingdom. Evidence exists that Herbalife distributors in various parts of the country are making product claims that are untrue and/or illegal, but it is unclear whether the literature involved originated at company headquarters or at local levels. The FDA has been investigating the company but has taken no enforcement action as yet. Several prominent journalists have conducted extensive investigations that should be made public within the next few months. Meanwhile, dietitians nationwide are experiencing considerable difficulty in coping with consumer questions about the safety and effectiveness of Herbalife products.

Diabetic fakery. A study at Albert Einstein College of Medicine (New York City) found that 14 of 19 diabetics using home blood glucose devices reported lower test values than were actually found. Unknown to the patients, the devices contained memory chips that stored actual values with times and dates of the readings. After patients were told about the memory chips, their recording became 100% accurate. Experts interviewed by *Medical World News* [Feb. 25, 1985] thought that many diabetics report better-than-actual blood and urine test results in an attempt to please their doctors.

Aspartame hearings sought. The Community Nutrition Institute, aspartame's most persistent opponent [see NF 1:2-4], has asked the U.S. Court of Appeals for the District of Columbia to require the FDA to hold "factual hearings" on the sweetener.

"Organic" legislation. During the current session of Congress, proponents of the Agricultural Productivity Act will seek its passage either separately or as part of 1985 omnibus farm legislation. Sponsored by Rep. Jim Weaver (D-OR), this bill provides \$2 million for activities related to "organic" farming [see NF 1:6].

BLUE-GREEN MANNA WINS LOWELL AWARD!

James Lowell, Ph.D.

Having analyzed hundreds of product promotions, I believe I can spot questionable ones with great facility. Given this experience, I've decided to give annual recognition to the company which, in my opinion, has produced the most outlandish sales campaigns and marketing schemes. I believe such recognition should be based on three criteria:

- 1) How imaginative is the pseudoscientific rationale for its use?
- 2) How long and ridiculous is the list of conditions against which it is claimed effective?
- 3) How well has it survived government attempts to remove it from the marketplace?

Although competition—as usual—was quite stiff, the 1984 winner is clearly K.C. Laboratories of Klamath Falls, Oregon. This company markets a product called Blue-Green Manna, along with such variations as Mannapep, Mannacol, Mannazen, Mannapro, Mannastat, and Animal Repair Manna.

Basic to all the formulations is a pond scum which has been extracted from Upper Klamath Lake (located 4000 feet above sea level) and freeze-dried to maintain its "biological integrity." The organism involved was originally claimed by its promoter, Victor Kollman, to be a blue-green alga known as *Anabaena*. He later claimed that the genus was actually *Aphanizomenon*, and finally settled on *Alpanae-Klamathomenon*.

Blue-green algae are microscopic green plants, but what alga, if any, is really in these products is unclear. *Alpanae-Klamathomenon* is not a recognized algal genus, and Kollman recently told the FDA that his products don't contain *Aphanizomenon*, either. I bought a bottle of Mannacol and am sure only that it contains something green and lots of alcohol. The product's nutrient value is not impressive, either. Its label lists chlorophyll, 9 vitamins, 10 minerals and ash, and says nothing about the alga. However, at the suggested dosage of 1 to 2 droppers-full per day, a user would receive less than 1/500th of the U.S. Recommended Daily Allowances of most of them.

Although various algae have been studied as possible sources of food for both humans and animals, they have never come into wide usage because they are not sufficiently digestible. Some, like dried kelp, are used primarily as seasonings and as "sea vegetables" in certain kinds of cooking.

Literature from K.C. Laboratories describes Kollman's algae in the following imaginative ways:

- *Alpanae Klamathomenon* is the oldest living cell in the history of the world that has never changed. They never get sick. They cannot be poisoned with insecticides, poisonous sprays, smog or other toxic chemicals . . . They can even withstand bombardment with

laser beams. They do not mutate and they cannot be destroyed by any ordinary means.

- This amazing cell is resistant to all diseases known to man.

- These organisms are special because they contain the native germ plasm in its intact and non-evolved state from which the human race emerged.

Kollman claims that the alga works because it is "essentially a pure breatharian" and can live on air alone. This, he says, causes it to have a "high concentration of neurotransmitter-like compounds." Because neurotransmitters are chemicals necessary for brain function, the Blue-Green Manna is advertised as a "brain food."

The credentials of Kollman and his "research" are as questionable as his "scientific" explanations. Bruce Detlefson of *The Howard County Times*, Columbia, Maryland, reported recently that although Kollman's promotional literature claims he has a Ph.D. in biochemistry from the University of Iowa, the school's registrar said that no one by that name had ever been enrolled. Moreover, when my college library attempted to secure copies of the scientific articles upon which Kollman bases his claims, it found that they either did not exist or that they were in journals so obscure they could not be found, even through the inter-library network.

Promoters of Blue-Green Manna claim that their products are effective against allergies, Alzheimer's disease, arthritis, diabetes, epileptic seizures, herpes, high/low blood pressure, Hodgkin's disease, hyperactivity, leprosy, leukemia, menstrual cramps, migraine headaches, psoriasis, sickle-cell anemia, senility, stress/strain, ulcers, warts, and even poor grades in school. The manna is claimed not only to help narcolepsy (a condition in which adults fall asleep suddenly and uncontrollably) but also to help babies sleep better at night. It supposedly reverses the aging process and can cause weight loss. In fact, according to Kollman, if everyone took his products, there would probably be world peace.

Promotional material touting blue-green algae for Alzheimer's disease is especially blatant. A 1982 article by Kollman claims that his manna has been able to "alleviate or minimize symptomatology" associated with this condition. Literature from a distributor of another line of alga products even contains a diet plan plus a 2-page "suggested protocol" of dosage schedules for six weeks of "nutritional support."

Manna is also supposed to help with sexual problems. In an ad in the March 1984 *Hustler* magazine, publisher Larry Flynt, who has been paralyzed from the waist down since being shot in 1978, said he experienced his first orgasm in years after taking Manna for only five months. According to Detlefson, Kollman has

even claimed in lectures that his products can turn gay males into heterosexuals.

Kollman has advised his distributors that Blue-Green Manna was approved by the FDA in both 1980 and 1983—a claim vigorously denied by David Chesney, Supervisory Investigator at the Portland FDA office. Kollman has also advised his distributors that the products don't fall under FDA jurisdiction and that they aren't obligated to speak to FDA investigators. But Chesney believes that the products are subject to FDA control.

During the summer of 1983, a deputy U.S. marshal, accompanied by an FDA investigator acted on FDA charges that the alga was an "unsafe food additive" and attempted to seize Manna pills with a retail value of more than \$100,000. The first seizure attempt was unsuccessful because the seizure papers contained the wrong scientific name (Kollman was in the process of one of his name changes). On August 5th, the seizure

was completed and Kollman was arrested on charges of interfering with a federal law enforcement official performing his duty—but the charges were later dropped. On November 8th, the court ruled that the alga was not a food additive as charged by the FDA, but the agency is determined to take further legal action.

Regardless of the litigation's outcome, potential buyers should keep in mind that these products, which retail for \$20 to \$48 a bottle, contain little in the way of nourishment. Someone wanting alcohol could buy Manna for \$20 an ounce—the equivalent of paying \$512 for an ounce of booze.

Dr. Lowell, a board member of the National Council Against Health Fraud, is Professor of Life Sciences at Pima Community College, Tucson, Arizona and a columnist for The Arizona Daily Star.

AVELOZ

Varro E. Tyler, Ph.D.

"Exotic Shrub may be key to victory in cancer battle! Aveloz now being used for tumor reduction cancer treatment."

"One drop of [aveloz] sap, diluted in a glass of distilled water and taken by the tablespoonful every hour, eliminates cancerous growths in one week."

These are just some of the statements used to publicize aveloz, a remedy prepared from the milky sap of a Brazilian shrub with the scientific name *Euphorbia heterodoxa* Mull. Arg. The saps of various *Euphorbia* species have been used in folk medicine since at least 400 B.C. because of their corrosive properties. *Euphorbia heterodoxa* is commonly known as killwart because its sap—used by the Amazon Indians and later the Dutch, Portuguese and Spanish Galician settlers in northeastern Brazil—was thought to be effective when applied to warts and tumors, particularly those located on the face.

A Brazilian physician named Pamfilio is said to have introduced aveloz into conventional medicine sometime in the 1880s or 1890s, but it remained obscure until just a few years ago. Today it is sold in the United States in liquid form by herbal practitioners. The promotional literature recommends consumption of five drops in a half glass of water or herb tea, three times a day, for the treatment of cancer, benign tumors, cysts and warts. Aveloz is also marketed in the form of an ointment intended for local application.

Because of its relative obscurity, the aveloz plant has apparently never been analyzed chemically. However, it is common knowledge that about 90 percent

of the species of the Euphorbiaceae (spurge) family yield a white latex-like sap that is extremely irritating to the skin and mucous membranes and can produce skin inflammation, conjunctivitis of the eyes, burning of the mouth and throat, diarrhea, and gastroenteritis.

Recently it was found that the chemical compounds (certain diterpene esters) responsible for these irritant effects also act as tumor promoters. Such compounds do not cause cancer by themselves but seem to interact with sub-threshold doses of carcinogens to induce cancer in laboratory animals. (Experiments to test this in human beings are obviously not possible.) So, although its exact chemical constituents are unknown, it is apparent that aveloz has serious potential for harm.

Curiously, there may also be some potential for good. In recent years, researchers have shown that extracts of certain plants in the *Euphorbia* family do indeed show antileukemic activity that could be attributed to their content of certain diterpene esters. Obviously, it is important to learn which specific structural features of these constituents cause them to act as tumor promoters, on one hand, and as antileukemic agents on the other. Obviously, too, it would be highly imprudent for cancer patients to experiment with this possibly two-edged sword at this time.

Dr. Tyler, Dean of Purdue University's Schools of Pharmacy, Nursing, and Health Sciences, is an expert in pharmacognosy (the science of medicines from natural sources) and author of *The Honest Herbal*, an evaluation of popular herbs.

STUDY FINDS ABILITY TO SMELL DECREASES WITH AGE

A study of 1,955 volunteers ranging in age from 5 to 99 found that the ability to smell is usually at its best between the ages of 20 and 40 [Science 226:1441-1443, 1984]. It diminishes slightly through a person's 50s and 60s but drops rapidly through the 70s and 80s. The researchers found that more than 60% of those between the ages of 65 and 80 had severe losses in the sense of smell, and nearly one-fourth had lost all ability to smell. After age 80, more than 80% had major impairment and almost half had lost all ability to smell. At all ages, women scored higher than men, and smokers scored lower than nonsmokers.

The study was led by Dr. Richard L. Doty of the University of Pennsylvania School of Medicine. Each volunteer was tested with 40 substances, using the recently developed University of Pennsylvania Smell

Identification Test described in *Physiology and Behavior* 32:489-502, 1984.

It is known that the ability to smell is closely linked with the ability to taste, and that aromas hitting the nose from a dish of food are interpreted by the brain similarly to sensations from the taste buds. Commenting on this in a newspaper interview, Dr. Doty added, "It's no surprise that elderly people complain that food doesn't taste good anymore. Many people don't realize it's because they can't smell . . . Because food is no longer enjoyable, many don't eat well and become malnourished."

Reprints of the above references are available from Richard L. Doty, Ph.D., Director, Smell and Taste Center, 5 Ravdin Building, Hospital of the University of Pennsylvania, 3400 Spruce St., Philadelphia, PA 19143.

COURT RULES IN HAIR ANALYSIS CASE

On January 30th, in response to a Complaint by the Federal Trade Commission [see NF 1:12], the U.S. District Court for the Eastern District of Virginia issued a permanent injunction against Arthur, Ethel and Alan Furman and any business entities through which they may act. The order forbids "holding themselves out . . . to persons other than health professionals, as being able on the basis of hair analysis, to measure accurately the element content of a person's body or to recommend vitamin, mineral or other dietary supplements which can correct chemical excesses and deficiencies in a person's body." Although evidence in the case indicated that the defendants' company, A & A Laboratory, Inc., had grossed over \$1½ million for the years 1979 through 1983, the judge ordered no fine or restitution.

On February 25th, the Court issued an amended

order defining the health care professional as "one who, directly through a business entity, with or without state authority, holds himself or herself out as a nutritionist or as one who deals with the prevention, diagnosis, treatment, cure or alleviation of human physical or mental ailments, conditions, diseases, pain or infirmities."

Companies which had been marketing hair analysis directly to consumers prior to the FTC's action against the Furmans appear to have stopped doing so. However, use of hair analysis by licensed health practitioners (mostly chiropractors) and unlicensed "nutritionists" will remain a problem without further government action. The judge in this case apparently believes that "professional" use of hair analysis should be regulated by state rather than federal authorities.

LOCAL HEALTH PROMOTION LAW

An ordinance to encourage food establishments to engage in health-promoting activities was enacted in September of 1984 by the Allentown, Pa., City Council. Under the program, the annual license fee was raised from \$30 to \$100, but \$25 is rebated for each of the following achievements: 1) at least 10% of employees become certified in cardiopulmonary resuscitation and anti-choking procedures; 2) at least 25% of seating is in nonsmoking sections; and 3) at least one food service manager becomes certified by completing a 14-hour FDA-approved course and passing a written test. (The course, which has been endorsed by the National Restaurant Association, is given annually by the Allentown Health Bureau.) Owners doing all three thus pay \$25 instead of \$100 for the license fee. The ordinance also requires food establishments using food fresheners (e.g.,

sulfiting agents) to conspicuously display a notice identifying the type of freshener used. A first aid for choking poster must also be conspicuously displayed.

Four months after enactment of the ordinance, 25 out of 500 establishments had met the CPR requirement, and the Health Bureau estimated that 50 to 75 more would comply by the end of 1985. The number with nonsmoking facilities had risen from 15 to 35, with another 25 more expected by year's end. The number with certified food managers is expected to increase from 40 to 80. Details of the program can be obtained from its originator, Gary Gurian, Director, Allentown Health Bureau, 723 Chew Street, Allentown, PA 18102. Information on the Food Service Manager Training and Certification Program can be obtained from the Division of Retail Food Protection (HFF-220), Food and Drug Administration, 200 C Street, S.W., Washington, DC 20204.

UPDATE ON FOOD IRRADIATION

Kathleen A. Meister, M.S.

"Frozen foods are antedated, ask for yours IRRADIATED!"

Twenty-eight years ago, when this little verse appeared in *Science Digest*, food irradiation was new and seemed quite promising. Although subsequent research has been favorable, opposition to government approval still exists.

Irradiation is accomplished by treating foods with ionizing radiation (gamma rays) from radioactive cobalt or cesium, or from devices that generate electron beams (beta rays) or x-rays. Irradiation has many possible uses in food processing, most of which prolong the useful life of foods. It cannot make foods radioactive because the nuclei of the atoms in food cannot be changed by the types of radiation used. The permitted treatments are specified by government regulations. Two general categories of radiation dosage can be used. "High-dose" radiation means exposing foods to 1 to 6 megarads. "Low-dose" radiation refers to treatments below (often far below) 1 megarad.

High-dose radiation can kill all the microorganisms in food just as heat does during the canning process. Irradiated foods are often superior in flavor and texture to their heat-sterilized counterparts because irradiation doesn't cook the food as heating does. Although high-dose irradiation is not likely to have widespread commercial use in the U.S., it has great potential value to two groups. One is the military, which needs decent-tasting foods that can be stored without refrigeration for use by troops in the field. The other is hospitals, which need bacteria-free foods for immunosuppressed patients whose resistance to infection is so low that they can develop serious infections when exposed to the otherwise harmless organisms found normally in most foods.

The U.S. Army sponsored much of the early research on food irradiation. Irradiated foods are still not included in Army field rations, since they do not have legal approval. But NASA has been using them for astronauts' in-flight meals.

The Fred Hutchinson Cancer Research Center in Seattle has received special FDA permission to serve

irradiation-sterilized foods to bone marrow transplant patients and to those with immunosuppressive diseases. This enables patients to enjoy such foods as bread, cereals, pasta, nuts and candy, none of which would be palatable after heat sterilization.

Low-dose irradiation has many possible commercial uses because it can kill insects and reduce the number of microorganisms in fresh or processed foods without significantly affecting flavor or nutritional quality. The recent ban on the fumigant ethylene dibromide (EDB) prompted much of the renewed interest in irradiation as a substitute. Irradiation can also extend the shelf life of perishable foods such as seafoods, inhibit the sprouting of potatoes and onions, delay the ripening of some types of fruit, and decrease mold growth on fresh produce. The pork industry is excited about irradiation because it can virtually eliminate the hazard of trichinosis at a cost of less than 1 cent per pound of pork.

Extensive research has been conducted to determine whether irradiated foods are safe to eat. Although the process does not induce radioactivity, it does cause chemical changes. It turns out, however, that virtually all of the chemicals produced also occur naturally in foods or are produced by cooking or other conventional food processing techniques. Scientists studying irradiation have concentrated their attention on whether it produces chemicals not found in foods processed in other ways. At first it was thought that there were many such substances. But now it appears that very few exist and that none is cause for concern.

Many animal feeding studies have been carried out on irradiated foods to determine their safety. Although some of the early researchers reported adverse health effects, it is now clear that they resulted from faulty experimental design rather than from the irradiated foods. For example, when animals were fed a diet consisting almost entirely of the irradiated food product under study, the diets were so unbalanced that the animals became ill from malnutrition. More recently, properly conducted studies have not shown similar adverse effects.

Food irradiation is regulated by the FDA under the terms of the 1958 Food Additives Amendment to the Federal Food, Drug and Cosmetic Act, which specifies that irradiation must be regarded as a food additive. Of course, irradiation is a process, not an additive. However, Congress apparently grouped it with food additives in order to ensure that irradiation would have to meet the stringent safety standards for additives.

Although no evidence has been found so far that irradiated foods pose any hazards, government authorities have deferred final judgment on the safety of foods sterilized by high-dose irradiation until some current studies are completed. The findings of a recent large-scale study of irradiated chicken conducted by the U.S. Department of Agriculture are now in the hands of the FDA, which has the unenviable task of interpreting more than 10,000 pages of data.

Low-dose irradiation treatments are generally agreed to be safe and are being used in at least 25 countries. In 1981, an expert committee of the World Health Organization concluded that foods irradiated with doses up to one megarad (which encompasses almost all applications of irradiation other than food sterilization) were safe.

In the United States, irradiation has been approved for only three specific uses. In the 1960s, it was approved for sprout inhibition of potatoes and insect disinfestation of wheat and wheat flour. Neither application has been used commercially. Some people have construed this to mean that there is little commercial interest in food irradiation. Actually, there is great interest, but the process isn't economically viable unless facilities can handle large quantities of food on a year-round basis—which can't happen until more uses are approved. It would not be cost-effective, for example, to construct an irradiation facility that could be used only during the short period each year that potatoes are harvested. Irradiation was approved in 1983 for control of microorganisms in spices, and commercial application has begun.

The fact that irradiation is defined as an additive has led to some problems in getting it approved. It is not possible to test the safety of a process in the same ways that additives are tested, and for a long time it was unclear just what kind of evidence the FDA would require for approval. In 1979, the agency began to take steps to resolve this uncertainty by establishing a committee to recommend criteria for safety evaluation of irradiated foods. In 1980, the committee made its recommendations. And in March 1981, the FDA took the first step toward translating them into formal agency policy by publishing in the *Federal Register* an "advance notice of proposed rulemaking" which proposed general approval of low-dose irradiation treatments for many foods.

Although this was a major step forward, it was still a long way from actual approval. The type of notice is merely an announcement that a government agency is considering the possibility of doing something. It is

customarily followed by an opportunity for people to submit comments, an evaluation of those comments, a second agency announcement called a "proposed rule," another comment period, and then the actual regulation. This process can take years. In the case of low-dose food irradiation, it has already taken four years and has not been completed. The proposed rule didn't appear in the *Federal Register* until February 1984, and a final rule has not yet been published, although it is expected this year.

The FDA's low-dose irradiation proposal, in its most recent form, would do the following:

- 1) Permit irradiation of fruits and vegetables to inhibit growth and maturation (i.e., sprouting, ripening)
- 2) Permit irradiation of any food with doses up to 100 kilorads for the purpose of insect control
- 3) Permit irradiation of foods for other purposes at doses up to 100 kilorads if it can be shown that this would accomplish its intended purpose
- 4) Not require irradiation to be declared on retail food labels (a change from the current law, which requires it).

The FDA proposal has received widespread support but has also encountered disappointment and opposition.

The 100-kilorad limit is one source of disappointment. This is only one-tenth of the radiation level permitted by the World Health Organization. It eliminates some potential uses of irradiation that require slightly higher doses and it would impede international trade in irradiated foods. The pace of the rulemaking process is another cause of disappointment. It has been unusually slow even by the turtle-like standards of federal regulatory agencies.

The proposal's most notable opponents are the Health Research Group (HRG), a component of the Public Citizen organization founded by Ralph Nader, and the National Health Federation (NHF), a health food industry organization which has campaigned in favor of laetrile and unpasteurized milk [see NF 2:1-4] and against water fluoridation, compulsory immunization of children, and government regulation of vitamin sales.

HRG's director, Sidney Wolfe, M.D., contends that irradiation has not been adequately tested for safety. Most experts, including those at the FDA, disagree. Dr. Wolfe has also expressed concerns about radiation hazards to workers at food irradiation facilities and about the transport and disposal of hazardous radioactive materials.

Wolfe and some like-minded opponents of irradiation make it sound as though the transport and occupational safety issues are new. In fact, the necessary precautions are well understood because a substantial irradiation industry already exists. At least 30 percent of the sterilization of medical devices in the U.S. is done with irradiation, according to John Masefield, head of the irradiation firm Isomedix, Inc. There are some 50 medical product irradiation facilities in this country already. In addition, more than 1,000 hospitals use radi-

oactive cobalt for radiation therapy. The occupational safety record of the irradiation industry is excellent, and the shipment of cobalt rods to and from irradiation facilities is routine. In fact, the shipping containers for these rods are so durable and well shielded that the Department of Transportation allows shipment by common carrier.

Health Freedom News, NHF's monthly magazine, has published several articles suggesting that irradiation is dangerous. In its February 1985 issue, a letter from one reader even insists that, "Eventually, *all* edibles will be zapped with radiation . . . When this happens, all life-giving vitamins, minerals, enzymes, amino acids, and other food nutrients necessary to health will be destroyed. Foods POISONED to death! And—we, in turn, also POISONED to death! Literally millions of people will develop cancer and other degenerative diseases to suffer and die five to ten years down the road." The magazine's editors (NHF's president and board chairman) respond by thanking the reader for "manifesting this very real problem."

Unlike HRG, however, NHF has not expressly opposed FDA approval of irradiation. Instead, it has been generating a nationwide letter-writing campaign aimed at getting FDA to require that irradiation be declared on food labels. NHF's philosophy states that people should be allowed to take any risk they want with their health, so long as they are informed of the risk. This viewpoint is contrary to the basic concept of U.S. food and drug law that only safe new products and processes should be approved. However, consumers who do not support the NHF's view of "health freedom" have also called for labeling of irradiated foods.

The case for labeling is simply stated. Some people want to know whether their food has been irradiated so they can make an informed choice of foods. The arguments against labeling are more complex. Obviously, some proponents of irradiation oppose labeling because they think that people won't buy foods labeled "irradiated." But even if people were perfectly willing to buy labeled foods, the cost and logistics of labeling might make it impractical.

When unprocessed foods are sold directly to consumers, they usually have no label at all. The difficulty and expense of putting labels on foods that don't normally have them might mean that fresh fruits, vegetables, meats, and seafood would never be irradiated. Yet

most of the potential applications of irradiation involve just these commodities.

If irradiated commodities were used as ingredients in processed food products, extensive recordkeeping would be necessary to ensure correct labeling of the final products. This would put irradiated ingredients at a competitive disadvantage.

Radiation Technology, Inc., which is irradiating spices, reports that some food companies won't accept irradiated spices because of the costs of recordkeeping and labeling. Instead they are using spices decontaminated with ethylene oxide, which does not have to be declared on food labels, even though they acknowledge that many of the irradiated spices are of better quality.

There is no health reason to declare irradiation on labels. No special population subgroup that needs to avoid irradiated foods in the way that phenylketonurics need to avoid aspartame. There is no allergy to irradiated foods as there is to Yellow Food Dye #5 (tartrazine). Nor do consumers need to know that a food has been irradiated in order to handle it safely. It might even become desirable to label some foods that were not irradiated! If irradiated pork becomes the standard, as the pork industry hopes it will, warning labels may well be required to warn consumers that pork that had not been irradiated should be thoroughly cooked.

Senator Slade Gorton and Representative Sid Morrison (both R-WA) are the principal sponsors of the Federal Food Irradiation Development and Control Act of 1985, which is designed to promote commercial use of food irradiation in the U.S. Even if this bill never passes, its introduction has generated interest in irradiation and helped to publicize its positive aspects. The Morrison-Gorton bill would redefine irradiation as a process, but still maintain FDA responsibility for assuring its safety. More important, the bill would establish a governing commission to coordinate and encourage governmental and private research and development.

If the FDA publishes its long-awaited final rule this year, commercial use of food irradiation could start quickly. Several companies have been gearing up for it for years. By the end of 1986, you may be able to "ask for yours irradiated" at the supermarket.

Mrs. Meister is a research associate with the American Council on Science and Health.

Briefs

FDA won't ban raw milk. On March 15th, FDA Commissioner Frank E. Young, M.D., Ph.D., denied the Public Citizen Health Research Group's petition to ban sales of certified raw milk [see NF 2:1-4]. Dr. Young claimed that "the small amount in interstate commerce does not justify federal action, particularly in light of the fact that effective state regulation would eliminate the problem." Although recognizing that certified raw milk has no significant health benefit and is a public health problem, Dr. Young said that preventing a small amount from being shipped by one or two dairies to "a few neighboring states" would be "an inefficient use of federal authority in light of the truly national problems that need to be addressed." [Editors note: Remember, this is the FDA Commissioner who last year roared into office promising strong opposition to quackery. About 30 states now prohibit intrastate sale of unpasteurized milk and milk products. Apparently, Dr. Young doesn't think that a federal ban would encourage additional state action.]

Wheat germ oil. Under a proposed FTC consent agreement, the makers of Octacol 4 cannot make unsupported claims that the product or its ingredients can improve any aspect of physical fitness or athletic performance. The product contains wheat germ oil and four other ingredients—octacosanol, triacontanol, hexacosanol and tetracosanol—which the companies claimed were the "four sports stamina factors." Octacol 4 is manufactured by P. Leiner Nutritional Products Corp. (formerly PLNP Holdings Inc.) and its subsidiary, P. Leiner Nutritional Products Inc. of Delaware (formerly P. Leiner Nutritional Products Inc.).

Health food store sales drop again. Based on its annual survey, *Health Foods Business*' estimates that total 1984 sales at "natural food" stores were \$1.68 billion, a 16% drop from the previous year. Sales figures for individual categories included: vitamins and supplements, \$526 million (-29.6%); herbal teas, \$47.1 million (-13.1%); other herbal products, \$139.6 million (+0.7%); and books, \$63.9 million (+17.7%). The number of health food stores dropped from 7,700 to 7,320. The industry experienced a 17.6% drop in 1983 [see NF 1:5]. *Health Foods Business* attributes the 2-year slump to "new forms of competition not only from mass market retailers, but also from giant food processing companies and large pharmaceutical houses which apparently found the appeal of the word 'natural.'"

Diet and cancer report. "The idea that specific foods can cause or prevent cancer has taken on the aura of a national policy, yet behind the scenes there is tremendous disagreement among the experts on this issue." So states the American Council on Science and Health (ACSH) in the press release for its latest publication, *Diet and Cancer*. The 30-page booklet was written by Professor Michael W. Pariza of the University of Wisconsin's Food Research Institute and was reviewed prior to publication by more than 40 other prominent scientists. Noting that "some individuals may want to modify their own diets on the basis of tentative evidence currently available," the report concludes that the evidence is insufficient to warrant establishment of a public policy of dietary guidelines for the purpose of reducing cancer risk. A free copy can be obtained by sending a self-addressed, 4½" x 9" envelope with 39¢ postage to Diet and Cancer Report, ACSH, 47 Maple St., Summit, NJ 07901.

CU stings health food industry and FDA. After a 5-month investigation, *Consumer Reports* magazine has concluded in its May issue that "lack of an effective FDA enforcement policy" has been a significant factor in the growth of quackery in the United States. Research for the story included purchase of more than 300 questionable products and 11 distributorships in multilevel companies, including Herbalife. The report lists 42 companies that appear to be illegally marketing or distributing at least one product. Unacceptably high levels of bacteria were found in "raw glandular" products made by two other companies. Copies of the May issue are available for \$3 from the Back Issue Dept., *Consumer Reports*, P.O. Box 2840, Boulder, CO 80322.

Robertson-Taylor update. Acting on an FDA complaint, U.S. marshals seized more than 110,000 bottles and jars of 24 illegal products with an estimated retail value of \$2.4 million from the warehouse of the Robertson-Taylor Co., of Fort Lauderdale, Florida. The company has also done business as Connor Freeman Laboratories, Bio-Technic Laboratories, Intra-Medic Formulations, Inc., W.G. Charles Co., J.F. Pharmaceuticals, and Customer Service Distribution Center. The action came after a warning letter sent in November 1984 was ignored. [See NF 1:19 for other government actions against Robertson-Taylor.]

Raw fish parasites. Consumers of sushi (raw fish) risk acquiring parasites that cause acute abdominal pain within 12 hours, often accompanied by nausea and vomiting. In the February 15, 1985 *Journal of the American Medical Association*, Japanese researchers reported 178 cases of acute anisakiasis—caused by infection with the larvae of an intestinal worm from the ascaris family. Most of the patients had eaten raw mackerel; a few had eaten horse mackerel, bream, squid, sardines or bonito, and the rest did not know what type of fish they had consumed. The disease is prevalent in Japan and rare in the United States. However, an official of the U.S. Centers for Disease warns that some fish in U.S. waters are infected and that increased international travel and acceptance of raw fish have increased the potential for anisakiasis in this country. Smoking or cooking fish to a temperature of 140°F or higher or freezing it at -4°F for 3 days kills the larvae; salting, marinating and cold smoking do not.

Herbalife attacked. The California Attorney General and two other California agencies have filed a civil suit accusing Herbalife and several of its executives of “numerous unfair and illegal statements and practices.” These include making unapproved drug claims for some products, misrepresenting that herbal ingredients will curb appetite, and marketing an illegal pyramid scheme.

Bee pollen suspected of toxicity. The *Tucson Daily Star* reported that a family of three were treated in the emergency room for nausea, dizziness and inability to focus their eyes after eating bee pollen in their cereal at breakfast. Dr. William Banner, medical director of the University of Arizona’s poison and drug information center, said that the adverse reactions appeared to be caused by a toxin that affected the central nervous system, and that he has asked the FDA to help identify it.

SCHISANDRA

Varro E. Tyler, Ph.D.

Perhaps the newest of the old drugs resurrected by the American herbal medicine industry is schisandra, or schizandra, the dried ripe fruit of *Schisandra chinensis* (Turcz.) Baill., a tree native to China. Its ancient folkloric use there was as an antiseptic, astringent, tonic and the like. During the last decade or so, Chinese doctors began using the drug to treat hepatitis, and a few studies have been done of its potential for liver-protective effects and the nature of its active constituents.

Western herbal advocates now acclaim schisandra as an “adaptogen,” an agent supposedly capable of increasing the body’s resistance to disease, stress, and other debilitating processes. In 1980, claims to this effect appeared in *Maa Bra*, a Swedish health magazine. Citing this source, Carlson Wade, author of many books and articles on unproven methods, suggests that schisandra can “supercharge the body and create vigor.” (Curiously, he says it can help insomnia as well.) He also recommends it for fatigue, exhaustion, chronic gastritis, neuroathenic disorders, and eyesight difficulties.

Herbalife International claims that its herbal/vitamin/mineral mixture Schizandra Plus can “help to combat damage that can lead to premature aging.”

Freedom Marketing Corporation, of Westmont, Illinois, has been advertising to “nutrition consultants” and chiropractors that its schisandra-containing product, Adaptogen, is “capable of providing a more healthy, active and longer lifespan.” The ads also claim that it is effective against premenstrual syndrome, stimulates immune defenses, balances body function, normalizes body systems, boosts recovery after surgery, protects against radiation, counteracts the effects of sugar, optimizes energy in times of stress, increases stamina, protects against motion sickness, normalizes blood sugar and blood pressure, reduces high cholesterol, shields against infection, improves the health of the adrenals,

energizes RNA-DNA molecules to rebuild cells, and “produces energy comparable to that of a young athlete.”

Limited studies of schisandra’s effects have been carried out in small animals. An investigation conducted by L. Volicer and colleagues in Czechoslovakia in 1966 noted that the drug had a stimulating effect in low doses, but this was reversed with large doses. These actions are similar to those of nicotine.

The constituents responsible for the liver-protective effects of schisandra are apparently lignans—molecules composed of two phenylpropanoid units. More than 30 of these have been isolated from schisandra, some 22 of which were tested in 1984 by the Japanese investigator H. Hikino for their ability to reduce the cytotoxic effects of carbon tetrachloride and galactosamine on cultured rat liver cells. Most were found effective, and some were quite active. However, when galactosamine was used as a cytotoxic agent, the protective effects of the lignans were reduced at higher doses. Dr. Hikino concluded that the lignans of schisandra were themselves toxic to the liver when administered in large doses over a long period of time.

Thus the reported evidence that schisandra has stimulatory and liver-protective effects is equivocal and quite preliminary in nature. To determine whether schisandra has practical value as a drug, long-term studies of safety and effectiveness at various dose levels—first in animals and ultimately in human beings—would be needed.

Dr. Tyler, Dean of Purdue University’s Schools of Pharmacy, Nursing, and Health Sciences, is an expert in pharmacognosy (the science of medicines from natural sources) and author of *The Honest Herbal*, an evaluation of popular herbs.

DHEA: FACTS VS. HYPE

John J. Cunningham, Ph.D.

The Life Extension Foundation of Hollywood, Florida, calls DHEA "the miracle weight-reducer of the '80s" and suggests that "if DHEA can do for humans what it's done for laboratory animals, we'll be able to eat all the food we want and still lose weight." It also calls DHEA an "anti-cancer agent that may slow down the aging process."

Ads for General Nutrition Corporation's "Fat Fighter" tablets containing 500 mg DHEA claim that "DHEA lets you eat . . . just as you normally do and still keep the pounds off."

Ads for CAL CONTROL DHEA, sold by the Health Savings Center of Valley Stream, N.Y., claim that "DHEA converts the calories we eat into energy instead of fat."

Flyers for Great Earth Vitamin Stores, the second largest health food store chain, claim that its MAINTAIN DHEA Complex enables dieters to "resume normal eating habits without gaining back weight. MAINTAIN will not suppress your appetite. Its 'fat-fighting' effect is cumulative; the longer you stay with it, the more effective it is."

The above claims are said to be based on experiments which showed that laboratory animals given DHEA lived longer and had a lower incidence of obesity and cancer than expected. This rationale is spelled out clearly in a 1983 article titled *DHEA*, written by Earl Mindell, author of *Vitamin Bible* and co-founder of the Great Earth chain. Let's look at some of the statements in his article and place them in perspective. (I have numbered the statements for the reader's convenience; they are not numbered in the article.)

Statement #1: DHEA is a natural hormone produced by the adrenal glands in mammals.

This is true. DHEA (dehydroepiandrosterone) and its sulfated conjugate DHEAS constitute the most abundant steroids secreted by the adrenal glands in adults. Actually, circulating levels of DHEAS are 150-250 times those of DHEA throughout life, perhaps due to the improved solubility of the sulfated form. Degradation products of DHEA account for 10-30% of the total 17-ketosteroids excreted in the urine. The DHEA sold in health food stores is extracted from bovine tissue or from Mexican yams.

It is important to remember that the body normally exerts tight regulation over hormone levels so that they circulate in optimum amounts. The fact that DHEA is "natural" does not mean that it cannot harm the body. Excess amounts of steroids can disrupt normal body processes whether they are generated by the body or come from an outside source.

Statement #2: The body produces the peak amount of DHEA at the age of 25. As we age, the produc-

tion of this hormone declines steadily, so that at the end of life, the amount found in the body is only about one twentieth (1/20) of the peak level.

This is true. Little DHEA/DHEAS is produced during childhood, with the exception of the first few weeks of life when the placental-fetal hormonal interactions are tapering off. Production increases at about age six in both sexes, and thereafter circulating DHEA/DHEAS levels increase in parallel with pubertal progression. During adult life, DHEA/DHEAS levels are lower in women than men and decline with age in both sexes. Most people gain weight as they get older. The subtle suggestion here is that aging and weight gain are caused by decreased DHEA production and therefore can be reversed by DHEA supplementation. There is no evidence that this is true.

Statement #3: Schwartz et al. at Temple University School of Medicine have shown that . . . when DHEA was fed to mice, it increased their life expectancy from 24 to 36 months, which is the equivalent of 35 to 40 human years. The mice seemed younger and had a lower incidence of many of the traditional diseases of aging than mice on regular diets.

Mice fed DHEA may live longer and more healthy lives, but younger-looking mice are not necessarily less aged. Studies at the Jackson Laboratory in Maine have found that DHEA fed to old mice improves glucose tolerance and reduces plasma insulin to "younger" levels. But aging involves much more than carbohydrate metabolism.

Statement #4: DHEA appears to be the first substance that allows animals to lose weight without changing their appetite. They eat normally. The calories are converted to heat rather than fat, thereby allowing the animals to lose weight.

Several studies of DHEA have been conducted on special strains of mice or rats that are genetically predisposed to obesity. When fed DHEA, these rodents gained less than expected, but they did not lose weight. If DHEA affected obese humans similarly, it would prevent further fat accumulation but would not cause weight loss. The doses given these rodents were at least 50 times greater than those presently marketed for humans. Moreover, genetically obese BL/Ks mice studied at Jackson Laboratories gained weight normally while consuming the highest dose of DHEA. And genetically obese Zucker rats gained less weight but developed heavier livers—as did lean Zucker rats fed DHEA—which may signify that excess DHEA is toxic to the liver.

Statement #5: Terence T. Yen, a biochemist at Eli Lilly in Indianapolis, found that when DHEA is fed to obese mice, their weight drops significantly.

Not true. Dr. Yen found that DHEA prevented un-

derweight mice from getting fat.

Statement #6: It reduces the risk of developing breast, colon and lung cancer in the mice. Other studies have found that DHEA can reduce the risk of developing cancer of the liver, skin and lymphatic tissues.

It is true that studies in rodents have shown high-dose oral DHEA to be an effective agent in the treatment of rats bred to be highly susceptible to tumor development and diabetes. But what these have to do with humans is anybody's guess.

Statement #7: More research is going on with DHEA to test for harmful side effects.

Despite being the most abundant circulating steroids in adults, the functions of DHEA and DHEAS are not completely known. But it is known that they are converted into a male sex hormone (androgen) that stimulates the growth of secondary sexual hair and other maturation effects during puberty.

While no adverse side effects have been reported to date in either animals or humans, *the unproven benefits of DHEA for weight control should be considered in light of abnormalities associated with elevations of this steroid.* It is known that in females, excess DHEA production causes excessive male pattern hair growth (hirsutism) and enlargement of the clitoris—a condition called the adrenogenital syndrome.

The pubertal rise in DHEAS in girls (as well as oral supplements of 100 mg DHEAS in men with insufficient androgen hormone) induces sebum production and may thus contribute to acne. A study reported in the *New England Journal of Medicine* in 1983 found that 80% of both men and women suffering from treatment-resistant acne had elevated blood levels of DHEAS. Virtually all of these patients benefited from therapy designed to reduce this steroid excess.

Athletes consuming 40 mg DHEAS daily for one month have been found to have a 26% reduction in red blood cell 2,3-DPG, a substance active in oxygen deliv-

ery to tissues. Oral doses of 60 mg given to men daily for two months decreased circulating testosterone by 60%. Rodent models of DHEA feeding may be inappropriate for detecting these side effects.

The above facts indicate that people who use DHEA with the hope of losing weight are unlikely to succeed and could be inviting trouble by tampering with their hormones. As with other situations of fadism, it is likely that some users will take more than the "recommended" amounts, especially when they see that the recommended dose fails to deliver the desired weight loss.

The cautions in this article are based on the assumption that products sold through health food stores might contain pharmacologically potent amounts of DHEA. Actually, they may not. Progenics, a New York City firm which supplies DHEA and its metabolites to Jackson Laboratories and other research facilities, recently analyzed three different "DHEA" products from a health food store. According to company president George Krsek, Ph.D., two contained less than 10 mg of DHEA per 100-tablet bottle and none could be detected in the third!

Regardless of their potency, the fact that unproven therapeutic claims are being made for DHEA products makes them "unapproved new drugs" that are illegal to market in interstate commerce. On April 9th, after about a year of "active investigation," the FDA warned their manufacturers and distributors to stop selling them.

It is conceivable that etiocholanolone, beta-etiocholanolone or some other chemical derivative of DHEA could favorably alter energy balance without posing a risk of serious side effects. However, this possibility has not been scientifically documented.

Dr. Cunningham is a pediatric endocrinologist at the Shriners Burns Institute in Boston.

WRITER SUED FOR "MALPRACTICE"

Dr. Morton Walker, a Stamford, Connecticut podiatrist who has been writing full-time for more than 15 years, is a defendant in a suit filed last year by a Detroit man treated with chelation therapy [NF 1:9]. To help persuade the patient that chelation was effective for improving circulation to the legs, the doctor in the case had displayed a copy of *Chelation Therapy: How to Prevent or Reverse Hardening of the Arteries*, written by Walker. Originally published in 1976, the book had been specially reprinted in 1981 by M. Evans & Co., of New York City, for use by the American Academy of Medical Preventics, an organization of chelation doctors—which sold copies to its members.

Biographical material distributed by Walker states that he "specializes in writing self-help books in the holistic health field" and has written more than 15 books and 1,000 published articles. According to a recent article he wrote in the National Health Federation's *Health Freedom News*, the suit papers allege that he had committed malpractice by practicing medicine without

a Michigan license and had been negligent because his book gives medical opinions and advice. The book's publisher then sued Walker in a cross-complaint, stating that he had warranted that the book contain no injurious instructions. Walker's article states that he has instructed his attorney to countersue the plaintiff and his attorneys for violating his civil rights.

A highly talented wordsmith, Walker is a former editor of the American Medical Writers Association and is an active member of the American Society of Journalists and Authors. The Society has voiced objection to the suit and wants it dismissed by the courts because of its possible chilling effect on authors. On the other hand, Dr. William Jarvis, president of the National Council Against Health Fraud, believes that "no one need fear the responsible reporting of health information, even if it turns out to be in error, as long as they acted in good faith," and that "misleading the public in serious health matters is more freedom than socially responsible writers need."

TRAVELERS' DIARRHEA

The common practice of taking medication to prevent travelers' diarrhea (TD) is inadvisable because, except in certain high-risk situations, the risk outweighs the benefits. So judged the majority of 14 experts who met January 28-30 for a consensus development conference at the National Institutes of Health. Instead the group recommended: 1) avoidance of raw foods and tap water; and 2) bringing an antimotility drug for treatment of mild diarrhea and an antimicrobial agent for severe cases. By being prepared, travelers can avoid buying potentially dangerous drugs abroad and can begin treatment promptly when needed.

TD is by far the most frequent health problem of travelers to foreign countries. About a third of the more than 8 million Americans traveling to developing countries this year are expected to get it. The condition is caused by a variety of infectious agents in fecally contaminated food or beverages. The most common organism is *E. coli*, but many other bacteria, viruses and protozoa have been implicated in some cases. The usual symptoms are diarrhea, cramps and nausea. Bloody diarrhea, vomiting and fever are less common.

The basic rules of prevention can be summarized as "boil it, cook it, peel it, or forget it." But a recent study in which visitors to the tropics kept records of their first three days abroad found that only 13 out of 688 committed no dietary mistakes. Seventy-one percent consumed salads or raw vegetables; 70% ate fruit that could not be peeled; and 53% did not refuse ice cubes. The incidence of diarrhea depended on the number of die-

tary mistakes. Those who used tap water for brushing their teeth had a slightly higher percentage of diarrhea than those who did not (22% vs. 16%).

Prudent dietary and hygienic practices will prevent some cases of diarrhea, but not all. For mild diarrhea, an antimotility drug such as diphenoxylate (brand name, Lomotil) or loperamide (Imodium) can be taken. Or bismuth subsalicylate (Pepto-Bismol), which works somewhat slower, can be used. For severe diarrhea, an antimicrobial agent can be used, the panel's favorites being trimethoprim/sulfamethoxazole (Bactrim, Septra and others), trimethoprim alone (Proloprim, Trimplex), or doxycycline (Vibramycin). Fluid and electrolyte balance can usually be maintained by consuming uncontaminated fruit juices, soft drinks and salted crackers. Alcohol, caffeine-containing beverages and possibly dairy products should be avoided if TD occurs.

Antimicrobial agents are not recommended for routine prevention of TD because widespread usage will cause side effects in many people and may lead to the development of antibiotic-resistant organisms. Antimotility drugs taken for prevention may actually increase the incidence of TD. And Pepto-Bismol is not recommended prophylactically because large doses of bismuth may cause neurological difficulty while ringing of the ears may result from the salicylate. A more sensible approach is rapid institution of effective treatment that will shorten the disease to 30 hours or less in most people. Before traveling abroad, one's doctor should be consulted about the suitability and usage of the various drugs.

FTC KILLS PROTEIN RULE

On December 20, 1984, the Federal Trade Commission voted 3-1 not to promulgate a trade regulation rule governing the advertising and labeling of protein supplements. Instead, it will handle violations individually. The rulemaking proceeding—which began with great fanfare in 1975—focused originally on false claims that protein supplements could burn fat, boost athletic performance or have special therapeutic properties. A ban on representing that protein supplements were suitable for infants was also considered. Commissioner Patricia P. Bailey, the lone dissenter, charged that the

agency had "abdicated its responsibility to protect the health and safety of consumers against irresponsible and possibly life-threatening commercial practices." She also expressed disagreement that "at the conclusion of a responsible rulemaking proceeding that supports modest provisions to regulate known abuses in the marketing of protein supplements, the Commission stopped just short of an effective, low-cost, industry-wide remedy and turned instead to an ephemeral new program of case-by-case law enforcement."

SOME NOTES ON LINUS PAULING

James Lowell, Ph.D.

The widespread public belief that vitamin C can prevent or alleviate colds is directly attributable to Linus Pauling, Ph.D., winner of the Nobel Prize for chemistry in 1954 and for peace in 1962. Currently, however, there is growing concern over his scientific integrity.

Pauling introduced the scientific community to his vitamin and health theories in 1968 in an article for *Science*, the journal of the American Association for the Advancement of Science. In this report, he coined the term "orthomolecular," meaning "right molecule." He postulated that people's nutrient and vitamin needs vary markedly and that to maintain good health, many people need amounts of nutrients much greater than the Recommended Dietary Allowances. And he suggested that megadoses of certain vitamins and minerals might well be the treatment of choice for some forms of mental illness.

In 1970 he published a book for the general public called *Vitamin C and the Common Cold*, which suggested that 1 gram of vitamin C daily would reduce the incidence of colds by 45% for most people, but that some persons might need larger amounts. The book recommended that if symptoms of a cold do start, 500 to 1,000 mg of vitamin C should be taken every hour for several hours (or 4 to 10 grams daily if symptoms don't disappear with smaller amounts). It also suggested that most people need a daily intake of 2,300 mg or more for "optimum" health and to meet stresses, including infections. A second edition, published in 1976 as *Vitamin C, the Common Cold and the Flu*, recommended even higher dosages, and Pauling himself says he takes 12 grams daily, increasing to 40 grams daily when symptoms of a cold appear.

Pauling says his initial interest in vitamin C was aroused by a letter from biochemist Irwin Stone, with whom he subsequently maintained a close working relationship. (Although Stone was often referred to as "Dr. Stone," his only credentials were a certificate showing completion of a 2-year chemistry program, an honorary chiropractic degree from the Los Angeles College of Chi-

ropractic, and a Ph.D. from Donsbach University, an unaccredited correspondence school. He died last fall after reportedly choking on a piece of meat at a banquet held in his honor.)

Pauling's case for vitamin C was not based on his own studies but on his evaluation of the research and statistics of others. However, the vast majority of reputable medical and nutritional scientists who have looked at the same evidence believe that supplementation with large doses of vitamin C does not prevent colds and, at best, may slightly reduce the symptoms of a cold. A thorough analysis of this subject—including the results of 16 well designed clinical studies—is contained in *Vitamins and Minerals: Help or Harm?*, by Charles W. Marshall, Ph.D. [George F. Stickley Co., 1983].

In 1973, Pauling, Arthur B. Robinson, Ph.D., and Keene Dimick, founded the Institute of Orthomolecular Medicine (subsequently renamed the Linus Pauling Institute of Science and Medicine) in Palo Alto, California. Robinson was a former student and long-time associate of Pauling. Dimick was an admirer of Pauling's work who made his fortune by developing the gas chromatograph, a device for analyzing the composition and structure of chemical compounds. Robinson became the Institute's president and director, and Dimick became a member of its board of trustees.

In the same year that the Institute was founded, the American Psychiatric Association released its classic *Task Force Report on Megavitamin and Orthomolecular Therapy in Psychiatry*. The report's conclusion, perhaps the most strongly worded statement ever published by a scientific review body, stated:

"The credibility of the megavitamin proponents is low. Their credibility is further diminished by a consistent refusal over the past decade to perform controlled experiments and to report their results in a scientifically acceptable fashion. Under these circumstances this Task Force considers the massive publicity which they promulgate via radio, the lay press and popular books, using catch phrases which are really misnomers like 'megavitamin therapy' and 'orthomolecular medicine,' to be deplorable."

Pauling, who had been promoting vitamin C for schizophrenia and other mental problems, defended his viewpoint in the *American Journal of Psychiatry* [131:1251-1257, 1974], claiming that the APA committee had used faulty arguments, drawn unjustified conclusions and was biased. But his arguments were thoroughly rebutted by Richard Wyatt, M.D., Acting Chief of the National Institute of Mental Health Laboratory of Psychopharmacy, and two other prominent psychiatric researchers [*Am. J. Psychiatry* 131:1258-1267, 1974].

During the mid-'70s, Pauling began claiming that vitamin C could be useful in the prevention and treatment of numerous other conditions, including cancer. He and Dr. Ewan Cameron, a Scottish physician, reported that a majority of 100 terminal cancer patients treated with 10,000 mg of vitamin C daily survived 3 to 4 times longer than similar patients who did not receive vitamin C supplements [*Proceedings of the National Academy of Sciences* 73:3685, 1976, and 75:4538, 1978.] However, this research was heavily criticized because the patient groups were not comparable.

As noted in a devastating critique by Dr. William DeWys, chief of clinical investigation at the National Cancer Institute, the vitamin C patients were Dr. Cameron's, while the other patients had been cared for by other physicians [*Your Patient and Cancer* 31-36, May 1982]. Cameron's patients were started on vitamin C when he labeled them as "untreatable" by other methods. Their subsequent survival was then compared to the survival of the "control" patients after they were judged "untreatable" by their doctors. If the two groups had been comparable, the lengths of time from entry into the hospital to being labeled untreatable should have been equivalent. However, Dr. DeWys found that Cameron's patients were labeled untreatable much earlier in the course of their disease—which means that they entered the hospital less sick than those of the other doctors and would naturally be expected to live longer.

In 1979 Cameron and Pauling co-authored *Cancer and Vitamin C*, which introduced their ideas to the lay public. In a July 1979 interview with *Prevention* magazine, Pauling even claimed that "mortality from cancer could be decreased by 75 percent by the proper use of vitamin C alone."

Three carefully designed studies have been conducted to explore the role of megavitamin C and cancer. In 1979, the Mayo Clinic reported a double-blind study covering 123 patients with advanced cancer [*New Engl. J. Med.* 301:687-690]. Half of the patients received 10,000 mg of vitamin C daily while the others received a placebo. No differences were found between the two groups in survival time, appetite, weight loss, severity of pain, or amount of nausea and vomiting.

An almost identical result was obtained in a study by the North Central Cancer Treatment Group, composed of physicians in seven states and Canada. As reported in the August 22, 1983 *Medical World News*,

survival curves for 71 patients receiving 10,000 mg of vitamin C and 73 patients receiving a placebo essentially overlapped, and median survival time for the placebo group was actually one week longer.

Pauling criticized the Mayo Clinic test, claiming that chemotherapeutic agents might have suppressed the patients' immune systems so that vitamin C couldn't work. But he appears to have contradicted himself on this point. His 1976 report on Cameron's work states clearly that: "All patients are treated initially in a perfectly conventional way, by operation, use of radiotherapy, and the administration of hormones and cytotoxic substances." In an interview in the June 25, 1979 *Medical World News*, Pauling claimed that only 4 of the 100 patients had received chemotherapy "and then in rather small amounts." And at a meeting which I attended in February 1985 at the University of Arizona, he stated that vitamin C therapy could be used along with all conventional modalities.

Nevertheless, because of Pauling's criticisms, the Mayo Clinic experiments were repeated using untreatable cancer patients who had not received chemotherapy. As reported in the January 17, 1985 *New England Journal of Medicine*, vitamin C did no better than a placebo in a double-blind study of 100 patients. In an accompanying editorial, Robert Wittes of the National Cancer Institute in Bethesda, Md., explains why the study was excellent and would be difficult to fault in design or execution.

Undaunted, Pauling has called the new experiments "a fraud on the American people." He has charged that the Mayo group's study did not last long enough and therefore was not a proper challenge to his conclusions. A UPI story even reported that Pauling asked *The New England Journal of Medicine's* editors to retract the "lies" in their article and apologize to him. Otherwise, he said, he might file suit.

Evidence exists that taking high doses of vitamin C may actually promote some types of cancer. In a recent telephone interview, Robinson told me that his own research led him to conclude in 1978 that the high doses (5-10 grams per day) of vitamin C being recommended by Pauling might be harmful and could actually promote some types of cancer in mice. Robinson found, for example, that animals fed quantities equivalent to the recommended ones contracted skin cancer almost twice as frequently as the control group. Only doses of vitamin C that were nearly lethal, according to Robinson, had any protective effect.

Robinson (now director of the Oregon Institute of Science and Medicine in Cave Junction, Oregon) told me that shortly after he made these findings known to Pauling, he was asked to resign from the Institute. His experimental animals were killed, his scientific data were impounded, and some of the previous research results were destroyed. Pauling also declared publicly that Robinson's research was "amateurish" and inadequate.

Nevertheless, according to Robinson, Pauling

sent a manuscript to him 19 months later including some of Robinson's results but omitting mention that certain doses had doubled the cancer rate in mice and that "protective" doses were almost lethal. In fact, Robinson said, Pauling's final paragraph stated that if the dose were doubled again, vitamin C would give complete protection against skin cancer in the test animals. He said that Pauling had not done the research, so he was not aware that doses that high (given by mistake) had actually killed all the mice. Eventually, he said, Pauling published the misleading reports on his own in a Brazilian symposium.

Pauling's version of the research is somewhat different. During a recent interview at the University of Arizona Health Sciences Center, he told me that he had designed the experiments and that Robinson had just carried them out. Pauling contradicted himself, however, because he also said that the part of the research he published was his half of the work (apparently the part that didn't show the toxicity), and that Robinson could have published his own research himself. But Robinson told me that the research was never completed and therefore was unpublishable.

In 1978, Robinson filed a \$25.5 million libel and slander suit against the Institute and its trustees. [An excellent account of the case was published in the June 11, 1979 *Barron's*.] In 1983, the suit was settled out of court for \$575,000. Quoted soon afterward in *Nature* [303:103], Pauling said that the settlement "represented no more than compensation for loss of office and the cost of Robinson's legal fees." However, the court-approved agreement states that \$425,000 of the settlement was for slander and libel and the balance was for attorneys' fees and other expenses.

Over the years, several studies have supported Robinson's contention that large doses of vitamin C may be harmful. Dr. H.F. Stich, for example has reported that the vitamin can cause damage to proteins and genetic material of the body and may cause mutations to certain types of cells. [*Nature* 260:722, 1976, and *Cancer Research* 39:41, 1979.]

Pauling told me that damage is not caused by the doses he recommends. He admitted that vitamin C can damage cells under certain conditions, but said that this damage may well be caused by factors other than the vitamin C itself, such as from the ions accompanying high doses of ascorbates.

Science aside, it is clear that Dr. Pauling is politically aligned with the promoters of unscientific nutrition practices. In *Vitamin C and the Common Cold*, Pauling attacked the health food industry for misleading its customers. Pointing out that "synthetic" vitamin C is identical with "natural" vitamin C, he warned that higher-priced "natural" products are a "waste of money." And he added that "the words 'organically grown' are essentially meaningless—just part of the jargon used by health food promoters in making their excess profits, often from elderly people with low incomes." But *Vitamin C, the Common Cold and the Flu*, issued six years

later, contains none of these criticisms.

This omission was not accidental. In correspondence with Dr. Stephen Barrett in 1981, Pauling explained that after the 1970 edition was published, he was "strongly attacked by people who were also attacking the health food people." He decided that his critics were so biased that he would no longer help them attack the health food industry while another part of their attack was directed at him.

During the mid-70s, Pauling helped lead the health food industry's campaign for legislation to weaken FDA protection of consumers against misleading nutrition claims.

Pauling, now 84, has been a frequent speaker at health food industry conventions and received the National Nutritional Foods Association's highest award in 1977. (The NNFA is the major trade association of all health food retailers, distributors and producers.) In 1981, he accepted an award from the National Health Federation for "services rendered in behalf of health freedom" and gave his daughter a life membership in this organization. (As detailed in *Vitamins and "Health" Foods: The Great American Hustle* [George F. Stickley Co., 1981], NHF promotes the gamut of quackery. Many of its leaders have been in legal difficulty and five have even received prison sentences for various "health" activities.) Pauling has also appeared as a speaker at the Parker School for Professional Success Seminar, a meeting where chiropractors are taught highly questionable methods of building their practices. An ad for the meeting invited chiropractors to pose with Dr. Pauling for a photograph which presumably could be used for publicity when the chiropractors returned home.

In 1983, Pauling and Irwin Stone testified at a hearing on behalf of Oscar Falconi, a vitamin promoter charged by the Postal Service with making false claims for several products. As reported in *Nature* [303:275, 1983], Pauling supported Falconi's contentions that vitamin C was useful not only in preventing cancer, but also in curing drug addicts and destroying both viruses and bacteria.

Pauling also testified in 1984 before the California Board of Medical Quality Assurance in defense of Dr. Michael Gerber, a Mill Valley physician accused of improperly administering to patients. One was a 56-year-old woman with treatable cancer who—the Board concluded—had died as a result of Gerber's neglect while he treated her with herbs, enzymes, coffee enemas and chelation therapy. The other patients were 3-year-old twin boys with ear infections for which Gerber had prescribed 70,000 or more units of vitamin A daily and coffee enemas twice daily for several weeks. Gerber, now an NHF board member, lost his license to practice medicine as a result of the hearings. [*Oncology Times*, August, 1984.]

The largest corporate donor (over \$500,000) to Pauling's Institute has been Hoffmann-La Roche, the pharmaceutical giant which is the dominant factor in world-wide production of vitamin C. Many of the In-

CANCER QUACKS PLEAD GUILTY

stitute's individual donors have been solicited with the help of Rodale Press (publishers of *Prevention* magazine) and related organizations which have publicized the Institute and allowed the use of their mailing lists.

The Institute's fund-raising brochures have been fraught with questionable information. They claim, for example, that no significant progress has been made in cancer treatment in the past 20 years. This viewpoint, which is frequently expressed by promoters of unproven cancer therapies, is simply untrue.

Two years ago, the Pauling Institute increased its connection with the promoters of unproven therapies by hiring Jeffrey Bland, Ph.D., to direct special research projects and oversee the Institute's laboratory program for analyzing food supplement products and certifying their contents with a seal of approval. Bland is a biochemist who often decries the methods of the traditional medical community and promotes questionable and unproven methods of treatment. For example, he recommends the use of hair analysis in "designing a program to optimize your health" and the use of ground-up animal organs ("glandulars") for treating diseases in corresponding human organs.

Robinson told me that Pauling was fond of saying that he and his wife never got colds because they were taking 10 grams of vitamin C a day, but that Pauling actually had colds "frequently." During the mid-1970s Pauling's wife contracted stomach cancer (which later resulted in her death). Pauling claimed she had stopped taking vitamin C by that time, but Robinson, who was a frequent visitor at the Pauling ranch, said the couple regularly put teaspoons of vitamin C into their orange juice.

According to a recent article in the *Chicago Tribune*, Pauling's 1984 speaking agenda included some 150 talks on science, world peace, nutrition and disease, and the benefits of megadoses of vitamin C. And he is working on a book whose tentative title is *Vitamin C for a Better Life*.

Dr. Lowell, a board member of the National Council Against Health Fraud, is Professor of Life Sciences at Pima Community College, Tucson, Arizona, and a columnist for *The Arizona Daily Star*.

More than a dozen individuals have pleaded guilty to various criminal offenses in connection with the operation of the Universal Health Center in Matamoros, Mexico, just across the border from Brownsville, Texas. The clinic was closed by Mexican officials in December 1983, and its operator, James Gordon Keller and his brother Ronald are wanted by the FBI on a fugitive warrant.

Government action in this matter was triggered by a lengthy investigation by the *Brownsville Herald* that involved more than 100 interviews. Among other things, the newspaper reported:

- Keller had run a similar clinic in Baton Rouge, Louisiana, which was closed by FDA and state authorities in 1983. He then opened the Matamoros clinic and bought condominiums in Brownsville to rent to patients who paid about \$3,000 for two weeks of treatment. The operation grossed over \$100,000 per month.
- Almost all of Keller's patients were referred by a woman in Salt Lake City who operated as "Western Health Research" and the "Western Research Center." Until her recent indictment for interstate wire fraud, callers to her 800 number could have travel arrangements and appointments made for one of several "cancer clinics."
- The Universal Health Center's brochure offered "an effective therapeutic approach to treatment of cancer and other diseases, including multiple sclerosis, lupus erythematosus, Parkinson's muscular dystrophy, rheumatoid arthritis, cardiovascular and other degenerative diseases." For cancer therapy, Keller used "Tumorex" and a wide variety of other unproven remedies. (Analysis of samples of Tumorex in an Arizona case revealed that it was merely L-arginine, an amino acid.)
- Keller's cancer patients fit into two main types: terminal patients deemed incurable by orthodox treatment and treatable patients who would have a high cure rate with standard chemotherapy or x-ray therapy.
- Keller reportedly claimed that his treatment could cure over 80% of cancers if there was no previous conventional treatment and 50% if conventional methods had already been tried.
- The Matamoros clinic kept few records of its patients, many of whom died soon after returning home, despite being pronounced "cured" by Keller.
- Patients were told that insurance companies would cover claims for Keller's treatments—which was not true.

A few weeks after Keller's Matamoros clinic was closed, he opened the St. Jude International Clinic in Tijuana, Mexico, which is still in business.

PAYMENT DENIED FOR UNPROVEN TREATMENT

On April 8th, a New York State appeals court panel ruled unanimously that denial of insurance coverage for an unproven therapy "will have the desirable effect of affording greater protection to the general public and, in particular, cancer patients who are especially vulnerable to unfounded claims of miraculous cures. The Court hoped further that its decision would insure that the treatment rendered on behalf of patients is administered in facilities comporting with certain minimal standards and that its effectiveness has been adequately demonstrated by studies conducted in accordance with appropriate scientific methodology before the resources of a major insurer are utilized to support it."

One issue in the case was whether La Gloria Hospital, of Tijuana, Mexico, could be considered a hospital under the terms of a policy issued by Blue Cross and Blue Shield of Greater New York. Noting that it "specializes almost exclusively in an unorthodox and scientifically unproven treatment of cancer," the appellate court said La Gloria was not a qualified hospital. The court also ruled that Gerson dietary therapy came within the policy exclusion for "experimental procedures." The new ruling reversed that of a lower court which in 1983 had ordered payment of \$15,583.78 for services rendered in 1981 and 1982 to plaintiff Harry J. Zuckerberg. Zuckerberg died subsequent to the 1983 trial.

IDENTIFICATION OF CAFFEINE IN SLIM TEA

Varro E. Tyler, Ph.D.
Deepa Bakshi, Ph.D.
Jerry L. McLaughlin, Ph. D.

The advertisement reads: "Now! Secret Beverage Can Help You LOSE WEIGHT NATURALLY! (It's worked for over 1500 years.) LOSE 30 lbs. or more—EASILY!" Slim Tea is the product. Supposedly, drinking a cup after each meal will make "the pounds disappear!" The ad suggests that because of this product, "Chinese stay slim . . . rarely suffer from excess cholesterol, high blood pressure or other ills caused by the retention of fatty substances." The price: only \$12.95 for 60 tea bags—a 20-day supply.

What is this secret beverage now available to the millions of weight-conscious Americans? The ad claims it is a "rare species of tea leaves grown in misty mountainous regions" and that it is "natural," 99.6% caffeine-free, and without additives. Being skeptical of the advertised claims, we bought a sample (6 tea bags for \$1.99) and examined it carefully. It looked and smelled like ordinary black tea. We then made a cup according to the directions on the package, allowing it to steep for 10 minutes. It tasted like strong black tea, and the central nervous system stimulation it provided suggested that it was loaded with caffeine.

So we took the product to the laboratory and boiled a 7.47g sample in 38 ml of water for 15 minutes and processed the resulting extract for caffeine as described by Tyler and Schwarting in the 3rd edition of *Experimental Pharmacognosy*. [Burgess Publishing Co., Minneapolis, 1962]. The procedure yielded 80 mg of a white crystalline solid which, on the basis of its melting point, co-chromatography, and infrared spectrometry was proven to be caffeine. This amount of caffeine constituted 1.07% of the weight of Slim Tea examined.

Comparisons were then made with the material in an ordinary Lipton's Orange Pekoe and Pekoe cut black tea bag. A quantity of 4.46 g was extracted, yield-

ing 110 mg of a white crystalline solid that was shown by the above tests to be caffeine. The yield in this case was 2.47%, well within the range of 1-4% commonly found in teas. It must be concluded, therefore, that the specimen of Slim Tea examined was simply a variety of black tea that had not been decaffeinated and was definitely not 99.6% caffeine-free as advertised.

Our findings thus support the statement of S.D. Uretsky in the February 1985 *American Pharmacy* that Chinese weight-reducing teas are just teas and have no more value in facilitating weight loss than the much less expensive name-brand black teas. There simply is no scientific evidence that caffeine or any ingredient in black tea has an appetite-suppressant effect. Any temporary feeling of satiety brought about by drinking quantities of liquid is probably more than counterbalanced by the diuretic effects of the caffeine and other contained xanthine bases, especially theophylline. Nor does long-term use of diuretics have any effect on fatty tissue.

The mislabeling of Slim Tea—like the contamination of comfrey tea with deadly nightshade that resulted in a serious case of poisoning reported in 1983—illustrates the poor quality control within the herbal products industry.

Dr. Tyler, Dean of Purdue University's Schools of Pharmacy, Nursing, and Health Sciences, is an expert in pharmacognosy (the science of medicines from natural sources) and author of *The Honest Herbal*, an evaluation of popular herbs. Dr. Bakshi holds a postdoctoral appointment and Dr. McLaughlin is Professor of Pharmacognosy in Purdue's Department of Medicinal Chemistry and Pharmacognosy.

Briefs

Insightful comment. "Even men and women who are not ill or in pain seek out health gurus and eat special foods or supplements that are supposed to enhance health or delay aging. Many are disillusioned with a medical establishment they feel is arrogant, impersonal and uncaring. With 'self-care' or 'lifestyle' approaches; they feel more in control of their bodies. They become convinced that all disease can be prevented or cured by living, thinking and eating differently. There's some truth in this, of course, but carried to extremes the philosophy is dangerous."—from "How to Spot a Health Hustler," by Dianne Hales [*Woman's Day*, 5/21/85].

"Stress vitamins" criticized. The Center for Science in the Public Interest (CSPI) has called Lederle Laboratories' program of marketing Stresstabs "a cynical attempt to perpetuate—and profit from—a public misconception." Quoted in CSPI's April *Nutrition Action Health Letter* (formerly called *Nutrition Action*). Lederle's chief nutritionist, Dr. Leon Ellenbogen, denies that his company recommends Stresstabs for psychological stress: "We want to completely absolve ourselves from that. We make it clear in the ads we're talking about physiological stress, such as alcohol consumption, smoking, pregnancy, drug therapies, and severe malnutrition from hospital stays or surgery." But CSPI nutritionist Bonnie Liebman notes that Lederle's messages to people who are "burning the candle at both ends" do suggest that Stresstabs are appropriate for emotional stress. She also notes that the ads are targeted toward the general public rather than to alcoholics, smokers and pregnant women—and that individuals in these groups don't require "the hefty levels of nutrients" found in "stress tablets."

SNE journal to increase frequency. The George F. Stickley Company has been named publisher of the *Journal of Nutrition Education*. Although its price will remain the same (\$30/year), the journal will be expanded and will appear six times a year instead of four. The first issue by the new publisher will be displayed at the Society for Nutrition Education's annual meeting in Los Angeles on July 7-10, 1985. Information concerning subscriptions and renewals can be obtained from the George F. Stickley Co., 210 W. Washington Sq., Philadelphia, PA 19106.

Herbalife drops suit. Herbalife has withdrawn its lawsuit against the FDA. Filed last November, it had charged that the agency had "engaged in a widespread and even corrupt 'trial-by-publicity' campaign to misinform the public by false and defamatory statements" against the company's products.

Grapefruit pillmaker squeezed. On December 3, 1984 a U.S. District judge signed a temporary restraining order against Citrus Industries of Beverly Hills and Los Angeles. The company, which advertised "Super Grapefruit Pills" as an effortless diet aid, had estimated monthly revenues of \$350,000 with an estimated high of \$900,000 in October 1984. A subsequent consent agreement with the Postal Service promised that the disputed claims would never be used again.

Spirulina also loses. A supply of spirulina tablets manufactured by Earthrise Co. Inc. of San Rafael, Calif. and shipped to Florida was ordered destroyed by the federal District Court in Miami. The pills, which had been falsely advertised as "one of nature's best sources of protein," were also judged to be contaminated with insect, animal and bird filth.

CCK warning issued. Manufacturers and distributors of alleged weight-loss products containing "CCK" (cholecystokinin) have been warned by the FDA to discontinue marketing them or face "regulatory action" by the agency. CCK is a hormone involved in the digestive process. Products said to contain it have been sold by mail and in health food stores with claims that they decrease hunger and can cause sudden and dramatic weight loss. However, although injections of CCK appear to decrease hunger in test animals, FDA scientists say that this research is not applicable to pills for human use. Even large doses of the hormone taken by mouth would have no effect on weight because the chemical is destroyed in the digestive tract.

Free alcohol pamphlet. As part of their education program to reduce drunk driving, Blue Cross of the Lehigh Valley and Pennsylvania Blue Shield have issued an attractive pamphlet describing the relationships between eating, drinking, and blood alcohol level. Single free copies can be obtained by sending a self-addressed, stamped 4½" x 9" envelope to Alcohol Guide, P.O. Box 1602, Allentown, PA 18105.

Hair analysis promotion. Probably in response to adverse publicity from the recent FTC hair analysis case [see NF 1:12, 2:24], Chicago-based Doctor's Data, Inc., has contracted with a public relations firm "for the purpose of getting positive media coverage on multi-element testing of hair." The company, which recently purchased the business of two other labs and is negotiating with a third one, is now the largest commercial hair analysis lab in the country. It has asked professionals who use its services to submit case reports so that the media can be given "a new, verified, case history every other week or even more often."

FTC may abandon another rule. The Federal Trade Commission staff has recommended that the Commission abandon its rulemaking proceeding (which began in 1975) on health spas in favor of case-by-case enforcement. The proposed rule provided for pro-rata refunds on memberships, a 3-day cooling-off period for rescinding contracts, a 5% limit on payments before a facility has actually opened, and a 2-year limit on the duration of membership contracts. The deadline for public comment is May 24th.

New antiquackery program. The FDA and the Council of Better Business Bureaus, Inc., have begun a joint program to issue special reports on health and medical frauds to consumer journalists. The first one, entitled "Arthritis: Quackery and Unproven Remedies," was distributed last month. Regarding nutrition, it states: "Except for gout, no specific diet has been proven useful in relieving arthritis symptoms . . . No herb, either singly or in combination with other herbs or ingredients, is a cure for any form of arthritis. Furthermore, there is no medical evidence that suggests that the lack of vitamins or minerals causes arthritis or that taking vitamins or minerals will offer a cure. A well-balanced diet is the best choice."

Free weight-reduction information. Single copies of a new FDA brochure, "How to Take Weight Off (And Keep It Off Without Getting Ripped Off)," can be obtained by sending a postcard to Weight Loss, HFE-88, 5600 Fishers Lane, Rockville, MD 20857. Quantities up to 200 can be obtained by writing to Weight Loss, HFW-40, at the same address. In addition, for groups and clubs, the agency has an exhibit, a slide/tape show and an 8-minute videotape that can be borrowed from the nearest FDA office.

New Rodale magazine. Rodale Press, publisher of *Prevention* magazine and many books that promote unproven nutrition methods, has launched *Superfit*, a quarterly magazine intended to appeal to "affluent, college educated males, 32 years of age, who are not super athletes but persons who want to be super." According to an article in the *Allentown Morning Call*, Rodale Press had gross sales of \$140 million in 1984.

Vitamin A going to Africa. Millions of megadoses of vitamin A donated by drug companies are being sent to combat nutritional blindness in Ethiopian and Sudanese children suffering from extreme vitamin A deprivation. Called Operation Sightsaver, the project is expected to span at least three years and is being coordinated by Helen Keller International, 15 W. 16th St., New York, NY 10011.

New FDA policy statement on cytotoxic testing. The FDA has issued a Compliance Policy Guide stating that cytotoxic testing kits [see NF 1:17-19] are devices under federal law and therefore require FDA approval prior to marketing. Noting that the test remains an unproven diagnostic procedure, the Guide warns that "the agency will consider appropriate regulatory action to enforce the statute, should violative test kits be discovered." [Editor's note: Considering how widely cytotoxic testing has been promoted, the FDA may have to work hard to avoid discovering the kits.] Single copies of the 4-page guide can be obtained by writing to the FDA Dockets Management Branch (HFA-305), Room 4-62, 5600 Fishers Lane, Rockville, MD 20857.

Vegetarian politics. Taking its cue from the American Cancer Society's Great American Smokeout, a California-based vegetarian group sponsored a "Great American Meatout" on March 21st, asking Americans not to eat meat for 24 hours. *American Medical News* reported that the campaign was launched with a demonstration at a slaughterhouse by 13 people who carried signs saying, "Meat is Murder" and "Here's the Beef." The group, which calls itself the Farm Animal Reform Movement, claims that meat consumption causes kidney failure, cancer and premature sexual development. It also claims that raising animals for food depletes agricultural resources and that "causes intense suffering to six billion animals annually."

Infant formula recalled. The FDA has announced that supplies of Kama-Mil powder are being voluntarily recalled by its distributors. According to an agency news release, the product would be hazardous if used as a sole source of nutrition. In addition, the manufacturer failed to comply with the Infant Formula Act which requires FDA notification prior to marketing in interstate commerce.

QUESTION BOX

Q. Is it true that chocolate milk interferes with the absorption of calcium?

A. Chocolate contains oxalic acid, which binds to calcium in the intestine, thereby preventing its absorption. However, because chocolate contains only a small amount of oxalic acid and milk contains a large amount of calcium, the amount of calcium absorption blocked in this manner has no practical importance. On the other hand, a few foods such as spinach and rhubarb contain enough oxalic acid to significantly decrease absorption of the calcium they contain.

WHY LICENSING OF "NUTRITIONISTS" IS NEEDED

Stephen Barrett, M.D.

Dietitians throughout America are spearheading legislation to achieve licensure for themselves and to restrict use of the word "nutritionists" to individuals with recognized credentials. Some of the bills being lobbied also define "nutrition practice" and restrict it to licensed practitioners. Opponents claim that bills of this type are motivated by greed and an intention to create a monopoly for one school of thought. But in my opinion, the key issues are credentials and public protection.

During the past century or so, our educational system has established a system of accreditation to ensure that schools meet appropriate standards of quality. At the same time, state governments have established licensing systems for many professions to ensure that practitioners meet appropriate standards of competence. In many fields, professional groups have established certification procedures that recognize additional levels of expertise.

Accreditation of a school means that its credits can be transferred to other schools and be used as a basis for entering various professions. If a person is licensed on the basis of an examination, it means that the state government has recognized the achievement of a certain level of competence. Certification conveys an additional endorsement of expertise.

Occasionally self-taught individuals acquire expertise with little or no formal education. However, the fields of health and nutrition are sufficiently complex that this is unlikely. Accreditation, licensure and certification are important because they can help to identify who is qualified. They offer no guarantee, but they do increase the odds of getting a competent practitioner.

Within the past five years, a very peculiar thing has happened in the area of nutrition. A number of individuals and organizations have developed several types of "credentials" which resemble those of established medical and nutrition organizations. I am aware of no other field in which this phenomenon has ever taken place.

During the past 50 years, perhaps 50 individuals without valid credentials have pretended to be medical doctors and actually managed for a time to practice. So far as I know, no one has ever been exposed as a fake dentist, podiatrist, optometrist, or even chiropractor. But in nutrition, unaccredited correspondence schools and other organizations have issued thousands of "degrees" and certificates which suggest that the recipient is a qualified expert in nutrition. What's wrong with this situation is that these documents are promoted as though they are equivalent in meaning to established credentials—which they are not.

I'm not going to get into the issue of what makes 5 to 7 years of full-time training for a masters or doctoral degree in nutrition superior to a correspondence course of 6 to 9 months based on unproven theories. The important thing is that at present, both kinds of practitioners can represent themselves as "nutritionists" and display their diplomas on the wall as though they mean the same thing.

I believe that it is unfair to expect people to check the credentials of every health practitioner they encounter. Rather, it should be the role of government to set licensing standards and to prevent individuals who don't meet the standards from representing themselves as equivalent to those who do. Licensing will not offer complete protection against all forms of nutrition practice conducted in private between consenting adults. But it will make it difficult for unqualified individuals to advertise widely that they are experts.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is editor of *Nutrition Forum* Newsletter and co-author/editor of 20 books including *Vitamins and "Health" Foods: The Great American Hustle*. In 1984, he received an FDA Commissioner's Special Citation Award for Public Service in combatting nutrition quackery.

ISSN 0748-8165

A FEW THOUGHTS ON THE RDA'S

Victor Herbert, M.D., J.D.

RDAs are the Recommended Dietary Allowances of the Food and Nutrition Board (FNB) of the National Research Council of the National Academy of Sciences (NAS), a private quasigovernmental agency. Members of the RDA Committee meet for several days at a time, 3 or 4 times a year, to discuss new scientific data; and they engage in extensive correspondence between meetings. The Committee deliberations result in a revised RDA book every four or five years, with the next report due for publication later this year. The book discusses each nutrient and the evidence upon which the RDA values are based. It concludes with a table of RDA values, which winds up—partially or totally—in practically all nutrition textbooks and numerous other publications.

The RDAs are set to encompass the range of individual variability of virtually all healthy Americans and usually include an additional margin for storage against days, weeks or sometimes months of no intake of a specific nutrient. The additional margin is kept below the level at which toxicity from overdose begins.

The RDA for any given vitamin or mineral usually is considerably more than the amount needed daily by any individual. Not only is it unnecessary to reach the RDA each day, but the 7-day RDA over an average week more than exceeds the need for virtually all normal people. RDAs are also set for energy (calories), but these levels are related to average needs without additional margin for storage.

The U.S. Recommended Daily Allowances (U.S. RDAs) are set by the Food and Drug Administration (FDA) based on the RDA table. The RDA for each nutrient varies somewhat with age and sex, and whether a woman is pregnant or lactating. U.S. RDAs are the largest values for each life-cycle category of the RDA table (currently based on the 1968 table). Percentages of U.S. RDAs per portion are listed on cereal boxes and the labels of many other food products. They are also required by law on the packaging of all vitamin and mineral products.

The RDAs and U.S. RDAs are appropriate guidelines for determining whether an individual con-

sumes adequate quantities of each RDA nutrient over the long term to assure normality plus a storage reserve. Whether each storage reserve should be as high as the FNB sets it is a policy decision rather than a scientific one. Over the years, some of the RDA values have become progressively lower as new evidence indicated that the excess over need can be lowered.

Health food industry critics of the RDA system suggest that differences in values set by scientific bodies in different parts of the world are evidence that the scientific community is racked with controversy or does not know what it is doing. Such criticism is unfounded. Differences from area to area are not great. In most cases, they are based on the fact that dietary habits of the various populations covered are different. The World Health Organization/Food and Agricultural Organization (WHO/FAO) recognized this by including in its international standards two RDAs for iron. Since iron is much more readily absorbed from meats than from vegetables (an average of 15% vs. an average of 3%), the vegetarian populations need a higher dietary intake than do meat-eating populations (such as Americans, whose mixed diets are considered to average 10% absorption). Similar considerations apply to zinc.

The Basic Four Food Group system, which classifies foods according to similarities of their leader nutrients, provides adequate amounts of nutrients when properly used. It is admittedly simple and suffers from minor shortcomings as a result. When scientists began to devise guidelines, they divided food choice into 17 groups. But this number was too unwieldy for people to remember, so it was reduced to 11, then 7, and finally 4. Thus each of the Basic Four has several of the original 17 groups compressed into it. For example, the current "grain group" includes breads, cereals and pastas. And the current "meat" group has six subgroups: meat, fish, poultry, eggs, nuts and legumes—all of which have protein as their leader nutrient. The key to using the Basic Four is to eat a variety of foods within each food group, and to use moderation in choosing portion sizes.

Supplements have a clear role in pregnancy, lactation and infancy. In these situations, nutrient needs may run ahead of nutrient supply. Because iron, calcium and folic acid often run low in pregnancy, supplements of these three nutrients have been recommended by the NAS Committee on Maternal Nutrition and are regularly prescribed by physicians. In 1981 it was discovered that the most popular prenatal vitamin/mineral preparations contained iron in an almost unabsorbable form, so that many pregnant women taking them remained deficient in iron. Such a situation can be avoided if supplement manufacturers were required to carry out studies comparing the absorbability of each nutrient in their products with that of the same nutrient taken alone as a pill by human volunteers eating an average Basic Four diet. It was a study of this type which revealed the problem with iron in prenatal supplements, caused by the way the pills were formulated. It would also be a good idea for absorbability to be indicated in labeling so that consumers can tell what they are actually getting.

Ads for "stress" vitamins suggest that daily intake of the water-soluble vitamins (C and the 8 B-vitamins) is so critical for good health that supplements should be taken for "insurance" against deficiency. That simply is untrue. Storage of these vitamins is limited but not nonexistent. Although the percent stored decreases as the quantity consumed increases, the more that is consumed, the more that is stored.

For example, look at vitamin C, whose 1980 RDA was set at 60 mg for adults. The range of daily need for virtually all healthy people is about 5 to 7 mg, and it is highly unlikely that any normal person needs more than 10 mg daily. Averaging 60 mg per day will result in storage in the liver and other tissues of approximately 1500 mg of vitamin C. This would be enough to last for 150 days, assuming a daily utilization of 10 mg and zero intake of vitamin C during that entire period.

It is very difficult to avoid taking in vitamin C regardless of what you eat. In the United States, vitamin C deficiency (scurvy) is rare, except among those alcoholics who never consume fresh fruits, fruit juices or vegetables, and whose damaged livers have reduced storage capacity for nutrients. One has to work really hard at it to develop vitamin C deficiency in this country, as noted in our case report on "Scalded Sardine Scurvy" [*JAMA* 246:2155-2156, 1981].

The patient in this case was not an alcoholic but had severe economic problems. Eight months before he sought medical attention, the man's refrigerator had broken down so that he could no longer store large portions of perishable foods. Since that time his daily total caloric intake consisted of a pound of well-boiled rice plus a pound of sardines in tomato sauce for dinner. Rice and sardines contain no vitamin C, but tomato sauce does: 12 mg/can (20% of the U.S. RDA) according to the product label. However, instead of eating the sardines fresh from the can, he would pour the can's contents

into a pan, cover with water, bring to a boil and pour onto the separately boiled rice. This cooking method destroyed enough of the vitamin C in the tomato sauce to bring the man's daily intake below the amount needed to prevent scurvy.

Another use of the U.S. RDA and of the RDA is to help determine whether an individual is getting too much of a given nutrient. When intake of a nutrient exceeds the U.S. RDA or RDA, it is often greater than need plus storage, and should raise the question of possible harm. Rough guidelines for toxicity thresholds are 5xRDA for fat-soluble vitamins, 10xRDA for some of the water-soluble vitamins, and 3xRDA for minerals. Again, this applies to normal people and not to those with disorders of nutrient absorption or who are addicted to alcohol, tobacco or drugs of abuse. For a thorough analysis of the hazards of megadosage, see *Vitamins and Minerals: Help or Harm?*, by Charles W. Marshall, Ph.D., published by the George F. Stickley Company.

In regard to tobacco, there is no credible scientific evidence that smokers need more than RDA amounts of vitamin C. The 1980 RDA amounts are six times the amount a normal person would ever need in a day. So even if smokers' needs were doubled, they would still not need more than 20 mg daily. No scientific report of scurvy in a smoker consuming 20 mg of vitamin C daily has ever been published.

Actually, it is conceivable that taking megadoses of vitamin C could increase the incidence of cancer in smokers. Acidification of the urine is known to help flush nicotine out of the body. Since addicted smokers strive to maintain high blood nicotine levels, increased nicotine excretion will lead them to smoke more and thereby increase their risk of cancer. In 1977 it was reported that acidification of the urine with 3.4 grams of vitamin C, three times daily, led to a 20% increase in the number of cigarettes smoked by average smokers [*Journal of Experimental Psychology* 106:13-19]. Since urine can be acidified by 500 mg, four times daily, dosages in this range may have a similar effect.

Dr. Herbert, a member of the Food and Nutrition Board and its RDA Committee, is Vischer Professor and Chairman of the Department of Medicine at Hahnemann University School of Medicine. He is also a member of the WHO/FAO Expert Group on Vitamin A, Iron, Folic Acid, and Vitamin B₁₂.

BOOK REVIEWS

Title: *Chicken Soup & Other Folk Remedies*
 Author: Joan Wilen and Lydia Wilen
 Publisher: Fawcett Columbine, New York, 1984
 Price: \$4.95
 Reviewed by: Varro E. Tyler, Ph.D.

Recently, this attractively packaged paperback caught my eye as I browsed through a bookstore's healthcare section. I picked it up and, as usual, first turned to the back to learn the qualifications of the authors. There I was informed that Joan Wilen was named for her father's cousin, the town hypochondriac, and her sister Lydia was named for her mother's aunt, the town herbalist and midwife. For these reasons, they felt "particularly qualified" to write this book. The Wilen sisters' background in the home remedy field was equally revealing: "As soon as we signed the contract for *Chicken Soup and Other Folk Remedies*, we went to all our relatives, asking for their home remedies." Let's take a random look at some of the information they gathered in this way. The comments in brackets are mine.

Page 3: Alfalfa seed "is very high in . . . vitamins A, E, K, B-8, D and U." [There are no such things as vitamin B-8, or vitamin U.]

Page 11: "Comfrey is also called knitbone because from the time of the Crusaders, the leaves were used for repairing and drawing fractured bone segments back together." [It may have been used to reduce the swelling and inflammation around a broken bone, but not to heal the bone itself.]

Page 26: "Strawberries . . . contain . . . salacin, which soothes inflammatory conditions." [I assume the authors mean the anti-inflammatory compound salicin. Authorities deny its presence in strawberries.]

Page 59: "Eat 2 ripe bananas a day to chase the blues away. Bananas contain the chemicals serotonin and norepinephrine, which are believed to help prevent mental depression." [These compounds are not active when taken by mouth.]

Page 61: "Sage tea also helps strengthen one's brain and memory." [Other references list more than 60 ailments for which sage is claimed to be therapeutic. The only proven use of sage is as a flavor, especially in turkey dressing.]

Page 63: "Jerusalem artichokes . . . have been said to help stimulate the production of insulin." [Who said so? They may have been said to help, but they don't.]

Page 89: "Bee pollen contains a combination of male and female hormones." [It actually contains neither.]

Page 92: "Licorice has female hormones in it." [Not so!]

Page 127: "When the prostate gland is inflamed, apply a watercress poultice to reduce the inflammation." [Just where should this poultice be applied? The prostate is, to say the least, rather inaccessible.]

Page 151: "A Pennsylvania man . . . rid himself of body odor by taking 30 mg of zinc every day. Within two weeks, he was smelling like a rose." [Of course, since the zinc had no effect, it must be presumed that he supplemented it with rose water baths.]

It is not possible to list here all of the factual errors I noted on first reading. The Wilen sisters admit on page xi they are not authorities, even though one did date a pharmacist and the other enjoys Doc Simon's plays. This being the case, one can only wonder why they would risk tampering with people's health and why their publisher would do the same. Stick to humor, ladies. You're not bad at it, but label your efforts as such.

Dr. Tyler, Dean of Purdue University's Schools of Pharmacy, Nursing, and Health Sciences, is an expert in pharmacognosy (the science of medicines from natural sources) and author of *The Honest Herbal*, an evaluation of popular herbs (George F. Stickley Co., Philadelphia).

Title: *Your Basic Guide to Nutrition*
 Authors: Fredrick J. Stare, M.D., Ph.D., and Virginia Aronson, M.S., R.D.
 Publisher: George F. Stickley Co.
 Price: \$11.95
 Reviewed by: William Jarvis, Ph.D.

This volume contains the accurate information characteristic of nutrition experts in a style as readable as "Dear Abby." The principles of good nutrition are reduced to *variety, balance, and moderation*. Chapters include basic nutrition concepts, how to evaluate nutrition information, food supplements, "junk foods" and "fast foods," and a mini-encyclopedia of "health foods" and related products. The widely misunderstood topics of food additives, sugar in the diet, healthy vegetarian eating and practical weight control are presented extremely well. Alcoholic beverages, caffeine-containing drinks, and hard vs. soft water are dealt with as "fluid facts." "Tips for teenagers" covers crash dieting, eating disorders, and alleged performance aids for athletes. After providing much-needed information on the role of diet in cancer and heart disease, the book offers some practical sample diets, a glossary of terms and an excellent list of reliable information sources.

The outstanding feature of this book is its *readability*. This is the book for unsophisticated readers who desire practical nutrition advice. Nutrition educators can benefit by seeing how scientific nutrition concepts can be simplified without sacrificing accuracy.

Dr. Jarvis is Professor of Health Education at Loma Linda University and President of the National Council Against Health Fraud, Inc.

VARIETY AND BALANCE: WHAT DO THEY MEAN?

Eleanor N. Whitney, Ph.d., R.D.
Linda K. DeBruyne, M.S., R.D.

Nutrition professionals commonly say that people should eat a "balanced" and "varied" diet. This article discusses what these terms mean and why this advice is given.

A diet is balanced if it contains appropriate amounts of each nutrient. The importance of dietary balance can be illustrated by the essential minerals, iron and calcium. Inadequate iron intake causes iron-deficiency anemia, while insufficient calcium intake can cause poor bone development during childhood and contributes to bone loss (osteoporosis) in adults. Foods rich in highly absorbable iron, such as meats, are poor sources of calcium. On the other hand, foods rich in calcium (milk and milk products) are relatively poor sources of absorbable iron.

The notion to grasp from this illustration is that a diet is balanced only when a variety of foods are eaten in moderation. Iron and calcium are only two of more than 40 essential nutrients, and meats and milk products are only two of the groups into which foods are usually classified. No single food is complete or perfect (except perhaps breast milk for newborn infants). An ideal balance of foods requires a varied selection from all the food groups to deliver optimal amounts of all the nutrients.

To simplify food selection, various systems of food grouping have been devised. The most familiar one in the United States is that of the U.S. Department of Agriculture. It fits the major foods into four groups:

1. Meat and meat alternates (poultry, fish, eggs, nuts, dried peas and beans)
2. Milk and milk products
3. Fruits and vegetables
4. Grains (breads, cereal and pasta products).

This plan is commonly referred to as the Basic Four Food Group concept or "Basic Four." It specifies that certain quantities of food must be consumed from each group as noted in the table in the next column.

Items that don't fit into any of the Basic Four Food Groups can be grouped into a fifth (non-basic) miscellaneous or "extras" category which includes candy and confectionery products, butter, margarine, cream, sour cream, salad dressing, mayonnaise, jam, jelly, broth, coffee, tea, alcoholic beverages, sodas, and various synthetic products. Some of these products contribute nutrients to the day's intake, but their main contribution is calories. They do not contain enough

other nutrients to warrant inclusion in one of the basic food groups, and most contain mainly fat, sugar and/or water.

The Basic Four Food Groups

Food Group	Daily Servings (for Adults)	Main Nutrient Contribution
Meat and meat alternates	2	High-quality protein; iron, riboflavin, niacin, zinc, B-12, ^a thiamin
Milk and milk products	2	Calcium, high-quality protein, riboflavin, zinc, B-12, thiamin
Fruits and vegetables	4	Vitamin A, vitamin C, ^b thiamin; additional iron and riboflavin; fiber, folacin
Grains (bread and cereal products)	4	Additional niacin, iron and thiamin; zinc in whole grains; fiber

a. Vitamin B-12 is contributed only by the animal food sources in this group.

b. Dark green and deep orange vegetables are reliable vitamin A sources; other fruits and vegetables are not. For vitamin C, citrus fruits, green leafy vegetables, and other selected fruits and vegetables are superior sources.

c. One serving is not a significant source of any of these nutrients, but the recommended four servings contribute significant quantities to the diet. Whole-grain bread and cereal products provide more fiber than do refined ones.

Despite much study and effort in its development, the Basic Four Food Group concept has critics. One critical comment has been that two of the four groups (milk and meat) are animal products, which might lead people to think that half the foods they consume should be milk and meat—which would cause the diet to be undesirably high in saturated fats. However, this criticism ignores the presence of non-meat foods in the meat group and the recommendation of two portions from the milk group, two portions from the meat group, but eight portions from the plant food groups. Calorie and portion sizes vary among foods within each group.

Another criticism is that it is possible for some people to follow the plan's rules and still fail to meet the day's needs for a few nutrients—most notably iron, vitamin B-6, zinc and magnesium. This criticism is only valid if one ignores the need for variety within each food group.

"Serving size" has been defined for exchangeable portions containing approximately the same number of calories and energy nutrients (protein, fat, and carbohydrate). The exchange system used in this country was

devised by the American Dietetic Association and is available in booklet form for \$1.00 from the Association (430 N. Michigan Ave., Chicago, IL 60611). This system contains six food lists, each with a typical member and portion size specified to help remember it:

- Milk—1 cup skim milk (80 calories)
- Vegetable— $\frac{1}{2}$ cup green beans (25 calories)
- Fruit— $\frac{1}{2}$ small banana (40 calories)
- Bread—1 slice bread (70 calories)
- Meat—1 ounce lean meat or low-fat cheese (55 calories)
- Fat—1 teaspoon butter (45 calories)

Although exchange lists were originally developed for diabetics, they are now in general use for diet planning. For nutrient adequacy, a food group plan should be used. To control calories as well, it is convenient to use the exchange lists as guides. For example, the bread list notes that one slice of bread, which contains 15 grams of carbohydrates, 2 grams of protein and 70 calories is equal to:

- $\frac{3}{4}$ cup ready-to-eat cereal
- $\frac{1}{2}$ cup cooked beans
- $\frac{1}{3}$ cup corn
- 1 small potato.

When nutrition professionals speak of "variety," they are suggesting not only that foods be selected from all of the basic food groups but also that selections within each group be varied. Variety is important for two reasons. First, even within the food groups, some foods are better sources of certain nutrients than other foods are. For example, when you drink orange juice, you do well in vitamin C and potassium; and when you eat a peach, you get the benefit of its vitamin A and riboflavin.

The second reason why eating a variety of foods within each group is important is that many foods contain small amounts of undesirable constituents and also a variety of contaminants. The wider the variety of foods consumed, the smaller the chance that any adverse substance will reach a hazardous level in the overall diet.

Dr. Whitney is president of The Nutrition Company, Tallahassee, Florida, a professional group which develops educational materials and presents workshops on nutrition and health topics. She is also co-author of the third edition of *Nutrition Concepts and Controversies* [West, 1985]. Ms. DeBruyne is an associate of The Nutrition Company.

BRIEFS

Sodium labeling postponed. The FDA's requirement that sodium content information be added to product labels disclosing other nutritional data has been delayed one year to July 1, 1986. According to an agency spokesman, the extension was based on requests from about 40 manufacturers and supermarket chains who said they needed more time to comply.

Study of salt intake. Intersalt, administered by Northwestern University and the London School of Hygiene and Tropical Medicine, has begun a study relating salt intake to blood pressure in more than 50 population groups throughout the world. According to an article in *Medical World News*, the researchers plan to collect data from 100 men and 100 women ages 20 to 59 in each study population by mid-1986.

Vitamin classic revised. An updated edition of *Vitamins and Minerals: Help or Harm?*, by Charles W. Marshall, Ph.D., is now available in paperback for \$10.95 from the George F. Stickley Co., 210 W. Washington Sq., Philadelphia, PA 19106. Judged the best trade book of 1983 by the American Medical Writers Association, Marshall's work has also been adopted by Consumer Reports Books as a special publication of Consumers Union.

Action on saccharin moratorium. By a 94-1 vote, the U.S. Senate approved legislation extending for two years the ban on FDA action to bar saccharin from the marketplace. An attempted amendment to require diet drink manufacturers to indicate the amount of aspartame per serving on their product labels was defeated by a 68-27 vote.

EDITORIAL BOARD

EDITOR: Stephen Barrett, M.D. **ASSOCIATE EDITORS:** Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; Manfred Kroger, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Linda K. DeBruyne, M.S., R.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Suzanne Pelican, M.S., R.D.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.

Raw milk implicated in salmonella outbreak. Government investigators probing the largest recorded outbreak of *Salmonella typhimurium* in U.S. history have found evidence that the problem was caused by small amounts of unpasteurized milk that became mixed with the supply of pasteurized low-fat milk at the Hillfarm Dairy in suburban Chicago. After the milk was sold through Jewel Food Stores, the infection—a type of diarrhea—was spread to more than 15,000 people in Illinois and several neighboring states.

Fluoridation case. The Pennsylvania Public Utilities Commission (PUC) has ruled that it does not have the authority to make fluoridation a condition for approval of a rate increase. Instead it said the decision about fluoridation rests with the Department of Health and the Department of Environmental Resources, agencies which have a more primary concern with water quality. The ruling was prompted by a formal complaint against the Philadelphia Suburban Water Company by Sheldon Rovin, D.D.S., who charged that the company—which serves about 50 communities—was providing substandard service by not fluoridating the water. (Dr. Rovin is a professor at the University of Pennsylvania School of Dental Medicine and a contributing editor to *Nutrition Forum*.) Health professionals who testified at a hearing last year argued that lack of fluoridation should have direct bearing on rates since unfluoridated water has less value. The PUC decision has been appealed to Pennsylvania's Commonwealth Court.

Superhealthy doctors? According to a report in *Medical Tribune*, the nearly 22,000 physicians in the nationwide aspirin/beta-carotene study [see NF 1:7, 1:23] are proving so healthy that study leaders have proposed extending the trial from five years to eight in order to gather more data. At the 2-year mark, the participants' death rate appears to be less than 25% that of white males aged 40-84 in the general population. Only 11% of the trial population are smokers.

Free newsletter for professionals. Nutrition, health care or home economics professionals in the U.S. and territories can obtain a free subscription to *Food & Nutrition News*, published five times a year by the National Live Stock & Meat Board, 444 N. Michigan Ave., Chicago, IL 60611. For those in other countries, the cost is \$2 per calendar year or \$5 for three years. Subscription requests should specify job category.

Diet products trimmed. According to the FDA Press Office, all manufacturers of DHEA and CCK diet tablets contacted by the FDA have agreed to stop marketing their products. The promises came in response to warning letters issued in April by the agency [see NF 2:31 and 2:38].

Hope springs eternal for dieters. The monthly newsletter *Life Extension Digest* observed in its April issue: "We were able to account for 338 diet plans and products over the past four years. Many have gone out of business. However, new promoters, most with the same old claims and exaggerations, continue to appear."

Caries vaccine. The National Institute of Dental Research has estimated that an oral vaccine to immunize children against *Streptococcus mutans*, a bacterium that causes tooth decay by converting sugar into acids which erode tooth enamel, may only be three to five years away.

Malnutrition seen in hospitals. A study coordinated by the University of Illinois has found that 58% of 3,172 patients admitted to 33 Illinois hospitals showed evidence of malnutrition. The indicators measured were serum albumin, hemoglobin, total lymphocyte count, and weight-for-height measurement. Savatri Kamath, Ph.D., head of nutrition and medical dietetics at the University told *American Medical News*: "While our study included the largest number of patients and widest spectrum of institutions of any study to date, the results are consistent with a number of single-hospital studies in other parts of the country. Taken as a group they suggest that malnutrition is a pervasive problem among people being admitted to U.S. hospitals."

Infant tooth protection. The Maine Department of Human Services has published a 12"x16" color poster to warn parents that putting infants to bed with bottles containing milk or sweetened liquids can be hazardous to their teeth. The poster depicts mild, moderate and severe cases of "nursing bottle mouth syndrome" and recommends that if a bottle is needed for comfort, it should be filled with water. The agency also suggests that teeth and gums be cleaned after every feeding with a washcloth or gauze square. Posters are available for \$1 from the Maine Department of Human Services, Office of Dental Health, State House, Station 11, Augusta, ME 04333. Checks should be made payable to "Treasurer, State of Maine."

More troubles for GNC. On April 13th, Gary A. Daum was dismissed as president of General Nutrition Inc., the nation's largest health food store chain. In an article in *The Wall Street Journal*, Daum attributed his dismissal to disagreements over authority between him and the heirs of GNC's founder, David Shakarian, who died last September. GNC's earnings for the fiscal year ending February 2nd had plunged to \$11 million from \$24.9 million the year before. And actions against GNC by a former supplier, a competing health food store chain, and several federal agencies were running up legal bills into the millions.

GNC AGREES TO STOP CLAIMS CHALLENGED BY POSTAL SERVICE

General Nutrition Corporation (GNC) has promised to stop making various unproven claims for 14 of its products sold by mail. Nine had been alleged to cause weight loss, three were claimed to enhance mental acuity, one was alleged to prevent cancer, and one was claimed to have special muscle-building properties.

Advertisements for these products had been challenged in False Representation Complaints filed last year by the U.S. Postal Service. (Thirteen of the products were discussed in the January 1985 issue of *Nutrition Forum*; the other was *Risk Modifier*, a vitamin/mineral mixture that supposedly helps prevent cancer.) On February 26, 1985, the company signed consent agreements which, if violated, could trigger fines of up to \$10,000 per day per product. Unless based on competent scientific studies, claims of the following type are now prohibited:

- that any product consisting of vitamins, minerals, RNA, amino acids, choline or other lipotropic substance, phenylalanine, lecithin, or any mixture or combination thereof, will benefit memory or help mental performance.
 - that ingestion of l-glutamine will have a significant effect on the user's emotional balance or mental acuity
 - that ingestion of any product consisting of proteins, amino acids, vitamins, minerals, or any mixture or combination thereof, will, by itself, cause significant build-up of muscle tissue
 - that ingestion of any food supplement consisting of vitamins and minerals will decrease the risk of being afflicted with cancer
 - that spirulina can "turn off" or otherwise affect the appetite control center in the brain, thereby causing the user to eat less
 - that ingestion of glucomannan or any similar fibrous substance will cause an overweight person to eat significantly less food, cause significantly fewer calories to be absorbed by the body, or cause an overweight person to lose any significant amount of weight
 - that any product consisting of amino acids, vitamins, minerals, "lipotropic substances," dietary fiber, herbs, or any mixture or combination thereof, can cause significant weight reduction
 - that "growth hormone releasers" or dehydroepiandrosterone (DHEA) are safe to ingest
 - that application of any product to the skin can result in significant loss of body fat.
- Several of the consent agreements state that un-

less a product has been proven effective, it cannot be advertised as a weight-reduction aid without a clear and conspicuous disclosure that adherence to a reduced calorie diet or an exercise program is necessary for weight reduction. Consistent with this requirement, recent ads for GNC's *Grapefruit Diet with Glucomannan* contain the following statement: "Losing weight requires a reduction in calorie intake. Use this diet product with the included reduced calorie menu plan. Weight loss will depend upon your body size, calorie intake and level of activity." [Editor's note: This is the first disclaimer of this type I have seen in a diet product ad.]

The main weapons used by the Postal Service to combat deceptive mail-order schemes are False Representation Orders that block receipt of money mailed by prospective customers. Years ago, such orders applied only to specific advertising claims for specific products sold by companies named in the orders. But they did not prevent offenders from making similar claims for similar products or changing company names with the hope of profiting before the Postal Service was able to stop the new scheme. However, amendments to the mail fraud laws that took effect in 1983 enable the Postal Service to investigate cases quickly and to seek large financial penalties against repeat offenders.

QUESTION BOX

Q. What is the American Academy of Certified Medical Nutritionists?

A. It is a nonprofit professional organization founded in February 1984 to represent physicians with proven competence in the subspecialty of clinical nutrition. Members must be certified by the American Board of Nutrition, which requires: board-certification in a medical specialty, completion of significant nutrition research, and passage of written and oral examinations. The Academy's goals include: 1) development of accreditation standards for clinical nutrition services, practice and training; 2) promotion of interprofessional collaboration and information exchange; and 3) dissemination of accurate information through the media to the general public. The Academy's address is 1119 Rockville Pike, N. Bethesda, MD 20852. A membership directory is available for \$5.

FDA RESPONDS TO CONSUMER REPORTS ARTICLE

Stephen Barrett, M.D.

The Food and Drug Administration wasted no time in responding to *Foods, Drugs, or Frauds?*, the 9-page cover story in the May 1985 *Consumer Reports* which sharply criticized the agency's regulatory policies toward quack products. On April 16, FDA Commissioner Frank E. Young, M.D., Ph.D., sent a letter to the editor citing recent agency actions and stating that "increased activity against quackery is one of FDA's top priorities in our soon-to-be-released Action Plan." An *FDA Talk Paper* dated April 24, 1985, distributed with copies of Dr. Young's letter, added that: "Many of the products mentioned in the article were known to the FDA and were under investigation, covered by the OTC drug review or already acted upon by the agency. Those new to the agency will be scheduled for coverage in the future."

The *Consumer Reports*' article contains a chart of 42 companies marketing or distributing products in violation of federal laws, and the article's text names several others. According to FDA press officer Bruce Brown, four of the companies are under investigation and ten have been subjected to FDA enforcement action (including one that took place 23 years ago). But, said Brown, the agency had no knowledge of the illegal activities of 25 companies cited in the magazine's report.

This is a very dismal record. The methods used by *Consumer Reports* to gather information were simple and took little time. Moreover, several weeks before the investigation began, I mailed the names and addresses of 8 of the 25 companies to Joseph Hile, the FDA's top enforcement official, suggesting that he send for their catalogues because I believed these companies might be breaking the law. After personally confronting Commissioner Young at the FDA's October 9th press conference on quackery [see NF 2:9], I mailed the same list to him and to a member of the FDA's health fraud branch. How the agency can claim no knowledge of these companies or their products six months later is beyond my comprehension.

Just as serious is the pretense that the FDA's dealings with the companies "known," "under investigation," or "acted against" are significant. Most of these companies did not stop breaking the law as a result. (For example, most who made labeling changes for a single product continued to market others just as illegally. Moreover, the agency commonly "investigates" for more than a year before taking action against illegally marketed food supplements.) The actions referred to by the talk paper involve warning letters, seizures, and civil court procedures under a regulatory policy that rarely

prevents lawbreakers from making large profits [see NF 1:1-2].

A similar report, published on April 29th by *Newsday* (Garden City, New York), described how local company officials knew they were violating the law by making unsubstantiated claims. One even said he had notified the agency of what he was doing (with the hope of gaining approval) and, having had no response within 30 days as requested, was restoring label claims forbidden by the FDA in 1982. (In the interim, the agency had taken no action when he continued to make the illegal claims in literature sold with the product.)

The *Consumer Reports* investigation collected evidence regarding hundreds of products marketed with unapproved therapeutic claims. Although Consumers Union is willing to provide this material to the FDA, no request from the agency has been received so far.

During the past year, the FDA has greatly stepped up its educational efforts against quackery—a program that deserves great praise. It has also increased its investigatory efforts. (For example, after undercover agents gathered evidence at a health expo held last February, thirteen companies were warned to either stop selling their products or face legal action.) But I believe—as do the editors of *Consumer Reports*—that only a systematic program of early detection and *criminal* prosecution that deters violations can solve the problem of illegally marketed food supplements. No such policy appears to be under consideration. The FDA's "soon-to-be-released Action Plan," drafted last September, is merely a list of generalities.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 20 books including *Vitamins and "Health" Foods: The Great American Hustle*. In 1984, he received an FDA Commissioner's Special Citation Award for Public Service in combatting nutrition quackery. The May 1985 issue of *Consumer Reports* can be obtained for \$3 from the Back Issue Dept., *Consumer Reports*, P.O. Box 2840, Boulder, CO 80322.

THE SULFITE DILEMMA

Kathleen A. Meister, M.S.

Bills are now pending in both houses of Congress to ban certain uses of the food additives known as sulfiting agents and call for prompt reassessment by the FDA of all other uses of these substances. This situation is extraordinary; Congress has intervened only once before in FDA regulation of a specific food additive (by repeatedly preventing the agency from banning saccharin). However, the additives in question are also extraordinary. They have been thought safe for centuries and have a complex pattern of use. Yet in the past decade, they have been found to cause severe adverse reactions in sensitive individuals, presumably including 12 deaths, according to the most recent FDA figures.

The sulfiting agents comprise sulfur dioxide and five inorganic sulfite salts that release it: potassium bisulfite, potassium metabisulfite, sodium bisulfite, sodium metabisulfite and sodium sulfite. Their use in foods can be traced back to the ancient Romans, who burned sulfur and bubbled the resulting sulfur dioxide gas through wine in order to stop fermentation at the desired point. Sulfiting agents are still used today to control microorganisms that could produce undesirable changes in wine. In addition, they are used in many foods and drugs as antioxidants to delay undesirable chemical changes such as browning. Sulfites are used with various frequencies in the processing of food ingredients such as gelatin, beet sugar, corn sweeteners and food starches. And they are ingredients in many processed foods, including certain baked goods, dried fruits (except dark raisins and prunes), a few types of fruit drinks, beers and vegetable products (especially dried vegetables).

Contrary to popular belief, sulfites are not used only for cosmetic purposes; they have a variety of useful technical effects. For example: during the wet milling of corn, they control microorganisms; in frozen doughs, they serve as reducing agents or dough conditioners; and for some foods, such as maraschino cherries, they serve as bleaching agents. They can also prevent both enzymatic browning (in fresh fruits and vegetables) and

non-enzymatic browning (in dried fruits and dehydrated potatoes).

Sulfites are added to some domestic and virtually all imported fresh shrimp to prevent blackening. Sulfiting agents are also sold as "vegetable fresheners" and "potato whitening agents." As such, they may be used in restaurants and other food service establishments to keep raw fruits and vegetables (particularly those displayed in salad bars) looking fresh, and to prevent discoloration of a wide variety of potato products.

Sulfiting agents are legally classified as Generally Recognized As Safe (GRAS) substances. In 1976, as part of a comprehensive review of the safety of GRAS substances, an expert panel organized for the FDA by the Federation of American Societies for Experimental Biology (FASEB) concluded that the available scientific evidence did not indicate that customary use of sulfites posed a health hazard to the public. In 1982, based largely on this report, FDA proposed to affirm the GRAS status of four of the sulfiting agents. However, in these intervening six years, reports of adverse reactions had begun to appear in the scientific literature. Since 1982, they have been widely publicized in the lay press as well, and some consumer organizations have been campaigning for restrictions on sulfite use.

One such group was founded by B. Carolyn Knight, a woman from California who has suffered severe adverse reactions to sulfiting agents. Ms. Knight, an asthmatic, describes herself as a "canary in a coal mine" and wrote a book by that name which was published this year by Aristan Press [P.O. Box 395, Placentia, California]. Although her story is moving, her analogy is incorrect. Unlike the canaries which were taken into mines to alert miners to poison gases, individuals who react to sulfites do not represent an advance warning of danger to the general public. Sulfites are hazardous to only a small fraction of the population which is especially sensitive to them.

It has been estimated that between 5 and 10 percent of asthmatics are sulfite-sensitive, although recent

data from the University of Wisconsin indicate that the prevalence is more like 1 to 2 percent. The Wisconsin data also show that steroid-dependent asthmatics are the primary population at risk. When exposed to sufficient amounts of sulfiting agents, these individuals may experience asthma attacks of varying degrees of severity. Other symptoms such as hives, diarrhea, other gastrointestinal symptoms, and symptoms suggestive of anaphylactic shock have been reported, but these symptoms have not been documented in controlled challenge trials. The well-documented cases of sulfite sensitivity all involve asthmatics, some of whom have been shown to suffer asthma attacks when exposed to sulfiting agents under controlled laboratory conditions or to sulfites used in preservatives contained in medications used to treat asthma. There have also been a few anecdotal reports of people with no history of asthma becoming very ill after exposure to sulfites. However, in most of these cases, it is not clear whether the sulfites were actually responsible.

The mechanism of sulfite sensitivity is not known. One hypothesis, proposed by Drs. Donald D. Stevenson and Ronald A. Simon of the Scripps Clinic and Research Foundation, two of the leading researchers on sulfite sensitivity, is that sulfite-sensitive asthmatics have a partial deficiency of sulfite oxidase, the enzyme that converts sulfites into harmless sulfate. Stevenson and Simon believe that sulfiting agents can trigger asthma attacks in all asthmatics if a sufficient quantity reaches the lungs. Ingested sulfites are ordinarily converted to sulfate before they reach the lungs via the bloodstream. However, in a person with the postulated enzyme deficiency, a dangerous amount of sulfite could reach the lungs intact.

It is known that some people are born with a total deficiency of sulfite oxidase, but the existence of partial deficiencies has not been conclusively established. Individuals with the total deficiency are mentally retarded and have other severe abnormalities, presumably because they cannot handle the sulfite generated by their own bodies (mostly from the metabolism of the amino acid cysteine). According to Stevenson and Simon, individuals with asthma who have the postulated partial deficiency have enough enzyme to deal with this endogenous sulfite but may not be able to handle a sulfite load introduced from outside the body.

Other researchers suspect that sulfite sensitivity may be caused by direct irritation rather than an enzyme deficiency, and they suspect that sulfiting agents may reach the lungs directly (through inhalation of sulfur dioxide given off from sulfited foods or through burping when sulfites are present in the stomach) rather than through the bloodstream.

Most of the clinical research on sulfites has involved the administration of known amounts of free sulfite to sulfite-sensitive individuals. However, it is not known—and it is desirable to know—whether the adverse response of sensitive individuals is influenced by

the form of the sulfite (free, irreversibly bound, or reversibly bound) and by the presence of other food ingredients that accompany sulfites in normal diets.

Sulfites pose complex regulatory problems. Ordinarily, substances are not banned from the food supply because a small segment of the population is sensitive to them. If this were done, most foods would have to be banned, since there are people allergic or intolerant to practically everything we eat. However, there is an urgent need to protect sulfite-sensitive individuals from life-threatening exposure to sulfites, and this may well require banning some uses of sulfiting agents.

The usual regulatory solution to allergy and sensitivity problems is labeling to help sensitive individuals avoid the offending ingredient. Currently, not all uses of sulfites appear on the label. When sulfites are used as direct food additives (as in dried fruit), they must be listed as ingredients. However, when they are present as indirect additives (used in the processing of ingredients which later become part of the final food product) they are not listed. The use of sulfiting agents on bulk foods, such as raw shrimp, is not indicated on the label (if indeed these products are labeled at all). Nor is their use required on the label of alcoholic beverages, which are under the jurisdiction of the Bureau of Alcohol, Tobacco, and Firearms (BATF) rather than the FDA.

The use of sulfiting agents on restaurant foods poses the most difficult problems. Most of the reported severe reactions to sulfites involve restaurant foods, probably because the free sulfite residues remaining on these foods, which are treated shortly before consumption, are generally much greater than those on processed foods treated with sulfites. Also, the potential for abuse of sulfites may be greater in restaurants. No mechanism for warning diners about potential hazards in restaurant foods has been accepted by all of the parties concerned. Moreover, although the FDA probably has the authority to regulate the use of sulfiting agents in restaurants, control of food in restaurants has traditionally been left to state and local authorities.

The FDA has urged states to require restaurants to warn patrons about the use of sulfites through menu statements, placards, or similar means, but few states have complied. The restaurant industry (through its trade group, the National Restaurant Association) has vehemently opposed sulfite labeling in restaurants, con-

tending that it is unworkable, that non-sensitive individuals would be misinformed by it, and that restaurant personnel often do not know whether sulfites are present in a food, since they may be added by suppliers. Fresh fruits and vegetables for salads and potatoes for cooking are often sold to restaurants in cut-up form and treated with sulfiting agents by the supplier.

The National Restaurant Association has urged its members to discontinue the use of sulfiting agents and reports that most have done so (although the supplier problem remains). The Association would prefer a ban on the use of sulfites in restaurants to a labeling requirement.

A total ban on sulfites is not under consideration. Some uses of sulfites appear to be essential. It has been claimed, probably correctly, that both wine and dried fruit could not be produced commercially without them. There are substitutes for some other uses of sulfiting agents, but they are generally more expensive and less effective. Many uses of sulfiting agents in food processing leave such small residues that they are not likely to pose hazards even to highly sensitive individuals.

The FDA has stated in the past that the sulfite problem can be solved by labeling, but it is doubtful that the agency still holds this view. A special FASEB panel which reexamined the status of sulfiting agents for the FDA contended in a tentative report issued in the Fall of 1984 that labeling would be sufficient. The panel concluded only that "appropriate identification of foods containing sulfiting agents should be instituted to enable those sensitive to these substances to avoid them." However, after considering the information presented in an open hearing and in written comments, the panel concluded in its final report issued in January 1985 that additional labeling requirements alone would not assure protection. The panel said that problems are "particularly likely when sulfite-treated fresh fruits and vegetables and precut potato products are dispensed in food service establishments or sold in grocery stores, and consumers, servers, and store personnel are not aware that sulfiting agents are present" and that "discontinuance of these uses should be encouraged by appropriate use of the regulatory process."

These specific uses of sulfites would be banned under legislation proposed by Senator Albert Gore (D-Tenn) and Representative Ron Wyden (D-Oregon). Their identical bills introduced in both houses of Congress

would declare sulfiting agents unsafe for use on any fruit or vegetable sold for consumption in the raw state and on any potato which is cut and sold to be cooked before consumption (except for dehydrated potatoes).

The Gore/Wyden bills may never reach a vote, however, because the FDA may take similar action and make their passage unnecessary. At a Congressional hearing in March 1985, FDA Commissioner Dr. Frank E. Young was severely criticized for his agency's inaction on sulfites. Following that hearing, the agency has reportedly taken steps toward several sulfite-related actions. One is a field survey of the uses of sulfites in foods. This may sound ridiculously basic, but it is necessary because reliable data on sulfite use and consumption do not exist. The reasons for this lack include: 1) difficulty in accurately assessing the amounts of sulfites added to foods; 2) the often substantial differences between the amount of sulfite added to a food and the amount remaining in the final product; 3) inadequate methods of accurately measuring free and bound sulfites in food; 4) the extensive use of food-grade sulfites in drugs and other non-food products; and 5) the fact that some people are exposed to sulfites through the air.

On April 3rd, the FDA proposed that sulfites be declared on the labels of all foods which contain detectable levels of 10 parts per million (ppm) or higher, whether they were added to the food or to one of its ingredients. Whether this regulation could be enforced is uncertain, however, because some experts contend that even the best analytical methods for sulfites are not reliable at levels below 50 ppm.

Finally, the FDA is apparently planning to propose a ban similar to that proposed by Gore and Wyden, except that it may not exempt dehydrated potatoes. In the past, the BATF has stated that it would follow the FDA's lead if it decides that sulfite labeling is necessary. The FDA has made this decision and has informed BATF of its action.

Mrs. Meister is a research associate with the American Council on Science and Health. A free leaflet that tells hypersensitive asthmatics how to avoid sulfiting agents when dining out has been released by the National Restaurant Association together with the American College of Allergists. For a copy, send a self-addressed 4"x9½" envelope to Kathy Hall, National Restaurant Association, 311 First St., N.W., Washington, DC 20001.

BILL TO OUTLAW FLUORIDATION APPEARS DEAD

On March 19th, U.S. Congressman John Seiberling (D-Ohio) introduced legislation intended to stop fluoridation throughout the United States. The proposed bill (H.R. 1589) would amend section 1450 of title XIV of the Public Health Service Act (the Safe Water Drinking Act) to prohibit the addition of any chemicals to drinking water for any purpose except: 1) to make the water safe for human consumption; 2) to test the water for contamination; or 3) to improve the water's taste or clarity.

With the bill's introduction, Seiberling stated into the *Congressional Record* his belief that fluoride may be a threat to health "for at least some people." He also said, "We should be especially concerned about the precedent created by adding chemicals to the public water supply in order to treat a small segment of the public . . . whether they want it or not. If it can be done with one chemical in the name of combatting tooth decay, why not add iodides to combat goiter, potassium to combat high blood pressure, tranquilizers to combat tension,

and so on. The possibilities are endless. The dangers are obvious."

The National Health Federation initiated a letter-writing campaign in support of H.R. 1589. Among its arguments are assertions that "fluorine is a cumulative poison" and that "storing fluoride at the source of our water supplies is an open invitation to terrorists."

Both houses of Congress subsequently approved reauthorization of the Safe Water Drinking Act without Rep. Seiberling's amendment. Differences between the House and Senate versions are being worked out in conference committee, but Seiberling's amendment can no longer be considered part of this process. Although H.R. 1589 could conceivably see action as an independent bill, knowledgeable observers give it little chance for further consideration. So far only six congressmen have become co-sponsors: Norman Lent (R-NY), Robert Lagomarsino (R-CA), Walter Fauntroy (D-DC), Parren Mitchell (D-MD), Joseph Addabbo (D-NY), and Edolphus Towns (D-NY).

CHINESE FOOD: DIET OF THE PAST MAY BE DIET OF THE FUTURE

Jacqueline M. Newman, Ph.D., R.D.

In the American culture, food is viewed in many ways. In the March *Nutrition Forum*, dietitian Virginia Aronson said that eating should be one of life's great pleasures. How unusual to be reminded of this. Every month, many magazines recommend food restrictions and diets for weight loss, disease prevention, and/or cure. Amazingly, most are purported to be new and revolutionary. If new diets are needed that frequently, of what value are they?

The Chinese have not had a new diet for centuries. Their old one was intended not only for enjoyment but also for good health. Food and diet, especially for the prevention of ill health, have always been of great importance to the Chinese. Their culture expresses care and concern in the acts of purchasing, preparing and cooking food, and especially in eating, a joy appreciated at all levels of society.

In the 8th century A.D., a Chinese book called *One Thousand Golden Prescriptions* advised that rice polishings could be used for a disease whose symptoms are now recognized as those of beri-beri. It was not until many centuries later that a cure for this vitamin B deficiency was discovered in the West. Records from 300 years later indicate that an emperor's physician pre-

scribed a special diet for the recovery of his majesty, a diet he believed would help—and help it did. In the late 1500's, a Jesuit priest commented after a visit that Chinese people who did not die of famine or contagious disease were living longer than Europeans. Furthermore, the priest said, the Chinese retained physical powers as they aged and lived to 70 and beyond.

The Chinese traditionally believe that each meal has five basic taste sensations: sweet, sour, briny, hot and bitter. To make such meals, a large assortment of foods must be prepared, though few in large amounts. This broad variety of foods at each meal provides nutritional balance and a large variety of needed macro- and micronutrients. Great flexibility in meal planning and food consumption is possible because of unlimited use of fresh fruits and vegetables, limited amounts of animal protein, and less animal fats than in typical American diets. Since foods are cooked quickly (mostly stir-fried or steamed), they retain more vitamins and minerals than do those cooked by most Western methods, and no cooking liquids rich in nutrients go uneaten.

An additional principle is frugality. The Chinese believe that overindulgence in food or drink is a sin. At the dinner table, many a wise Chinese parent tells his

offspring that the ideal amount for every meal is "chi fen pao," which translates to "70 percent full." The degree of fullness is to be kept in mind throughout the day. The Chinese rarely snack between meals because they want to stay "chi fen pao." Soups are their beverage of choice at mealtime, and desserts, as Americans know them, are only special occasion foods. After meals, the Chinese eat fresh fruit or nuts.

Another dietary principle involves the division of "fan" and "tsai." Fan, the grain or starch component of the meal is considered the primary food without which one truly cannot be full. The importance of the word "fan" is indicated by its use in the Chinese language. *How are you* is an expression asking whether you have had your fan. And those who are unemployed have no "fan," or more exactly translated, no rice bowl. "Tsai," the vegetable or vegetable plus meat component, is said to complement or enhance the "fan."

Under Chinese philosophy, meat is rarely served in large pieces or large amounts. Rather it accompanies or is mixed with vegetables to enhance the meal's taste. Meat is also believed to make the meal healthy, but only if used in appropriate amounts. The Chinese consume both fan and tsai at every meal. The amount of fan considered appropriate is about 60%. More than half of the remainder, counted in calories, will be from fruits and vegetables, which leaves only 15% from meat and fat. However, on holidays and special occasions, meat can be served in fan amounts, and fan itself takes a lesser role.

The last important principle of Chinese eating embodies balancing "yin" and "yang," which are said to denote the negative and positive cosmic polarities: female versus male, darkness versus light, or cold versus hot. Many foods and cooking processes are classified as yin or yang. The Chinese believe that balance of these opposing forces is vital to good health because excess of either results in disease.

When illness occurs, counterbalance is believed to restore the body to health. For example, "weak blood," pregnancy, menstruation, shivering, cancer, being elderly, and wasting are considered "yin" health conditions that require rebuilding of lost strength with "yang" foods. These include beef, chicken, chicken soup, eggs, garlic, ginger root, pork liver, shellfish, tangerines, and tomatoes.

On the other hand, "yang" health conditions, such as fever, hypertension, sore throat, upset stomachs, general infections, and blood ailments are said to warrant a diet rich in "yin" foods. These foods include boiled items, most greens, lots of water, bland foods, and many white foods including potatoes, bean curd, turnip and milk.

Overall, Chinese dietary principles bear striking resemblance to today's modern principles of dietary balance, variety and moderation. The traditional Chinese diet is well-balanced, high in fiber and low in saturated fats. Almost one-fourth of the world's population is eat-

ing the Chinese way. It well may be the diet of the future.

QUESTION BOX

Q. Does charcoal broiling produce cancer-causing substances?

A. This question has been raised as a result of the discovery a few years ago of cancer-causing substances in charcoal-grilled meats. These substances are not formed by the cooking process itself but are contained in the smoke that arises when fat from the meat drips onto the hot coals. According to the American Council on Science and Health (ACSH), the significance of this discovery has been greatly exaggerated, the amounts of carcinogens found were extremely low, and these chemicals are also produced to a lesser extent by other methods of cooking. ACSH believes "there is no convincing evidence that eating charcoal-grilled meats poses any hazard to health." However, those still worried about this issue can avoid or minimize it by positioning their coals so that fat from the meat can't drip on them or by placing a barrier such as aluminum foil between the meat and the coals.

The objectionable substances produced during severe heating of fats are called polyaromatic hydrocarbons, with benzopyrene being the best known example.

BRIEFS

Consumer attitude poll. According to the Food Marketing Institute's annual survey of consumer attitudes, consumer concern about the nutritional quality of foods has declined during the past year. This year, 59% of 1,005 shoppers said they were "very concerned" about the nutritional content of what they eat (down from 63% in 1984). Among males, this figure dropped sharply from 62% to 51%. The survey found little change in attitudes toward food safety, with the following concerns viewed as serious hazards: residues such as pesticides (73% of participants), cholesterol (44%), salt (39%), additives and preservatives (36%), sugar (29%), and artificial coloring (28%). The survey, conducted by Louis Harris and Associates, is available for \$30 from FMI's Research Division, 1950 K Street, N.W., Washington, DC 20006.

Drug laws being tightened. The FDA wants to require reporting of adverse reactions to drugs marketed before Congress passed the 1938 law requiring FDA approval of new drugs. The absence of a reporting system for older drugs (and their newer versions) may have delayed the recall of E-Ferol, an intravenous vitamin product associated with the death of 30 premature infants in 1983 and 1984. The proposed regulations would extend the reporting requirements to 4,200 prescription drugs being sold without premarket approval, including vitamin products used in medical treatment. Under these regulations, any serious, unexpected adverse drug reaction or significant increase in the rate of expected reactions must be reported within 15 working days—or sooner if possible. This is the second major step the FDA has taken to prevent situations similar to the E-Ferol tragedy. Last September the agency announced that manufacturers can no longer market new versions of old drugs without FDA approval unless they are intended for the same use and are identical in chemistry, strength, route of administration, intended patient population, and dosage form.

Paleolithic nutrition revisited. An article by Drs. S. Boyd Eaton and Melvin Konner of Emory University in the January 31, 1985 *New England Journal of Medicine* suggested that the diet of prehistoric people might be desirable because it is "nutrition for which human beings are . . . genetically programmed." This viewpoint was rebutted by a letter to the editor in the May 30th issue by Dr. Ted Bader of St. Luke's Hospital, Denver, who said: "Natural selection means the passing on of genetic traits that enhance reproductive ability, but not necessarily the traits that promote old age." So it should not be assumed that the prehistoric diet will protect people against the chronic diseases of older adult life.

Mayonnaise and food safety. Many people are uneasy about eating chicken salad, potato salad or similar dishes at summer picnics because they have heard that food made with mayonnaise is the most likely to cause food poisoning. However, scientists at the University of Wisconsin have shown that adding mayonnaise to meat salads tends to retard the growth of harmful food-borne bacteria [*Journal of Food Protection* 45:152-156, 1982]. This protective effect is not a substitute for refrigeration. The American Council on Science and Health suggests that a basic rule to prevent bacterial food poisoning is to keep hot foods hot and cold foods cold. Perishable foods (with or without mayonnaise) may not be safe to eat after staying at temperatures of 60°F or higher for three or four hours. A practical way to keep foods safe for a summer picnic is to keep them in a cooler with ice or reusable cold packs. Packing the food (or the ice) in plastic bags or waterproof containers will prevent the food from becoming wet when the ice melts. Raw meats, which may contain harmful bacteria, should be kept separate from other foods. Bacteria in the meat will be killed during cooking but could cause problems if they contaminate foods that are not cooked prior to eating.

USDA food safety hotline. Since July 1st, the Food Safety and Inspection Service of the U.S. Department of Agriculture has had a toll-free number for questions about the safety or wholesomeness of meat and poultry products, and about FSIS programs such as meat and poultry inspection, labeling, additives, and residues. Calls are answered between 10:00 a.m. and 4:00 p.m. Eastern Daylight Time at 800-535-4555 (or 447-3333 in Metropolitan Washington, DC). A list of free (or nominal cost) consumer publications on food safety and other topics can be obtained by writing to the FSIS Publications Office, Room 1163-South, U.S. Department of Agriculture, Washington, DC 20250.

Few newspapers list health ad standards. According to a survey by *Con\$umer New\$weekly*, only 301 (17.9%) of the nation's 1,688 daily newspapers list anything under "advertising not accepted" in the just-published 1985 *Editor & Publisher International YearBook*. But only 25 papers (1.5%) list questionable therapies or doubtful medical products as classes of ads they won't accept—up from 20 in 1984. About 60 others won't take "objectionable" ads or state that all advertising requires approval of the publisher, double the number with such a disclaimer last year. In May 1984, the FDA and the Council of Better Business Bureaus mailed guidelines to all papers and asked them to screen out fraudulent health ads (see NF 2:9).

Free reprints. Single copies of "Critiquing Quack Ads," "Rethinking the Need for Food Standards," and "Riding the Coattails of Homeopathy's Revival" from the *March FDA Consumer* are available on request from the Food and Drug Administration, HFE-88, 5600 Fishers Lane, Rockville, MD 20857. Multiple copies can be obtained by using the agency's "internal zip code" of HW-40 instead of HFE-88. Copies can also be obtained from FDA's consumer affairs offices in 29 cities.

New radio programs. The Center for Science in the Public Interest is broadcasting 90-second commentaries on nutrition called "Eater's Digest." Programs are transmitted five days a week by satellite to about 1,500 radio stations which have the option of using it. The People's Medical Society, a Rodale Press offshoot, has begun syndication of its weekly "People's Medical Hour." This organization is primarily concerned with "abuses" within the health care system, but it has also been promoting unproven nutrition practices.

SOY DRINK PAMPHLET RECALLED

On June 19th, the FDA and Eden Foods, Inc., of Clinton, Michigan, warned consumers not to use Edensoy and similar soy drinks as an infant formula or sole source of nutrition. This action was triggered by a report that a 6-month-old Canadian infant had developed vision problems and rickets due to deficiency of vitamins A and D after consuming only Edensoy for five months. A pamphlet, various advertisements, and other promotional materials distributed by Eden Foods since 1983 have erroneously suggested that Edensoy can substitute for breast milk or infant formula. The pamphlet also said (falsely) that "Edensoy compares very favorably with cow's milk." Clerks in 2 out of 24 health food stores visited by FDA inspectors on June 14th recommended Edensoy as an infant formula substitute. The company has issued warning placards to health food stores and asked the stores to destroy or return supplies of the misleading pamphlet.

Soy drinks (sometimes sold as soy milk) typically contain water, soybeans, vegetable oil and other ingredients such as kelp, pearl barley, barley malt, and salt. They should not be confused with soy protein formulas that are specially formulated with essential amino acids, vitamins, minerals and other substances to provide all of the nutrients required by infants or others consuming them as a sole source of nutrition. Use of these special formulas is generally limited to infants born allergic to cow's milk.

BOOK REVIEW

Title: *Thirty Days to Better Nutrition* (1984)
Author: Virginia Aronson, R.D., M.S.
Publisher: Doubleday & Co., Inc., Garden City, NY
Price: \$10.95, softcover
Reviewed by: Beulah W. Harmon, M.S., R.D.

Thirty Days to Better Nutrition is a compendium of basic nutrition-and-lifestyle written as a workbook with daily assignments. Each chapter explores a single topic such as basic food groups, major nutrients, calories, weight goals, menu and market planning, exercise, health quackery, and diet-drug interactions. One chapter is intended for study on each of the 30 days. Chapters progress in a logical manner from general topics of food, dietary and lifestyle habits and attitudes to specific subjects of nutrient functions, requirements and sources. Also considered are nutrient balance, desired caloric levels, adequate nutrition in planned menus, efficient supermarket shopping (including a detailed "Supermarket Psychology Map" with tips on how to avoid problem areas and temptations), physical activity, and stress reduction. The information is current and scientifically based.

The book seems most appropriate for laypersons with an avid interest in their own nurturing. Some colleges are using it as a supplementary textbook. Active personal involvement requires making lists, recording daily food intake and aspects of lifestyle, analyzing the data recorded, and reviewing various lists in light of the new information presented in subsequent chapters. Pre-tests, post-tests, numerous questions and reference assignments guide the reader in gathering information and analyzing individual values and goals. This approach intends to motivate the participant and requires commitment to the program. Making lists and preparing charts may become tedious with the increased need to record personal data, to make evaluations, and to organize plans of action as the program progresses. However, laypersons with the tenacity to complete daily assignments and to follow the book's guidelines will enjoy the rewards of increased self-awareness and nutrition knowledge.

Confusion on Diet and Cancer

MOVIE TO PROMOTE VITAMIN PRODUCT

Alacer Corporation of Buena Park, California, has announced that screen star Sylvester "Rocky" Stallone plans to plug *Emergen-C*, the company's vitamin C/electrolyte mix, during his next film. Stallone's enthusiasm for the product is vividly described in the poster pictured below, distributed June 1 to health food retailers throughout the United States. The poster claims that Stallone was the only member of a film company exposed to chilling temperatures who escaped the flu during filming of the movie *First Blood—Part II*—a circumstance he attributes to ingesting a packet of *Emergen-C* every 45-60

minutes during the physically stressful scenes. Each packet provides 1,000 mg of vitamin C, small amounts of five minerals, and 25% of the USRDA of six B-vitamins—plus fructose and lemon-lime flavoring. The contents are added to water or juice to produce an effervescent drink. A box of 36 packets retails for \$10.95. According to *TIME* Magazine, gross earnings during the first two weeks of Stallone's current hit, *Rambo: First Blood, Part II*, were the third highest in motion picture history. A claim that *Emergen-C* or any other nutrient mixture can prevent "flu" would be illegal to make on a product label.

Sylvester Stallone and *Emergen-C*[™]

Sylvester "Rocky" Stallone has been for many years an enthusiastic user of Alacer's *Emergen-C*[™], the fizzing Vitamin C, electrolyte, drink mix which has been for years the #1 seller among health food supplements.

Indeed, Sly, as he's known to his friends, says he doesn't know how, without *Emergen-C*[™], he could have gone through his training program for *Rocky III*, which included trimming his weight by 41 pounds and developing the muscles and stamina required for the great fight of the picture.

Jay Patrick, Alacer President, visits with "Rocky" in the fabulous California home of the famous actor-author-director.

Emergen-C[™] has also had an active role in production of *First Blood* and in the latest, sensational hit, *Rambo: First Blood, Part II*.

Probably the most severe test of *Emergen-C*[™] came during the filming of *First Blood*.

As Rambo, the highly trained veteran of Vietnam who has "flipped out", he had to wade some 20 times through 33 degree waters, torrential downpours, and mud, often sleeping outside when the wind was blowing with a chill factor of 40 to 45 degrees below zero.

"But I took a packet of Emergen-C[™] every 45 minutes or an hour. I was the only one in the whole company who escaped the flu. In one scene where I had to spend five days in a cave, up to my neck in freezing water with over 200 rats, I was scratched and bitten, going through this putrid water. The rats had a horrible smell.

"But my immune system must have been working, I guess. I was just totally impervious to it all. There seemed to be nothing I could do to get sick, literally. Yet a few years ago, if someone would cough three blocks away, I would catch it."

Reviews of *Rambo: First Blood, Part II* have been overwhelmingly favorable. Indeed, it's being described as "a block buster hit".

Coming! . . . Rocky IV

No payment has been made to Mr. Stallone for his endorsement of *Emergen-C*[™]. Indeed, Sly has reported to Mr. Patrick that he plans several scenes in the forthcoming *Rocky IV* that will show him using *Emergen-C*[™] as he continues his role of the hard-hitting fighter who wins out against enormous odds.

NEW BOOK REFLECTS CONFUSION ON DIET AND CANCER

Kathleen A. Meister, M.S.

Should Americans change their diets in an effort to prevent cancer? If so, what changes should they make? These questions are the focus of a major controversy in the scientific community—a controversy that involves policy questions as well as scientific ones.

In *What You Can Do to Prevent Cancer* [Simon and Schuster, 1985], Oliver Alabaster, M.D., Director of Cancer Research at the George Washington University Medical Center, presents views on the diet/cancer issue that are at one extreme of the spectrum of scientific opinion. He suggests that dietary changes intended to prevent cancer "may be one of the greatest investments in living that you ever make." He reports that as much as 60% of cancer in women and 40% of cancer in men are attributable to dietary factors. And he states that "it has also been estimated that at least 35% of all cancer in the United States could be eliminated by simple changes in the nation's diet, using our current knowledge of dietary risk factors."

To those unfamiliar with the scientific literature on diet and cancer, these percentages may seem startlingly high. However, they are actually derived from the work of distinguished cancer epidemiologists. The 60%/40% figures come from an epidemiological study by Drs. Ernst Wynder and Gio Gori published in 1977 in the *Journal of the National Cancer Institute* [58:825-832]. (The principal reason for the sex difference is that men smoke more cigarettes than women do.) The 35% figure comes from a landmark paper by Sir Richard Doll and Richard Peto which estimated and compared the avoidable risks of cancer in the United States [*J. Natl. Cancer Inst.* 66:1192-1308, 1981].

These authors and many other experts do not attribute the same significance to these percentages that Dr. Alabaster does. Drs. Wynder and Gori specify that their figures are *estimates*, not facts, and were derived primarily from comparisons of cancer rates, not from direct evidence about diet. Regarding their 35% figure, Doll and Peto emphasized that it was "highly speculative and chiefly refers to dietary factors which are

not yet reliably identified." Although Dr. Alabaster uses this figure as the basis for claiming that 20 million cases of cancer a year in the United States could be prevented by "relatively simple changes in the national diet," Doll and Peto themselves made no claim that cancer could be substantially reduced by applying *current* scientific knowledge about dietary factors. Similarly, the Committee on Diet, Nutrition, and Cancer of the National Research Council (NRC), in its extremely influential report *Diet, Nutrition and Cancer* [National Academy Press, Washington, DC, 1982], concluded that "the data are not sufficient to quantitate the contribution of diet to the overall cancer risk or to determine the % reduction in risk that might be achieved by dietary modifications."

Despite this disclaimer, the NRC committee saw fit to propose "interim dietary guidelines" for cancer risk reduction. The American Cancer Society (ACS) later proposed similar guidelines, and the National Cancer Institute (NCI) is promoting the same concepts. So while Dr. Alabaster goes farther out on a limb, other distinguished authorities are perched on the same tree.

It is important to recognize, however, that the idea of a national policy of diet modification for cancer prevention has many distinguished opponents. The majority of the scientists contributing to a Council on Agricultural Science and Technology (CAST) critique of the NRC diet and cancer report said that NRC's recommendations for public policy were premature and based on inadequate evidence [*Diet, Nutrition, and Cancer: A Critique*, CAST, Ames, IA 1982]. And review papers in two of the nation's most prestigious medical journals have pointed out the many gaps in the scientific evidence [Willett, W.C. and MacMahon, B: *New Engl. J. Med.* 310:633-638, 697-703, 1984; and Pariza, M.W.: *JAMA* 251:1455-1458, 1984].

The American Council on Science and Health (ACSH) has opposed dietary guidelines for cancer prevention on similar grounds, stating that "specific dietary recommendations should be given only when there is

sufficient basis to expect that they will in fact accomplish what is promised." and that the evidence on diet and cancer doesn't meet this requirement. As noted by Dr. Michael Pariza of the University of Wisconsin in his recent report, *Diet and Cancer* [ACSH, 1985]: "The debate really is as much over *when* to give advice as it is over *what*, if any, advice to give."

A poll conducted at the conclusion of a conference on diet and cancer sponsored in 1983 by the American Cancer Society (ACS) found that two-thirds of the scientists in attendance believed that, based on current knowledge, no dietary advice was warranted or that general advice stressing the desirability of eating in moderation was adequate. (Despite this, ACS issued dietary guidelines shortly thereafter.)

Some people wonder why there is a controversy at all over diet and cancer. Even if the evidence is tentative, they ask, why not advise people to change their diets, as long as the proposed changes are not dangerous? What is there to lose?

Those who hesitate to make policy on the basis of tentative evidence believe that there is much to lose if advice to the public based on "educated guesses" draws attention from advice based on real proof of benefit. Dr. Alabaster's book illustrates this. Tobacco products are responsible for 30% of fatal cancers in the United States, and the appropriate preventive measure—stopping their use—is the paramount public health issue of our time. Although Dr. Alabaster mentions the serious health problems caused by smoking, some passages of the book seem to offer his unproven diet modifications as an alternative to the proven benefits of smoking cessation. For example, he states in the introduction: "How to get rid of an addiction is really beyond the scope of this book. Instead, I will concentrate on the even more important task of explaining the complexities of dietary cancer, and how to reduce your chances of getting cancer by understanding and changing your diet." Just as serious, his brief mention of smoking cessation is pessimistic despite the fact that 33 million Americans have quit for good during the past 15 years. In a boom whose title implies comprehensive coverage of cancer prevention, how could anything be "even more important" than advice on how to eliminate the most significant proven cancer risk factor from your life?

Most scientists who advocate diet modifications generally agree that the following four suggestions are the ones best supported by the scientific evidence:

- Reduce total fat intake from 40% of total calories to 30%. (Dr. Alabaster recommends 20%.)
- Avoid obesity. (The evidence relating cancer to obesity is actually quite limited, but since weight control has other health benefits, it is usually recommended anyway.)
- Increase consumption of fruits and vegetables, particularly those high in vitamin C or carotene and cabbage-family vegetables.
- Avoid excessive use of alcohol.

Dr. Alabaster goes beyond these points and recommends dietary changes that many others consider dubious. For instance, he advocates an increase in fiber. The NRC committee and others have not recommended this, because the evidence linking fiber intake with a reduced risk of colon cancer is equivocal, and if there is such an effect, specific components of fiber, rather than total fiber, are likely to be responsible. Different foods contain different fiber components. Until more is known about the effects of these specific components, it is difficult to know what foods to recommend.

Dr. Alabaster also recommends "optional" dietary supplements of beta-carotene, folic acid, selenium, zinc, and vitamins C and E. In contrast, the NRC committee and others have advised *against* supplementing with high doses of individual nutrients. The NRC committee report stated: "The vast literature examined in this report focuses on the relationship between the consumption of foods and the incidence of cancer in human populations. . . . There is very little information on the effects of various levels of individual nutrients. . . . Therefore, the committee is unable to predict the health effects of high and potentially toxic doses of isolated nutrients consumed in the form of supplements."

Dr. Alabaster advises avoidance of foods containing mutagens and carcinogens, commenting that "asking you to avoid these foods is like asking you to approve a resolution in favor of motherhood." But he gives little specific advice in this area, on the grounds that our knowledge of which foods contain these substances is inadequate. Although virtually everyone would agree that the evidence in this area is muddled, Dr. Alabaster's advice should not be in the same category as motherhood because some of the same foods that contain mutagens and carcinogens also contain cancer-inhibiting substances. It is not at all clear whether these foods should be proscribed or prescribed.

One of the prevailing myths about diet and cancer, repeated in Dr. Alabaster's book, is that Americans would benefit from avoiding smoked, cured and pickled foods. This myth originated with the NRC committee which, unfortunately, did not include an expert in food science. Had one been present during the committee's deliberations, he or she would probably have pointed out that products of this type which have been associated with increased risks of stomach and esophageal

cancers in Japan, China and Iceland are distinctly different from those sold in the United States under similar descriptions. The committee might then have avoided the regrettable sentence in the news release accompanying the NRC report which advised avoidance of hot dogs, ham, bacon, bologna, sausages and smoked fish. This sentence has been described by a U.S. Department of Agriculture report as "a straightforward case of distortion," because these are not the foods associated with stomach and esophageal cancers in international studies.

Actually, stomach and esophageal cancers are very uncommon in the United States, and the food preservation methods used in places where these cancers are more prevalent are also uncommon here. The American Cancer Society acknowledged this in its diet/cancer report by pointing out that the recommendation to avoid smoked, cured, and pickled foods does not apply to meat or fish products processed by the commercial methods currently in standard use in the United States. Unfortunately, the ACS dietary guidelines that have been reproduced in many places lack this caveat. (One example is a brown-paper grocery sack recently sent to ACSH by a friend from Northern California.)

Given the current state of the controversy over diet and cancer, the question of whether to change one's diet is probably best left to individuals. For those individuals who do elect to modify their diets, a clear set of instructions on how to do it without compromising the nutritional adequacy or palatability of one's meals would be welcome. Dr. Alabaster's book fails miserably in this respect.

In addition to including recommendations that few scientists would consider warranted, the book contains numerous careless errors and inconsistencies. For example:

- Many key points are oversimplified to the point of error, e.g., that sugar causes obesity and that nitrate is a carcinogen.
- The possible nutritional risks of a poorly planned low-fat diet are understated. For example, the author says that iron deficiency is likely in "only" four situations—infancy, childhood and adolescence, women of childbearing age, and pregnancy—but he neglects to note that this accounts for about half of the human species.
- Much outdated information is included. For ex-

ample, cyclamate is labeled a "powerful carcinogen" despite the fact that carcinogenicity was considered dubious at the time of its ban, and current evidence indicates that it is not a carcinogen at all.

The section of Dr. Alabaster's book that gives specific dietary advice might have benefited from a thorough reworking by a skilled dietitian. The author seems overwhelmed by the complexities of translating general dietary advice into specific meal plans. (Indeed, at one point he urges avoidance of dishes that consist of combinations of different foods, on the grounds that they are hard to analyze.) He also seems unaware of the similarity between the food group system he proposes and the standard exchange system long used by diabetics and others. Had he used the standard system instead of creating a new one with different groupings and serving sizes, people attempting to follow his advice could have taken advantage of the many recipes and cookbooks that have been developed using the standard exchanges. Instead, they have only the small collection of unexciting recipes included in this book.

Dr. Alabaster's meal plans are consistently low in calcium (his week's sample menus meet the Recommended Dietary Allowance (RDA) for this nutrient only once in seven days), a totally unnecessary problem since the addition of skim milk to the meal plans could have boosted their calcium content without any increase in fat. Furthermore, the actual calcium content of the meals, as consumed, is likely to be less than the calculated values, since the only milk allowed is that consumed with breakfast cereals (some of which is likely to end up in the bottom of the bowl rather than in the diner). Most of the meal plans also fail to meet the adult woman's RDA for iron.

Equally important, the meal plans are unappetizing, often calling for unrealistically large amounts of single foods or for similar foods in the same meal (e.g., 2½ cups of zucchini and 1½ cups of Brussels sprouts in the same dinner, and raisin bran and raisin bread in the same breakfast), and the author offers little guidance for such realities of life as the lunch eaten away from home.

So even if Dr. Alabaster's general dietary guidelines should someday prove valid, those who try to follow his diet are likely to find it impossible.

Mrs. Meister is a research associate with the American Council on Science and Health.

STIR-FRYING CAN HELP MEET THE DIETARY GUIDELINES

Darlene Forester, Ph.D., R.D.

The idea of stir-frying evokes images of leaping flames, hot woks and a flurry of motion. This style of cooking comes from China, where it is one of the most common forms of cooking.

Vegetables and meats, cut for uniform cooking, are quickly cooked in a wok or frypan with a small amount of oil. A wok is a pan with a rounded bottom and sloped sides. It is designed to minimize fuel use while providing high cooking temperatures toward the base. Usually one food at a time is cooked in the oil and pushed up the side of the wok to keep it warm. Meats or slower-cooking vegetables are done first. The process usually takes two minutes or less per item.

Woks should sit on a metal ring or specially designed burner for safety. Electric woks are available with temperature controls that can be set from warm to 425°F or more. Some woks are coated with teflon to prevent food from sticking. Temperature control is more difficult with this type. Stir-frying does not require a wok; an electric skillet or heavy pan can work just as well. A wok can also be used for steaming, deep-fat frying, or as a skillet or saucepan.

Stir-frying has many advantages as a cooking method. Since little oil is used, it adds less fat and fewer calories than deep-fat frying. Vegetables retain more vitamins when stir-fried than when boiled or simmered. During boiling, much of the water-soluble vitamin C and B vitamins are leached out into the cooking liquid. Stir-frying can save cooking time. Cleanup time is also short because an entire meal can be prepared in one pan. And because many recipes can be made with little or no meat, stir-frying can help save money on food costs. Some say a disadvantage of stir-frying is the amount of slicing and chopping needed to prepare the foods for cooking, but frequent use of this technique reduces this time.

Careful preparation of stir-fried foods can help diets meet five of the seven guidelines described in *Nutrition and Your Health, Dietary Guidelines for Americans* [USDA/HHS Home and Garden Bulletin No. 232, Washington, D.C., 1980]:

Guideline #1: Eat a variety of foods. Stir-fried dishes typically contain a number of ingredients. A main dish consisting of two or more vegetables and meat or poultry often is eaten along with rice. A cup of milk as a beverage would make this meal meet the basic food groups and provide a variety of nutrients.

Guideline #2: Maintain ideal weight. (Soon to be designated as "maintain reasonable weight" in revised guidelines.) Calories can be reduced by using fewer fatty foods and less fat for preparation, as described below.

Guideline #3: Avoid too much fat, saturated fat and cholesterol. Trimming visible fat is easier when meat is cut into small pieces than it is with other methods. Many tasty stir-fried dishes can be made with small amounts of meats, and many recipes can be modified to reduce fat content. Poultry (without the skin) can be used instead of fattier meats. Use of crunchy vegetables instead of nuts such as cashews can save hundreds of calories per cup. Use of a wok or electric frypan with non-stick coating can eliminate most of the fat needed for cooking. Small amounts of polyunsaturated oils can be used. Safflower, sunflower or corn oil can be used in place of sesame or peanut oil specified in some recipes. Care must be taken to watch the temperature so that the smoking point is not reached and the oil does not become damaged or catch on fire.

Guideline #4: Eat foods with adequate starch and fiber. Fruits and vegetables contribute toward meeting this guideline. Familiar vegetables that can be incorporated into stir-fried dishes include broccoli, cabbage, carrots, celery, cauliflower, green beans, green peppers, mushrooms, onions, snow peas, spinach, turnips and zucchini. Common Oriental vegetables can include: Chinese cabbage (a vegetable that resembles a celery stalk with pale green leaves); bamboo shoots (young tender shoots from the bamboo root which add a crisp texture to foods); bean sprouts (young sprouts of mung or soy beans, which add crisp texture. You can buy them or grow your own); snow or Chinese pea pods (flat peas eaten pod and all. They can be grown in your garden or purchased fresh or frozen); sugar snap peas; and water chestnuts.

Most of these are low in calories and high in vitamins C, A or both. For example, an entire cup of bean sprouts has less than 40 calories and contains about 20 mg vitamin C. Also keep in mind that you can substitute inexpensive common vegetables for more exotic ones named in recipes. Radishes, for instance, can substitute for the crispness of water chestnuts. Use of home-grown vegetables can save money.

Guideline #5: Avoid too much sodium. The high sodium content of many stir-fried foods, typical of dishes of Oriental origin, prevents them from meeting this guideline. The sodium content is largely due to monosodium glutamate and soy sauce. Just one tablespoon of soy sauce adds over 1,000 mg sodium to a dish and many foods contain several times this. The new low-sodium soy sauce can reduce this considerably, as can the use of oyster sauce. Also, water or stock can be used to meet the need for liquid supplied by some soy sauce if additional soy flavor is not needed. Mono-

sodium glutamate (MSG) adds about 500 mg sodium per teaspoon. Since it does not actually supply flavor, it can be omitted with considerable sodium reduction.

Since one teaspoon of table salt contains roughly 2,000 mg sodium, using salt in addition to the above seasonings can add up to a total of several thousand milligrams per dish. But salt can be omitted from many stir-fried items. Use of garlic or onion powder rather than the "salt" form of these condiments can save 1,500 or more mg sodium per teaspoon. Try some of the following to add flavor without sodium:

- Crushed garlic cloves
- Red wine vinegar
- Lemon juice
- Scallion or onion (can be removed before adding other foods if only the flavor is needed).
- Dry white wine or sherry (cooking wine has salt added). Water may be substituted spoon for spoon.
- Ginger: If ginger is necessary, substitute ground ginger for fresh ginger (ginger root) if necessary. Use ¼ to ½ teaspoon instead of two to three slices of fresh ginger. To keep fresh root, tightly wrap it and freeze it. Cut off as needed; peel and grate while frozen. Peeled root can also be stored in dry sherry in the refrigerator for a year or two.
- Sesame seeds: toast seeds before using for more flavor.

MORE TIPS FOR STIR-FRYING

- Keep in mind that the color of vegetables intensifies during the first 2-3 minutes they are stir-fried.
- Slice vegetables diagonally for better appearance.
- Don't cut or chop vegetables too soon before cooking. Cut vegetables have more surface area exposed to oxygen, which destroys some of the vitamins.
- Stir-fry each 1 to 1½ cups vegetables in one tablespoon oil for one to three minutes until tender but crisp. Canned vegetables, such as bean sprouts, bamboo shoots or water chestnuts can be used to add crispness to mixtures. They can be rinsed first to reduce sodium content.
- Partially freeze meat to make slicing easier before cooking.
- Canned tuna can be substituted for crab and shrimp.
- Leftover bits of meat, poultry or fish can be combined for use as the protein source.

Dr. Forester is State Extension Specialist and Associate Extension Professor at the University of Kentucky College of Agriculture. Additional information on stir-fry cooking can be obtained by sending a stamped, self-addressed 4"x9½" envelope to the author at 120 Erikson Hall, University of Kentucky, Lexington, KY 40506.

STIR-FRIED MIXED VEGETABLES

- 3 tablespoons vegetable oil
- 1 cup thinly sliced carrots
- 1 cup thinly sliced celery
- 1 cup fresh snow peas, ends trimmed
- 1 cup fresh mushrooms, washed, sliced lengthwise through stems
- 2 tablespoons lemon juice
- ½ teaspoon salt
- dash pepper
- dash garlic powder
- 1 teaspoon soy sauce

Clean and slice all vegetables. In a wok or a large heavy skillet, heat oil. Add carrots and celery; stir to coat well. Stir-fry 3 to 4 minutes. Stir in snow peas and mushrooms; stir-fry 2 minutes. Cover and cook 2 minutes longer or until vegetables are cooked as you like them. Add seasonings; stir to mix well. To serve, sprinkle with chopped parsley. Makes 4 to 6 servings (92 Calories, 8 grams of fat, 320 milligrams sodium/serving). To reduce sodium content and vary the flavor, celery can be replaced with another vegetable and 1 teaspoon of sugar can be substituted for the ½ teaspoon of salt.

BRIEFS

Dietitian licensure. According to the American Dietetic Association's *Legislative Newsletter*, the number of states regulating nutrition counselors rose to 11 with passage of licensure bills in Iowa and Maryland during the month of May.

Information center for rare diseases. The FDA has established the National Information Center for Orphan Drugs and Rare Diseases to provide information to patients and their families, physicians, clinical researchers, and other health professionals. Rare diseases are considered those that have a prevalence of 200,000 or fewer patients in the United States. Voluntary organizations dealing with these diseases will be listed in a directory compiled by the Center that will include information about the diseases, their causes and symptoms, ongoing research, current treatments and treatment centers. Inquirers may be directed to the Center at P.O. Box 1133, Washington, DC 20013 or by calling 800-336-4797 (except in Virginia, where the number is 703-522-2590).

Position paper on chiropractic. A brilliant analysis of the nature and shortcomings of chiropractic has been issued by the National Council Against Health Fraud, Inc. Stating that "chiropractic presents a chaotic picture," and is "a major consumer health problem," the report spells out how to distinguish the small number of "scientific chiropractors" from the rest who engage in unethical or unscientific practices. Signs of the latter include opposition to proven public health measures (fluoridation, pasteurization) and use of such unproven methods as cytotoxic testing, hair analysis, iridology, "glandular therapy," chelation therapy, and computerized "nutrition deficiency" tests. The report concludes with detailed recommendations for consumers, insurance carriers, legislators, basic scientists, educators, law enforcement agencies, and health practitioners. A free copy can be obtained by sending a stamped, self-addressed 4" x 9 1/2" envelope to Chiropractic Position Paper, P.O. Box 1276, Loma Linda, CA 92354.

Mail-order merchant facing criminal charges. An article in the *Miami Herald* states that Mitch Friedlander has been charged with 41 racketeering and fraud-related charges related to the operation of his Robertson-Taylor Company. On July 9th, officers from the Economic Crimes Unit of the Fort Lauderdale police shut down company operations by seizing its computer mailing lists and stocks of baldness remedies, weight-loss compounds, vitamin formulas, and other "miracle cure" products. The company, whose mail-order business grossed an estimated \$4 million during 1984, has also been prosecuted by the U.S. Postal Service and the FDA [see NF: 1:19, 2:28].

New suit seeks raw milk ban. Public Citizen's Health Research Group and the American Public Health Association have filed suit in federal court to overturn FDA Commissioner Frank Young's refusal to ban interstate sales of raw milk [see NF 2:28].

Government action against cytotoxic testing labs. In February, Bio Health Centers (BHC), a branch of Tan-nare International Inc., of Costa Mesa, California, was ordered to stop marketing its cytotoxic testing services in New York State. BHC operated through blood collection clinics set up in local hotels and also by mail [see NF 1:17-19]. After a woman's blood sample was mailed by an investigator for the New York attorney general, BHC incorrectly reported that the woman was sensitive to many foods. When an FDA investigator submitted a sample of cow's blood as his own, BHC claimed that allergy was present to 22 substances, including cow's milk, cottage cheese and yogurt. Authorities in California have also taken action against BHC.

Laetrile bill. On March 7th, Rep. William Goodling (R-PA) introduced H.R. 1471, to amend the Federal Food, Drug, and Cosmetic Act so that the effectiveness requirement of section 505 "shall not be applicable to laetrile when used under the direction of a physician for the treatment of pain." Although a double-blind test of laetrile conducted by the Mayo Clinic showed that laetrile is not effective against pain [see NF 1:15], the bill would enable laetrile to be sold when a doctor claims to be treating someone for that purpose. Presumably, laetrile promoters would have no difficulty in securing a "prescription" from a laetrile doctor for any patient who wants one. Such a legal loophole appears similar to the affidavit system for importing personal supplies of laetrile maintained by an Oklahoma federal judge despite higher court orders to dismantle it [NF 1:15]. According to a legislative aide, Goodling has made no effort as yet to secure co-sponsors.

Health food promoter dies. Bob Hoffman, founder of York Barbell Co., died on July 18th at the age of 86. A prominent figure in the sport of weightlifting (he was U.S. Olympic coach for more than 30 years), he was a major proponent of protein supplements. He also served on the board of governors of the National Health Federation, a health food industry group that promotes unproven methods. In 1960, 1961, 1968, 1972 and 1974, federal agencies forced his company to discontinue various false claims for its wheat germ oil, protein supplements, and other products.

Fluid intake during hot weather. Fitness authorities Mona Shangold, M.D., and Gabe Mirkin, M.D., advise those who engage in strenuous exercise during hot weather not to rely upon thirst to signal when their body needs water. In *The Complete Sports Medicine Book for Women* [Simon & Schuster, 1985], they explain: "You won't become thirsty until you have already lost 2 to 4 pounds of water and, by then, it's too late to make up the deficit. Special cells in your brain called osmoreceptors, which tell you when you are thirsty, are called into action only when the concentration of salt in your blood stream rises to high levels. Since sweat contains some salt, the concentration of salt in your blood stream rises more slowly than it would if sweat contained only water. Thus, sweating leads to considerable fluid loss, even though it promotes the thirst signal slowly. By the time you have lost 3 percent of your body weight as fluid, your temperature will have risen and your performance will have deteriorated markedly." The best fluid to drink is plain cold water because it is absorbed most quickly by the body. A good schedule to follow is a cup a few minutes before starting and another every 15 minutes during exercise.

Antiquackery group expands. Membership in the National Council Against Health Fraud has grown to 1,369, up 33% from one year ago. About 20% of members are dietitians. Chapters now exist in Arizona, Michigan, Minnesota, Oregon, Washington, and Wisconsin, and an affiliate group is operating in Kansas. Information on the group can be obtained by writing to NCAHF, Inc., P.O. Box 1276, Loma Linda, CA 92354.

"Quick-chilled" poultry. Most poultry plants now pack poultry in ice and hold it at 28°F or chill the birds with nitrogen. The result of these processes is a slight crust of ice crystals. Although the product's surface feels frozen, the inside is not. Thus, according to U.S. Department of Agriculture home economists, the birds can be cooked with the same temperature and cooking times as unfrozen poultry.

USDA report available. "Meat and Poultry Inspection, 1984: Report of the Secretary of Agriculture to the U.S. Congress," which summarizes the activities of the USDA Food Safety and Inspection Service, can be ordered from USDA-FSIS Public Awareness, Room 1163 South Building, Washington, DC 20250.

New aspartame report. After reviewing evidence available as of June 1985, the AMA Council on Scientific Affairs has concluded that "consumption of aspartame is safe except by individuals with homozygous phenylketonuria or other individuals needing to control their phenylalanine intake" [JAMA 254:400-402, 1985]. Reprints of the report are available from the Council on Scientific Affairs, Division of Drugs and Technology, American Medical Association, 535 N. Dearborn St., Chicago, IL 60610.

ACSH DEFENDS ANTIBIOTICS IN ANIMALS

A new report by the American Council on Science and Health concludes that the addition of subtherapeutic levels of penicillin and tetracyclines to animal feed does not present an immediate human health hazard and should therefore be permitted. This practice increases the amount of meat that can be produced from a given amount of feed and helps to prevent bacterial disease in animals.

According to ACSH, calls for a ban increased after publication last year of a study by the U.S. Centers for Disease Control (CDC) which concluded that 18 cases of human salmonellosis caused by antibiotic-resistant bacteria were probably acquired by eating hamburger originating from cattle fed subtherapeutic doses of chlortetracycline. The Natural Resources Defense Council has petitioned the Department of Health and Human Services, asking that nontherapeutic usage of penicillin and tetracyclines be banned as an "imminent hazard" to human health. A public hearing was held on January 25, 1985, but no decision has been rendered on the petition so far.

"The CDC study is not the 'smoking gun' some people claim it is," said Richard A. Greenberg, Ph.D., ACSH's associate director and author of the ACSH report. "There is considerable doubt that subtherapeutic feeding of antibiotics to beef cattle was at fault in this disease outbreak. A dairy herd adjacent to the beef cattle location was a more likely source of the antibiotic-resistant microorganism. Because of the missing links in the CDC study, and in light of other scientific evidence in this area, we do not believe that the use of these

antibiotics needs to be discontinued."

The Food Marketing Institute's 1985 survey of consumer attitudes found that 43% of consumers were "very concerned" and another 30% "concerned" about the possibility that fresh meat products might contain residues of antibiotics and other drugs. However, this concern is unwarranted, says Dr. Greenberg: "The feeding of antibiotics to farm animals is stopped several days before slaughter, so that the drugs can clear out of the animals' bodies. The U.S. Department of Agriculture prohibits the sale of meat containing antibiotics in excess of legal tolerance levels. Antibiotic residues in meat sold in the United States are negligible. The controversy in the scientific community is over antibiotic-resistant bacteria, not antibiotic residues in meat."

A free copy of *Antibiotics in Animal Feed: A Threat to Human Health?* can be obtained by sending a self-addressed 4"x9 1/2" envelope with 39¢ postage affixed to Antibiotic Report, ACSH, 47 Maple St., Summit, NJ 07901.

RAW MILK INVOLVED IN LEGAL BATTLES

San Francisco pediatrician John Bolton and the American Academy of Pediatrics have been sued by Alta-Dena Certified Dairy for comments made about the company's certified raw milk products. The statements were made in February at a hearing of the House Subcommittee on Health and Environment Subcommittee, chaired by Rep. Henry Waxman (D-CA) and held in Los Angeles. Dr. Bolton, who testified on behalf of the Academy, reportedly called raw milk a "toxic waste problem" and said that there is no way to prevent intermittent contamination by *Salmonella dublin* and other potentially lethal bacteria. [For related information, see NF 2:1-4 and 2:28]. The suit asks for \$10 million in actual damages and \$100 million in punitive damages. A similar suit was filed last year for comments made during 1983 and 1984.

Interview by the Los Angeles Times, Bolton's attorney David Raub said: "It looks to me like the dairy is trying to keep Dr. Bolton from being so vocal a critic." Raub also said that Bolton's legal defenses are sufficiently adequate that the suits are unlikely to ever go to trial. The article noted that although Alta-Dena raw milk has been recalled from store shelves more than 20 times during the past 20 years because routine government tests discovered the presence of salmonella bacteria, the company maintains that its products are free from contaminants and that no one has ever become ill from consuming Alta-Dena certified raw milk. In subsequent letters to the editor, Alta-Dena's manager said that suing Bolton was "not a move to intimidate but rather to serve notice that the dairy suffers financially from irresponsible statements" but Rep. Waxman said "it may well be a violation of a federal law designed to protect witnesses appearing before congressional committees."

On June 26th, the Los Angeles district attorney's office announced that it had seized about 20 boxes of records from Jalisco Mexican Products, Inc., a manufacturer whose Mexican-style cheese was implicated in the death of more than 40 California residents from *Listeria monocytogenes* infection. According to an article in *The Los Angeles Times*, it appears that Jalisco received considerably more raw milk at its processing plant than it could possibly pasteurize. Although company officials deny that unpasteurized milk was used to make cheese, state health officers suspect that it was. After tests by the U.S. Centers for Disease Control showed that Jalisco products were contaminated with *Listeria* bacteria, production was stopped and a recall was ordered.

Since August 1984 the San Francisco Health Code has required all stores that sell raw milk to post a prominent warning: "Raw milk products are not pasteurized and may contain organisms that cause human disease. They therefore should not be consumed by the very

young; the very old; persons with illnesses which alter, or who take drugs which affect, the immune systems; and persons with severe chronic medical problems." Although California law requires that dairy herds be checked for evidence of infection with several disease germs, *Listeria monocytogenes* has not been one of them. According to an article in the *San Francisco Examiner*, much of the raw milk used by Jalisco was delivered by Alta-Dena Dairy. However, it is not yet clear whether the milk came from Alta-Dena's herds or from its contract farms.

QUESTION BOX

Q. What was the outcome of the legal case of the 2½-month-old infant who died as a result of the advice of Adelle Davis?

A. Your question refers to Ryan Pitzer, who died in 1978 after his mother gave him potassium chloride drops for colic as advised in the book *Let's Have Healthy Children*. The case was settled out of court. In 1981, the publishers paid \$25,000 and the estate of Ms. Davis paid \$75,000, and in 1982, the potassium supplement manufacturer agreed to pay \$60,000 over a 5-year period. The book containing the fatal advice was withdrawn from the marketplace (as demanded by the suit) but was reissued after revision by Marshall Mandell, M.D., a physician allied with the health food industry. Ryan's parents were represented by attorney Peter Portley of Pompano Beach, Florida.

Q. Is honey pure fructose?

A. No. Honey contains almost equal amounts of glucose and fructose plus smaller amounts of several other sugars. Honey is formed, with the aid of an enzyme in the bee's stomach, from the nectar of flowers. Depending on the source of the nectar, honey can vary considerably in composition and flavor. Its constituents (by weight) include fructose (27-44%), glucose (22-41%), water (13-23%), maltose (3-16%), sucrose (.25-7.5%), other sugars (.13-13%), and undetermined substances (0-13%). Honey is used in food products where its intense and distinctive taste is desired. Like yogurt, wheat germ, sea salt and similar products, honey has long been considered a "miracle" food by pseudoscientific practitioners. But no special health-giving characteristic has ever been scientifically demonstrated.

HERBALIFE CRITICIZED AT SENATE HEARINGS

Odom Fanning

Opening two days of hearings, Senator William V. Roth, Jr. (R-DE), chairman of the Senate Permanent Subcommittee on Investigations, made it clear that their purpose was not to "get" Herbalife or any other product, but resulted from five months of investigation into weight reduction products and plans of all types. The Subcommittee is authorized to investigate the efficiency and economy of all branches of the government and also has jurisdiction over "all aspects of crime and lawlessness within the U.S. which have impact upon or affect the national health, welfare, or safety."

Roth acknowledged that following announcement of the hearings (held in Washington, D.C., May 14th and 15th), he had received a "very large number of phone calls and letters from individuals who are very satisfied with the Herbalife products, and have lost large amounts of weight." Many of these correspondents, and an estimated 3,000 Herbalife distributors who marched on the second day, were obviously on the defensive. So was the Food and Drug Administration, for, as the Senator put it, the purpose of the hearings was "to find out if the public is being adequately protected when it buys and consumes diet products."

In his opening remarks, Roth made a distinction between "miracle pills and creams," tinted sunglasses, plastic ear forms and other "patently fraudulent products" and the very low calorie (VLC) products that can actually produce weight loss but may not be safe. His major concern with the VLC products, he specified, "is with what the Food and Drug Administration is doing and what it is not doing, particularly when serious questions have been raised both within the FDA and outside this agency about the safety of such products. . . . We are dealing with a multi-billion dollar industry which produces items ingested into the human body. Yet the FDA has been reticent to involve itself in low calorie diets. I want to know why, because I think the public deserves to know conclusively about the safety of individual products now in the marketplace."

On the first day Roth's subcommittee heard testimony from scientists and VLC product users, all of whom submitted written statements as well. Most of the scientists favored more regulation of such dietary products; the users were pro and con.

One scientific witness was Judith S. Stern, Sc.D., professor of nutrition and director of the Food Intake Laboratory at the University of California, Davis. She conceded that "the inadequacy of traditional medicine to provide a permanent cure for obesity has given rise to an entire industry of entrepreneurs who claim to be able to relieve the frustrations of the overweight. The ironic tragedy is that most diets work—at least initially—when they are followed. However, fad diets are usually quite restrictive in their food choices, may have unpleasant side effects, and most people cannot follow them for any length of time. In addition, when daily calories are restricted below 1,200, it becomes difficult to satisfy all other nutrient needs."

Dr. Stern also made the distinction between "miracle cures" and VLC products. Products in the former category include the hormone cholecystokinin (CCK), claimed to decrease hunger [see NF 2:38], and various amino acid pills, said to release growth hormone [NF 1:24]. Both have been promoted with false claims based on legitimate scientific discoveries that were overgeneralized and misrepresented, she noted.

Debunking claims that grapefruit or grapefruit extract can act in a catalytic manner enhancing breakdown of fat, Dr. Stern described her testimony last year which helped the U.S. Postal Service stop sales of Super Grapefruit Pills by a California company [NF 2:38]. Noting that these pills contained glucomannan, she reported that in 1980 she had conducted a double-blind study in which the test group received one gram of glucomannan while the control group was given a placebo. Both groups were placed on a behavior modification program. Both groups lost weight, she noted, but there were no statistically significant differences in

hunger ratings or weight loss between them.

Dr. Stern also zeroed in on kelp/lecithin/cider vinegar/vitamin B₆ combinations found in dietary products since 1974. Iodine-rich kelp is potentially harmful to a small number of individuals in whom high amounts of ingested iodine can cause thyroid trouble. The other three ingredients are worthless, she noted.

Another expert witness was Varro E. Tyler, Ph.D., professor of pharmacognosy (the science of medicines from natural sources) and dean of Purdue University's School of Pharmacy and Pharmacal Sciences. Here is my summary of Dr. Tyler's detailed analysis of various Herbalife products contained in the lengthy packet of written material released by Roth's subcommittee to the press:

- *Slim and Trim Formula #1* (46¢/day), described in the sales literature "as a balanced protein powder made from natural vegetable soy, casein and whey protein." Tyler said the product is falsely represented in company literature because there is nothing about a protein powder, per se, that will curb the appetite any more than an equivalent amount of protein derived from eating lean meat, nuts, or the like. Further, no protein powder will "cleanse the system" or facilitate "burning excess calories." It will supply needed daily nutrients, but no more effectively than a low-calorie diet, carefully balanced for carbohydrates, minerals, and vitamins—as well as protein.

- *Slim and Trim Formula #2* (21¢/day), described by the Herbalife organization as a special blend of 14 herbs plus kelp, lecithin, vitamin B₆, and cider vinegar designed to cleanse the digestive system and naturally help curb the appetite. Tyler said that, of its many herbal ingredients, none is actually present in sufficient quantity to produce significant physiological effects by itself. But he noted that four ingredients—senna, cascara sagrada, dandelion root, and kelp—might work together to exert a laxative effect in sensitive individuals.

- *Slim and Trim Multivitamin and Multiminerals Formula #3* (23¢/day) is a fairly standard vitamin/mineral preparation with some herbal products added in such tiny amounts that they exert no significant effect. Unless vitamin deficiency was present, Tyler noted, the product would be a complete waste of money.

- *Slim and Trim Linseed Oil Formula #4* (10¢/day) contains small amounts of linseed oil but has no advantage over less expensive vegetable oils ordinarily used in the kitchen of the average home. (Moreover, as noted by the next witness, the amount found in the formula will be obtained in food consumed in just one balanced meal per day.)

- *Cell-U-Loss* (43¢/day) is described in Herbalife literature as a product designed to attack cellulite, promote circulation, and eliminate excess fluids, is recommended for use with the Slim and Trim formulas. Tyler noted that its tiny amounts of herbs would at most cause

a slight diuresis (output of body water), but would have no effect whatsoever on appetite or body fat.

- *Herbal-aloe* is said to aid digestion and cleanse the system. Although uncertain of the type of aloe contained in this product—which may be a laxative—Tyler expressed deep concern over two of its other herbal ingredients. Comfrey, he said, is a known carcinogen, shown to produce malignant tumors in the livers of rats when included in their diet. And the active constituent of chapparal, nordihydroguaiaretic acid (NDGA), was removed from the FDA's GRAS (Generally Recognized As Safe) list many years ago after it was shown to cause cysts and kidney damage in rats.

- *N.R.G. (Nature's Raw Guarana)* (80¢/day), claimed to increase energy, aid in mental alertness and produce a nutritional lift, is sold in tablets that contain small amounts of granular guarana, the seed of a South American plant known to contain about 5% caffeine. The amount of caffeine in the recommended dose of N.R.G. is about the same as that in a cup of strong coffee—but the presence of caffeine is not revealed in product labeling or literature. Thus, individuals sensitive to caffeine might be unwittingly harmed.

- *Schizandra Plus* tablets are said to help combat stress and damage leading to premature aging. Although he suspected that the dosage of its ingredients was too low to exert pharmacological effects, Tyler indicated that tests are needed to determine whether chemicals extracted from schizandra can protect or harm the liver [see NF 2:29].

- *Tang Kuei* (50¢/day), said to help establish menstrual regularity and provide "herbal nutrition" for the whole body, contains dong quai (also known as dang gui and pinyan) and chamomile. These drugs—used in traditional Chinese medicine—have not been proved by Western standards. Tyler noted that even if they are effective, the amounts contained in Tang Kuei are far below those used in China. Moreover, under federal law, Schizandra Plus and Tang Kuei are unapproved new drugs that are not legal to sell in the United States.

Overall, Tyler objected that: 1) some Herbalife products may well be toxic, at least to some consumers; 2) Herbalife literature and word-of-mouth recommendations build up false hopes in consumers, most of whom are not able to benefit from the placebo effect; 3) it is particularly deceptive because they lead the public

to believe that Herbalife products "contain a lot of wonderful herbs with marvelous health-giving properties when the amounts present in the products are too small to have any significant physiological effects in normal persons; and 4) consumers are thus paying good money for products which have no proven value.

Many of the same points were reiterated in an analysis of the various Herbalife formulas by F. Xavier Pi-Sunyer, M.D., associate professor of Medicine, Columbia University College of Physicians and Surgeons, and a division chief at St. Luke's Roosevelt Hospital Center, New York City.

"With very rapid weight loss, and particularly with diets low in carbohydrate, there is an early diuresis, that is, loss of water via the urine. This accounts for much of the weight loss of crash diets and much of this water is reaccumulated when the diet is stopped," said Dr. Pi-Sunyer. "With this water loss, great amounts of sodium, potassium, and chloride are lost, as well as lesser but substantial amounts of calcium, magnesium, and other minerals. These must be replaced. If they are not, the electrical integrity of biological membranes may be lost, and one outcome of this may be cardiac arrhythmias."

Because dieters wish "to get on with it," there may be a tendency to take only the protein preparation, without supplementing it, as sometimes recommended, by a meal to bring the daily intake to at least 800 to 1,000 calories (of which 300 to 400 may be provided by the dietary product). Consumers also may ignore the limited period, say four weeks, recommended by some diet purveyors, and incur added risk by consuming the preparation for a longer time, said Dr. Pi-Sunyer.

He also reported that a colleague, Theodore B. Van Itallie, M.D., had reexamined data of the victims of the liquid protein diets of 1977-1978 and found that "the less fat you are the more dangerous these diets are for you, the more likely you are to lose life-requiring protein, and the more at risk of dying you are. Since these preparations are bought without restriction, many people take them who are not very fat, and these people seem to be particularly at risk."

Two of the four laypersons who testified were constituents of Senator Roth's—one for Herbalife, the other against. Patricia Stombaugh, of Smyrna, Delaware, began taking Herbalife in August 1984. "After taking it

for two months, losing five pounds and feeling much better," she was asked by friends "for more information about Herbalife." She soon became a distributor. She and her representatives since have sold it to over 300 people. "Herbalife has worked for me and my customers," she told Roth and the subcommittee. "I believe the people who said they felt better using the Herbalife products are stating the facts: their health problems improved through weight loss and sound nutrition. They are not saying that Herbalife is like a medicine that cures a disease. No one I know has ever claimed this."

Another user, Greg Martin, of Dover, Delaware, lost about 13 pounds in three months and "felt better than I had in years," after starting on Herbalife products in September 1984. He and his wife began selling the products in October, eventually building a customer list of 100 with ten distributors. But most of his customers suffered from constipation when using Slim and Trim Formulas, and 10 to 15 percent had other problems, he reported. One man who had had two previous heart bypass operations was taking Herbalifeline because Martin "understood from the literature that it was good for heart problems. This man became extremely constipated."

Because he was unable to get answers to his questions from Herbalife headquarters, Martin stopped selling its products to retail customers at the end of February. "I do not want to be associated with a company who claims its products are safe for everyone to use and then will not deal with [health] problems," he testified. He expressed the conviction "that diet products and food supplements can do a lot of good. I would not want to see them prohibited." He suggested, however, that standards be established and that the FDA "enforce these standards so that the public can be confident that these products are safe."

The final two lay witnesses testified to personal tragedies. Bernard Lehman, of Anaheim, California, formerly from a town near Nashville, Tennessee, said that he is not able to work because he has Hodgkin's lymphoma, a form of cancer. A few months ago, while "basically bedridden," he claimed that a distributor in Tennessee told him and his wife that she could lose weight taking Herbalife products, that both could earn needed income, and that "the Herbalife products would help to cure my cancer."

Jarvis, Ph.D.; Manfred Kroger, Ph.D.; James Lowell, Ph.D. **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Linda K. DeBruyne, M.S., R.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Suzanne Pelican, M.S., R.D.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.

Lehman named the distributor and charged, "He told us this orally and showed us some brochures which said this" in writing. "However, he gave us different brochures without this information and said that he only had one copy of the special brochure, and he had to keep it for his use." Lehman summarized by saying that the distributor "basically said that the Herbalife products would act as a cure-all."

Although he and his wife had "bad reactions" to the Herbalife products, they continued taking them "because we believed that we could make lots of money and we thought our own bad reactions to taking the products were unusual." They spent about \$1,800 for inventory and publications and sold about \$100 worth of Herbalife products before asking to get out and get their money back. They eventually received \$1,000 from the distributor and still have \$700 worth of product they "would just like to get rid of . . . and forget about."

Cynthia Guillaume Lee, of New Orleans, told the pitiful story of her late husband, Bivian Lewis Lee, Jr., who had retired as a National Football League player in 1976. He became a Herbalife distributor in October 1984 because "the extra money sounded real good," said Mrs. Lee. Although he was not overweight and "was very much against taking any kind of diet product," he began taking a Herbalife product because "he said that if he was going to sell it, he would at least try it out."

Two weeks later, Bivian, age 35, was dead. His widow testified: "I know that I'm not a doctor. I know that I'm not qualified to give medical opinions. But I do know that my husband was a perfectly healthy man. I saw him deteriorate from the perfectly healthy man to his death. And it all began when he started taking Herbalife. I want to tell what happened to me—it's not easy for me to do this—because I want this subcommittee, or the Federal Food and Drug Administration or somebody to investigate why my husband was alive and well until he started on the Herbalife products and now he's dead. I want to encourage the subcommittee to look into this so that other young mothers won't find themselves in my position."

Mrs. Lee submitted an affidavit by Dr. Van Itallie, who had reviewed the autopsy protocol prepared by the Orleans Parish Coroner's Office and other records relating to Bivian Lee's death. The affidavit cites an article Van Itallie co-authored, entitled "Cardiac dysfunction in obese dieters: a potentially lethal complication of rapid, massive weight loss" [*American Journal of Clinical Nutrition* 39:695-702, 1984]. The article discusses the cases of 17 obese but otherwise healthy persons on VLCs who died of cardiac arrhythmia. "Basically," the affidavit says, "severe restriction of caloric intake causes the body to utilize and deplete its protein. The heart is a muscle, made of protein, and it is not spared . . . depletion of protein from the heart may be followed by car-

diac arrhythmia and death. I refer to this as the 'liquid protein syndrome', but it may develop from any drastic reduction in caloric intake. My thesis further holds that persons with lesser stores of body fat are more likely to experience the cardiac dysfunction. Fatter dieters seem to survive longer because they are better able to conserve their body protein."

Van Itallie found this thesis consistent with Bivian Lee's case, particularly because he was "persuaded by Lee's Body Mass Index, indicating that he had lesser stores of body fat."

The second day of the hearings, which featured the FDA Commissioner and the executive heads of Cambridge and Herbalife, will be discussed in next month's *Nutrition Forum*.

Mr. Fanning, formerly science writer for *The Atlanta Journal* and director of information for the Centers for Disease Control, is editor and publisher of *Consumer Newsweekly*.

QUESTION BOX

Q. Is it hazardous to swim after eating?

A. There is no need for healthy persons to restrict mild or moderate physical activity after eating. After you eat, your stomach muscles require increased blood supply while churning the food. During exercise, blood supply to the voluntary muscles must be increased. According to sports-medicine expert Gabe Mirkin, M.D., if you are reasonably fit and exercising moderately, your heart can handle both jobs at the same time. However, if you are exercising very vigorously or are in poor physical condition, the simultaneous demands will be too much, and the supply of blood carrying oxygen to the stomach may be inadequate, resulting in stomach cramps.

Q. Does the term "holistic medicine" have a specific meaning?

A. No. Orthodox practitioners use the term to mean treatment of the "whole patient," with attention to emotional factors as well as physical ones. But most people who refer to themselves as "holistic" utilize unscientific methods of diagnosis and treatment. Because the holistic label is a potential source of public confusion, knowledgeable observers have suggested that scientific practitioners abandon it.

FDA MAY PERMIT HEALTH CLAIMS ON FOOD LABELS

The Food and Drug Administration has indicated that it will revise regulations concerning health claims made for foods. *The New York Times* has reported that details of the plan will be announced soon and that a committee of government scientists will then review available evidence, invite public comment and suggest health labels suitable for use on food products. According to Joseph P. Hile, Associate Commissioner of Food and Drugs (the FDA's top enforcement official), the agency's problem is "how to permit appropriate health claims without opening the door to outright fraudulent ones."

The Federal Food, Drug, and Cosmetic Act (FDCA) defines drugs as "articles intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease in man or other animals." This law also makes it illegal for sellers to make new drug claims without FDA approval (which requires proof of safety and effectiveness prior to marketing). Thus foods for which disease-related claims are made can now be regulated by the FDA as drugs.

Paul Sage, the FDA consumer safety officer who last year petitioned the agency to set up a more vigorous enforcement program against misbranded food supplements (see NF 1:1-2), believes that the "FDA cannot lawfully adopt a policy that sets aside a statute's definition and contravenes its intent—only Congress can change a law in this manner." Instead, he feels that a streamlined approval process can be designed in which manufacturers file "new drug applications" based on scientific data supporting their claims. But others think guidelines can be used.

Controversy in this area began last fall when the FDA objected to an advertising campaign begun for Kellogg's All-Bran cereal. One ad had listed four "preventative tips from the National Cancer Institute": 1) eat high fiber foods; 2) eat foods low in fat; 3) eat fresh fruits and vegetables; and 4) eat a well-balanced diet and avoid being over or under weight. Another had stated that no cereal has more fiber than All-Bran. The ads, which appeared on radio and television as well as on the backs of cereal boxes, had been designed with help from the National Cancer Institute (NCI) itself.

Federal Trade Commission officials expressed the belief that the ads are within their primary jurisdiction and have endorsed them as truthful food claims that can benefit the public. But FDA officials said that linking a specific food product to NCI's advice put the manufacturer in the position of making a "special health claim" that may make All-Bran a drug subject to premarket proof of effectiveness. Meanwhile, NCI was contacted

by other manufacturers who believe that their products fit within NCI's guidelines.

On May 22nd, Kellogg Company filed a 550-page petition asking the FDA to allow such claims in food advertising or labeling without making the foods "new drugs" that need FDA approval. Kellogg wants the FDA to change its policy so that foods shall not be considered misbranded or drugs because of labeling, advertising or other statements that refer to relationships between diet and health, provided that such statements: 1) are substantiated by studies generally recognized as valid by experts; 2) are made only in the context of a diet and refer only to a food that is an appropriate component of that diet; 3) specify the dietary property(ies) or ingredient(s) which make that food an appropriate component of the diet, and the amount in a serving of the food is disclosed on the label; and 4) are not false or misleading to consumers.

The National Food Processors Association—representing such companies as Del Monte, Campbell, Kraft, Beatrice, and Hunt Wesson—has also petitioned the FDA to relax its rules so that health claims supported by "unbiased authorities" can be made for foods. Other groups supporting relaxation of the rules are the Council for Responsible Nutrition (an association of supplement manufacturers) and the Center for Science in the Public Interest, which wants a moratorium on health claims until formal guidelines are adopted.

Seizing upon the controversy, the National Health Federation is promoting "Foods Are Not Drugs" bills to amend the FDA Act so that "foods for special dietary use" would not be classified as drugs. H.R. 1819, introduced by Representative Howard Nielson (R-UT), and H.R. 2583, introduced by Representative William Dannemeyer (R-CA), would exempt such products as encapsulated herbs, foods, and vitamins. Passage of either bill would virtually cripple the FDA's ability to protect the public against "food supplement" concoctions labeled as "dietary supplements" but promoted as effective against disease. Theoretically, the FDA could still act against false claims made for these products. But instead of merely showing that a company has not secured necessary FDA approval, the agency would face the impossible task of disproving false claims for hundreds or even thousands of products on a case-by-case basis.

Comments on the Kellogg petition (Docket #85-N-0061) can be sent to Dockets Management Branch, HFA-305, Food and Drug Administration, 5600 Fishers Lane, Rockville, MD 20857.

NUTRITION FRAUDS ATTACKED BY NEW YORK ATTORNEY GENERAL

A "holistic nutritional consultant," three testing facilities he utilized, and the school from which he obtained his "Ph.D." are the targets of five suits filed July 22nd by New York State Attorney General Robert Abrams. Assistant Attorney General Leslie E. Rossen of the Department of Law's Bureau of Consumer Frauds and Protection is managing the cases. The court papers, which encompass more than 500 pages, state:

- Gary Pace, 50, of Garden City, N.Y., "has engaged in a scheme to defraud consumers by repeated fraudulent and illegal acts and practices including the illegal practice of medicine and fraudulent misrepresentations. By virtue of this scheme, Pace has induced hundreds of consumers to each pay hundreds of dollars to him for improper physical examinations, worthless laboratory tests, bogus nutritional advice, and unnecessary vitamin, mineral, and herbal supplements."

- Herbal Tracers, LTD., of Hewlett, N.Y., and its president, David Fishman, have been: 1) operating a laboratory without possession of a valid permit; 2) accepting specimens from and rendering reports to persons not legally authorized to use the findings of a laboratory; 3) illegally billing providers of the tests rather than those who took the tests; 4) performing "herbal crystallization analysis," a test not approved by the New York State Department of Health; and 5) making false and misleading statements to promote the test to health professionals and the general public.

- Doctor's Data Laboratories, Inc., of West Chicago, Illinois, has been: 1) doing unauthorized business in New York State; 2) operating without a laboratory permit; 3) accepting specimens from unauthorized persons; 4) illegally billing providers of the tests; and 5) performing an unapproved laboratory test (hair analysis) which Pace used as a basis for nutritional advice to clients.

- The International Institute of Natural Health Sciences, Huntington Beach, California, and its president, Kurt Donsbach, have been: 1) doing business in New York State without authority to do so; and 2) engaging in a scheme to defraud consumers by means of a "Nutrient Deficiency Test," claimed to be useful in analyzing nutritional status and prescribing dietary supplements to correct supposed deficiencies.

- Donsbach University and its president, Kurt Donsbach, have been: 1) conducting business in New York State without legal authorization; and 2) violating state education laws by advertising unaccredited degrees to state residents.

Action in these cases was triggered by a complaint from the mother of a client of Gary Pace, whose "Ph.D." in nutrition is from Donsbach University. Pace is "certified" as a "nutritional consultant" by the Amer-

ican Association of Nutritional Consultants and is a member of the group's "national board of consultants," of which Donsbach has been chairman. Pace's ads also state that he is registrar of the American Nutritional Consultants Association, another group that promotes unscientific nutrition practices based on Donsbach's theories.

The case against Pace was supported by affidavits from thirteen aggrieved clients and two undercover investigators, all of whom were advised to take vitamins, minerals and/or herbs. Some of the female clients reported that Pace examined their breasts or genitals. A number of the clients underwent significant expense to obtain medical reassurance that they did not have various diseases that Pace said they had. One client was advised by her medical doctor to stop taking vitamin A supplements because her palms had become yellow as a result of vitamin A overdosage.

According to the Attorney General's office, at least 251 clients paid Pace an average of \$307 during the past four years. Many of them had been attracted by his 2"x4" ad in the Nassau County Yellow Pages, which claimed he would "determine your body's true vitamins, minerals, enzymes and glandular needs" with hair and diet analysis, nutrient deficiency testing, herbal saliva testing, metabolism testing, computerized urine testing, iridology, reflexology, kinesiology, herbology, homeopathic and allergy tests. The ad offered nutritional counseling for weight problems, diabetes, high blood pressure, insomnia, natal care, hyperactive children, ulcers, and other related conditions. The ad also offered a "free consultation," which, the investigators discovered, consisted of the brief telephone conversation he has before advising prospective clients to make an appointment.

The saliva test was performed by having the client lick a slide which was sent to Herbal Tracers for analysis. The lab would then issue a report based on crystal patterns that supposedly indicated organ dysfunctions and herbs that could be used to remedy them.

Doctor's Data, the largest commercial hair analysis lab in the United States, held a permit to operate in New York State for a short period in 1982 until state authorities discovered that its director lacked the credentials required by state law. The permit was revoked and the lab was ordered to stop accepting, testing or reporting on specimens received from New York State residents—an order that the company ignored. A recent Cable News Network report stated that Doctor's Data performs 200-400 tests per day for an average of \$28 per test.

Donsbach's Nutrient Deficiency Test is composed of 245 yes/no questions about symptoms. When fed into a computer, these data yield a printout of supposed nutrient deficiencies and medical conditions. The court papers indicate that experts who have evaluated the questions do not believe they provide a basis for evaluating nutritional status. Moreover, a scientist with the FDA's Buffalo district office who analyzed the test's computer program found that no matter how the questions are answered, the test finds several "nutrient deficiencies" and almost always recommends an identical list of vitamins, minerals and digestive enzymes. The ques-

tionnaire also contains a section with questions about the subject's food intake during the past week. However, the answers given do not affect the printout of supposed nutrient deficiencies!

Each of the above complaints asks the court to order a permanent injunction against the illegal acts as well as payment of costs, civil penalties, and restitution to consumers. In addition, to help protect consumers from other unqualified "nutrition consultants," Attorney General Abrams plans to ask his state legislature to pass a nutritionist licensing law.

BRIEFS

Hair analysis exposé. When 52 hair samples from two healthy teenagers were sent to 13 commercial hair analysis laboratories, the reported levels of minerals varied considerably between identical samples sent to the same lab and from lab to lab. The labs also disagreed about what was "normal" or "usual" for many of the minerals. Most reports contained computerized interpretations that were voluminous, bizarre, and potentially frightening to patients. Six labs recommended food supplements, but the types and amounts varied widely from report to report. Literature from most of the labs suggested falsely that their reports were useful against a wide variety of diseases and supposed nutrient imbalances. The 5-page report, published in the August 23/30 *Journal of the American Medical Association*, was summarized in the AMA's weekly press packet to more than 2,000 health and science writers and was widely reported through the media. A copy of the article can be obtained by sending a self-addressed 4"x9 1/2" envelope stamped with 39¢ postage to Hair Analysis Report, P.O. Box 1747, Allentown, PA 18105.

Herbalife layoffs. Negative publicity appears to have hurt Herbalife seriously. According to *Newsday* [June 6], enforcement action in California [see NF: 2:29] plus negative publicity from the recent weight-loss hearings have dampened sales so much that more than 500 employees (about one-third of Herbalife's work force) have been laid off. Another factor in the slump is competition: similar products are being marketed through health food stores and through Uni-Life, a multilevel sales company started by former Herbalife distributors.

Irradiated foods report. A free copy of the American Council on Science and Health's new 27-page booklet can be obtained by sending a self-addressed 4"x9 1/2" envelope with 39¢ postage to Irradiated Foods Report, A.C.S.H., 47 Maple St., Summit, NJ 07901.

Irradiation information center. The National Agricultural Library has created a clearinghouse to provide scientists and consumers with information about the potential uses of food irradiation. Information about the facility can be obtained by contacting Carole Shore, Food Irradiation Center Coordinator, National Agricultural Library, Room 304, Beltsville, MD 20705 (telephone: 301-344-4369).

Cholesterol labeling? According to an article in *The New York Times*, the FDA is considering allowing manufacturers to provide information about the amount of cholesterol in particular foods—perhaps with use of the terms "low cholesterol" or "reduced cholesterol" in labeling.

Consumer protection bill. S. 1313, introduced by Senator Howard Metzenbaum (D-OH), would enable state attorneys general to bring action under the Federal Trade Commission Act's provisions against unfair and deceptive practices. Currently, state agencies are generally limited to obtaining court orders to stop illegal practices within their own state. The new bill would enable them to initiate complaints in federal courts, and would allow the courts to make rulings with nationwide impact.

Antifluoridation propaganda exposed. The Ohio Department of Health has completed an analysis of *Lifesavers Guide to Fluoridation*, an 8-page pamphlet by John Yiamouyiannis, Ph.D. Painstaking research over a 2-year period by Coleen A. Wulf, R.D.H., and 13 colleagues showed that many of the references used to back up antifluoridation claims actually support fluoridation but were selectively quoted and misrepresented. Moreover, of 250 "references" cited in the pamphlet, 116 had no relevance to community water fluoridation.

Book Review

Title: Fluoride, The Aging Factor (1983)
 Author: John Yiamouyiannis, Ph.D.
 Publisher: Health Action Press, Delaware, Ohio
 Price: \$11.95
 Reviewed by: Stephen Barrett, M.D.

Dr. Yiamouyiannis, who considers himself "the world's leading authority on the biological effects of fluoride," has been working full time for more than ten years to defluoridate the world. Hired in 1974 by the National Health Federation (NHF) to "break the back of fluoridation," he served as the group's "science director" for six years. In 1980 he left NHF and founded the National Health Action Committee and the Safe Water Foundation. In 1984 these groups merged their assets into the Center for Health Action, "a union of virtually every effective anti-fluoridation group in the country" [see NF 1:7].

Fluoride, The Aging Factor accuses fluoridation of causing cancer and a wide range of chronic ailments from skin wrinkles to arthritis. Although the author cites valid scientific reports to back up his claims, reviewers at the Ohio Health Department have found that the actual articles either support fluoridation or are irrelevant to it. Unfortunately, the book may frighten laypersons and help delay implementation of fluoridation in communities exposed to its ideas. A second edition is expected soon.

Title: Arthritis and Common Sense #2
 Author: Dale Alexander
 Publisher: Witkower Press, West Hartford, CT
 Price: \$14.95
 Reviewed by: Alan A. Halpern, M.D.

This is a major revision of the highly popular book, *Arthritis and Common Sense*, first published in 1954. It is touted as the "best selling book on arthritis ever written," with over 1,200,000 copies sold. As I began reading it, I conjured up an image of a sincere and dauntless individual searching throughout the world for the mystical "answer" to arthritis. But at the end, it was clear that the author had somehow managed to bypass virtually every institution of higher learning and serious arthritis research. Along the way, I noted factual errors on most pages and an alarming tendency to endorse the work of other questionable promoters.

Mr. Alexander, who has no recognized academic or scientific credentials, says he began formulating his

ideas while serving as a medical technician in the Air Force. His "research" is nothing more than a compilation of anecdotal reports and uncontrolled projects.

According to Alexander, the basic cause of arthritis is "poorly lubricated joints." His central premise is that dietary measures—particularly the use of cod liver oil—are effective in preventing and/or curing arthritis. The book asserts that oils in the diet can act as lubricants in the joints if only the diet is correct, and furthermore that "diet can increase or enhance the quality of synovial fluid in arthritic joints." He postulates that while 90% of cod liver oil reaches the joints and other tissues, only 65-75% of oils from salad oil or meats do so—and that, "Even worse, if you drink ice-cold beverages or carbonated soda pop with meals, oil delivery will be reduced to only 5% or 10%."

Serious scientists have been examining the effects of different diets on the course of rheumatoid arthritis. The results so far are inconclusive and certainly don't support Alexander's global conclusions. But Alexander tells readers what many of them want to hear: that there is a simple answer to their problem. They do not have to understand their particular disease or its standard treatment, or to settle for their doctor's advice that most cases of arthritis can be controlled but not cured.

The book's commercial success is no doubt testimony to the fact that faced with a chronic and painful condition, desperate individuals, no matter how sophisticated and well educated, often grasp at unproven treatments. I read it with a mixture of envy and anger: admiration of the author's marketing skill, yet saddened by the American public's continued appetite for simple answers and easy home cures. Mr. Alexander is a master of his craft. Those who devote their energies to informing the public about arthritis might do well to learn from his style, so that perhaps reason could be communicated as effectively as fiction.

Alexander states in the book's first chapter that many people have reported long-lasting relief with his methods. It would be fascinating to see an objective study of Alexander's approach and what happens to those who read his book. Perhaps some day he or a member of the scientific community will undertake such a survey.

Dr. Halpern is an orthopedic surgeon who practices in Kalamazoo, Michigan. He is a clinical instructor in the department of surgery at the Michigan State University College of Human Medicine and is author of *The Kalamazoo Arthritis Book* and *Runner's World Knee Book*.

“HERBALIFE HEARINGS,” PART II

Odom Fanning

May 15th was a sunny Spring day, ideal for a demonstration. About 8 a.m., an estimated 3,000 Herbalife supporters from across the country began gathering on Capitol Hill, each wearing a large button reading: “I lost X pounds. Ask me how.” They had been called to Washington for a rally whose main purpose was to grab media attention and get television reporters to ask, on camera, how they had lost their claimed poundage. The evening before, they had shared their enthusiasm in a ballroom at the Hyatt Regency Hotel, where they received buttons and instructions from a platoon of officials from Herbalife International headquarters in Los Angeles.

The 5-block walk from the hotel to the Dirksen Senate Office Building was covered by camera crews from the networks, alerted by the Washington offices of Herbalife’s public relations counsel, Rogers & Cowan, Inc., of Beverly Hills, Calif. Of the 100 or so demonstrators who gained entrance to the building, only about 50 could fit at any one time into the spectator section of crowded Room 342 where the U.S. Senate Permanent Subcommittee on Investigations held its 2-day hearing on weight reduction products and plans.

To the credit of the audience and chairman, Senator William V. Roth, Jr. (R-DE), decorum in the hearing room was maintained at all times. Nor did the Herbalife representatives who stood for hours in the hallway hoping that space inside would become available require anything of Capitol police other than normal crowd control.

At the first day’s hearing, Senator Roth had indicated that although many very low calorie (VLC) dietary products are being sold, his subcommittee’s review had focused on Cambridge and Herbalife, “largely because they have pervaded the market.” Reading from his staff’s report, Roth had noted that the FDA had collected 12 reports of deaths and 138 complaints of illnesses associated with use of the Cambridge diet. The agency had also received 90 complaints of alleged illness due to Herbalife products, four reports of death, and 32 allegations of fraud.

“While these numbers may pale in comparison to those persons who experienced no side effects or adverse reactions,” the report said, “they may nevertheless be significant enough to warrant more scrupulous attention by the FDA to better determine whether there is, in fact, a cause and effect relationship.”

Testifying for the FDA, Commissioner Frank E. Young, M.D., Ph.D., conceded that under provisions of the Federal Food, Drug, and Cosmetic Act, his agency has authority over food, drug, and medical device products that are specifically promoted for weight loss. Reading his 15-page statement, Dr. Young said, “FDA has attempted, over time, to modify its strategy to make the most effective use of resources for dealing with those products which represent a health fraud. Until the 1960’s, the most common tool used was criminal prosecution. A number of cases were successfully tried, and these achieved some deterrent effect. But because this is a more time-consuming and resource-intensive approach to the problem, the agency has expanded its enforcement program to include other judicial and administrative measures such as seizures, injunctions, and regulatory letters.”

With all seriousness, the nation’s highest-ranking health regulator declared, “I believe that public education is probably the most effective and cost-efficient way of combating health fraud, especially economic fraud. This is because the surest way to reduce health fraud is to reduce consumer demands for fraudulent products. In the weight loss product area, FDA has begun a public awareness campaign that includes a slide show, exhibit, and videotape focusing on diet books, low-calorie diets, body wraps, starch blockers, and other weight loss products and urges consumers to consult their physicians prior to beginning diets and to be aware of the general principles which apply to reduction diets.”

Regarding VLC diet products, Dr. Young said, “Some manufacturers and distributors are promoting herbal mixtures for a variety of weight control programs. The diet plans may replace one or more meals

a day with low-calorie product mixtures including herbs, vitamins and minerals, lecithin, senna leaves, kelp, chickweed, and dandelion, but no significant data have been provided to demonstrate that such ingredients do anything to control weight gain or ensure weight loss . . ."

"In addition to not being the magic answer to weight loss, herbs can be unsafe. No one would knowingly consume poisonous herbs, of course. And no responsible herb company would even consider putting such herbs in its products. But the fact is that poisonous herbs have been found in diet aids in low levels, and FDA has taken action against products in such cases. And although we know about the toxicity of some herbs, we do not know enough about many to conclude that they are safe as currently promoted in some weight reduction plans."

In response to a question, Dr. Young acknowledged that the FDA regards dietary products as drugs if any therapeutic claim is made for them. But he added that if the agency attempted to regulate them on the basis of more general claims, Congress might reduce its authority as it did in 1976 with the Proxmire Amendment (which ended FDA jurisdiction over the dosage and composition of ordinary food supplements).

That answer was not acceptable to Senator Warren B. Rudman (R-NH), who asked: "If a company encourages witnesses to make claims that the company can't make, and these claims are made on TV time paid for by the company, and the FDA has such evidence, how long is it going to take you to act?" (Rudman was obviously aware that the FDA has had sufficient evidence for more than two years to initiate criminal prosecution of Herbalife for making illegal therapeutic claims.) Dr. Young hedged, saying he didn't want to compromise his agency's investigation of the company. On advice of his accompanying legal counsel, he declined to go further—and the Senators did not press him to do so. But when Rudman asked whether the FDA had a timetable for deciding whether the evidence warranted enforcement action, FDA General Counsel Tom Scarlett replied, "It is going to be in the relatively near future. Another year."

Testifying for Cambridge Plan International of Pacific Grove, California, was its president, Vaughn Feather. He said he welcomed the subcommittee's investigation because it gave him the opportunity to explain how his company had made major changes in its products and programs since 1982, when sales and (adverse) publicity concerning the Cambridge Diet were at their peak.

Feather said his company had begun in 1980 with a single product composed of nonfat dry milk and soy flour enriched with 100% of the USRDAs of vitamins and minerals plus trace elements and electrolytes to create a nutritionally dense formulation providing 330 calories per day. "It was originally marketed as an exclusive source of nutrition for periods up to four weeks,"

he explained. Next was to be "a week of recommended low-calorie meals, followed if necessary by further use of the diet as a sole source of nutrition."

Feather also said that when Cambridge was only two years old, it was doing a little over \$390 million in Cambridge Plan dietary products. Then its sales fell just as steeply in late 1982 and early 1983, and in September 1983 the company filed for reorganization under Chapter 11 of the Federal Bankruptcy Act. Its 1985 sales are expected to be about \$15 million.

When asked to explain the downturn in the company's fortunes, Feather replied, "We ran out of money. We had thought matching up a good product with a network of peer support, copied after Mary Kay cosmetics, was a good idea. But pyramiding didn't work with us. Rather than selling the diet, we had people circling the United States signing up new counselors. They were selling opportunities to make a lot of money."

Late in 1982 Feather met with the director of FDA's Bureau of Foods, who suggested improved quality assurance, a dialogue with critics of the plan, and research in this country—all of which the company did, Feather said. The original 330-calorie/day program was abandoned in favor of three new plans which provide 800 or more calories per day and which advise medical consultation prior to use. Feather also said that proceedings of a 1983 scientific symposium on VLC diets will soon be published in book form. Though sponsored by Cambridge, the meeting was organized by three prominent nutritionists: Drs. George Blackburn and Fredrick Stare of Harvard University, and Dr. George Bray of the University of Southern California. (Curiously, Dr. Blackburn was one of the experts against Cambridge in the court case described in the editor's note accompanying this article.)

When called by Senator Roth, Mark Reynolds Hughes, 29, Herbalife's founder and president, bounced forward with a retinue of corporate officials and consultants. Accompanying them to the witness table was Representative William E. Dannemeyer (R-CA), whose district contains a manufacturer of Herbalife products which employs 200 people.

"Consumers should be allowed a maximum of freedom of choice to make decisions for themselves," the Congressman said. "Those that make false claims or otherwise violate the law must answer at the bar of

justice. We must not, however, indict a health program generally, or particularly weight control products, merely because they are 'unconventional' or 'nontraditional' by the standards of the established medical profession."

"Before coming to Congress, I was involved in matters of this nature," Dannemeyer said, referring to his former role as legal counsel for the Alta-Dena Certified Dairy, the nation's largest marketer of certified raw milk. Last October, Dannemeyer testified on behalf of Alta-Dena against federal regulation of raw milk at an FDA hearing [see NF 2:1-4].

After introduction by Dannemeyer, Hughes said that practically everybody in his family has had a weight problem and that he became interested in doing something about this after his mother got "hooked" on a prescription weight control product. Thus inspired, he founded Herbalife International in February 1980 when he was 23 years old and built it to gross sales of almost \$500 million last year.

Hughes himself, elegant and trim, "welcomed the opportunity to be a part of this Subcommittee's effort to inform the American consumer about the worthless products which are threatening the reputations of the responsible companies." After further remarks, he presented a company consultant, David Brandeis Katzin, M.D., Ph.D., a private practitioner from Los Angeles, who said that during the past five years he had personally treated well over 1,000 individuals, many with weight-related problems. Herbalife's program is nothing more than sound basic nutrition, Dr. Katzin asserted.

Diets that contain less than 500 calories per day and consist exclusively of formula drinks "can be potentially extremely dangerous and must, under all circumstances, be supervised medically. Even then serious side effects may occur; however, medical supervision reduces the risk of prolonged or permanent complications," Katzin said. "Herbalife does not have 500 calories, it has 1,000 or more . . . In addition, the balance of protein, carbohydrates and fat is entirely different. Very low calorie diets are deficient in potassium, whereas the Herbalife nutritional program contains adequate potassium according to RDA recommendations. In addition, the Herbalife nutritional program contains a balance of vitamins and minerals which meet or minimally exceed the RDAs for these nutrients."

Katzin declared: "Literally billions of portions of the product have been served to more than a million

individuals with only minimal transient side effects. I know of no other nutritional program which has been used as widely as the Herbalife program or as safely."

Katzin presented a series of charts and graphs. One, he said, was based on evaluation at the University of California, San Diego, of seven Herbalife consumers who had used the products for one to four years and showed "no deficiencies of serum potassium, magnesium, calcium, iron, zinc and copper." From this he concluded that the Herbalife nutritional program is safe." (Under questioning he listed as exceptions: "individuals on dialysis, with intestinal bypass, and others under a doctor's care.")

"How about for a pregnant woman?" Roth asked.

"If told to reduce by a physician, then it would be safe for her," replied Dr. Katzin. However, he added, he wouldn't recommend that a pregnant woman lose weight. Hughes later agreed with a suggestion by Senator Roth that such products be labeled to warn pregnant women that they should consult a physician before taking them.

Other charts Katzin presented were based on a retrospective study of 428 users, including one chart of "transient side effects" which indicated that of 428 Herbalife users, 18.6% had experienced headache, 12.5% had constipation, 11.3% had diarrhea, 9.7% had nausea, 9.6% reported lightheadedness, 2.6% had heart palpitations and 10.1% had other symptoms. Altogether, about 40% of those surveyed had some symptoms that might be attributed to taking Herbalife products, Katzin said. (The above numbers add to more than 40% because individuals can have more than one symptom.) Hughes, basing his estimate on feedback from distributors had said earlier that roughly 10-15% of users have such side effects, which usually last only a week.

Senator Rudman was relentless in questioning both Herbalife witnesses. To Dr. Katzin:

"You were hired about three months ago?"

"Yes."

"That was about the time Mr. Hughes learned that Herbalife would be invited to testify," said the Senator. After more exchanges in which Katzin was evasive, he insisted on a yes-or-no answer to the question: "Weren't you hired to come to this hearing?"

"Yes," replied Dr. Katzin.

Senator Rudman asked Hughes why Richard Marconi, the manufacturer of Herbalife products, was not present for the hearings.

"Doctor Marconi is in China," said Hughes. (Marconi claims to have a Ph.D. in nutrition from Donsbach University, which is a correspondence school located in Huntington Beach, California.)

"... This doctorate this man allegedly has is from a totally unaccredited university... he, in fact is really not a Ph.D. in nutrition. Do you know that?" Rudman asked.

"I don't know about that..." Hughes came back. "Dr. Marconi is one of the most brilliant guys I know."

"Isn't it true that you have no college degree?" Rudman then asked Hughes. "You completed the ninth grade in school, but consider yourself an authority on nutrition?"

"I know that this plan works," responded Hughes. Later he called himself "an authority on helping people lose weight."

Rudman focused much of his questioning on an early edition of Herbalife's *Official Career Book*, a training manual for distributors, and read statements of claims for cures of cancer, arthritis, and other diseases. Hughes replied that the copyright laws required picking up significant amounts of material where Herbalife products are endorsed—"in order not to take statements out of context." Therefore, said Hughes, the *Career Book*

had reproduced many pages from magazines, in which the authors may make unrelated claims.

"Because some quack somewhere said something might cure cancer, you thought it all right to publish?" Rudman exploded.

"No, I am not saying that," insisted Hughes.

"That's one of the most incredible bits of snake oil I've ever heard!" the Senator declared.

Rudman's final line of questioning had to do with Herbalife's cable television broadcasts. "People come up on your cable program and give testimonials about being cured of cancer, don't they?" he asked.

Hughes admitted that that had happened, but insisted. "After two live shows, when we found out that happened, we went to the tapes and edited out any health claims."

"The representatives, might they not make health representations?" Rudman pressed him.

"No, we have three categories for representatives being suspended, and 358 representatives have been terminated for misadvertising, failure to make refunds, etc. I terminated one representative who was making \$30,000 a month."

"Do you believe it's safe to use your products without consulting a doctor?" Roth asked.

EDITOR'S NOTES

- Dr. Young's claim that the FDA "expanded" its enforcement program during the 1960s is preposterous. A tabulation by FDA Historian Wallace Janssen shows that between April 15, 1960 and September 30, 1963, the agency successfully concluded about 150 civil and 12 criminal cases involving misbranded food supplements. During the next 20 years, only one such criminal prosecution was filed (and settled by a guilty plea). Moreover, the FDA has no data to demonstrate that criminal prosecution is more "resource intensive" than civil actions. Dr. Young's idea that education is "most effective" against health frauds is simplistic. Although education can protect many people, enforcement actions will always be needed to protect individuals who look for "miraculous" solutions to their health problems.

- The Cambridge Diet actually began marketing as a mail-order product with advertised claims that it could produce weight loss of up to 15 pounds in 1 week and 48 pounds in 6 weeks, and that it would reduce body fat as rapidly as fasting or complete starvation. After the Postal Service complained that these claims were false, a U.S. District Court Judge temporarily halted sales through the mail and commented that the diet appeared to be deadly. The company then signed a consent agreement to discontinue the claims and to label the product with a statement that it should not be used as a sole

source of nutrition for more than four weeks. The switch to person-to-person sales began soon afterward.

- The questionable credentials of Richard Marconi were exposed prior to the hearings in a 4-part investigative report on Herbalife that was aired nationally by Cable News Network. CNN revealed that although Hughes claimed that Herbalife products had been formulated with the help of Marconi and his "research staff," no research on effectiveness had actually been done before the products were marketed. And Herbalife's supposed "research laboratory" turned out to be a conference room that housed a large table and books on herbs, located at one of Marconi's factories. Marconi told a CNN interviewer, "We employed hundreds... even thousands of Ph.D's in the research program for our products." But when asked who they were, he replied, "Why, the research papers that are published and printed that we have access to on our computer..."

The CNN report also demonstrated that Herbalife's *Official Career Book* once claimed that ingredients in Herbalife products were effective against arthritis, bronchitis, emphysema, gangrene, snake bites, ulcers, venereal disease and a wide range of other serious health problems. Vigorous FDA enforcement action at that time might well have stunted Herbalife's growth.—Stephen Barrett, M.D.

"Sure," replied Hughes. "Everybody needs good, sound basic nutrition. We all know that."

Senator William S. Cohen (R-ME) asked Hughes about the use in Herbal-aloe of comfrey and chaparral, which witnesses on the previous day had testified have cancer-causing properties. Hughes said that neither he nor the FDA was concerned because quantities in the formula were well below the unsafe level. Although Commissioner Young had indicated a few hours earlier that the agency was still considering action against the company for unfounded medical claims made on behalf of its products, Hughes also said Herbalife was cooperating with the FDA.

Regarding side effects, Senator Roth asked, "Shouldn't there be warnings . . . on the labels?"

Warnings are made "basically by word of mouth" through the distributors, Hughes replied.

"But isn't the public entitled to know about these?" Senator Roth pressed him.

"Yes," conceded Hughes. "This company is open and willing to consider labeling."

Senator Rudman closed the questioning of Hughes: "Last night there was a rally of 3,000 to 4,000 Herbalife representatives at the Hyatt Regency/Capitol Hill Hotel. Towards the end, Larry Thompson, executive director of sales for Herbalife International, solicited tes-

timonials and obtained them from three people. One said she was told by a doctor that her child was dying, put the child on the product, and the child didn't die. Another was supposedly cured of diabetes. And the third supposedly was on crutches for some time, took Herbalife, and no longer had to use them. If you were running a first-rate company, do you think you should allow such testimonials?"

Before Hughes could respond, Rudman added a final question: "Don't you think you ought to clean up your act?"

"I think we should," Hughes agreed, "and we're trying to do that right now."

The hearing was adjourned at 3:00 p.m., too late for a 1:30 press conference Herbalife's public relations firm had planned for Hughes at the Hyatt Regency.

Mr. Fanning, formerly a science writer for *The Atlanta Journal* and director of information for the Centers for Disease Control, is editor and publisher of *Consumer New\$weekly*. A complete transcript of the hearing may be requested by sending a self-addressed mailing label to Weight Reduction Hearings, c/o Mr. Howard L. Shapiro, Staff Counsel, Permanent Subcommittee on Investigations, U.S. Senate, Washington, DC 20510.

BOOK REVIEW

Title: *Cancer & Nutrition*

Author: Charles B. Simone, M.D.

Publisher: McGraw Hill Book Company, New York

Price: \$15.95

Reviewed by: Stephen Barrett, M.D.

The author is described on the jacket as a former researcher at the National Cancer Institute and belongs to the radiation therapy department at the University of Pennsylvania Hospital. The foreword is by Robert A. Good, Ph.D., M.D., former president and director of Memorial Sloan-Kettering Cancer Hospital. Seeing credentials like these you might think this book is well reasoned. But even superficial inspection reveals otherwise.

Simone's grasp of vitamin facts appears grossly deficient. He states, for example, that "the RDAs represent the minimum nutrient levels needed to prevent obvious signs of vitamin deficiencies" and suggests (based on claims by Linus Pauling) that the levels of vitamins required to maintain good health vary by as much as 2000% from one person to another. He cites a published claim that daily doses of 100,000 IU of vitamin

A have been given to adults for many months without serious side effects. And he claims erroneously that no case of vitamin E toxicity has ever been recorded. Presumably ideas like these induced Rodale Press to pick this book for its Prevention Book Club.

Simone's advice is summarized in a "ten-point plan for risk factor modification." Some of the advice is standard and appropriate (e.g., don't smoke or chew tobacco, moderate alcohol intake, be alert to cancer's early warning signs, use sunscreens). But his lists of dietary don'ts—which include salad dressings, pickle relish, whole eggs, cooked, canned, or frozen fruit with added sugar, all jams, jellies, and bleached white flour—strike me as irrational.

Most curious is his claim that "Risk Modifier," a vitamin/mineral supplement he formulated for General Nutrition Corporation (GNC), should be taken by everyone. This product was one of 14 GNC products accused by the Postal Service of being falsely advertised. In February 1985, the company signed a consent agreement promising to discontinue unproven claims that any food supplement consisting of vitamins and minerals will decrease the risk of cancer [see NF 2:47].

THE DENTIST AND NUTRITION QUACKERY

John E. Dodes, D.D.S.

In the good old days, the only nutritional counseling a dentist provided was advice to avoid sugary snacks between meals. Today "holistic" dentists are promoting a wide variety of ideas that have no scientific foundation. Recent topics in *The Mittelman Letter*, a popular holistic newsletter published by Jerome S. Mittelman, D.D.S., of New York City, illustrate the nature of these ideas:

"How a D.D.S. uses Vitamin C powder for hemostasis and why it's better in restorative dentistry."

"Food intolerance can lead to bleeding gums"

"A food supplement to help eliminate mercury from your body . . . a must for the intelligent dentist"

"Using semantics in nutritional counseling"

"Stress, ulcers and Vitamin A"

"About research that shows cholesterol may help body's defense cells to fight cancer"

Nexus is another popular dental newsletter that often promotes holistic concepts. Its October 1983 issue tells how hair analysis can help to predict personalities prone to extreme violence.

Emanuel Cheraskin, M.D., D.D.S., and William Ringsdorf, D.D.S., have also been active in attempting to convert dentists to questionable nutrition. Their books, *New Hope for Incurable Diseases* and *Psychodietetics*, make many scientifically unsupported claims that nutritional methods have exceptional value in the treatment and prevention of diseases—particularly incurable ones. They claim, for example, that a diet low in sugar and processed carbohydrates will demonstrably tighten loose teeth in less than 10 days. Drs. Cheraskin and Ringsdorf lecture widely and are quoted in "holistic" journals. They have made serious inroads into dentistry because until recently both taught at the University of Alabama's dental school. Their books, although scientifically discredited, are cited to support the dubious claims of others.

"Applied kinesiology," founded in 1964 by George Goodhart, D.C., is a system of diagnosis and treatment based on the theory that every organ dysfunction is accompanied by a specific weak muscle. Kinesiologists also claim that nutritional deficiencies, allergies and other adverse reactions to food substances, can be detected by placing substances in the mouth so that the patient salivates. "Good" substances will make specific muscles stronger, whereas "bad" substances will cause specific weaknesses. Treatment of muscles diagnosed as "weak" may include special diets, food supplements, acupressure, and/or spinal manipulation. "Dental kinesiology" is concerned with connecting supposed muscle weakness with problems of the head and neck, particularly the temporomandibular joint (TMJ).

Harold Gelb, D.D.S., former director of the Temporomandibular Joint Clinic of the New York Eye and Ear Infirmary and currently a professor at the College of Medicine and Dentistry of New Jersey, believes that failure of the teeth to fit together properly can have far-reaching effects on the rest of the body. He believes that the TMJ can cause weakness and disease far from the joint itself and vice versa. Dr. Gelb uses applied kinesiology to diagnose and treat TMJ problems.

Kinesiological concepts do not conform to accepted scientific beliefs about the cause of disease; and critics cite studies showing that apparent results are due to patient suggestibility and the fact that 80-90% of patients with facial pain not due to tooth or gum infection will recover spontaneously. However, despite its absurdity, many insurance companies pay for "TMJ therapy" based on applied kinesiology.

Actual tests of several kinesiological techniques on college students were reported in the March 21, 1981 *Journal of Prosthetic Dentistry*. Each student, seated behind a screen with one arm exposed, was instructed to hold an arm parallel to the floor and resist the examiner's downward force. In the first test, muscle strength was measured before and after decreasing the overlap of front teeth. In the second, muscle strengthening and weakening techniques were performed on a shoulder muscle using kinesiologic techniques. In the third study, subjects were tested after ingesting a small amount of candy and retested after ingesting 400 IU of vitamin E. In the final test, students were told that the candy would give them instant energy and that they would probably test stronger. In the first two tests, techniques which kinesiologists claim will increase or decrease muscle strength produced no overall change. In the second two tests, while ingestion of sugar caused a majority of students to test weaker, simple suggestion reversed this trend.

Two others who support a "holistic" approach to dental problems are Lendon Smith, M.D. and Carlton Fredericks, Ph.D. Smith acknowledges that fluoridation is helpful while Fredericks feels that it leads to increased use of sugar and can cause dangerous vomiting. In his *New and Complete Nutrition Handbook*, Fredericks proposes instead an "anti-tooth-decay diet," high in fiber, low in sugar and carbohydrates and supplemented with vitamins and minerals. Fredericks uses Dr. Cheraskin as one of his authorities. Recently, Fredericks has been advising his radio listeners that their silver fillings may be the cause of many diseases. According to a report from the Food and Drug Administration, Fredericks has no formal training in nutrition and obtained his doctoral degree in the field of communications. Dr.

Smith, a pediatrician, was placed on probation from 1973 to 1981 by the Oregon State Board of Medical Examiners for prescribing medication that was "not necessary or medically indicated" for six adult patients.

Another prominent promoter of questionable nutrition is Hal E. Huggins, D.D.S., of Colorado Springs, Colorado, a leading exponent of "balancing body chemistry." He appears to believe that most diseases are caused by "imbalances" that can be cured by dietary practices. Special diets and food supplements are recommended in order to become "balanced." Various laboratory tests, especially hair analysis [see NF 1:12], are used to determine the supposed biochemical health of the patient. Dr. William Jarvis calls this approach a form of "simpleton science."

Dr. Huggins is also deeply involved in the "silver-amalgam toxicity" issue. "Silver" fillings are made from a silver/tin/copper/zinc alloy mixed with mercury. Huggins and his followers claim that silver amalgam fillings can cause multiple sclerosis, Parkinson's disease, arthritis, headaches, etc., and many other chronic conditions. Dentists who espouse this idea are advising their patients to have all of their silver fillings replaced with either gold or plastic ones and are prescribing vitamins, "chelating agents," and sometimes vitamin-enriched "purifying diets."

Since mercury was introduced over 150 years ago, its possible dangers have been considered, debated, and thoroughly investigated. Many studies have shown that amalgam fillings are safe. This conclusion is now being questioned, not within the refereed journals and respected research facilities of the dental profession, but in the media and in "holistic dentistry" courses. For example, on April 6, 1984, *The CBS Evening News* in New York aired a poorly investigated and highly distorted story which included an interview with a dentist who has a "degree" in nutrition from Donsbach University, an unaccredited correspondence school. Early this year, the Colorado State Board of Medical Examiners began investigating Dr. Huggins to determine whether his involvement in diagnosing and treating "mercury toxicity" constitutes practicing medicine without a license.

Perhaps the most alarming thing about the practices described in this article is that they are being presented at dental meetings and occasionally even at dental schools and in dental journals. For example, the July 1983 *Dental Clinics of North America*, which dealt with temporomandibular joint dysfunction, contained a chapter in which chiropractor Goodheart advocates

chelated iron and raw veal bone tablets as appropriate treatment.

In another chapter, osteopath Viola Frymann claims that skull bones can move and that the "integrated activity of central nervous system, cerebrospinal fluid, dural membranes, cranial bones, and sacrum made up the primary respiratory mechanism, the physiologic function in the body, the primary expression of life itself." Although these ideas contradict established anatomical and physiological facts, Dr. Frymann teaches them to postgraduate students at Georgetown University's school of dentistry.

At Boston University's Henry M. Goldman School of Graduate Dentistry, a course on the diagnosis and prevention of amalgam intoxication was given on March 10, 1984 and again on November 3, 1984. This course is taught by Victor Penzer, D.M.D., who also teaches courses titled "Acupuncture for the Dentist" and "Adventures in Dental Hygiene" for hygienists. In this course hygienists are instructed in acupressure and reflexology, systems of treatment which claim that pressure on the hand or foot can cure diseases throughout the body. This course description states that "the benefits of comprehensive oral health include: for hygienists—enlarged therapeutic scope, enhanced status; for dentists—escalated utilization of personnel, increased income."

Dr. Penzer belongs to the International Academy of Preventive Medicine. Other "holistic" dental associations are the American Society for Preventive Dentistry, the American Academy for Functional Prosthodontics, the American Academy of Physiologic Dentistry, and the Holistic Dental Association International. These organizations and their spokespeople seem unable to correctly assess the scientific validity of a study, and promote unproven theories as though they are facts. Dr. Penzer has written that "holistic dentists not only use orthodox knowledge but also look for new horizons towards optimal health." So do true dental scientists, but they don't market methods based solely on personal philosophy and anecdotal reports. The "holistic dentists" appear to have become so "open-minded" that their brains have fallen out.

Shaklee Corporation, according to its brochure, is "the number one nutrition company in America," with annual sales of food supplements in the hundred of millions. June Stone of the Markstone Shaklee Center in N.Y.C. told me that my dental assistant, although untrained in nutrition, could increase my income up to \$50,000 per year with part-time counseling. Shaklee then sent me a pamphlet entitled "Why Food Supplements" by Bruce Miller, D.D.S., who advises the use of only "natural" vitamins.

Dental education does not include courses on skeptical thinking or the scientific method. Like the general public, dentists are inundated with pseudo-scientific articles, and massive advertising campaigns. Special vitamins to "support the body's natural mecha-

COMING SOON

The American Association of
Nutritional Consultants—
Who and What Do They Represent?

nism for the elimination of mercury" are promoted and sold to dentists, and many dentists and their families take megadoses of vitamins.

The increase in quack dental practice may also be related to the fact that during the past 15 years, water fluoridation has caused a major reduction in tooth decay while dental schools have increased their enrollment. Together these mean less work per dentist. Economics has always been a factor in the acceptance of pseudoscience, and even many years of graduate and postgraduate education do not appear to prevent irrational behavior.

The problem has become so serious and pervasive that the lead article in the July 1984 *Journal of the American Dental Association* was "Diet, Nutrition, and Oral Health: a rational approach for the dental practice." Written by a panel of qualified health, dental and nutrition experts, it begins with this statement:

"Hair analysis, megavitamin therapy, cariogenicity of foods [and] nutrition counseling—all are issues relating to diet and nutrition that dentists are increasingly being called upon to address in their prac-

tices. Dentists' ability to separate fact from fiction in nutrition and diet is essential in a time when consumer magazines are filled with articles touting the therapeutic effect of vitamins or outlining the latest health fads. Patients naturally turn to their dentists for sound, scientific, and rational advice on questions of nutrition, diet, and oral health."

Concerned dentists are requesting that dental schools, dental meetings and dental journals become more stringent in upholding scientific standards. *Courses in skeptical thinking are needed at every dental school.* Dental insurance companies and malpractice carriers should become better informed about the problems created by quack dentistry. Most important, the American Dental Association should warn the public about unscientific practices and try to discipline dentists who use them.

Dr. Dodes practices general dentistry in Woodhaven, New York, and lectures on quackery vs. quality in dentistry.

BRIEFS

Anti-mercury dentist under investigation. The Colorado State Board of Medical Examiners has been investigating Hal A. Huggins, D.D.S., to determine whether he has been practicing medicine without a license. According to a report in the *Denver Post*, Huggins began restricting his dental practice two years ago to working with patients he believes may be suffering from toxic effects of mercury-based fillings—which he believes can cause such illnesses as arthritis, multiple sclerosis, epilepsy and severe depression. His \$1,200 fee (recently raised to \$1,500) covers a lengthy consultation and laboratory analyses of hair, blood and urine. He then recommends dietary changes, use of vitamin and mineral supplements, and removal of mercury fillings.

Contempt ruling in cancer case. On April 24th, M.T. Products, of Tulsa, Oklahoma, was fined \$50,000, and its owner Mildred Trumbull, was placed on three years' probation for violating a 1980 consent decree prohibiting interstate shipment of Lilverum, an Easter lily extract that has been claimed to "surround and neutralize cancer within 30 minutes after use." Although an Oklahoma law allows its sale within the state, shipment across state lines still violates the federal Food, Drug and Cosmetic Act. According to the prosecuting attorney, the highest penalty levied previously in an FDA-sponsored contempt case was \$1,000. Further violation can lead to imprisonment.

AMA action against drunk drivers. Modifying a 25-year-old policy, the American Medical Association House of Delegates recently voted to ask states to establish a blood alcohol concentration (BAC) of 0.05% (40 mg alcohol per 100 ml blood) as conclusive evidence of drunk driving. The vote occurred in response to a report from the AMA Council on Scientific Affairs that deterioration of driving skills begins at that level and progresses rapidly as the level rises. The report also noted that drivers with BAC's between 0.05 and 0.10 are significantly represented in road crash statistics and that 55% to 65% of drivers fatally injured in single vehicle accidents have BAC's of at least 0.10, the level previously recommended as conclusive evidence of intoxication.

Update on Weider case. Joseph Weider and Weider Health and Fitness have agreed to pay a minimum of \$400,000 to settle FTC charges that they misrepresented two mineral supplements, Anabolic Mega-Pak and Dynamic Life Essence [see NF 1:13]. Weider and the company agreed not to falsely claim that these products can help build muscles or are effective substitutes for anabolic steroids. They also agreed to make refunds to anyone who purchased these products. If the amount refunded is less than \$400,000, the difference will be donated to fund research on the relationship of nutrition to muscle development.

BE WARY OF THE PEOPLE'S MEDICAL SOCIETY

Stephen Barrett, M.D.

The People's Medical Society (PMS) is engaged in a wide variety of projects that may affect medical practice and consumer protection against nutritional quackery. Some of its aims are laudable, but make no mistake about it: the organization is rooted in deep antagonism to the medical profession and to medical science itself.

PMS is the brainchild of Robert Rodale, board chairman of Rodale Press (reported gross income \$140 million/year), which publishes *Prevention* magazine, *Organic Gardening and Farming*, and many books that recommend unscientific nutrition practices. During 1982, Robert ran a series of editorials in *Prevention*, criticizing the medical establishment and promising "a grassroots campaign that will turn America's medical system on its head."

Prevention, published monthly, contains easy-to-read articles on health topics. Many present practical tips, but the editors preach that everyone should supplement with extra nutrients. Articles that concern nutrition are usually slanted to suggest that supplementation is useful in the prevention or treatment of disease, and each issue contains letters from readers telling how nutritional remedies have supposedly helped them. Vitamins and other "food supplements" are heavily advertised, and ads for unproven remedies and for unaccredited courses that can lead to questionable nutrition credentials appear regularly in the classified section.

Although water fluoridation is an extremely valuable and real way to use dietary supplementation to prevent disease, Rodale Press has never recommended it. Before founder J.I. Rodale's death in 1971, almost every issue of *Prevention* contained a vicious attack on fluoridation. Rodale Press has also engaged in unfair criticisms of pesticides and other agricultural chemicals.

In 1980, an article by Walt Harrington, top investigative reporter for the *Allentown Call-Chronicle*, revealed that *Prevention's* executive editor, Mark Bricklin,

knew that fluoride prevents tooth decay. When asked why the magazine has never admitted this to its readers, Bricklin replied, "It would only confuse them." Harrington also surveyed four medical school professors who had been quoted in *Prevention* articles. All four indicated that although they had been quoted accurately, the articles were slanted to promote unnecessary supplements.

In 1984 the American Council on Science and Health evaluated nutrition articles in 30 popular magazines to determine whether they were scientifically sound and factual. *Prevention* came in 28th, with an accuracy rate of 31%—less than half that of the *National Enquirer*. Not long afterward, *Prevention* began asking prominent nutritionists and medical groups to help prepare some of its articles. But its overall thrust remains misleading. Rodale Press also operates the *Prevention* Book Club, many of whose selections promote unscientific and unproven nutrition practices.

The People's Medical Society, located in a separate building near the editorial offices of Rodale Press in Emmaus, Pennsylvania, was officially launched on January 1, 1983. It has been supported through dues payments (now \$15 per year) plus a large initial loan and continuous publicity from Rodale Press. Robert Rodale heads the group's board of directors, which also includes Mark Bricklin and seven other persons presumably handpicked by Rodale. In October 1985, the group reported a membership of 85,000.

It is clear that PMS is very antagonistic to doctors. Most articles in its newsletters imply that doctors cannot be trusted, and cartoons in every issue ridicule medical care as expensive, unnecessary, dangerous or impersonal. Executive Director Charles B. Inlander has informed members that "PMS is determined to put an end to the medical and health-care abuses that have caused millions of Americans to suffer." Inlander reported that during a PMS publicity tour in Florida last year, "we gave out the telephone number of the licens-

ing board. They had more complaints filed during the next two weeks than in the history of the entire department." A doctor who attended the meetings held during the tour told me that PMS representatives made unfounded criticisms of medical care, both local and nationwide.

In June 1984, PMS announced that it had asked all members of Congress their positions on 1) freezing all doctor fees for one year, 2) requiring all doctors to accept Medicare assignment, 3) including all doctor fees in the DRG program, and 4) federal limitation of the number of doctors licensed. PMS members were subsequently asked to promote legislation to force Medicare to round down payments to doctors to the next lower dollar, which supposedly will save Medicare \$45 million per year (out of doctors' pockets).

PMS members have been given forms to report their experiences with doctors so that this information can be computerized and published. In addition, members are being encouraged to form local "Health Action Groups" to carry out projects designed by PMS leaders.

PMS members have also been asked to have their doctors sign a 10-point Code of Practice which would make them eligible for a directory of those who sign. It is not clear, however, how well this project is proceeding. By August 1984, the last time a list was published in the *PMS Newsletter*, there had been only 199 signers nationwide, including 52 chiropractors and 7 naturopaths.

In 1983, during a talk in Allentown, Inlander indicated interest in: 1) gathering data so consumers can compare hospitals on the basis of cesarean section rates, staph infections and medical disciplinary actions; 2) lobbying for state laws to require all doctors to accept Medicare assignment; and 3) filing lawsuits to help alternate practitioners gain more freedom to practice. "You and I," Inlander told the audience, "should control the system."

The group's national office (which Inlander claims is independent from Rodale Press) is orchestrating a "Campaign for Medical Honesty" which, among other things, is generating complaints to Congress, state legislators, hospital administrators and other officials about the difficulties PMS members have encountered with the health care system. The "People's Medical Hour" radio program is being syndicated nationwide. And PMS plans "massive public information campaigns" and lobbying in states whose legislatures are considering proposals to solve the malpractice insurance crisis (in which premiums for some doctors are so high that they cannot afford them or must stop doing "high-risk" procedures).

PMS has also been involved in promoting unscientific nutrition practices. One issue of its newsletter referred readers to the Hearing and Tinnitus Help Association (HTHA), whose executive director, Paul Yanick, Jr., claims to have helped thousands to overcome tinnitus and other forms of hearing and balance disorders through nutrition methods. Contributors to HTHA are

eligible for a discount on the \$200 price of "The Comprehensive Nutrient and Lifestyle Program," which Yanick helped design. According to a flyer distributed by HTHA, this is a computerized analysis that recommends nutrition supplements after analyzing information on dietary and exercise habits, "tissue mineral analysis," tests on pH, urine, stool and saliva, and "over 400 questions relating to changes that take place in your body when a nutrient becomes deficient."

The 48-page PMS report on high blood pressure contains sound advice but also suggests that practitioners of chiropractic, acupressure, homeopathy, herbal therapy and megavitamin therapy may have something to offer: "While many of these practitioners can't produce the years of studies and double-blind experimental results that the medical professionals can, they nonetheless provide treatment—often less invasive, less costly and with fewer side effects than traditional medicine's—that has its adherents and success stories."

Another PMS booklet encourages members to start a People's Medical Library in their community. However, along with such authoritative references as the *AMA Family Medical Guide*, *Cecil's Textbook of Medicine*, *JAMA* and *The New England Journal of Medicine*, the kit recommends *Prevention*, Rodale encyclopedias on natural healing and natural home remedies, and a few other highly questionable publications.

A third PMS booklet, *Deregulating Doctoring*, suggests that medical licensing laws be substantially limited in scope or even repealed. Written by Attorney Lori B. Andrews, vice-chairman of PMS' board of directors, the report suggests that all persons should be free to engage in "such nonhazardous, relatively innocuous activities like advising, giving tips on prevention, making recommendations and offering simple treatments." It recommends that "as a minimum, the definition of the practice of medicine should be restricted so that only inherently dangerous health care activities require a medical license."

PMS also publishes bibliographies on various health topics. Like the People's Medical Library lists, however, these lists include unscientific publications as well as reputable ones. For example, the bibliography on arthritis includes a book which claims that food allergy is a major cause of arthritis; the cancer bibliography includes one boosting macrobiotics [see NF 1:14];

Copyright © 1985 by the GEORGE F. STICKLEY COMPANY
 Nutrition Forum ISSN 0748-8165 is published monthly by the George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106. Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES \$30/yr., \$57/2 yrs., \$81/3 yrs., prepaid VISA and Mastercard acceptable. Foreign postage by airmail add \$10.00. Manuscripts, books for review, and other editorial correspondence should be sent to Dr. Stephen Barrett, P.O. Box 1747, Allentown, PA 18105. Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

and the diet and nutrition bibliography includes questionable books—and refers readers to the Academy of Orthomolecular Psychiatry, a Canadian group that promotes megavitamin therapy for mental problems.

PMS has engaged in political activities which, in my opinion, are antagonistic to consumer protection. One was to support legislation to provide funds for research into organic farming [see NF 1:6]. Another was a petition drive against the bills introduced last year by Representative Claude Pepper to increase government efforts against quackery. (One would increase criminal penalties for certain health frauds, another would establish a government strike force against quackery, and the third would create a government clearinghouse for information on unproven methods.)

Early this year Inlander sent members a letter claiming that these bills were “just the first of what may be a long line of legislation to take away our ability to choose the health care we want.” The letter also urged members to return an enclosed petition with a special donation and assured members that PMS would be “doing everything we can to defeat these bills—and to fight for real protections against medical fraud.” Subsequently he announced that “thousands and thousands of PMS members sent letter . . . By early March, we were

receiving calls from members of Congress telling us they would not support this legislation if it were re-introduced. We are told that the volume of mail we generated was enormous. While members of Congress knew that many nontraditional practitioners were opposed to these bills, they had no idea of the enormous opposition of the public. Just three weeks after we asked for your help, Pepper's office told us the bills would not be introduced.”

Properly directed, organizations of medical consumers can accomplish a great deal by educating their members and working constructively to reduce health care costs and increase consumer protection. But in my opinion, the People's Medical Society is doing neither, and will do more harm than good in the long run.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is editor of *Nutrition Forum* Newsletter and co-author/editor of more than 20 books including *Vitamins and “Health” Foods: The Great American Hustle*. In 1984, he received an FDA Commissioner's Special Citation Award for Public Service in combatting nutrition quackery.

Briefs

Health food industry rift? Raw milk enthusiast William Campbell Douglass, M.D. [see NF 2:2], has written a blistering attack on *Prevention* magazine. In the National Health Federation's *Health Freedom News*, he accuses *Prevention* of selling out to the establishment and betraying everything its founder (J.I. Rodale) stood for by accepting ads for nonprescription arthritis medications. Campbell, a member of NHF's board of governors, is also upset that columns by Carlton Fredericks and Jonathan Wright, M.D., no longer appear in the magazine. Unmentioned is the fact the *Prevention* was very critical of raw milk in its March 1985 issue [p. 45].

Total food costs. According to a Food Institute report, Americans spent \$270 billion at food stores and \$124 billion at commercial eating and drinking places last year. The percentage of after-tax income spent for food at home has been dropping slowly and reached a new low of 10.8% in 1984. Comparable figures were 16% in 1960, 13.2% in 1970 and about 12% in 1980. The portion of after-tax income spent for food away from home in 1984 was 4.3%, a figure that has held fairly steady in recent years.

New Sweetener on horizon. Chemists at the Triangle Research Institute have developed a new artificial sweetener, DL-amino-malonyl-isopropyl ester. The new compound—called RTI-001—contains neither phenylalanine nor methanol and is said to have longer shelf life than aspartame. An Institute spokesman said it will probably take five years to complete the necessary safety tests and get FDA approval for marketing.

Final report on salmonella epidemic. The 21-member task force formed to examine possible causes of the salmonella outbreak in Midwestern states last Spring is unable to pinpoint what caused it. At first it was thought that the cause was a faulty pipeline [NF 2:46] at the Hillfarm Dairy in suburban Chicago. However, despite a massive 5-month study, the panel is unable to rule out other possibilities. The outbreak is the largest ever recorded in the United States. *American Medical News* has reported that 16,000 to 18,000 people became ill, thousands of lawsuits were filed by victims and their families, and 6,000 of the suits have already been settled out of court. The dairy—reportedly the largest in the Midwest—shut down voluntarily on April 9th.

More B₆ toxicity reported. Two doctors have reported on 16 patients who developed neurological damage associated with use of high doses of pyridoxine (vitamin B₆). Eight were examined by the doctors and eight were interviewed by telephone after a local television report publicized the problem. All 16 experienced "pins and needles" and numbness of the hands. 13 had difficulty walking, and many experienced various other symptoms. The pyridoxine dosage ranged from 200 mg to 5 grams daily, with most of the victims starting on lower doses and increasing gradually. Symptoms appeared from one month to three years after starting pyridoxine, but always appeared less than one year after reaching the 2 gram/day level. One patient claimed to have been taking only 200 mg daily, but did so for three years. All of the 13 patients who could be reached for questioning 3 to 18 months after stopping the vitamin had improved, but none had recovered completely. Reprints of the report, which appeared in the October 1985 *Neurology* [35:1466-1468], can be obtained from Dr. Gareth J. Parry, UCSF Department of Neurology, M-794, San Francisco, CA 94143.

New report on premenstrual syndrome. The American Council on Science and Health advises women seeking treatment for premenstrual syndrome (PMS) to be skeptical of clinics or practitioners who: 1) claim 100% success rates; 2) claim to be able to diagnose the condition with tests on blood, urine or hair; 3) offer a "secret formula"; 4) charge inordinately high prices; 5) fail to warn about possible risks or side effects of a particular therapy; or 6) fail to inform that treatment with progesterone, other steroid hormones, bromocriptine, spironolactone, pyridoxine (vitamin B₆), vitamin E, evening primrose oil, or magnesium are still experimental and that some of these approaches have not been proven safe. A free copy of the report can be obtained by sending a self-addressed 4"x9½" envelope with 39¢ postage to PMS Report, ACSH, 47 Maple St., Summit, NJ 07901.

Plans brewing to boost herb claims. According to *Natural Foods Merchandiser*, members of the American Herbal Products Association (AHPA) have donated \$20,000 to launch a campaign to "upgrade the regulatory status of herbs at the federal level." A newly formed AHPA committee hopes to: 1) develop a panel of industry experts and FDA scientists to review and revise federal regulations dealing with herbs; 2) have herbs evaluated for possible inclusion in over-the-counter drug products; and 3) eventually establish regulations to permit truthful claims that herbs can prevent disease—a proposal one committee member likened to Kellogg's desire to make preventative claims for its bran products [see NF 2:69].

Free USDA handbook. *Agriculture Policy: A Citizen's Guide to the American Food and Fiber System*, is available free of charge from Christina Mosher Wilson, Office of Public Liaison, Room 102A, U.S. Dept. of Agriculture, Washington, DC 20250. Designed to help consumers understand agricultural policy, the handbook contains a glossary of agricultural and food policy terms and explains farm price and income support programs, domestic food and nutrition programs, soil conservation, the global food system, international trade, and other issues.

Cytotoxic setback. The Health Care Financing Administration (HCFA) of the Department of Health and Human Services, which administers Medicare, has decided that cytotoxic testing will not be a covered service. HCFA proposed this policy in 1983 because the test "lacks an acceptable rationale" and does not correlate with clinical evidence of food allergy [see NF 1:17-19].

More diet and cancer studies. *Medical Tribune* [Sept. 26] reports that the National Cancer Institute is funding 26 clinical trials to assess possible preventive effects of dietary manipulation, retinoids, beta-carotene, vitamins C and E, and trace minerals against various cancers. Included are two studies to see whether diets low in fat (under 20% of calories) can prevent or retard breast cancer and five studies to see whether vitamin supplementation can reduce the incidence of lung cancer in high-risk populations.

Sulfite regulations proposed. On August 9th, the FDA proposed to ban all use of sulfites on raw fruits and vegetables in supermarkets and in restaurants, where the preservatives have been used to keep salad bars looking fresh. In announcing the ban, HHS Secretary Margaret Heckler said that FDA review of the hazards had included consideration of reports of "about 500 alleged adverse reactions including 13 deaths." FDA regulations already require that the presence of sulfites must be noted on the labels of certain finished packaged foods, including lemon juice, dried fruits and vegetables, some canned soups, and some packaged fresh mushrooms. The agency had previously proposed to require sulfite labels on other foods where sulfites were used during processing and are detectable in the final product. This would apply, for example, when sulfites are used as dough conditioners in making cookies. The Bureau of Alcohol, Tobacco and Firearms has proposed that wine and beer containing sulfites also be so labeled. (See NF 2:49-51 for background information.)

Health fraud conferences. A national conference on health fraud, sponsored jointly by the FDA, FTC and Postal Service, was held on September 11th at the National Press Club in Washington, DC. Twenty-one speakers (four of whom were *Nutrition Forum* editors) addressed the audience of more than 350 persons, including journalists, local, state and federal government officials, and representatives of about 100 consumer groups. The FDA plans to host regional health fraud conferences in 18 large cities during the coming year. The national conference will probably become an annual event.

Ad standards. The *Louisville Times and Courier-Journal* and the *St. Petersburg Times* have active programs to protect their readers from misleading advertising. At the National Health Fraud Conference, officials from both papers distributed copies of their published standards and described how they are enforced. Ads with "miraculous" claims are immediately rejected, and other questionable types of health claims may be judged with the help of outside medical consultants. Both papers also try to prevent distribution of misleading ads through inserts. When *Parade Magazine* included a fraudulent 2-page ad for a CCK "fat cure" in its December 24, 1984 issue, the *St. Petersburg Times* published a front-page notice that the ad did not meet the paper's ad standards and contained unsubstantiated claims. The Times Publishing Company also informed *Parade* that it would refuse to distribute future issues that did not comply fully with the paper's advertising standards. Times' advertising manager Andrew Kohut, Jr. said that he had observed no misleading ads in *Parade* since that time.

Alcohol advertising. PROJECT SMART (Stop Marketing Alcohol on Radio and Television), a coalition led by the Center for Science in the Public Interest (CSPI), wants Congress to mandate equal time for health and safety messages to balance the views of drinking created through more than \$900 million spent each year on alcohol advertising. The Fairness in Alcohol Advertising Act (H.R. 2526), introduced by Rep. John Sieberling (D-Ohio), would require broadcasters to match alcoholic commercials with an equivalent amount of information about the consequences of alcohol use. Testifying for the bill before the House Energy and Commerce Subcommittee on Telecommunications, CSPI Director Michael Jacobson presented a 950,000-signature petition and called for elimination of ads that connect drinking with sports or other activities that require a high degree of alertness.

New antiquackery programs. According to a recent FDA press release: 1) the FDA has contracted with Louis Harris and Associates to undertake a comprehensive poll on health fraud; 2) the U.S. Council of Better Business and the FDA will distribute a new consumer publication about weight loss frauds; 3) the Association of Food and Drug Officials (an organization of state officials) is proposing state surveillance and action teams to deter the distribution of health fraud products; 4) the National Association of Consumer Agency Administrators plans to develop a demonstration project for the exchange of health fraud resources; 5) the United States Pharmacopeia plans to examine unproven remedies for cancer in a program similar to their system for developing information about recognized medications; 6) anti-quackery ads developed through joint efforts of the FDA and the Pharmaceutical Advertising Council will soon be distributed to the media; and 7) the FDA is developing a speakers bureau to make experts on health frauds available for meetings, workshops and talk shows.

Aspartame suit loses another round. A 3-member panel of the U.S. Court of Appeals has ruled that the FDA was not obligated to hold public hearings on complaints that aspartame causes health problems. The Community Nutrition Institute, the Arizona Dietetic Association and others had asked the appeals court to order such hearings and to ban use of the sweetener until further tests were performed. Aspartame now has FDA approval as a sweetener in diet soft drinks and chewing gum and for tabletop use. Senator Howard Metzenbaum (D-OH), who filed a friend-of-the-court brief supporting CNI's suit, has introduced legislation for a moratorium on expansion of aspartame's use. (See NF 1:2-4, 2:16 and 2:63 for background information.)

Future GNC gimmick? According to the July 8th Business Week, General Nutrition's new chief executive Jerry D. Horn wants to portray GNC as "the voice of authority" on health and nutrition. Toward this end, the company is testing a computer terminal for answering questions about nutrition in stores.

More supermarkets carry "natural" foods. *Natural Foods Merchandiser* reports that over 3,000 supermarkets now have "natural foods" sections. Among the ten largest chains, the number has doubled from 1,200 two years ago to 2,400 today. K-mart reportedly expects to have large "vitamin-oriented units" in about 1,200 of its stores by the end of 1985. Safeway has 950 units now with total annual sales of \$150 million and expects to reach 1,000 units by the end of the year.

BOOK REVIEW

Title: Hypoglycemia, Fact or Fad? (1985)

Author: Lynn J. Bennion, M.D.

Publisher: Crown Publishers, Inc., One Park Avenue, New York, NY 10016

Price: \$12.95

Reviewed by: Harvey L. Katzeff, M.D., and Barbara S. Katzeff, M.D.

Almost everyone knows people who believe they have symptoms indicative of hypoglycemia (low blood sugar), and virtually every practicing dietitian, nutritionist and physician encounters many of them—often with frustrating results. At last, help has arrived! *Hypoglycemia: Fact or Fad?* is by far the clearest and most reliable discussion of this subject ever published. The author, an endocrinologist with a special interest in diabetes and metabolism, reveals why most people who think they have this condition are mistaken. He tells when to suspect its presence and how this possibility should be properly investigated. And he explains why the commonly used glucose tolerance test is not usually reliable for diagnosing hypoglycemia.

Hypoglycemia: Fact or Fad? is a model of organization, making it a delight to read. Each chapter ends with a summary of salient points and an introduction to the following chapter. Medical terms are explained simply in the text and also in a glossary. Concepts are developed from easily understood basics so that a scientific background is not needed to understand the material presented. Yet there is enough detail for the book to be of great value to health professionals.

Dr. Bennion does not burden the reader by listing every symptom that can be seen with low blood sugar. Instead, he stresses that its symptoms are nonspecific and can be produced by many other conditions. The diagnosis of hypoglycemia cannot be made on symptoms alone but by proving that the blood sugar is abnormally low while symptoms are occurring. Moreover, symptoms caused by hypoglycemia should disappear rapidly when the blood sugar is raised.

It is likely that laypersons reading this book will be seeking to learn whether they themselves have hypoglycemia. For these individuals, the chapter on "How to Find Out Whether You Have Hypoglycemia" should provide the answer. Indeed, someone in a hurry might find the answer just by reading the excellent summary at the chapter's end.

Just as a major problem with self-diagnosis of hypoglycemia by laypersons is related to its nonspecific symptoms, misdiagnosis by medical professionals is due to misinterpretation of the oral glucose tolerance test (OGTT). This test involves the administration of a large dose of glucose followed by measurements of blood glucose at intervals over the next 3 to 5 hours. In the chapter, "Beware the Glucose Tolerance Test," Dr. Bennion characterizes the test as a "six-hour bleeding session at a clinical laboratory where white-clad leeches sweeten the experience with an initial bottle of glucose syrup." He makes a strong scientific argument that the OGTT is at best useless and at worst misleading for evaluating most cases of suspected hypoglycemia.

Dr. Bennion has three main criticisms of the test: 1) injection of 50-100 grams of almost pure concentrated sugar is an abnormal situation and is unrelated to the circumstances of most patients' symptoms; 2) during the unnatural stress of the OGTT, up to 25% of normal individuals will develop low blood sugar; and 3) the OGTT is not reproducible, meaning that results may vary widely when the test is done repeatedly.

In addition to information on hypoglycemia, the book contains some excellent advice on consumer health strategy:

1. Reliable research is likely to be published first in carefully edited, scientific or medical journals where it can be duplicated and corrected rather than in such publications as the *National Enquirer*.

2. Intelligent treatment requires intelligent diagnosis.

3. Many people with symptoms are relieved when given a socially acceptable diagnosis which appears to be easily and painlessly treatable. But before you take the treatment, make sure you have the disease.

4. Avail yourself of the advantages of modern medicine.

5. When a doctor asks about your symptoms, it is more important to describe what you have been experiencing than it is to explain your theories of what is causing your symptoms.

6. Take steps to promote your general health.

Since most people who read this book will not actually have hypoglycemia, it would have been helpful if more attention had been given to common factors which may cause symptoms similar to those of hypoglycemia, particularly the ingestion of too much caffeine. Regarding the rare causes of hypoglycemia, there may be more information than necessary. However, these criticisms are minor and do not detract from the book's overall high quality.

Dr. Harvey Katzeff is an assistant professor of medicine at New York Hospital/Cornell University Medical College. His wife, Barbara, is an instructor in geriatrics at Mount Sinai School of Medicine in New York City.

CLASS ACTION SUIT AGAINST HERBALIFE

Seven Florida residents filed suit on behalf of themselves and "all others similarly situated" against Herbalife International, Mark Hughes (Herbalife's chief executive officer), and Lawrence Thompson (company vice president). Allegations in the suit include:

- "As a direct consequence of using the Herbalife products as advertised and directed," all seven plaintiffs "experienced . . . great mental and physical pain and injuries, including emotional trauma, depression, anxiety, rashes and skin irritation, headaches, nausea and diarrhea."

- Several of the plaintiffs experienced painful swelling of the breasts, severe vomiting, painful menstrual periods and rectal bleeding.

- One plaintiff had two cardiac arrests and was left with permanent cardiovascular damage.

- Herbalife failed to properly and adequately test and/or evaluate its products and should have stopped marketing certain ones when adverse effects were first reported.

- The company made false claims about the efficacy of its products and failed to properly instruct consumers and sales representatives in their use.

- Herbalife failed to warn of possible adverse effects of its products and "deliberately taught" distributors to deceive potential customers by falsely claiming that the products were safe.

- The company didn't put anything in writing as to the safety or effectiveness of its products because "if we put it in writing we might be violating federal law. We can't put it in writing because the government would come back to us and say 'prove it.' When you are doing something live, you can say anything you want under freedom of speech."

- The company instructed distributors: "No matter what you are asked about the products, do not answer directly. Just say, 'I don't know about that. The only thing I can tell you is that it worked for me (or some other testimonial) and that it will work for you too. If it doesn't, I will give you your money back.'"

The suit, filed on July 15th by attorney Ellis Rubin of Miami, Florida, asks for a total of \$4.5 million in compensatory damages and \$9 million in punitive damages.

INJUNCTION AGAINST RAW MILK CLAIMS

On September 23, a California Superior Court judge issued a preliminary injunction ordering Alta-Dena Certified Dairy to stop advertising its raw milk as safe and suitable for infants and invalids without also warning consumers that raw milk may contain dangerous bacteria that can cause disease and even death to babies, young children, pregnant women, the elderly, and other vulnerable groups. The injunction also directed the dairy to stop circulating an ad recommending that infants be fed a mixture of raw milk and honey.

The lawsuit, filed August 27 by Consumers Union, the California Gray Panthers, and the American Public Health Association, charged Alta-Dena with false and deceptive advertising of its raw milk products. The disputed ads claim that the dairy's raw milk is the "safest, purest, most wholesome milk money can buy" and

is "the ideal formula-milk for babies" as well as "a basic food for invalids." The suit charged that, in fact, Alta-Dena's raw milk products "frequently contain harmful bacteria, including *Salmonella dublin*, a virulent form of bacteria that can cause serious illness and even death to the very young, the very old, and the infirm."

The judge's order will remain until the court issues a final decision after trial, which is expected to take place in about six months. An editorial in the *Oakland Tribune* called the order "well advised" and urged the California legislature to make health warnings mandatory for all raw milk products. Other press reports indicate that publicity in the case may have caused a sharp drop in sales and that the dairy intends to appeal the preliminary injunction to a higher court.

CARNIVORA

Varro E. Tyler, Ph.D.

The desire of seriously ill people for hope rather than facts leads every few years to intensive promotion and temporary widespread popularity of a new quack remedy for cancer. In the 1950s, Dr. Andrew Ivy advocated Krebiozen with such enthusiasm that it became almost a household word. Laetrile, developed by Dr. Ernst T. Krebs, Sr., in the 1920s and nearly forgotten, blazed like a brush fire through the 1970s. Today, Carnivora, a remedy promoted by a German country doctor named Helmut Keller, is taking Western Europe by storm, and inquiries concerning it have become increasingly frequent in the United States.

Carnivora is a 30% (60-proof) alcoholic extract of an insectivorous plant, *Dionaea muscipula* Ellis, commonly known as Venus's-flytrap. Probably because of its relative scarcity, the plant had not previously been used as a therapeutic agent or herbal remedy. However, just a few years ago, Dr. Keller began using an extract to treat cancer patients and obtained some seemingly favorable results. Recently, the widely read German newspaper *Bild-Zeitung*—describable in American terms as a daily *National Enquirer*—featured Dr. Keller and his Carnivora results in an article headlined "New Anticancer Drug Frees 34 Patients from Tumors." The article implied the drug was also the secret plant juice that supposedly cured American film and stage star Yul Brynner of lung cancer during some visits to Germany. (Brynner, who at one time smoked five packs of cigarettes per day, died last month.) All of these factors have combined to stimulate a demand for Carnivora treatment that is unparalleled in recent years.

Germany's most notable cancer specialists have been unable to stop or even diminish this tidal wave of interest. Professor Rolf Sauer of the University Clinic in Erlangen noted that the drug "is not recommended at this time." Professor Dietrich Schmähl of the German Cancer Research Center called it a "phantom drug." The most critical comments were those of Professor Gerhard Nagel, representing the German Cancer Society, who characterized claims for the product as a "lie."

Due in part to the scarcity of Venus's-flytrap plants, treatment with Carnivora is expensive. One liter

of the extract costs more than 3000 DM (approximately \$1,200), and six weeks of treatment costs more than 15,000 DM (\$6,000). One critic in Berlin has characterized the extract as "the most expensive herb-flavored liqueur in Germany."

Dr. Keller's initial studies with Carnivora involved 195 cancer patients over a five-year period. Of these, 34 experienced a remission, 14 had complete disappearance of tumors, 84 patients found their tumors had stopped growing, and 63 patients died. The study was labeled by Professor Gerd Schönhöfer of the Bremen Central Hospital as "simply a description of the fate of the cancer patients." Because the patients were also treated with radiation, chemotherapy and/or surgery in addition to Carnivora, it is impossible to make any scientific judgment regarding the effectiveness of Carnivora alone from this report.

The fact that no satisfactory evidence exists has not prevented so many patients flocking to Nordhalben, the small town in Germany where Dr. Keller has his practice, that it has been necessary to erect a sign at the city limits directing them to his clinic. And according to the German weekly news magazine *Der Spiegel*, the mayor of Nordhalben is dreaming of erecting a magnificent cancer clinic that would turn the previously godforsaken town into a German Lourdes.

It seems just a question of time before news of Carnivora reaches herbal medicine producers in the United States. When that happens, we can only hope that the proper authorities will not only act to protect cancer patients from being victimized but will also try to prevent extinction of the very limited native stand of Venus's-flytrap in the coastal bogs of North and South Carolina. It would be a shame to sacrifice this intriguing but delicate plant on the altar of medical quackery.

Dr. Tyler, Dean of Purdue University's Schools of Pharmacy, Nursing, and Health Sciences, is an expert in pharmacognosy (the science of medicines from natural sources) and author of *The Honest Herbal*, an evaluation of popular herbs.

SUITS AIMED AT ANTIQUACKERY LAWS

Grace Monaco, J.D.
Rebecca Burke, J.D.

Despite an adverse ruling by the U.S. Supreme Court six years ago, 82-year-old federal judge Luther Bohanon is still permitting individuals to evade federal drug laws by importing "personal supplies" of laetrile provided they obtain a physician's affidavit that they have had cancer and understand that the FDA disapproves the drug's use. Bohanon's policy was a response to a class action suit brought against the FDA by Glenn Rutherford, a Kansas seed salesman who claims that laetrile cured him of cancer and is keeping him alive. In March 1984, Bohanon finally acceded to an order from the federal appeals court for the 10th circuit to dissolve the injunction supporting the affidavit system. But in May 1984, he restored the injunction after Rutherford's attorney filed an amended complaint based on a claim that laetrile can reduce pain.

In July 1984, a group called the Committee for Freedom of Choice in Medicine requested permission to intervene in the Rutherford suit on behalf of "physicians who practice medicine, using the systems of Eclectic, Homeopathic or Holistic Schools of medicine rather than the system of 'orthodox' Allopathic School of Medicine." The action also sought to block interference with manufacturers, sellers and distributors of supplies to unorthodox physicians, to cancer patients, and to others suffering from "chronic degenerative disease."

The intervening group (formerly called the Committee for Freedom of Choice in Cancer Therapy) was led by Robert Bradford, who in 1977 was convicted and fined \$40,000 for conspiring to smuggle laetrile into the United States. Bradford is president and administrator of American Biologics Hospital in Tijuana, Mexico, which offers a broad spectrum of unorthodox treatments, including laetrile. He also directs the Bradford Research Institute, which, according to its literature, "is able to 'rescue' for therapeutic use overlooked, abandoned or thwarted metabolic/nutritional disease management approaches discovered in the United States but not allowed to be developed because of an interlock of stifling political, economic and bureaucratic interests."

The Bradford Institute, the administrative office of American Biologics, and one office of the Committee

for Freedom of Choice in Medicine, are all located at 111 Ellis Street, Suite 300, San Francisco, CA 94102. American Biologics sells a wide variety of vitamin products, enzymes, "glandulars" and specialty products (including laetrile and DMSO) to professionals and health food stores, while Choice Metabolics (same address) offers many of the same products by mail to the public.

Another intervener in the Rutherford case was Bruce W. Halstead, M.D., a California physician, one of five persons charged by state authorities with conspiracy and grand theft for marketing an herbal tea called ADS as a cancer treatment [see NF 1:5]. (He was found guilty in October 1985 and is awaiting sentencing.) Other individuals involved in the action included John Richardson, M.D., Michael Gerber, M.D., and several other physicians whose licenses had been revoked by their state medical boards. (Richardson and Gerber are now practicing as "homeopaths" in Nevada, which in 1983 passed a homeopathic licensing act and set up a separate board to license homeopaths.) The interveners' concept of "chronic degenerative disease" was quite broad, and their action appeared to be intended to virtually end enforcement of FDA laws against use of unproven remedies such as DMSO, chelation therapy, megavitamin therapy, and other "nutrition" therapies.

The defendants in the suit were Health and Human Services Secretary Margaret M. Heckler, FDA Commissioner Frank E. Young, M.D., Ph.D., and their agents. Listed as "co-conspirators" were the American Medical Association, state and county medical societies, several state boards of medical licensure, the American Cancer Society, the American Heart Association, the Cystic Fibrosis Foundation, the Multiple Sclerosis Foundation, the National Council Against Health Fraud (which the interveners call "an AMA front organization"), the U.S. Postal Service, the Internal Revenue Service, the U.S. Veterans Administration, Dr. Victor Herbert and others claimed to be conspiring to restrict the practices of the interveners. The suit sought a court order restraining all "anticompetitive activities" of these parties, including law enforcement activities, license revocations, and public criticism of unorthodox practices.

Surprisingly, Bradford's efforts to expand the

Rutherford case to include therapies other than laetrile was opposed by Glenn Rutherford's attorneys as well as the National Health Federation, a health food industry group that characteristically supports legal actions to protect unproven methods. (Rutherford's chief attorney and several of the intervenors are past or present NHF board members.) The suit was withdrawn in September 1984 and has not been refiled as an independent action.

Mrs. Monaco, a partner of White, Fine and Verville, of Washington, D.C., specializes in health law as it applies to unproven methods of medical management. She is also a founder and current board chairman of the Candlelighters Childhood Cancer Foundation, an international peer support group for parents of children with cancer. Ms. Burke is an associate of White, Fine and Verville.

BRIEFS

Safety tips for roasting turkeys. The American Council on Science and Health recommends the following precautions to minimize the occurrence of food poisoning: 1) Frozen turkeys should be prevented from getting too warm while thawing. Thawing overnight in a refrigerator is a good technique. 2) Stuffing a turkey the night before cooking gives bacteria from the raw meat an opportunity to grow in the stuffing. It is safest to stuff immediately before roasting. Stuffing can be prepared a day in advance and stored in the refrigerator. 3) Stuffing should reach a temperature of at least 165°F during roasting. Heat penetrates most easily if stuffing is not packed tightly. 4) It is not safe to partially cook a turkey on one day and complete the cooking the next day.

Fast-food report. The American Council on Science and Health believes that individuals can incorporate "fast foods" into a prudent and balanced diet by varying their selections, choosing menus that contribute to nutrient needs, and choosing meals of appropriate calorie content. The third (1985) edition of its report, *Fast Food and the American Diet*, summarizes the nutrient content of more than 100 popular items, gives tips on selection, and provides the addresses of major chains for those who wish to obtain more information about ingredients. A free copy can be obtained by sending a self-addressed 4"x9½" envelope stamped with 39¢ postage to Fast Food Report, ACSH, 47 Maple St., Summit, NJ 07901.

Soviets to attack health problems. According to *Medical Tribune*, Soviet leaders have launched a campaign against obesity, smoking and excessive drinking. During the past 20 years, life expectancy in the Soviet Union has fallen from 66 to 62, cardiovascular mortality has doubled, and the alcoholism rate has been high.

Important new book. *The Smoke-free Workplace*, by William Weis, Ph.D., and Bruce Miller [Prometheus Books, 1985] provides a step-by-step guide to employers and employees interested in improving their work environment. It also gives tips for dealing with drifting smoke in restaurants and other public places. Copies are available for \$10 each plus \$1 postage per order from the Lehigh Valley Committee Against Health Fraud, Inc., P.O. Box 1747, Allentown, PA 18105.

Antiquackery publications. William Jarvis, Ph.D., president of the National Council on Health Fraud, has written two 32-page booklets useful to health educators and laypersons. *Food: Facts & Fallacies, A-Z* contains capsule analyses of more than 100 food myths and "health food" products. *Quackery & You* summarizes facts and myths about common forms of quackery. Both are available for \$1 per booklet plus \$1 postage per order from LVCAHF Inc., P.O. Box 1747, Allentown, PA 18105.

Fluoridation pamphlet. Free single copies of the American Academy of Pediatrics' new 10-page pamphlet, *Fluoride and Dental Health*, are available on request from Dental Disease Prevention Activity, Center for Prevention Services, Centers for Disease Control, Atlanta, GA 30333.

Nutrition Forum ISSN 0748-8165 is published monthly by the George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106. Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES: \$30/yr., \$57/2 yrs., \$81/3 yrs., prepaid. VISA and Mastercard acceptable. foreign postage by airmail add \$10.00. Manuscripts, books for review, and other editorial correspondence should be sent to Dr. Stephen Barrett, P.O. Box 1747, Allentown, PA 18105. Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

Fluoridation may prevent osteoporosis. A Finnish study has found that elderly individuals sustain fewer hip fractures (an indicator of bone fragility) in Kuopio, which has been fluoridated since 1959, than in Jyväskylä, which has only traces of fluoride in its water [*Lancet* Aug. 24, 1985]. The lower incidence in Kuopio suggests that fluoride is an essential mineral for strengthening bone tissue and that the incidence of fractures due to osteoporosis can be reduced by community water fluoridation at 1 mg/liter. Exposure to this level varied from 7 to 17 years in the population studied, apparently long enough for a beneficial effect. Previous epidemiological studies have found no beneficial effect on bone fragility of fluoridation at similar levels, but the Finnish study appears to be better designed.

Supplement promotion. According to a recent ad in *Health Foods Retailing*: "Informative books mean more profit to you. When you sell Larchmont Books you are informing your customers about the products you sell. Studies show that for every \$1 in health food book sales there is an estimated \$200-\$500 return on vitamin and supplement sales. It's no coincidence . . . information sells products!" Larchmont's line, composed of paperbacks retailing for \$1.25 to \$3.95, includes *Megavitamin Therapy, Improving Your Health with Vitamin E, All You Should Know about Health Foods* and *The Compleat Herbal*.

Pennsylvania outlaws cytotoxic testing. Reacting to false advertising claims that cytotoxic testing can reveal an allergic basis for a long list of medical problems, the Pennsylvania Department of Health's Bureau of Laboratories ordered such testing ended within the state by July 23, 1985. The action was taken after the Health Department determined that "the cytotoxic test is not an accepted procedure since it is an unproven diagnostic test lacking an acceptable scientific rationale, specificity, sensitivity and evidence of clinical effectiveness." The Department also concluded: "Cytotoxic testing poses a dangerous threat to the health and safety of individuals, especially those with serious health problems who may postpone seeking proper medical attention based upon the unsubstantiated claims made for cytotoxic testing."

Mountain climbers to attack hunger. A 15-person group led by three physicians plans to ascend 19,340 feet to the summit of Mt. Kilimanjaro, Africa's highest mountain, to symbolize their belief that resources exist to end world hunger—said to kill 25,000 children daily. Money raised—expected to exceed \$100,000—will be given to The Hunger Project and Save the Children.

Gift food precautions. Americans now spend about \$1 billion a year for mail-order foods, with 75% of sales taking place between Thanksgiving and Christmas. Food marketers say yuppies are the prime purchasers of gift foods from some 400 catalogues now available. According to an article in USDA's *Food News for Consumers* [2(4):6-9], mail-order foods enjoy an excellent safety record. However, a product should be rejected if any of the following occur: 1) bad odor; 2) food marked "keep refrigerated" doesn't arrive cold; 3) food supposed to be frozen on arrival is not; or 4) food shipped at room temperature arrives in a broken container. Because of the risk of botulism, Agriculture Department experts suggest that suspected food should never be tasted. Instead, refrigerate it immediately—preferably in the original container—and contact appropriate government officials who may wish to inspect it to see whether a product recall is necessary. Meat or poultry problems should be reported through USDA's hotline (1-800-535-4555, or 447-3333 in the Washington, D.C. area). Problems with other foods should be reported to the nearest FDA office, whose number will be found in the telephone directory under U.S. Government, Dept. of Health and Human Services.

Vitamin E and lumpy breasts. Two double-blind studies have found no significant benefit from administering vitamin E to women with mammary dysplasia (commonly called benign fibrocystic disease of the breast). In one study, Robert S. London, M.D., and colleagues at Sinai Hospital of Baltimore treated 128 patients for two months with either a placebo or 150, 300 or 600 IU of vitamin E. Although slightly more than half the patients improved during the trial period, those receiving vitamin E did no better than those receiving the placebo [*Obstetrics & Gynecology* 65:104-106, 1985]. In the other study by Virginia Ernster, Ph.D., and colleagues at the University of California in San Francisco, 62 women took either 600 IU of vitamin E or a placebo for 2½ months [*Surgery* 97:490-494, 1985]. These studies contradict earlier ones that had promising results but were smaller and not done double-blind. Hoffmann-La Roche provided financial support for both studies.

NUTRITION FORUM

VOL. 3 NUMBER 1

JANUARY 1986

ISSN 0748-8165

WHAT HAPPENED TO THE 1985 RDA'S

Stephen Barrett, M.D.

On October 7, 1985, claiming that too many changes had been proposed, Frank Press, Ph.D., president of the National Academy of Sciences (NAS), cancelled publication of the 10th Edition of the Recommended Dietary Allowances (RDAs). The action followed controversy between the Academy's Committee on Dietary Allowances, which had drafted the report, some members of the NAS Food and Nutrition Board, and outside reviewers.

Speaking a few days later at the American Dietetic Association's annual meeting in New Orleans, Henry R. Kamin, Ph.D., chairman of the RDA Committee, indicated that many important refinements in the RDA tables had been proposed. "This is a sad day," he concluded. "There is no scientific justification for the rejection of our report, which was put together by a superb and distinguished committee which worked harder and more carefully than any of its predecessors."

The proposed report—one version of which had been leaked to the press—had called for lower levels for vitamins A, C and B₆, magnesium, iron and zinc, and higher amounts of calcium for women. The Committee had also wanted to redefine the RDAs from the amounts needed "to meet the known nutritional needs of practically all healthy persons" to the amounts needed "to protect practically all healthy persons from nutritional deficiencies."

According to Dr. Kamin, the dispute really centered on vitamins A and C. The Committee had proposed lowering the RDAs for vitamin A for men from 1,000 retinol equivalents to 800 and for women from 800 to 700. (A retinol equivalent equals 5 International Units.) For vitamin C, the values would have been lowered from 60 mg for men and women and 35 mg for infants to 40 mg for men, 30 mg for women, and 25 mg for infants. "Correspondence between me and Dr. Press makes clear that all other issues had . . . been resolved, and that publication would have proceeded had our Committee agreed to the older [1980] figures for A and C preferred by the Food and Nutrition Board," Kamin said

in his American Dietetic Association talk. He also indicated that "despite repeated requests for scientific justification for this preference, it was not forthcoming."

The work of the RDA Committee was funded under a contract between the National Academy of Sciences and the National Institute of Arthritis, Diabetes, and Digestive and Kidney Diseases, a branch of the National Institutes of Health (NIH). On October 29th, in a strongly-worded letter to NIH Director James B. Wyngaarden, M.D., Dr. Kamin referred to "the sad history of inept communication and of the inability of the Academy staff and structure to give sophisticated advice in nutrition to a president who is an eminent geophysicist but needs good in-house guidance in this area. It is, of course, the inescapable duty of the NIH to evaluate the competence of the present nutrition establishment within the NAS in the course of making funding decisions."

The RDA Committee's proposed values for vitamins A and C were based primarily on estimates of body reserves and turnover rates for these nutrients. For vitamin A, the proposed value was judged sufficient to maintain blood levels and provide a 3-month reserve. For vitamin C, a reserve pool was selected that would prevent scurvy despite more than a month of very low intake. According to the Committee, no signs of deficiency have ever been reported in individuals with such reserves, and higher reserves are not known to provide increased health benefits. Moreover, the 1980 RDAs for vitamin C were considerably above the average of other nations, and the proposed values for vitamin C for adult men are still higher than those of the World Health Organization/Food and Agricultural Organization (WHO/FAO), Australia, Canada, Finland, the United Kingdom and ten other national and regional groups—all of which recommend 30 mg.

Although an NAS committee on diet, nutrition and cancer had concluded in 1982 that diets rich in vitamins A and C were associated with reduced risk of certain cancers, it did not define "rich" or recommend

specific intake levels of these vitamins. In his ADA talk, Dr. Kamin noted that specific intakes cannot be recommended on the basis of current data, and that recommendations of this sort have nothing to do with the traditional purposes of the RDAs. He also said that claims by the Food Research and Action Center (FRAC) that lowering the RDAs would lead to cutbacks in federal food programs were "irrational and irresponsible." (FRAC is a consumer advocacy group located in Washington, D.C.) Betty B. Peterkin, acting administrator of the U.S. Department of Agriculture's Human Nutrition Information Service, supported Dr. Kamin's viewpoint in a letter to him which noted that past changes in the RDAs have not affected the dollar-related aspects of school lunch or food stamp programs.

In other correspondence, two other Committee members, James Allen Olson, Ph.D., and Robert E. Hodges, M.D., have shed additional light on what happened: "In the formal review of our document by the Academy, many valuable constructive suggestions were made. We are assiduous in incorporating them in our report, but when we didn't, we clearly indicated the reasons for not doing so. While the Academy disagreed with the outcome of our detailed analysis of vitamins A and C, i.e., the RDA values, they provided no criticism of the approach, the data employed, or the logic leading to the final conclusion. No data or scientific publications were cited to show that the selected adequate body pools were, in fact, inappropriate to the nutrient needs or inconsistent with good health. In the absence of such data, the Committee understandably was unwilling to inflate the values artificially . . . The new RDA values are not 'minimums,' as some special interest groups have claimed, are not more narrow in scope, but are defined more precisely and operationally than in the past."

Dr. Press, quoted in *The New York Times* [October 13], said that the RDA committee's focus on prevention of deficiency was neither sufficient nor appropriate because it ignores the role of nutrition in "optimal health" and in preventing cancer and heart disease. He apparently would like to see RDA reports encompass a broader analysis of diet and health. But Dr. Kamin replied that dietary recommendations of that type cannot be expressed in terms of specific nutrient needs and should be addressed by a separate but complementary study. He also expressed concern that the National Academy of Sciences may be "drifting toward pop nutrition."

In *Medical World News* [Nov. 11], Kamin called Press's proposal "incomprehensible to nutrition scientists" and said it might "actually thwart two valid approaches—dietary guidelines and RDAs. Both are equally valid, but if you try to make a hybrid of them, you get chaos." He accused NAS of yielding to pressure from people who think vitamins offer protection against cancer, as well as from those who fear food program cutbacks. In *Family Practice News*, he added that "Everybody wants the RDAs to support their agenda,

and everybody has a different agenda." Victor Herbert, M.D., another member of the RDA Committee, has summed up the controversy as "a clash between nutrition scientists and nutrition politicians," and has called for a congressional investigation.

Early in December, Dr. Wyngaarden notified Dr. Kamin that NIH hopes to form an interagency committee that includes developers and users of the RDAs to determine their future course. Kamin—still hopeful, but not optimistic—replied by asking him to serve as a catalyst for scientific conversations between members of the RDA Committee, the Food and Nutrition Board and other interested scientists. "Opportunities for such discussions have not yet been accorded us," Kamin wrote, "but we continue to hope they can be arranged. I cannot predict the results of such discussions, but I expect them to provide a satisfactory result. Should this expectation be fulfilled, publication could proceed forthwith."

If not, since the draft report belongs to the RDA Committee, it will undoubtedly be published privately.

FDA ACTION PLAN ANNOUNCED

The U.S. Food and Drug Administration has released a 10-point plan to help chart the agency's future regulatory course. The plan, based on meetings with representatives of health professions, consumers, and the drug industry, stresses public education and voluntary compliance by industry. Four parts of the plan are related to food or nutrition:

- The agency plans to strengthen its postmarketing surveillance capability by implementing a program to analyze adverse reaction reports associated with foods, food additives and food ingredients.
- Efforts will continue toward modernizing food safety laws, probably including reform of the "zero-cancer" clause of the Delaney Amendment.
- National nutrition concerns will continue to receive attention. These include: infant formulas, weight control products, food fortification, and food labeling that concerns the relationship between diet and good health.
- The FDA plans to bring about "expanded national awareness" of health frauds by coordinating its educational efforts with those of state, local and other federal agencies, national consumer groups, health professional groups, and industry organizations. Enforcement against health frauds will also be increased, with emphasis aimed at "high-visibility or widespread fraudulent products that are known to snare large numbers of unknowing consumers." [Editor's note: The educational plan is excellent and is already progressing well. With respect to enforcement, however, it would be far more effective to deter illegal schemes than to crack down after they are well established!]

ALUMINUM: FEARS, FACTS AND FANTASIES

Janet L. Greger, Ph.D.

When aluminum makes the news, it usually gets criticized. In recent years, such headlines have appeared as:

"Scientist worries overusing antacids could cause problems"

"Aluminum could be next to join list of hazards"

"Alzheimer's and aluminum: An element of suspicion"

"Dementia from aluminum pots?"

Messages like this are reinforced by certain promoters of stainless steel cookware and by unqualified practitioners who diagnose "aluminum toxicity" through the use of hair analysis.

While some concerns about aluminum are reasonable, others have no factual basis. The problems for consumers—and even some health care professionals—are how to distinguish between facts, unproven hypotheses and fantasies about aluminum, and how to determine a safe level of intake.

During the past 15 years, aluminum has been demonstrated to cause osteodystrophy (a bone disease) and "dialysis dementia," a type of degenerative brain disease that can occur in long-term kidney dialysis patients. High tissue levels of aluminum have also been found in Alzheimer's disease (a progressive brain disorder characterized by memory loss) and in two less common degenerative conditions (amyotrophic lateral sclerosis and parkinsonism-dementia) found among natives of Guam. Some scientists have hypothesized that aluminum may contribute to the development of these diseases. However, despite interest in aluminum metabolism, few investigators have studied the effects of dietary aluminum, and it is not known whether aluminum accumulation is a cause or a result of these problems.

The average adult in the U.S. consumes 20-40 mg of aluminum from foods and water daily, with a probable range from 3-100 mg. Food additives constitute the major dietary source of aluminum for most people. Foods that contain the most aluminum from additives are baked goods processed with chemical leavening agents and some processed cheeses. Approximately 4.0 million pounds of aluminum were used in food additives in the United States in 1982. Assuming that not all was consumed, the average adult intake was less than 20 mg per day. However, individuals vary greatly in their use of aluminum-containing food additives. In 1979 it was estimated that 5% of adult Americans consumed 95 mg of aluminum daily from food additives.¹

Most foodstuffs contain small amounts of aluminum, but a few vegetable products such as herbs and tea leaves contain larger concentrations (over 100 mg/kg).²

An average cup of tea contains 1-4 mg. Most Americans probably consume only 2-10 mg of aluminum from natural sources daily.

Many foods stored or cooked in aluminum pans, trays or foil absorb small amounts of aluminum.³⁻⁵ Most accumulate less than 0.2 mg/100g of food during preparation and storage, but tomato sauces cooked for several hours in aluminum pans can accumulate 3-6 mg aluminum in a 100-gram serving.

The amount of aluminum in the diet is small compared to the amount of aluminum in some antacids, buffered pain relievers, diarrhea remedies, and at least one anti-ulcer drug. It has been estimated that antacid users ingest 840 to 5,000 mg, while users of buffered pain-relievers take in 126 to 728 mg daily.⁶ The long-term consequences of ingesting drugs with high levels of aluminum are not known. One reason is that it is difficult to measure aluminum in biological samples such as body tissues. We do know that aluminum is absorbed very poorly by normal healthy adults, but infants may absorb aluminum somewhat more efficiently. Although humans excrete little aluminum in urine (i.e., 100 µg/day), this appears to be the body's major excretory route for it.⁷

Rats fed even moderate amounts of aluminum (0.3-1 mg per gram of food) will accumulate aluminum in some tissues, especially bone. (These levels of dietary aluminum would be comparable to an adult man consuming 180-600 mg aluminum daily.) However, a number of studies have found that the accumulation is not directly proportional to intake levels or duration of exposure.⁸⁻¹¹

Tissue accumulation of aluminum also occurs in several disease states. Some patients with kidney failure (uremia) undergoing dialysis, especially those who develop dementia and/or renal osteodystrophy, have accumulated aluminum in various tissues from dialysis fluids and aluminum-containing antacids used to reduce absorptions of phosphates.¹² Recently, two children with uremia appeared to have received excessive exposure to aluminum from formula.¹³

There is considerable controversy about the significance of elevated tissue levels of aluminum in the brains of patients with Alzheimer's disease.^{13,14} Brain aluminum levels are generally higher in elderly adults than in young adults, regardless of mental state. However, blood aluminum levels are not elevated in patients with Alzheimer's disease and thus cannot be used as a diagnostic tool.¹⁵

Aluminum toxicity is believed to be part of the etiology of amyotrophic lateral sclerosis/parkinsonism-dementia of Guam. It has been hypothesized that the excess accumulation of aluminum is facilitated by inadequate intakes of calcium and magnesium, but this has not been proven.¹⁶

The mechanisms by which aluminum exerts toxic effects are poorly understood. Aluminum can directly interact with nucleic acids and cell membranes and hence exert direct toxic effects. Aluminum can also affect the metabolism of several minerals.

There is no doubt that drug-level doses of aluminum can depress phosphorus and fluoride absorption and eventually lower blood phosphorus levels.^{3,17} That is why aluminum-containing phosphate binders are used to remove excess phosphorus from the blood of uremic patients. The effect of moderate doses of aluminum on phosphorus metabolism is not clear. Although adding 120 mg/day of aluminum to the diets of young men initially depressed their absorption of phosphorus, the subjects appeared to adjust so that no such effect could be observed after two weeks.¹⁸ Oral doses of aluminum have been found to depress the absorption and/or tissue levels of calcium, iron and copper in some studies but not in others. These differences reflect differences in dietary composition, aluminum dosage, and age and health status of the experimental subjects.

At this time it appears that the amounts of aluminum Americans ingest from food are too low to cause significant changes in the metabolism of healthy adults. Thus, consumer concerns about cooking with aluminum utensils and drinking tea seem unwarranted. However, the long-term use of drug-level doses of aluminum needs further evaluation. Use of aluminum-containing drug products by sensitive individuals, such as those with impaired kidney function, the elderly, and very-low-birth-weight infants, is of particular concern.

Dr. Greger is a professor in the Nutritional Sciences Department of the University of Wisconsin-Madison.

GENETIC ENGINEERING HAS GREAT POTENTIAL FOR AGRICULTURE

Kathleen A. Meister, M.S.

Genetic engineering may soon have profound impact on food production. Among the many hoped-for advances from this new technology are: cereal grains that make their own fertilizer; farm animals that mature more quickly; plants that can tolerate cold, heat, drought, and salty soil; and crops that resist insects and diseases so that pesticides are not needed to produce them.

According to a 1983 report by L. William Teweles & Company, a plant science consulting firm, innovations in agricultural genetics should add \$5 billion a year to the value of major crops within 10 years and \$20 billion in 20 years. The company predicts that in 25 years, world food production could rise by 5-10% as a result of biotechnology. Advanced Genetic Sciences, a pioneering firm, projects a \$2-4 billion market for bio-engineered agricultural products by 1990.

Even if such projections turn out to be overly optimistic, the potential benefits of genetic engineering to agriculture are unquestionably extensive. But a few individuals are worried about the release of genetically modified organisms into the outdoor environment.

Most of the agricultural genetic innovations that will soon be ready for field testing involve microorganisms. One of the best known is "ice minus," a microorganism designed by scientists from the University of California at Berkeley, which may help to protect crops from frost damage. Another genetic innovation is a strain of the common bacterium *Pseudomonas fluorescens*, modified by Monsanto scientists to produce a pesticide that kills pests that invade corn plants through the roots. Other proposed experiments involve *Rhizobium*, a microorganism which lives on the roots of beans and related plants and enables them to produce their own nitrogen fertilizer from nitrogen in the air.

A few current projects involve genetic modification of plants rather than microorganisms. For instance, a California firm called Calgene is trying to make crop plants genetically resistant to a new type of herbicide that is effective in low doses and is much less toxic to animals and people than conventional herbicides are. These herbicides kill crops as effectively as they kill weeds. However, if crops could be made resistant to the new herbicides, they could be substituted for less potent ones.

People worried about the release of genetically engineered organisms into the environment are concerned about the possibility of creating new weeds, pests, or disease germs that might be difficult to control. But most experts believe that genetically engineered organisms should be judged no differently from conventionally altered organisms. In other words, each new

product should be considered on the basis of its properties rather than the process used to produce it.

Actually, many of the proposed applications of genetic engineering resemble those produced by traditional methods. During the past 40 years, plants have been bred for resistance to a wide variety of substances, organisms, and environmental extremes. None of these experiments was conducted under special quarantine precautions, because long experience has taught plant breeders that no such precautions are needed. And more than a dozen naturally occurring or conventionally modified bacteria have been licensed for years for various commercial applications.

Ralph W. F. Hardy and David J. Glass of Bio Technica International, a biotechnology firm, point out in a recent article in *Issues in Science and Technology* that genetic engineers introduce a single, specific change into an organism, while conventional plant breeders introduce random, unknown changes and may inadvertently introduce more than one change at a time. Noting that "no major negative health or environmental effects have resulted from the traditional breeding and selection of plants, animals, and microorganisms," they predict that the safety record for the newer techniques will be at least as good.

When work in genetic engineering began in the 1970s, many scientists urged extreme caution because of hypothesized hazards. Most work in this field began in the kind of highly quarantined laboratories used for experiments on biological warfare. As the technique became better understood, scientists learned that such extreme precautions were unnecessary, and the restrictions on laboratory research with genetically engineered organisms were gradually relaxed. No damage to health or the environment resulted, and it seems likely that field tests under scientific conditions will prove safe also.

Unfortunately, release of genetically modified organisms has been tied up in court by Jeremy Rifkin and other opponets of genetic engineering. (Mr. Rifkin is an activist and author who has opposed several advances in biotechnology.) Field tests of "ice minus" have been delayed for three years through legal actions, and developers of other products are afraid to apply them until the "ice minus" issue is settled.

Mrs. Meister is a research associate of the American Council on Science and Health. Additional information on genetic engineering appears in the Nov/Dec issue of *ACSH News & Views*, available for \$2.00 from the American Council on Science & Health, 1995 Broadway, New York, NY 10023.

BRIEFS

Warning against urine autoinjection. Calling it a "bizarre form of therapy," The Asthma & Allergy Foundation of America has warned that autogenous urine injection has been proved neither effective nor safe and can even produce life-threatening kidney disease in some cases. This method involves injecting patients with small amounts of their own urine which has been sterilized. It is based on the erroneous beliefs that the body rejects food and allergy-causing substances by excreting them in the urine and that reinjection of such substances allows the body to build up immunity to them. This warning is contained in *The Potential for Quackery and Questionable Treatment in Asthma and Allergy Medicine*, a 9-page booklet for laypersons on general concepts of allergy and its treatment. Copies are available for \$1 each or \$20 for 25 from the Foundation at 1302 18th St., N.W., Washington, DC 20036.

Michigan courts restrict chiropractic scope. In *Attorney General v. Beno* (No. 72852), the Michigan Court of Appeals had previously ruled that chiropractors may not perform general physical exams, collect blood, hair and urine samples, take blood pressure, or diagnose ailments unrelated to spinal misalignments. On August 27, 1985, the Michigan Supreme Court overturned part of this decision, ruling that chiropractors may legally prescribe, sell and dispense vitamins and food supplements. However, the lower court's prohibitions of general physical exams and of obtaining body samples for laboratory analysis were upheld. In 1983, Iowa's chiropractors persuaded their state legislature to expand their scope of practice after an unfavorable court ruling had ordered restrictions [see NF 2:5].

Salt and sugar in chewing tobacco. Accordingly to Neil B. Hampson, M.D., of Duke University Medical Center, the amount of sodium in chewing tobacco may pose a threat to individuals who must restrict sodium intake [*New Engl. J. Med.* 312:919-320, 1985]. Dr. Hampson, who measured the sodium content of 16 smokeless tobaccos, found it comparable to such foods as dill pickles and fried bacon. However, the amount absorbed by users has not yet been determined and probably depends upon how much tobacco juice is swallowed rather than spit out. Both sodium and sugar are added during the manufacturing process to enhance the flavor of the tobacco. The case of a diabetic whose blood sugar remained abnormally elevated as a result of chewing tobacco was reported several years ago [*N. Engl. J. Med.* 304:365, 1981].

Doctors in the diet business? Medical Nutrition, Inc., of Englewood, New Jersey, has begun marketing a program under which doctors' offices can offer services resembling those of franchised weight-loss clinics. Under the plan, physicians would sell the company's prepackaged meals to patients and monitor their progress during weekly office visits. The company suggests that patients be charged \$55 per week for food which costs the doctor \$27.50. The weekly visits (\$25 each), which usually can be handled by a nurse, would include weighing, blood pressure check and urinalysis. To help promote the "physician supervised" program, the company provides doctors with advertising aids, a 10-minute videotape for patient education, and buttons, posters and refrigerator magnets to encourage patients to stick to the program. According to the company, the typical marketing target is the woman who is 10 to 25 pounds overweight and is buying diet pills.

Patients asked to help pay for "health freedom". According to an article in the National Health Federation's *Health Freedom News*, some unorthodox practitioners have begun adding the cost of a \$20 NHF membership to their initial bill to enroll new NHF members and "strengthen the principal health freedom organization in the United States fighting for the right of physicians and patients to choose the modalities of health care they believe to be most effective." (NHF vigorously opposes government interference with unproven health practices.)

Meadow Fresh attacked by FTC. The Federal Trade Commission has charged Roy Brog, president of Meadow Fresh Farms, Inc., with making unsubstantiated claims. At the same time, the Commission accepted a consent agreement with Larry Brog, the company's former chief executive officer, that he engaged in the same law violations. The company, based in Salt Lake City, had sold Meadow Fresh White, a powdered, dairy-based milk substitute, through a nationwide distributor network. The FTC charged that the Brogs had no scientific basis for claiming that the product had a shelf life of up to ten years and that it would reduce the incidence of cardiovascular disease because it contained less xanthine oxidase, a milk enzyme, than does homogenized whole milk. The agency also charged that the Brogs substantially overstated the income distributors could reasonably expect to earn. In April, a district court placed Meadow Fresh Farms into involuntary bankruptcy.

New oral health group. The American Oral Health Institute (AOHI) is a national nonprofit corporation formed to promote the oral health of our nation's citizens. The organization was created in 1984 following a national conference on fluoridation where it was agreed that concerted effort is needed to educate the public on this issue. Although promotion of fluoridation will be a high priority, AOHI also plans to: 1) provide management services for professional groups; 2) conduct program evaluations, research initiatives and consultative services for public health agencies and private health programs; and 3) develop a strategic plan for improving the nation's oral health. Members receive a quarterly newsletter on oral health news, and a quarterly scientific journal will eventually be published. Annual dues are \$25 for individuals, \$10 for students and \$200 for sponsoring organizations. Applications and additional information can be obtained from OAH's president, Michael W. Easley, D.D.S., M.P.H., P.O. Box 151528, Columbus, OH 43215.

"Raincheck" rule reconsidered. The Federal Trade Commission has decided to amend its food store advertising rule rather than rescind it. The current rule, adopted in 1971 to prevent unethical "bait" advertising, forbids retail stores from advertising specials unless supplies are adequate "to meet reasonably anticipated demand." Under proposed amendments, grocers can offer rainchecks or comparable substitutes and can also advertise items in limited supply provided the limits are clearly disclosed. After a November 1984 staff memo suggested that the rule might be unnecessary [see *NF* 2:15], the agency received more than 3,700 comments from trade associations, industry members, other government agencies, academic organizations, and shoppers. Additional written comments can be submitted until January 24th. Public hearings will begin on March 17th.

New maximum fluoride standards. The U.S. Environmental Protection Agency (EPA) has proposed raising the maximum allowable fluoride level in naturally fluoridated drinking water from 2.4 milligrams per liter to 4 milligrams per liter. In water supplies where fluoride is added, the maximum will remain 1.2 milligrams per liter. Studies have shown that fluoride levels above 2 milligrams per liter can cause dental fluorosis, which results in discoloration, mottling and pitting of the teeth. However, a 1982 report by the U.S. Surgeon General concluded that fluorosis is not an adverse health effect. Antifluoridationists and environmentalists have opposed raising of the standard, while the American Dental Association believes that no standard is needed for naturally fluoridated water because problems are rare and purely cosmetic.

Information packets. The American Medical Association Division of Library and Information Management, 535 N. Dearborn St., Chicago, IL 60610, has prepared information packets on questionable health methods. Most packets contain 5-10 articles from journals and other sources, some of which have been gathered by the Lehigh Valley Committee Against Health Fraud. The subjects covered include hair analysis, cytotoxic testing, chelation therapy, holistic medicine, homeopathy, iridology, naturopathy, gerovital (procaine therapy), cancer quackery, and quackery in general. Packets cost \$7.50 each but are free to AMA members. For additional fees, computer searches can be performed on subjects for which packets have not been prepared.

Special food for the elderly? According to *The Wall Street Journal*, scientists at Duke University and elsewhere are trying to develop products that will make food tastier for the elderly. This may be possible by adding naturally occurring ingredients that heighten taste or add odors to foods. If the research succeeds, it will probably be several years before any taste-amplified foods are available to consumers. However, a prominent researcher quoted in the article cautioned that few elderly individuals who are healthy will need such products.

Suits seek to terminate artificial feeding. Court permission is being sought to stop artificial feeding of Nancy Ellen Jobes, a New Jersey woman who has been comatose for five years and is considered unable to recover. The attorney in the case is Paul Armstrong, who represented the family of comatose Karen Quinlan ten years ago in their successful fight to have a respirator turned off even though it was expected to result in her death. The issue in both cases is whether society should approve removal of artificial aids from a patient, who, while not terminally ill, will never wake up from coma and is being kept alive solely by artificial means. *American Medical News* estimates that some 10,000 persons in permanent vegetative states are being kept alive in the United States at an estimated cost of \$150,000 per year per person—money which many ethicists believe would be much better spent on technology to save patients whose underlying conditions are curable. In another current case, a Massachusetts lower court ruled that neither a hospital nor a nursing home could discontinue artificial feeding of Paul Brophy, a Massachusetts man who has been comatose for three years. The judge concluded that Brophy would not have wanted to be kept alive by artificial means. But since Brophy was not near the end of his normal span of years and did not actually appear to be suffering, the judge felt that the state has a duty to keep him alive.

Mendelsohn endorses yeast product. Naturally Vitamin Supplements of Scottsdale, Arizona, has announced that Robert Mendelsohn, M.D., has endorsed its product, Bio-Strath, and advocates its daily use. Bio-Strath is a yeast and herb mixture said to contain "10 B-vitamins, 19 minerals, 18 amino acids and important active enzymes." The company has begun advertising a statement by Mendelsohn that Bio-Strath "can help people who experience daily tiredness, fatigue and difficult concentration . . . may stimulate the immune system. And may actually help us to assimilate more natural fuel from the foods we eat." (Claims of this type make Bio-Strath a drug product which would be illegal to market without FDA approval.) Mendelsohn, who opposes immunization, fluoridation, and licensing of nutritionists, is a former president of the National Health Federation.

"Oral chelation" product seized. On September 5th, New York State Attorney General Robert Abrams announced that Orachel had been seized from retail outlets in the New York City area and that suit had been filed to block sale and distribution of the product throughout the state. The seizures were made at various locations of L&H Vitamins and Vitamin Shoppes, Inc., both of which sell large amounts of supplement products (at discounts from list price) through mail-order sales nationwide. Orachel, a Kurt Donsbach formulation of vitamins, minerals, amino acids and other substances, has been claimed effective for preventing and treating cardiovascular disease. A few months ago, the FDA ordered Donsbach and his company, HRG Distributors, of Huntington Beach, California, to stop marketing Orachel. (Shortly before the order was issued, however, another company had taken over distribution.)

Notable quote. "The problem of media misinformation also applies to politics, business, religion, ethics, medicine, and other topics of vital social concern. CSICOP is primarily interested in the reporting of the paranormal and the pseudosciences, but what happens in these areas is perhaps symptomatic of the broader problem—the need to develop in both the journalistic fraternity and the public some sort of appreciation for critical and reflective judgment in evaluating claims of truth. This need is made more critical by the fact that the public is constantly being bombarded by those who wish to promote their own views, sell a bill of goods, convert others to a cause, or convince us that they have discovered a special truth or found a unique road to salvation." From: "Responsibilities of the media and paranormal claims," by Paul Kurtz, Ph.D., Chairman, Committee for Scientific Investigation of Claims of the Paranormal [*Skeptical Inquirer*, Spring, 1985].

Why wait? The Life Extension Foundation, of Hollywood, Florida, sells Life Extension Mix, Life Extension Shampoo, Life-Extension Weight-Loss Formula, and various other supplement products claimed to improve memory, improve athletic performance, and strengthen the heart. For customers in a hurry, the company has made a special arrangement for Federal Express to deliver "rush" orders overnight for only \$3.50 extra.

QUESTION BOX

Q. What are chelated minerals? Do they have any advantage over other mineral supplements?

A. In simple terms, chelation is a process by which metal ions in solution become bound by certain organic molecules which surround them. Chelated mineral supplements can be found in just about every health food store in America. They are usually more expensive than their inorganic counterparts, but the proponents of chelated minerals claim that the extra expense is justified because they are better absorbed and utilized than inorganic mineral salts. They also claim that chelated supplements cause less gastrointestinal disturbance than inorganic salts. There is, however, no scientific evidence to support these claims. An extensive study comparing the absorption of inorganic iron (ferrous sulfate) with various iron chelates showed little or no difference among them [Brise and Hallberg: *Acta Med. Scandinav. Suppl.* 376:23, 1963].

The absorption of metallic minerals is a complex process. It is influenced by the solubility of the mineral salt or complex, the valence state of the mineral (ferric salts are absorbed poorly compared to ferrous salts), and the presence of compounds such as phytates, tannins or oxalates which reduce the absorption of some minerals by forming insoluble complexes. Other dietary components such as fats, proteins, vitamin C, and some types of dietary fiber can also alter mineral absorption. Excesses of some minerals will decrease the absorption and/or excretion of others. Excess zinc, for example, will reduce the utilization of copper.

It is clear that the absorption and utilization of minerals depends on many interrelated factors. Furthermore, metallic ions chelate with a large variety of molecules found in just about everything we eat. These include organic acids (e.g., citric acid), sugars (e.g., lactose) and amino acids (e.g., glycine and histidine). Since practically all minerals consumed in a normal diet will become chelated at some point during the digestive process, there is no theoretical justification for taking chelated minerals.

THE GERSON CLINIC

James Lowell, Ph.D.

About six miles south of Tijuana, Mexico, on the old Ensanada Road, is the Hospital La Gloria, one of six major "alternative" cancer clinics located in the area. Housed in a converted resort, La Gloria's operation is guided by Charlotte Gerson Straus, daughter of the late Dr. Max Gerson.

La Gloria resembles the turn-of-the-century sanitariums where patients went for rest, recuperation and various therapies. Its facilities are set on several acres among lush vegetation and dozens of palm trees, and include a two-story motel wing with spacious rooms, all of which overlook a large patio pool. The motel portion, plus rooms in two other buildings, can house up to 28 patients at a time, although the average census is 15. Other buildings contain treatment facilities, a lounge, and a combination dining room and lecture area. There is also a small store which sells literature and other products associated with Gerson therapy.

La Gloria opened its doors in 1977 with the avowed purpose of not only treating patients but also training their "assistants" (friends and relatives who accompany them to Mexico) and interested physicians in the Gerson methods. The facility, which is incorporated in Mexico, is operated for profit by Drs. Dan Rogers, an American, and Victor Ortuno, who is Mexican, both of whom were trained as general practitioners. There are about 60 employees, including several other physicians, guards at the gate, nurses, maids, kitchen staff, and drivers who chauffeur patients. About 600 patients are treated each year.

Although the promoters call La Gloria a hospital, a New York Appellate judge ruled recently that the facility did not meet the definition of a hospital for insurance purposes because it lacked operating rooms, laboratories, an emergency room and other facilities normally found in hospitals [see NF 2:37].

Max Gerson, M. D., was born on October 18, 1881 in Wongrowitz, Germany, and graduated from medical school in Freiburg in 1906. In 1938, at the age of 57, he fled the Nazi regime and entered the United States, where he was granted a license to practice medicine in

New York State. Meanwhile, his father, mother and seven brothers and sisters were annihilated in concentration camps.

Gerson summarized his basic theories about cancer and other diseases he considered "degenerative" in a paper in the *Review of Gastroenterology* in 1945. He believed that special diet, injections of raw liver extract, "detoxification" of the body with enemas and diet, sodium restriction and high intake of potassium could build up the body's immune system, thereby increasing resistance to disease. He claimed that his approach could cure not only cancers, but also such conditions as tuberculosis, lupus erythematosus and heart disease. His original dietary recommendations were: no sodium, no fat, little animal protein, high potassium, much carbohydrate, lots of fluids, dehydrated, defatted liver capsules and liver injections. Later he advised adding small amounts of linseed oil.

In 1947, the National Cancer Institute reviewed 10 cases selected by Dr. Gerson and found his report unconvincing. That same year, a committee appointed by the New York County Medical Society reviewed records of 86 patients, examined 10 patients, and found no scientific evidence that the Gerson method had value in the treatment of cancer. (Curiously, Mrs. Straus claims that these investigations never took place even though they are mentioned in Gerson literature.) Eventually, Gerson lost his hospital privileges and malpractice insurance, and received a two-year suspension from the New York County Medical Society for advertising his "secret" treatment on a radio talk show. He died in 1959.

Most referrals to La Gloria are made through the Gerson Institute, P.O. Box 430, Bonita, CA 92002. The Institute is described in the 1981 issue of its journal, *Healing*, as a nonprofit charitable organization which teaches methods for preventing and healing disease, "particularly . . . all the major killing and crippling diseases for which orthodox medicine has a 0% cure rate." One of the Institute's goals is "to get at least one copy of *Healing* into every home in the United States." According to staff member Gar Hildenbrand, whose testimonial

of recovery from lupus erythematosus using Gerson therapy appears in *Healing*, the Institute now has 2,200 contributing members. In addition, it sells publications about the Gerson therapy. Hildenbrand said he is paid about \$30,000 per year and that Mrs. Straus receives somewhat less.

Cancer, Think Curable! The Gerson Therapy, a booklet distributed by the Gerson Institute, specifies 21 conditions which the author claims are curable by the treatment. Included are cancers, heart disease and atherosclerosis, arthritis, allergies, multiple sclerosis, asthma, diabetes, amyotrophic lateral sclerosis ("Lou Gehrig's disease"), infertility, psoriasis and ulcers. Physicians at La Gloria also claim to be able to restore sight to some blind persons by treating them with ozone, a reactive form of oxygen.

Mrs Straus is president of the Institute and edits its bimonthly newsletter. She maintains a busy lecture schedule, traveling throughout the U.S., sponsoring and speaking at alternative health care conventions, and appearing on talk shows. Her media bookings are arranged by North American Consultants and Promotions, Ltd., headed by Cameron Frye, who advertises himself as a "specialist in obtaining free air time." Frye also represents Stanislaw Burzynski, another promoter of questionable cancer therapy. Although his mother died of cancer after being treated by Burzynski, Frye believes Burzynski helped alleviate her suffering in her final hours. Many of Straus' speeches are given at meetings sponsored by the National Health Federation, a group promoting the gamut of unproven practices.

The Institute's executive vice president is Norman Fritz, a former president of the International Association of Cancer Victims and Friends, a group devoted to unorthodox methods of cancer management.

In a 1984 speech to students at the National College of Naturopathic Medicine in Portland, Oregon, Straus claimed that Gerson therapy could get patients off high blood pressure medicine in only five days, although, she said, it would take a little longer to cure heart disease. She also claimed that milk and protein would cause pregnant women to get cancer, and that nuts cause the breakdown of the immune system because they contain arginine. Babies, she said, shouldn't get any vaccinations, shots or drugs. Instead, if an infant becomes ill, the nursing mother should be given food supplements, drops of iodine and coffee enemas.

At a meeting I attended last summer at La Gloria, the tables had been moved out of the dining room and replaced with chairs for the occasion. In an hour-long, highly emotional speech, Charlotte Gerson Straus explained that her treatment is designed to "bring the body back to normalcy and strengthen the immune system." This, she said, can only occur when the "toxins" have been removed and proper nutritional balance established so the body will be able to heal itself.

The Gerson therapy costs about \$1,700 per week. This does not include the \$30 a day for friends or relatives accompanying the patient or the cost of special medication or products (such as juice presses) which the

patient may need to continue therapy at home. Although Gerson Institute brochures recommend stays of up to eight weeks (which would cost \$13,600), Straus says most patients stay only four weeks.

For the first week's treatment, payment must be made within one day of admission to the facility. Either cash or traveler's checks with the payee line left blank are accepted, but U.S. personal checks or cashier's checks are not. Patients are asked to sign various releases including a disclaimer acknowledging that Hospital La Gloria "makes no claims assuring cures of the medical conditions treated, including cancer."

According to Hildenbrand, patients undergo a complete physical exam when they enter La Gloria. Then they are taken to their rooms and instructed in the use of coffee and castor oil enemas and oral castor oil. These procedures supposedly irritate the organs, especially the liver, intestines and brain, and stimulate the flow of bile, resulting in "detoxification" of the body. One-quart coffee enemas are taken every four hours and increased to every two hours with the onset of symptoms associated with "detoxification," such as headache, fever, nausea or intestinal spasms.

The oral doses of castor oil are given every second day along with a cup of "organic" black coffee and raw brown sugar, which supposedly facilitate movement of the castor oil into the large intestine. The rectal dose is mixed with coffee solution and given on the same day. Some patients may also receive up to 1,000 cc of ozone into the rectum through an enema device.

On a recent television talk show, Straus claimed that symptoms of the "detoxification" are transient, and that all her patients feel better within just a few days of admission to the hospital. However, *The Gerson Primer*, a book distributed to La Gloria patients, states that detoxification may cause flu-like feelings, loss of appetite, perspiration with strong odor, weakness, dizziness, cold sores and fever blisters. Arthritics can expect their joints to become painfully swollen, symptoms of other diseases may worsen, and tumor masses will become painful. High fever, intestinal cramping, diarrhea and vomiting may also occur but, the *Primer* states, these symptoms indicate that the patient is being healed.

Cancer Winner, by Jacquie Davison, a book included in Charlotte's publicity package, also describes the detoxification crisis—but states that patients undergoing Gerson treatment can expect to have symptoms

Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

caused by the release of toxins for about 1½ years.

The usual Gerson dietary regimen begins with an eight-ounce glass of juice each hour, a total of about 13 glasses a day. Included are carrot, apple, orange and "green" juices, the latter made from a mixture of vegetables, and three glasses of daily juice extracted from pressed raw liver. Patients also receive tablespoons of linseed oil, acidophilus-pepsin capsules, potassium solution, Lugol's solution (an iodine/potassium iodide solution) added to the juice, thyroid tablets, 300 mg of niacin daily, pancreatic enzymes, royal jelly capsules (for some patients only), and injections of vitamin B₁₂ mixed with liver.

Except for the liver juice, the first four weeks' diet contains no protein from animal sources and is strictly vegetarian. Thereafter, small amounts of dairy products such as yogurt and cheeses may be added. Food supplements given to patients in severe pain include 50 mg of niacin, 500 mg of vitamin C and one aspirin tablet. Castor oil poultices are also used to reduce pain over specific locations.

According to Mr. Fritz, the treatment process after leaving La Gloria Hospital is quite time-consuming. Making fresh juice 13 times a day, cleaning the juicer each time, preparing the fruits and vegetables, and shopping for them usually take 40-50 hours a week, although with experience this may drop to 30 hours a week.

Gerson Institute literature claims a recovery rate of 90% of early cases and "about 50%" for advanced cancer patients. These are patients, they say, who have no chance of recovery under orthodox treatment. Fritz claims that patients with melanomas or lung cancer with early metastasis have a 70-90% chance of recovery, while those with brain tumors have only a 30% cure rate.

Mrs. Straus says her success rate is very high in treating essentially all types of cancers. But she said in a recent TV broadcast that statistics have not been published because the establishment would try to compare her results with theirs, which would be unfair, because the patients who come to her have mostly been declared terminal and are close to death. "Comparing my patients with those undergoing standard treatment is like comparing apples to oranges."

Actually, it does not appear that genuine data exist on the survival rates of Gerson therapy patients. Hildenbrand told me that when La Gloria opened, Rogers and Ortuno had no interest in keeping records or documenting cures. Fritz told Dr. Stephen Barrett in a recent interview that no systematic follow-up takes place because the process would take more money and manpower than are available. Instead, the Institute's survival statistics are based on a combination of the doctor's estimate that the departing patient has a "reasonable chance of surviving," plus feelings that the Institute staff have about the status of people who call in.

According to Fritz, patients leaving the clinic are instructed to telephone every month or two to discuss problems, get additional instructions, or order sup-

plies—but that only about 25% do so. "We assume that those who don't call are not following the program," he told Dr. Barrett. If a patient dies, Fritz said, the Institute may not know the cause of death unless a family member happens to provide this information. This process, of course, contrasts sharply with the tumor registries used by hospitals and state health departments to keep track of cancer patients through questionnaires sent at regular intervals to treating physicians.

Mrs. Straus claims that patients who have not undergone the standard treatment modalities of radiation, surgery and chemotherapy have the best chance of being cured by her regimen. In fact, she says, once people have received chemotherapeutic agents, their immune system is destroyed, and the Gerson therapy will no longer work. Therefore, they will not admit them to La Gloria. However, Delmar Aiken, M.D., a tumor specialist from Loma Linda, California, has reported that a patient he treated with both chemotherapy and surgery was later accepted into the Gerson program for outpatient treatment.

Patients treated at La Gloria Hospital may be risking serious infection. Dr. Michelle M. Ginsberg of the San Diego Department of Health has reported that during the past six years, at least 13 patients who said they had been treated at La Gloria have been admitted to San Diego area hospitals with *Campylobacter* sepsis. Their physicians believe the source of the infection was the raw liver used at the clinic. Five of the patients were comatose when admitted due to low serum sodium (as low as 102 meq/l), presumably related to the no-sodium diet recommended by Gerson. None of these patients was cancer-free, and one died from his malignancy within a week of admission to the hospital.

Another disastrous result in a patient treated by Gerson therapy has been reported by William T. Jarvis, Ph. D., professor of health education at Loma Linda University and president of the National Council Against Health Fraud. In this case, a 24-year-old osteopathic student with testicular cancer had surgery but refused chemotherapy because of his religious beliefs. Instead he underwent Gerson therapy and other unproven methods that fit his interpretation of "God's remedies." Although his original probability of 5-year survival was over 90% with proper treatment, he died of his cancer at age 26.

Benjamin Wilson, M.D., a surgeon from Portland, Oregon, has reported that a young woman was told by "doctors" at the Gerson clinic that she had cancer of the breast when she did not. This woman had undergone conventional treatment several years previously and feared her cancer would return. Although a physical exam had found no malignancy, she was still frightened and decided to visit La Gloria—where she was told that the cancer had come back. According to Dr. Wilson, after several weeks on the Gerson treatment, she felt so miserable that she decided to take her chances with the supposed cancer. On her return home, her doctor again reassured her that no malignancy was present.

Straus claims this case is exceptional and that her staff seldom make mistakes of this sort. According to an article in *Healing* which describes their research and expansion goals, however, the testing methods used at La Gloria "do not, in many respects, equal those used by Gerson a half century ago . . . We need better and more complete methods of testing and monitoring." The fact is that La Gloria does not contain laboratory facilities for running the tests necessary to diagnose cancer. In fact, on a recent television broadcast, Straus said her doctors don't actually attempt to prove cancer exists but rely on the patients' word for it or on medical reports that the patients may bring with them.

Before any cancer treatment is considered "proven" and acceptable for general use by physicians, it must undergo rigorous scientific scrutiny. According to the American Cancer Society, standards of investigation for cancer treatments should include at least the following: 1) complete evaluation of all clinical and laboratory data presented by the proponent including case histo-

ries, x-ray films, and microscopic slides; 2) reproducible analysis of the drug and laboratory results; 3) observations on the effects of the therapy under study in a sufficient number of patients with biopsy-proven cancer; 4) assessment of treatment results for each case compared to other previous or concomitant therapy; 5) examination of autopsy data; and 6) consultation with investigating groups.

It seems clear that proponents of the Gerson therapy are not gathering data in a scientific manner with the hope of someday proving their case.

Dr. Lowell, a board member of the National Council Against Health Fraud, is Professor of Life Sciences at Pima Community College, Tucson, Arizona, and a columnist for *The Arizona Daily Star*. This article was based on more than five years of investigation which included many trips to "alternative" health conventions, visits to the Mexican cancer clinics, and interviews with promoters and practitioners of unproven methods.

Book Review

Title: Opportunities in Nutrition Careers (1986)
 Author: Carol Coles Caldwell, M.S., R.D.
 Publisher: VGM Career Horizons, 4255 W. Touhy Ave.,
 Lincolnwood, IL 60646
 Price: \$9.95 hardcover, 6.95 softcover
 Reviewed by: Denice Ferko-Adams, R.D.

This 150-page text is a concise and accurate resource which should be particularly useful for career counselors and individuals interested in pursuing a career in dietetics. In fact, it could well have been titled "Careers in Dietetics." Following an introduction to the American Dietetic Association's history and goals, much-needed emphasis is then placed on the rapidly changing roles of the dietitian. Educational requirements are detailed for Plan IV programs, dietetic internships, coordinated undergraduate programs, and dietetic technician programs. For each of these ADA membership routes, an appendix lists the names and addresses of programs in the United States and Puerto Rico. These lists are one of the book's most practical features. The author also tells how advanced degrees plus ADA-approved experience can qualify candidates for the Registered Dietitian examination.

Career roles and educational requirements are detailed for clinical dietetics, clinical dietetic specialties, community dietetics, and food service management. In these chapters, community dietetics dominates the section and includes evolving roles for the dietitian working in home health care, health maintenance organizations, fitness centers, private practice,

business and industry, and sales. The chapter devoted to the dietetic technician comprehensively covers roles and education, but does not include employment statistics, salary ranges, and future job opportunities as are detailed for the dietitian positions.

A realistic approach prevails throughout chapters focusing on the diverse roles and career opportunities for dietitians. This realism is illustrated by such statements as: "Nutrition experts can create the world in which they work; but it will take initiative, advanced knowledge, and the development of individual expertise." Courses of study are suggested for developing expertise in specific areas. Assertiveness and creativity are illustrated in the final chapter, "Interviews With Current Practitioners," which shows how eight dietitians have succeeded in "creating the world in which they work."

The book's foreword was written by the president of a health and fitness resort where the author is employed. He considers Adelle Davis profound for having said "we are what we eat." He also included superfluous claims that food can keep you alert, help you sleep, give you strength and endurance to compete, and "keep your body fueled for the highest performance and best health possible." Fortunately, these statements are out of character with the professionalism exhibited throughout the rest of the book.

Ms. Ferko-Adams is a nutrition consultant in private practice in Allentown, Pennsylvania. She also consults for the YWCA and a regional affiliate of the Dairy Council. From 1983 to 1985 she edited *Dietitians in General Clinical Practice*, the newsletter of the American Dietetic Association's Dietetic Practice Group.

BUTCHER'S-BROOM

Varro E. Tyler, Ph.D.

Broom is one of those indefinite common names that tend to make the field of plant-drug nomenclature such a difficult one. The name was originally applied to several plants whose tough stems and rigid leaves made them useful for sweeping up debris. Used without a qualifying adjective, broom refers to *Cytisus scoparius* L., a common roadside plant in the Pacific Northwest, distinguishable by its showy yellow flowers. Spanish broom or gorse (*Spartium junceum* L.) is another yellow-flowered leguminous shrub that flourishes in parts of California. Although both plants have been used in folk medicine, neither is the so-called butcher's-broom which is, so to speak, "sweeping the country" at the present time.

Butcher's-broom, also known as box holly or knee holly, is a fairly common short evergreen shrub (*Ruscus aculeatus* L.) of the family Liliaceae, native throughout the Mediterranean region from the Azores to Iran. It, too, has a long history of use in herbal medicine. As early as the first century, Dioscorides recommended butcher's-broom as a laxative and diuretic. The 17th century apothecary-astrologer Nicholas Culpeper suggested that a decoction of the root be drunk and a poultice of the berries and leaves applied to facilitate the knitting of broken bones. However, the drug never became popular in either Europe or the United States, and until recently, was seldom mentioned in standard references on drugs.

Then during the 1950s French investigators showed that an alcoholic extract of butcher's-broom rhizomes (underground stems) produced vasoconstriction (blood vessel narrowing) in test animals. Further studies identified the active principles as a mixture of steroidal saponins, the two main ones being identified as ruscogenin and neoruscogenin. In addition to its vasoconstrictive effects, the extract was demonstrated to have anti-inflammatory properties.

These studies convinced certain European drug manufacturers that butcher's-broom extract is superior to some of the conventional plant remedies, such as extracts of horse chestnut and witch hazel, that are marketed for their supposed beneficial effects on venous circulation. Consequently, they have made extracts of butcher's-broom commercially available in capsule form to treat circulatory problems of the legs, and as an ointment or suppository to relieve the symptoms of hemorrhoids.

Capsules containing 75 mg of butcher's-broom and 2 mg of rosemary oil are now being sold in the United States, mainly through health food stores. One such product is being advertised as "a proven European herbal formula—said to improve circulation in the legs," while another is being promoted with the claim that "millions of Europeans report it works wonders—particularly for women who often complain about a

'heavy feeling' in the legs." The ads also state that butcher's-broom is "rare" or "hard-to-find"—which is not true.

While there may be some basis for cautious optimism concerning butcher's-broom as a potentially useful drug, would-be consumers should recognize that manufacturers of butcher's-broom products have never presented proof of safety and efficacy to the FDA and that therapeutic claims for these products are therefore illegal. Moreover, self-diagnosis and self-treatment of circulatory disorders, or any other potentially serious health problem, are certainly inadvisable.

Dr. Tyler, Dean of Purdue University's Schools of Pharmacy, Nursing, and Health Sciences, is an expert in pharmacognosy (the science of medicines from natural sources) and author of *The Honest Herbal*, an evaluation of popular herbs.

QUESTION BOX

Q. Does the addition of isoascorbate to foods as a preservative increase their vitamin C value?

A. No. Isoascorbate or isoascorbic acid (most frequently called and labeled as erythorbic acid erythorbate) provides little if any vitamin C biological value. However, because common vitamin C assay procedures do not differentiate between vitamin C and isoascorbate, isoascorbate in foods can result in false high readings for the vitamin. The U.S. Department of Agriculture, which is the primary source of information about the nutrient content of foods, has researchers working to develop tests that differentiate between the two compounds.

Isoascorbate is a GRAS (Generally Recognized As Safe) food additive. Its main use is to help retain the natural color of red meats, such as cured pork, beef cuts, hamburgers and frankfurters. No more than 3/4 ounce is added to 100 pounds of meat. Its antioxidant action prevents the meat from changing color through reactions with oxygen.

During the 1970s a rumor circulated in North America that certain meat products contained "earthworms." The unfortunate process may have resulted from misreading of the "erythorbate" on a meat product label.

UNPROVEN ALLERGY CONCEPTS ATTACKED

The American Academy of Allergy and Immunology (AAAAI), the nation's largest professional organization of allergists, has issued position papers strongly criticizing the concepts of "clinical ecology" and "candidiasis hypersensitivity syndrome" and the diagnostic and treatment approaches used by their proponents. At the same time, the Academy issued another statement defining standards for evaluating proposed methods.

Clinical ecology, which is not a recognized specialty, is an approach founded by Theron Randolph, M.D., of Chicago. It ascribes a wide range of symptoms to exposure to numerous common substances in the environment. Advocates of this practice describe themselves as "ecologically orientated" and refer to their patients as "environmentally ill," "hypersensitive," or allergic to such factors as food, water, chemicals or pollutants. According to proponents, symptoms exhibited as a result of "ecological disease" are multiple and can include behavior disorders, depression, chronic fatigue, arthritis, hypertension, learning disabilities, schizophrenia, gastrointestinal symptoms, respiratory problems and urinary complaints.

Clinical ecologists postulate that symptoms are related to "immune system dysregulation," which many physicians, "faced with its incredible array of seemingly unrelated symptoms . . . misdiagnose as stress, psychosomatic disease or the like." Treatment usually requires major changes in the home environment and lifestyle, often with highly restricted diets, injections of suspect chemicals, and living in special isolation rooms where synthetic materials have been removed and the air is filtered.

To establish their diagnoses, clinical ecologists rely on such tests as provocation and neutralization, cyclical and elimination diets, assays of immune system components, and a few standard tests for food allergy. (Provocation and neutralization are unproven methods in which the patient is given a suspected allergic substance to provoke symptoms and then treated with weaker doses to neutralize supposed allergic reactions. The substances used can be injected or administered as drops placed under the tongue to be absorbed.)

Noting that there are very few symptoms which clinical ecologists have not considered related to environmental sensitivity, AAAAI warned that although the

idea that the environment is responsible for a multitude of human health problems is very appealing, "to present such ideas as facts, conclusions, or even likely mechanisms without adequate support is poor medical practice."

Candidiasis hypersensitivity is a supposed syndrome which has been popularized by C. Orian Truss, M.D., of Birmingham, Alabama, and William G. Crook, M.D., of Jackson, Tennessee. Its symptoms are said to be multiple and to include fatigue, depression, inability to concentrate, hyperactivity, headaches, skin problems (including hives), abdominal pain and bloating, constipation, diarrhea, respiratory symptoms, and problems of the urinary and reproductive organs. According to Dr. Crook, "If a careful check-up doesn't reveal the cause for your symptoms, and your medical history [as described in his book, *The Yeast Connection*] is typical, it's possible or even probable that your health problems are yeast connected." He also claims that tests such as cultures don't help much in diagnosis because "Candida germs live in every person's body . . . Therefore the diagnosis is suspected from the patient's history and confirmed by his response to treatment."

Crook claims that the problem arises because "antibiotics kill 'friendly germs' while they're killing enemies. And when friendly germs are knocked out, yeast germs (*Candida albicans*) multiply. Diets rich in carbohydrates and yeasts, birth control pills, cortisone and other drugs also stimulate yeast growth." He also claims that large numbers of yeasts weaken the immune system, which is also adversely affected by nutritional deficiencies, sugar consumption, and exposure to environmental molds and chemicals. Crook's proposed treatment program includes: a wide variety of questionable diagnostic tests; treatment with allergenic extracts; supplementation with vitamins, minerals and antioxidants; diets that avoid refined carbohydrates, processed foods, and (initially) fruits and milk; and treatment with antifungal drugs.

Due largely to Dr. Crook's promotion, public interest in "candida hypersensitivity" appears to be increasing rapidly. *Health Foods Business* notes that several new products (Yeast Fighters, Control, Candida-Guard and Candida Cleanse) are being marketed. One retailer reported "about 15-20 Candida customers a

Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Linda K. DeBruyne, M.S., R.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Suzanne Pelican, M.S., R.D.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.

week" with an average checkout ticket of \$80. Another said she had sold 350 copies of *The Yeast Connection* during the past 18 months. And the Price-Pottenger Nutrition Foundation says it receives about 500 letters a week asking for referrals to knowledgeable doctors.

AAAI's Practice Standards Committee has concluded: 1) the concept of candidiasis hypersensitivity is speculative and unproven; 2) its basic elements would apply to almost all sick patients at some time because its supposed symptoms are essentially universal; 3) overuse of oral antifungal agents could lead to the development of resistant germs that could menace others; and 4) adverse effects of oral antifungal agents are rare, but some inevitably will occur.

Regarding unproven procedures, AAAI notes:

- All newly proposed procedures start out unproven and should be subjected to a fair trial to determine whether or not they are effective.
- The responsibility for testing unproven procedures should rest with their proponents.
- During the trial period, a procedure should be considered experimental and reserved for use with informed consent in controlled trials which have been

approved for safety and scientific merit by competent institutional review boards.

- Neither patients nor physicians can determine effectiveness (as opposed to coincidence) without controlled trials. Because allergic symptoms can be influenced by many factors, including emotions, experiments must be designed to separate the effects of the procedure being tested from the effects of other factors.

- A procedure should not be accepted for general use until proof of effectiveness has been established and published in reputable, refereed medical journals.

- An unproven procedure can be proven effective, since it is possible to prove a positive point. However, under most circumstances, it is not possible to prove a negative point. Therefore the biomedical community should require proof of effectiveness before a procedure is accepted for routine use, but should not demand proof of ineffectiveness before discarding an unproven procedure.

Copies of AAAI's position papers can be obtained free of charge by sending a stamped, self-addressed envelope to the American Academy of Allergy, 611 E. Wells St., Milwaukee, WI 53202.

BRIEFS

AMA report on saccharin. The American Medical Association Council on Scientific Affairs has concluded that "in humans, the use of artificial sweeteners, including saccharin, is not associated with an increased risk of bladder cancer" [JAMA 254:2622-2624, 1985]. Although bladder tumors have been produced in male rats exposed to saccharin from conception through adult life, the Council concluded that this phenomenon has not been reproducible in other animals and appears to be specific for rats. Epidemiologic studies have found no association between saccharin use and bladder cancer in human adults. However, because little data exist on saccharin's possible effects on young children and pregnant women, the Council recommends that additional data be gathered and that saccharin use by these two groups be given "careful consideration."

Maternal/infant health promotion. The Healthy Mothers, Healthy Babies Coalition is an informal association of more than 70 national professional, voluntary, and governmental organizations with a common interest in maternal and infant health. Information on its activities and publications can be obtained by writing to the Coalition at 600 Maryland Avenue, S.W., Suite 300, Washington, D.C., 20024.

Fluoridation rejected. On November 5th, voters in San Antonio, Texas, defeated a referendum that would have fluoridated the drinking water of its one million residents. The vote, with only 17% of registered voters participating, was 42,140 to 39,045. Although an ordinance had been passed by the city council in 1984, anti-fluoridationists gathered enough signatures to force a referendum.

Media asked to reject blatantly false ads. Virginia H. Knauer, Special Advisor to the President for Consumer Affairs, has called for an end to ads touting perpetual youth, weight-reduction schemes, or phony cures for baldness, cancer and arthritis. In a recent address before the Media Luncheon Group, an organization of advertising review executives, she said: "I am not asking ad managers to be clairvoyant; nor am I asking that they make distinctions that call for great wisdom. I ask only that they use good, old-fashioned common sense. In other words, the media should make greater efforts to reject improbable, misleading and fraudulent ads." To provide further help in spotting questionable weight-reduction promotions, the Council of Better Business Bureaus and the FDA have distributed a detailed report on this subject to media outlets throughout the country.

Free brochures. Nine brochures on sports nutrition for amateur athletes have been published by the NutraSweet division of G.D. Searle & Co. The brochures were produced under the guidance of Sarah H. Short, Ph.D., R.D., professor of nutrition of Syracuse University and have been endorsed by the Amateur Athletic Union (AAU). The activities covered are: running, swimming, skiing, biking, racquet sports, hiking, aerobic dance, skating, and weight training. Free copies can be obtained by indicating the subject(s) of interest and sending a stamped, self-addressed envelope to Eat to Compete, c/o AAU, 3400 W. 86th St., Indianapolis, IN 46268.

Shaklee co-founder dies. Forrest Shaklee, Sr., the chiropractor who founded Shaklee Corporation in 1956 with his sons, Forrest, Jr., and Raleigh, died December 17, 1985 at the age of 91.

Aquaculture. According to an article in the November 1985 *Science of Food and Agriculture*, the supply of ocean fish is precarious but fish farming is a rapidly growing business. Although fish provide only a small percentage of the protein consumed in this country, they can supply much more as the market grows. Fish farming uses less energy for protein synthesis than either poultry or livestock production and can utilize land unsuitable for other agricultural purposes. The three main fish cultured in the United States are channel catfish, trout and crawfish. High quality can be maintained because farmed fish usually reach the processing plant alive.

Vitamin E information. The Henkel Corporation, which manufactures vitamin E products, has begun operating the Vitamin E Research & Information Service (VERIS) for health professionals, researchers, and nutrition and health communicators. Qualified persons are eligible to receive its free newsletter as well as a comprehensive annual compilation of research abstracts. For placement on the mailing list or additional information on vitamin E, write to Sharon Landvik, M.S., R.D., Manager, VERIS, 7900 W. 78th St., Minneapolis, MN 55435, or call her at 800-328-6199 or 612-828-8188.

Consumer Reports Blasts
Vitamin Pushers
Consumer Attitudes Toward Foods

Health promotion poll. When 1,040 primary care physicians in Maryland were asked about 25 health promotion behaviors, elimination of smoking scored highest, with 94% rating it "very important" and 6% rating it "important." Nutrition-related items scored very important or important as follows: avoid excess caloric intake (73%/24%); eat a balanced diet (68%/29%); avoid saturated fat foods (52%/42%); drink alcohol moderately (52%/31%); decrease salt consumption (41%/50%); avoid high cholesterol foods (41%/46%); eat breakfast every morning (33%/40%); limit daily caffeine intake (23%/54%); and minimize sugar intake (15%/47%). "Take vitamin supplements" scored lowest, with 6% very important, 21% important, 40% unimportant, and 34% very unimportant. [American Journal of Public Health 75:1427-1428, 1985.]

New fluoridation manual. Activists working toward community fluoridation can benefit from information in *Water Fluoridation—A Manual for Engineers and Technicians* (1985). Most of its 119 pages cover the mechanics and chemistry of fluoridation delivery systems, but excellent discussions of fluoridation's effectiveness, safety, opponents, and alternatives (including school fluoridation) are included. Free copies can be obtained from the author: Thomas G. Reeves, P.E., Fluoridation Engineer, Dental Disease Prevention Activity, Center for Prevention Services, U.S. Public Health Service Centers for Disease Control, Atlanta, GA 30333. (Telephone: 404-329-1833)

"Natural Foods Month." The National Nutritional Foods Association has urged health food industry personnel to ask their local and state officials to proclaim April as "National Foods Month." Promotional materials for retailers include coloring books, sample press releases, ad slicks, and posters opposing food irradiation.

Plans for giant educational center suspended. Citing market pressures, Tishman Speyer Properties of New York suspended plans for EcuMed, its proposed billion-dollar medical exposition center. The facilities were to include a high-tech learning/resource center, a museum of health technology, a 1,500-room resort hotel, a conference center that could handle more than 3,500 meetings a year, and an exhibition center that could eventually house up to 1,500 exhibitors. The project, which was expected to draw 600,000 professionals, administrators and suppliers annually, had been scheduled to open in 1988 on a 293-acre site near Fort Lauderdale, Florida. It would have been the largest health care educational facility in the United States.

CURRENT PERSPECTIVES ON FIBER

George E. Demetrakopoulos, M.D., M.P.H.

Dietary fibers, also referred to as "bulk" or "roughage," are substances found in foods that cannot be digested in the stomach or small intestine and therefore pass undigested from the mouth to the large intestine (colon). Although some fibers come from animal sources such as chicken cartilage, meat tendons, and the shell of soft-shell crabs, most come from plant products such as fruits, vegetables, roots, seeds or grains. Fibers can appear thready (in celery or spinach, for example), granular (in pears or berries), or as sheets (in onions or grain skins).

Scientists classify fibers into five main groups: celluloses, hemicelluloses, pectins and gums/mucilages—all of which are complex carbohydrates—and the noncarbohydrate lignins (see table of dietary fibers). Celluloses, hemicelluloses and lignins are components of wood as well as edible plants. They are tough, fibrous and insoluble in water. Pectins and gums can dissolve in water to form viscous or gel-like textures.

"Dietary fiber" and "crude fiber" are not identical terms. "Crude fiber" remains after a food sample is treated in the laboratory with a solvent, hot acid, and hot alkali. It is composed mainly of the lignin and most of the cellulose in the food being analyzed. But crude fiber is only a small part of dietary fiber, so its measurement has limited usefulness. The word fiber itself can be misleading since not all components of dietary fiber appear "fibrous," while some foods that contain recognizable fibers, such as muscle meats, do not yield indigestible residue and therefore are not part of dietary fiber.

Usually, several types of fibers are present in a given food, but often one type predominates. The amounts can vary with the ripeness of the food, where it was grown, how long it was stored, and how it was processed. For example, an unripened apple contains only a small amount of pectin, a ripened apple has much, while a mealy, overripe one has no pectin at all because of breakdown by the apple's own enzymes. With vegeta-

bles like cauliflower, the more mature or woody they become, the more lignin is present in their stalks. Fibers can be destroyed or altered when extracted from foods or during processing, as is the case with canned or frozen fruits and vegetables. It is not known whether fibers extracted from foods have the same effects within the body as those from intact foods.

A century ago, fibers were considered an unnecessary part of the diet, and painstaking efforts were made to refine many foods by removing their fiber. During the 1970s, after D.P. Burkitt, M.D., and H.C. Trowell, M.D., reported that certain African tribes whose diets were rich in fiber did not suffer bowel disorders common in the Western world, scientists realized that dietary fibers are an essential part of a healthy diet. However, uncertainties over the exact amount needed and the role of fiber in such high-fiber diets still make most of us cautious about suggesting what daily intake would be optimal.

Today, stimulated by news of President Reagan's colon cancer and reports that followed on the role low-fiber diets may play in increasing the risk of such cancer, recommendations for fiber-rich diets seem to be everywhere. But there is still much confusion about how much fiber is needed, what kind is best, and when it should be consumed. Experts agree that fiber is important, because with too little there is a greater risk of developing disorders, the most serious being colon cancer. But they also recognize that too much fiber can cause nutritional deficiencies or perhaps even increase the risk for stomach cancer! [See *National Cancer Program*, NIH Publication Number 85-2765, 1985, p. 143.] The National Cancer Institute, in its booklet *Diet, Nutrition & Cancer Prevention: a guide to food choices* [NIH Publication No. 85-2711, November 1984], states that the average American consumes about 10-20 grams of fiber daily. But recent surveys as well as detailed dietary records from my own patients suggest that this figure may be far too high.

Surprisingly, the U.S. Department of Agriculture

DIETARY FIBERS OF PLANT ORIGIN

CHARACTERISTICS	MAIN ACTIONS	FOOD SOURCES
CELLULOSES:		
Fibrous Soluble in water Absorb water readily Main component of the plant cell wall Most common fibers in nature	Make stools bulkier & softer Move stools quicker Help relieve constipation Speed elimination of toxic substances from the gut Do not lower blood cholesterol Block mineral absorption	Cereal bran Whole grain flours Cereal grains Skin of fruits Woody parts of vegetables Beans, seeds or nuts
HEMICELLULOSES: Intermingle with celluloses to form stalks, hulls, husks, etc.		
A. MIXED: Resemble celluloses in several aspects		
B. PENTOSANS:		
A specific group of hemicelluloses	The only fibers that have been associated so far with reducing the risk of cancer of the large bowel	Fruits: berries, prunes, bananas, cherries, plums, apples or pears. Vegetables: cauliflower, onions, broccoli, endives, mushrooms spinach, potatoes, eggplant, carrots, pumpkins or beans. Roots, leaves, etc.
PECTINS		
Soluble in water Gel-like plant fibers	Lower blood cholesterol Moderate effect on stool elimination. Do not block mineral absorption	Fruits: apples, pears, citrus fruits or figs. Vegetables: beets, okra, carrots, olives, etc.
GUMS & MUCILAGES		
Sticky and gummy Form gels when dissolved in water Found on trees like "teardrops" or collected by scraping the bark (like rubber)	Some help lower blood cholesterol Some help control blood sugar in diabetics Do not bind to minerals	Extracts from seaweed carob seeds and gum-trees. Oatmeal Dried beans Thickening agents (stabilizers) in salad dressings, ice cream, spreads, ketchup, etc.
LIGNINS		
Woody parts of plants Cannot be fermented by bacteria in the colon	Bind to bile acids protecting the bowel from irritation and can help lower blood cholesterol Make stools move faster Bind to minerals, block their absorption, and can cause mineral deficiencies	Whole grains Whole grain flours Bran and hulls Seeds of berries, figs, guava and tomatoes Woody parts of vegetables: cauliflower, cabbage, etc.

(USDA), the Department of Health and Human Services (DHHS) and the National Cancer Institute (NCI) are in conflict on how much fiber should be consumed daily. NCI, without specifying which types of fiber or citing any controlled studies, recommends that Americans consume 25-35 grams of fiber daily. USDA and DHHS, while agreeing that Americans should increase their fiber intake, feel that it is premature to set specific goals. Their *Dietary Guidelines for Americans* (DGAs) issued jointly in October 1985 state: "It has been suggested that diets low in fiber may increase the risk of developing colon cancer. Whether this is true is not yet known. How dietary fiber relates to cancer is one of many fiber topics under study. Some others are the fiber content of foods and the amount of fiber we need in our diets." USDA and DHHS are aware of the problems that too much fiber can cause and are concerned about possible unknown risks.

The DGAs are in agreement with the National Academy of Sciences report on *Diet, Nutrition, and Cancer* which was prepared under an NCI contract. This report states that there is "no conclusive evidence to indicate that dietary fiber exerts a protective effect against colorectal cancer in humans," although it does point out that one fiber component (pentosans, discussed later in this article) may protect against such cancer.

Unfortunately, a number of food manufacturers, consumer advocacy groups and others have jumped on the bandwagon and begun flooding the public with unfounded proclamations that consuming 25-45 grams of fiber daily will lower the risk of developing cancer.

Since various types of fibers work differently, it is important to know how they work to avoid the perpetuation of myths. One such myth is the belief that bran is the best and only source of fiber, when actually it is neither, and in some cases can even do more harm than good.

Fibers do their work in the digestive tract as part of a blended mixture. Once swallowed, they contribute bulk and some swelling of stomach contents as water is absorbed. Soluble forms of fiber (pectins and gums) increase the viscosity of stomach contents and slow down emptying of the stomach.

Once past the stomach, fibers absorb intestinal juices, forming soft and bulky matter which moves smoothly and swiftly. During this passage, celluloses, lignins and hemicelluloses absorb or bind substances, including toxic or inert products and even important nutrients, blocking their absorption.

In the colon, some fibers (primarily pectins and gums) are fermented and degraded by bacteria and yeasts, while others (primarily the celluloses and other insoluble fibers) are not. When fibrous foods are fermented, gas is released. Fibers that are not degraded act like blotting paper to absorb fluids within the intestines, soften stools and increase their bulk. This speeds up their elimination, which means that billions of bacteria

and yeasts as well as irritating wastes are excreted faster. Thus, with soft stools, there is less congestion and irritation in the colon and very little strain during bowel movements.

Straining during bowel movements can cause hemorrhoids, varicose veins and even diverticulosis, a condition where the wall of the colon weakens and forms small finger-like outpouches. Food and bacteria trapped in these pouches can cause diverticulitis, an inflammatory disorder common among elderly persons who have lived on low-fiber diets. By stretching the intestinal wall, bulk causes the diverticula to open and release trapped wastes, thus preventing diverticulitis. For similar reasons, diets rich in bulk-forming fibers can benefit patients with irritable colon.

In patients with high blood cholesterol, diets rich in pectin or lignin can help lower blood cholesterol levels and thus may help to reduce the risk of heart attacks. Fiber-rich diets smooth the absorption of sugars into the blood and can help to reduce the insulin needs in diabetics or the frequency of symptoms in hypoglycemics. Fiber-rich diets can also help to control high blood pressure.

Scientists suspect that diets rich in pentosans—a type of hemicellulose—may lower the risk of colon cancer, but the evidence is limited and not yet definitive. Pentosans—one component of plant cell walls—are common in fruits (e.g., apples, berries, bananas, citrus fruits and pears), vegetables (e.g., carrots, mushrooms, olives, onions, spinach, eggplant and broccoli), and whole wheat products. [See *World Review in Nutrition and Dietetics* 32:96, 1978.] A surer benefit from eating such foods is that they are low in fat and rich in vitamins A and C and beta-carotene, characteristics thought to help lower the risk for certain cancers.

How much fiber should be consumed daily by a healthy person? A daily intake of 25-45 grams of fiber from ordinary foods is next to impossible. To achieve this, most Americans would have to add to their usual diet the equivalent of several boxes of corn flakes or rice cereal every day. The NCI, in an attempt to make its recommendation for increased fiber consumption more realistic, joined forces with the Kellogg Company in a nationwide advertising campaign promoting consumption of food products such as bran cereals. (Bran is the broken coat of the cereal grain.) On its cereal boxes,

Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

Kellogg printed preventative health tips as though they applied to the enclosed product rather than dietary fibers in general [see NF 2:69]. No warning was given that overconsumption of such products can cause serious health troubles. NCI, aware of these problems, is reportedly reconsidering its position.

When bran is eaten, either in breakfast cereals, tablets, wafers, powders, biscuits, or as part of whole foods, it creates bulk which makes the stool move faster and relieves constipation. But bran can also bind essential minerals like zinc, calcium, iron and magnesium so that they are not absorbed into the body. Consequently, if excess bran is eaten at the wrong time (even a tablespoon of bran with or soon after each meal), it can lead to deficiencies in these elements. In addition, some animal studies show that during carcinogen exposure, high-bran diets enhance the development of colon cancer! [See *Cancer Research* 43:4057, 1983.]

Much better sources of bulk include fruits with their skins, vegetables with their stalks, beans with their coats, seeds, and whole grains. A few berries, a banana or a cup of dried beans can provide ample bulk along

with several essential nutrients—which bran lacks.

Although specific goals for daily fiber consumption must await further research, experts agree that fibers are an essential part of a balanced diet. To assure that your diet is not low in fiber, include in your daily menu a few servings of fiber-rich unprocessed foods such as fruits, vegetables, legumes and whole grain or seed products. If you can't eat such foods but need fiber supplements for a specific condition, ask your doctor which fiber type is best for you. (Examples are Metamucil, Pectin, Bran, FiberMed and Mixed Fibers.) If you take fiber supplements, take them several hours before or after meals; otherwise they may bind minerals in the foods you eat, preventing their absorption and possibly causing nutritional deficiencies.

Dr. Demetrakopoulos, a board-certified specialist in clinical nutrition, is medical director of the Medical Nutrition Center of Greater Washington, D.C. He is president of the American Academy of Certified Medical Nutritionists and has held an Expert appointment at the National Cancer Institute.

EDITOR'S NOTE

FURTHER BACKGROUND HISTORY ON "FIBER"

There is considerable inconsistency in the literature concerning the use of the term "fiber." It wasn't until the 1970s that "dietary fiber" became an important subject within the study of human nutrition. During prior decades, animal nutritionists had been determining "crude fiber" in feed. The value of "roughage" in the diet has been recognized since Hippocrates identified bran as a laxative as early as 400 B.C.

"Crude fiber" is defined as the residue remaining after treatment with hot 1.25% sulfuric acid, 1.25% sodium hydroxide, and alcohol. It consists primarily of chemically inert residues such as lignin, cellulose and trace amounts of other polysaccharides. Only a fraction (as little as one-seventh) of the total "dietary fiber" is "crude fiber." Crude fiber is a term of laboratory and

chemical analytical significance. To relate fiber to human nutrition, another definition was needed.

D.P. Burkitt, the British medical researcher who has done more than anyone else to focus attention on fiber, defined it as "mostly celluloses and lignin and lignin material, varying in different plants according to type and age. Basically, it passes through the small intestine undigested by our enzymes."

Other researchers of the 1970s have improved this definition so that "dietary fiber" is most commonly defined as that part of plant material in the diet that is resistant to digestion by the secretions of the gastrointestinal tract. Under this definition, dietary fiber consists of variable proportions of complex carbohydrates, such as celluloses (unbranched polymerized glucose), hemicelluloses (highly branched pentose polymers), pectins (polymerized galacturonic acids), and lignins, which are not carbohydrates but enormously complex

Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Linda K. DeBruyne, M.S., R.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Suzanne Pelican, M.S., R.D.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.

polymers of oxyphenylpropane units that occur in close association with the structural carbohydrate and hydrocolloid components of many plant cells.

Some scientists, including Dr. Demetrakopolous, believe it is advantageous to include certain animal fibers within the definition [see Van Soest, P.]: Component analysis of fiber in food, *American Journal of Nutrition* 31:75-76, 1978]. That may be true in theory, but since most Americans consume insignificant amounts of these fibers, it has not been customary to include them in discussions of fiber.

Crude fiber can easily be measured by traditional chemical analysis. The amount of dietary fiber can be measured by subjecting foods to chemical processes similar to those taking place in the digestive tract. But the presence of bacteria in the large intestine makes it impossible to measure the effects of human digestion on fiber by doing "balance" studies that compare the amount of fiber ingested in food to the amount excreted in the feces. There are two reasons for this. First, some

of the fiber that is not digested in the mouth, stomach or small intestine is fermented by bacteria in the large intestine. Second, bacteria also make fiber which, when excreted, cannot be distinguished from fiber of food origin. Bacterial cell walls contain fiber which is created from intestinal contents when the bacteria multiply. Bacteria also make mucopolysaccharides. Since one-third of dry (solid) fecal matter is of bacterial origin, it is clear that bacteria contribute a substantial proportion of the fiber in human feces.

Claims of potential benefits from fiber in the diet are still being researched. As many as 30 human diseases and disorders have been mentioned as benefiting from increased fiber intake. It remains to be seen what fiber fraction(s) may benefit which disorder(s), how such benefit occurs, what the optimal intakes might be, and whether any effect of dietary fiber will benefit everyone.

—Manfred Kroger, Ph.D.

CONSUMER REPORTS BLASTS "VITAMIN PUSHERS"

In December 1985, the FDA and the Pharmaceutical Advertising Council began a major advertising campaign of public service ads attacking quackery and encouraging people to ask their doctor or pharmacist about claims that seem too good to be true. Money used for the campaign came from donations of drug manufacturers plus a grant from the FDA. The "ask your pharmacist" theme was included despite warnings from independent consultants for the grant proposal that: 1) some companies supporting the campaign were themselves involved in misleading advertising of vitamin products; and 2) virtually all pharmacies sell irrationally formulated "food supplements" and thus are promoting and profiting from quackery.

These problems are illustrated in a devastating exposé in the March issue of *Consumer Reports* magazine. Called "The Vitamin Pushers," the six-page cover story describes how reporters from the magazine visited 30 drugstores in Pennsylvania, Missouri and California, complained of feeling tired or nervous, and asked whether a vitamin product might help. Seventeen were sold a vitamin product and one was sold an amino preparation. Only nine of the 30 pharmacists suggested that a doctor be consulted.

To explore how pharmacy students are taught to handle this type of situation, questionnaires were sent to the deans of all 72 U.S. pharmacy schools. Almost all of the 51 who responded thought that pharmacists should attempt through questioning to identify possible causes of tiredness or nervousness and ask whether a doctor had been consulted. More than half said that pharmacists should advise that vitamins are unlikely to help either condition.

CU's article provides basic vitamin information, refutes various megavitamin myths, and attacks the promotion of "nutrition insurance," "stress vitamins" and "sports vitamins." The article concludes with these recommendations:

- Rather than taking vitamins for "insurance," consumers should evaluate their diet to determine whether they are eating a variety of foods from the Basic Four Food Groups. Those unable to figure this out are advised to keep a food diary for a week and ask a registered dietitian or physician whether anything is missing. If anything is, the best course of action will probably be to improve eating habits.

- Amounts of vitamins that exceed the Recommended Dietary Allowances (RDAs) should not be taken without medical advice.

- Doctors or nutrition consultants who recommend vitamins as cure-alls should be avoided.

- The FDA should evaluate claims made by promoters of "stress vitamins" and publicize its findings. The agency should also work with the pharmaceutical industry to develop voluntary standards for vitamin product formulations.

- The FTC should try to stop misleading advertising for "nutrition insurance," "stress tablets," "sports vitamins," and the like.

- The pharmaceutical profession should recognize the pushing of unnecessary supplements as an ethical issue that deserves its serious attention.

Copies of the March *Consumer Reports* can be obtained by sending \$3 to Back Issue Dept., Consumer Reports, P.O. Box 2840, Boulder, CO 80322.

BRIEFS

Hair analysis statement. The public affairs committee of the American Institute of Nutrition/American Society for Clinical Nutrition has issued a position paper on hair analysis [*AIN Nutrition Notes*, 21(4):10-11, Dec. 1985]. The paper concludes that although hair analysis may have some value for comparing population groups as to status of various minerals or assessing exposure to toxic heavy metals, assessment of individual subjects appears to have "almost insurmountable difficulties." For this reason, says the paper, hair analysis might best be reserved for experimental studies designed to evaluate its potential as an indicator of nutrition status and perhaps for some public health surveys. Noting that about 100 articles per year are published on hair analysis, one nutritionist who reviewed the position paper suggested that the test's inherent limitations make much of the research useless.

Scientific consortium ends. The National Nutrition Consortium has ceased operations due to inadequate funding. It was founded in 1973 with the hope of forging an organization of nutrition-related societies that could represent the larger nutrition community in contacts with government and the public. Its original members were the American Institute of Nutrition, the American Society for Clinical Nutrition, the American Dietetic Association, and the Institute of Food Technologists.

Advertising standards. During the past few months *Prevention* magazine has greatly expanded its list of unacceptable advertising. The current list includes: tobacco products; alcohol beverages; diet pills; "miracle" or crash diet programs; pep pills (caffeine); sleeping pills; homeopathic remedies; herbs touted to cure disease; ginseng; vitamins in amounts believed dangerous; "natural" vitamin C; dubious products such as bee pollen, cell salts, RNA/DNA, spirulina and octacosanol; baldness remedies; unapproved medical devices; hair analysis; mail-order nutrition courses offering certificates or diplomas; and any ad asserting that natural vitamins are more effective than synthetic ones. According to executive editor Mark Bricklin, "These guidelines have cost us large amounts of revenue, especially in the diet product area. But we are proud of this policy, and that we were one of the very few magazines that refused to carry ads for the popular liquid predigested protein and starch blocker diet aids a few years back."

Ultramarathon complication. Two experienced runners were found to have dangerously low blood sodium levels following a 100-kilometer run in temperatures up to 89°F. [*Hyponatremia and Ultramarathon Running*, *JAMA* 255:772-773, 1986]. Both became severely disoriented, and one had a grand mal (epileptic) seizure. Doctors treating the runners attributed the problem to a combination of salt loss through sweating plus excessive intake of water or electrolyte replacement glucose (one drank 20 liters and the other drank 24 liters). Other cases have been reported in which blood sodium levels dropped in triathlon competitors. Reprints of the *JAMA* article can be obtained from S. Robert Lathan, M.D., 1938 Peachtree Rd., N.W., Suite 606, Atlanta, GA 30309.

End of health spa rule. The Federal Trade Commission voted unanimously to terminate its rulemaking proceeding (which began in 1975) on health spas in favor of case-by-case enforcement. The proposed rule had provided for pro-rata refunds on memberships, a 3-day cooling-off period for rescinding contracts, a 5% limit on payments before a facility has actually opened, and a 2-year limit on the duration of membership contracts.

Major diet and health study planned. Male pharmacists, dentists, veterinarians, podiatrists, optometrists and osteopathic physicians between the ages of 40 and 75 are being invited to participate in a 5-year study of diet and lifestyle habits. The \$2.6 million study, funded by the National Institutes of Health, will be conducted by Harvard's School of Public Health over a 5-year period—or longer if funding is renewed. The researchers expect that 60,000 to 65,000 enrollees will stick with the study, which will involve filling out lengthy questionnaires every two years. More than 100 questions will be asked about food intake.

Antibiotics in animal feed. Shortly before leaving office, outgoing HHS Secretary Margaret Heckler denied the Natural Resources Defense Council's petition to ban use of subtherapeutic use of penicillin and tetracyclines in animal feeds. These antibiotics are used to increase the amount of meat that can be produced from a given amount of feed and help to prevent bacterial disease in the animals [see NF 2:63]. H.R. 616, introduced by Rep. James Weaver (D-OR), would accomplish the same purpose as the NRDC petition.

Information on low-calorie sweeteners. Several free brochures are available from the Calorie Control Council Suite 500-D, 5775 Peachtree-Dunwoody Road, Atlanta, GA 30342. The brochures are: *Sweet Choices*, *Aspartame*, *Saccharin*, *Epidemiology* (a summary of human studies that support the safety of saccharin), and *Alternative Sweeteners* (facts on 12 low-calorie substances and 7 other alternatives to sucrose). A quarterly newsletter is also available. The Council, established in 1966, is an international association of 60 manufacturers and suppliers of low-calorie foods and beverages.

Irradiation update. Regulations permitting irradiation of pork (to kill trichinosis organisms) and fresh fruits and vegetables (to kill pests and prolong shelf life) appear close to final approval, and the U.S. Department of Health and Human Services is considering approval for poultry as well. Irradiated foods must now carry the word "picowaved" on their label together with the international logo pictured below. The logo, which depicts a stylized rose with two petals, was developed a few years ago in the Netherlands and is used on many packaged irradiated foods abroad.

Osteoporosis report. The American Council on Science and Health (ACSH) has issued a 28-page report on the prevention of osteoporosis (thinning of the bones). Inadequate calcium intake and lack of exercise are major contributing factors. Other possible risk factors include short stature; underweight; alcoholism; cigarette smoking; and excessive intake of protein, fiber, oxalate or caffeine. The report notes that adequate calcium can be obtained by including generous amounts of dairy products in the diet, but that most women fail to consume the Recommended Dietary Allowance for calcium. ACSH also advises women approaching menopause to discuss with their doctor the risks and benefits of postmenopausal estrogen therapy. For a free copy of the report, send a self-addressed stamped (39¢ postage) 4"x9½" envelope to Osteoporosis Report, ACSH, 47 Maple Street, Summit, NJ 07901.

College dietary dispute resolved. According to *Vegetarian Times*, the University of Maryland agreed to temporarily allow Hsia Jung Chang to prepare food in her dormitory room. Ms. Chang, a vegetarian, had been unwilling to pay \$700 to eat in the university's dining hall as is normally required of freshman and sophomores who live on campus. (Although vegetarian options were available, she had rejected them as inadequate.) Threatened with eviction, she received widespread publicity. The dispute was resolved by an agreement under which Ms. Chang could continue eating in her room for one semester but would provide the university with a weekly list of foods from which it would prepare her meals—to be eaten in the dining room. She would also pay 10% additional for the extra service.

Fat suction. According to an article in *Medical World News* [Dec. 23, 1985], more than 1,000 board-certified plastic and reconstructive surgeons are using liposuction, an operation in which unsightly localized areas of fat are sucked out through incisions in the buttocks, abdomen, face and other areas. The procedure is usually done on an outpatient basis using local anesthesia.

Suit against raw milk critics dismissed. The \$110 million lawsuit by Alta-Dena Dairy against John Bolton, M.D., and the American Academy of Pediatrics has been summarily dismissed by Marin County Superior Court Judge Henry Broderick who ruled that the dairy's charges were without merit. [See NF 2:64 for details.] Dr. Bolton believes that the suit was merely an effort to intimidate him and prevent him from continuing to warn consumers about the hazards of unpasteurized milk, especially to pregnant women, infants, and the elderly. Last September, the Alameda County Superior Court issued a preliminary injunction ordering the dairy to stop promoting its products as "the world's safest and finest" and to stop recommending them for infants and invalids [see NF 2:87]. In October, following a fatal epidemic of listeriosis attributed to raw milk contamination of Jalisco cheese [NF 2:64], the Los Angeles Grand Jury asked the California Department of Agriculture and Foods to consider banning raw milk sales in California. In the December *Western Journal of Medicine*, James Chin, M.D., M.P.H., noted that more than 95% of milk in the United States is pasteurized, but more than 95% of milk-borne disease outbreaks are due to raw milk. Despite the negative publicity, many AIDS patients admitted to San Francisco General Hospital have said they were drinking raw milk with the hope it could help them.

“STRENGTHENING THE IMMUNE SYSTEM” — A GROWING FAD

Health Foods Retailing (HFR) reports in its October issue that vitamin sales have increased sharply in response to Dr. Berger's *Immune Power Diet*, by Stewart M. Berger, M.D., a book purporting to tell how to “re-build your immune system” with dietary change and supplementation with vitamins, minerals and amino acids. The magazine's editor predicts that “as the general public becomes aware of the need to refurbish their immune systems, there will be a growing need for vitamin suppliers who can relate to a more sophisticated buying public. No longer will mass merchandisers be able to arbitrarily declare a trend in vogue and stock accordingly. The newly emerging buying public will understand the interlocking relationships between the thymus, T cells, antibodies and macrophages and the role vitamin supplementation can have in allowing the immune system to work effectively.”

Public concern about the immune system has been stimulated by the problem of Acquired Autoimmune Deficiency Syndrome (AIDS). According to HFR, this plus the discovery that President Reagan had developed cancer forced the domestic population as a whole “to admit the possibility that large numbers of Americans are being stripped of their ability to resist infections and, even more psychologically damaging, that no one, not even the President, was beyond the reach of many diseases.”

Stewart M. Berger, M.D., is a 32-year-old psychiatrist who represents himself as “a specialist in nutritional medicine treating immune disorders, food allergies and obesity.” He practices in Manhattan, writes a weekly column for the *New York Post*, and has written for many magazines, including *Parade*. The initial visit to his office, which costs \$375, includes cytotoxic testing and consultations with Berger and a staff nutritionist. Among other things, his newspaper columns recommend a minimum of 2 grams of vitamin C daily for everyone and suggest that about 40% of American adults are suffering from hypothyroidism. Berger's columns also indicate that he treats AIDS by detecting supposed intolerance to various foods and prescribing dietary changes plus vitamins, minerals and exercise. However, allergy experts such as Gabe Mirkin, M.D., have responded to Berger's theories by pointing out that although immunity is decreased in vitamin deficiency states, there is no evidence that adequately nourished individuals will increase immunity by taking supplements. William I. Bennett, M.D., editor of the *Harvard Medical School Health Letter* says Berger's book “is selling a collection of quack ideas about food allergies that have been around for decades.”

According to *People Magazine*, Berger's interest in diet was the result of his own weight problem (he weighed 420 prior to entering medical school and lost half this amount over a 1½-year period). His first book, *The Southampton Diet*, was published in 1981. Berger asserts that food allergies weaken the immune system and that almost everyone is allergic to some foods. His recent appearance on *The Phil Donahue Show* reportedly triggered sales of more than 50,000 copies of *Dr. Berger's Immune Power Diet* during the following three days. Over 300,000 copies are now in print, and a paperback edition is scheduled for release next year. So it is clear that a major new fad is under way.

Health News & Review, a bimonthly “health food” newspaper for the general public, reports in its November/December issue that, “there is now a growing public recognition that AIDS, cancer, arthritis, even colds—very nearly the whole spectrum of infectious and degenerative diseases—become manifest dangers only when the immune system is depressed. Strengthening the immune system—which can be briefly described as an ‘army’ of cells called T-lymphocytes which attack hostile organisms of substances—is clearly emerging as a health priority.” The article illustrates how promoters of a wide variety of unproven nutrition practices relate them to supposed immunological factors. Sugar, food allergies and mercury fillings, for example, are said to weaken the system while vitamin C, zinc, beta-carotene, and certain herbs are said to strengthen it.

In line with these ideas, many combinations of vitamins, minerals and/or herbs are being marketed with claims that they boost immunity. Although products of this type are unapproved new drugs, the FDA has shown no interest so far in attempting to remove them from the marketplace.

GUIDELINES FOR AUTHORS

CONSUMER ATTITUDES TOWARD FOOD

Robert O. Herrmann, Ph.D.
Rex H. Warland, Ph.D.
Marianne Goodfellow

To better understand the role of food in people's lives, Penn State researchers conducted a "food involvement" survey in December 1984. Using random-digit dialing to reach both listed and unlisted telephone numbers, interviewers contacted food shoppers from 322 households in Philadelphia and four surrounding counties. Most of those interviewed were women.

Thirty of the interview questions centered on meal planning, food shopping, food preparation, nutrition and health concerns, interest in new products and recipes, social uses of food (e.g., as gifts and for entertaining guests), and use of media sources dealing with food and nutrition.

Through computer cluster-analysis, the researchers grouped shoppers into four broad response categories: "involved," "disinterested," "standpatters" and "economizers."

The involved category of shoppers was the largest group identified, making up 33% of those surveyed. These shoppers are involved with almost every aspect of food.

Of all four groups, the involved are the most concerned with planning and managing their food purchases. They indicated that they usually make grocery lists and plan menus before shopping, check their menus for nutritional balance, and economize as much as possible on food purchases. The involved like to try new food products and new recipes, and are heavy users of media information about food.

The involved are very concerned about nutrition and health. Most try hard to avoid foods high in sugar, salt, fat and cholesterol, and calories, and to eat plenty of vegetables, fruits, and high-fiber foods.

The involved also reported the greatest social use of food. They invite guests for meals and snacks more often and give gifts of food more frequently than do the

other groups. In addition, they have little interest in using easy-to-prepare foods just to reduce preparation time.

Consumers in the disinterested group, who made up 22% of the households surveyed, are radically different from the involved consumers. They are generally not concerned about nutrition, new food products, and new recipes. However, they do express some interest in saving time and effort in food preparation. Of all the groups, they are the most interested in easy-to-prepare foods.

The standpatters' distinguishing characteristic is their lack of interest in changing shopping or eating patterns. Accounting for 23% of the households surveyed, standpatters reported almost no use of food information sources. They rarely watch television programs or read magazine articles about food and they seldom read the newspaper food pages. Nor are they likely to pick up recipe booklets distributed in grocery stores. Standpatters seldom try new recipes or food products, and they are the least likely of all groups to tell others about new recipes or products.

Despite their lack of interest in changing their food shopping and eating patterns, the standpatters did report nutritional concerns. Many try to avoid foods high in salt, sugar, calories, fat and cholesterol, and to eat plenty of fruits and vegetables.

The outstanding characteristic of the economizers, who comprised 22% of survey respondents, is a wish to minimize food costs. They expressed the most likely to shop for groceries at several stores in order to find the best values. Next to the involved, economizers are the most active readers of food ads.

Economizers expressed great concern about health and nutrition. Many try hard to eat plenty of vegetables and fruits and to limit foods high in salt,

sugar, fat and cholesterol, and calories. However, they are not particularly interested in menu planning. Only about 25% plan their menus before grocery shopping or check their menus regularly for nutritional balance. A large proportion of economizers said they prefer foods that are quick and easy to prepare.

Compared with the involved and even the disinterested, economizers have minimal interest in new recipes or new food products. Occasionally, however, they do tell others about new recipes and food products.

Economizers frequently read newspaper food pages and magazine articles on food. However, very few reported viewing television programs on food or picking up recipe booklets distributed in grocery stores.

A look at the socioeconomic characteristics of the four groups sheds some light on their patterns of food consumption. Of all groups, the involved have the highest levels of income and formal education. Their responses also show them to be physically active. A majority have home vegetable gardens or preserve vegetables for home use. The involved category includes the most people on weight-reducing diets.

The disinterested group includes the largest proportion of young shoppers (about half of those under 40 years old), males, and one-person households. Most people in this group do not feel it is worthwhile to fuss over food for just one person. A number of the disinterested reported being on health-related diets (low-sodium or cholesterol-lowering diets).

The standpatter group includes many one-person households, a comparatively high number of males, and the largest proportion of older adults (25% aged 70 or older). A substantial number of standpatters are on health-related diets.

Economizers have relatively low incomes and less formal education than the other groups. This group includes many non-whites and a sizable number (23%) of divorced or separated persons. Many economizers are on weight-reducing diets.

The survey paid special attention to the four groups' use of vegetables as a representative example of food involvement.

People in the involved group indicated that they usually eat fresh vegetables, and almost all reported eating vegetables every day. Therefore, very few involved shoppers feel the need to eat more vegetables.

The involved seem willing and able to make an extra effort to get good-quality vegetables. They are active gardeners and preservers, as well as frequent shoppers at roadside stands, farmers' markets, and urban produce specialty stores.

The involved are strongly interested in learning new ways to serve vegetables and in making homemade vegetable mixtures. Their responses show them to be

the most willing to spend extra time in obtaining and preparing vegetables.

Of all the groups, the disinterested were the most likely to report eating frozen or canned vegetables. This choice reflects their expressed interest in saving time and bother in food preparation. The disinterested eat vegetables less frequently than do consumers in other categories. Many recognize that they should be eating more vegetables, but most lack the motivation to do so.

Those in the disinterested group seem unwilling to spend extra time or effort to get vegetables. Few go to special sources to buy produce, and few garden or preserve. The disinterested expressed little interest in learning new ways to serve vegetables.

Standpatters include many people who reported regular use of fresh vegetables. However, in line with their lack of interest in dietary change, very few expressed interest in new ways to serve vegetables.

Economizers include a substantial number of people who said they usually use frozen vegetables. This preference reflects the group's concern for saving preparation time. The economizer group also has a relatively large proportion of gardeners, who are motivated perhaps by the desire to save money.

The characteristics of the four groups and the differences in their use of food information sources have important implications for planning promotional efforts. For vegetables, such efforts would benefit both the food industry and consumers. Many of those surveyed would gain nutritionally from changing their eating patterns, particularly by eating more vegetables.

The involved group's interest in and enthusiasm for food make them an obvious target for promotional efforts. The involved use media sources more than any other category of shoppers. Newspaper food pages are the most frequently used source, followed by magazine articles on food, booklets distributed through grocery stores, and television programs.

Of the four groups, the involved are the most familiar with the Pennsylvania product symbol. (This is the label used by producers of Pennsylvania food products under the supervision of the Pennsylvania Department of Agriculture.) They also react the most favorably to products bearing the symbol. Promotional campaigns aimed at the involved are sure to benefit from this group's role as information providers to others. Fifty-eight percent of the group say they frequently tell others about new recipes and new food products.

The disinterested's low media use and lack of involvement with food make them difficult targets for promotion. Their chief interest is saving preparation time and effort.

Promotion geared to the standpatters also appears difficult, since they seldom use media sources on food

and they do not seem interested in changing their shopping and eating patterns. However, one topic that does interest this group is health and nutrition.

The economizers' ability to make changes is clearly limited by constrained finances. This factor, along with their need to save preparation time, would have to be considered in any targeted promotional effort. Although the economizers expressed little interest in new recipes and new products, they frequently read newspaper food pages and magazine articles on food. Along with economizing, nutrition and health are strong concerns of this group.

Promotional barriers are tough to overcome. With the right appeal, however, each of the four groups can be reached. Promotion based on nutrition and health will appeal not only to the involved, but also to the standpatters and economizers. Money-saving ideas will appeal to both the economizers and the involved. The appeal with the greatest potential to reach the disinterested is the opportunity to save time and bother in meal preparation.

The survey's identification of a higher-income, more educated group (the involved) as the primary tar-

get for promotional efforts is probably not surprising. Many marketing studies have identified similar groups as promising promotional targets. What is surprising are the insights the survey provides into why other groups are not especially promising targets for promotional efforts. While the involved are open to and willing to consider dietary change, the other groups either are reluctant to change the way they eat, unable to afford significant changes, or disinterested in food and in the idea of making changes.

Surveys of this type are useful to the food industry for developing new products and planning retailing and promotional efforts. They can also be valuable to educators who wish to help make wiser food choices.

Dr. Herrmann is professor of agricultural economics; Dr. Warland is professor of rural sociology; and Marianne Goodfellow is project coordinator for the gerontology center and former instructor in rural sociology at The Pennsylvania State University. From 1974 through 1977, Dr. Herrmann served on the board of directors of Consumers Union, publisher of *Consumer Reports Magazine*.

A PROFILE OF THE FOUR SHOPPER GROUPS.

	Involved	Disinterested	Standpatters	Economizers
Key involvement characteristics	Great interest in almost all aspects of food	Little interest in most aspects of food	Little interest in changing food patterns	Great interest in economizing on food purchases
	Careful planners and shoppers	Interest in economizing on food	Little interest in new products, recipes, or information on food	Little interest in new products or recipes
	Substantial interest in new products, recipes and information on food	Substantial interest in saving time and effort in food preparation	Concern about nutrition and health	Some interest in information on food
	Strong concern about nutrition and health			Concern about nutrition and health
Key socio-economic characteristics	Highest incomes	Largest proportion of one-person households	Many one-person households	Lower incomes Less formal education
	Most formal education Many on weight-reducing diets	Largest proportion of young people	Fewest children	Many divorced or separated
		Smallest proportion of married couples	Many on health-related diets	Largest proportion of nonwhites
		Many on health-related diets	Large proportion of older people	Many on weight-reducing diets

CANDIDIASIS PROMOTION INCREASES

Nature's Way Products, Inc., of Springville, Utah, is expanding its promotional campaign through ads and in-store displays for Cantrol, its "complete program to fight yeast infections." On February 25th, Nature's Way wrote to retailers that the March issue of *Redbook Magazine* would carry a full-length feature article on yeast infections and that an ad in the same issue would "specifically instruct the consumer to go to their local health food store to purchase Cantrol."

Ads for Cantrol invite people to take simple self-tests which question whether they have various common symptoms and have ever taken antibiotics. Positive responses to at least 3 out of 6 questions (or 6 out of 14 in some ads) supposedly indicate "a high or very high probability" of yeast infection. Ads that began running last year state: "This self-test is provided for general information only and is not intended to be used for self-diagnosis without the advice and examination of a health professional." But these ads also say, "If you suspect you have a *Candida albicans* infection, put Cantrol

to the test."

The Cantrol program is based on the unproven theory that hidden "hypersensitivity" to *Candida albicans* is causing millions of people to suffer from such common symptoms as fatigue, irritability, constipation, diarrhea, abdominal bloating, mood swings, depression, dizziness, unexpected weight gain, difficulty in concentrating, muscle aches, and cravings for sugar or alcoholic beverages [see NF 3:14-15]. The program, which is claimed to "give nutritional support and help strengthen the immune system," involves dietary changes plus supplements (12 capsules/day) containing acidophilus, evening primrose oil, linseed oil, pau d'arco, vitamin E and other antioxidants. A 3-week supply of Cantrol retails for \$23.35.

The American Academy of Allergy and Immunology regards "candidiasis hypersensitivity" as speculative and unproven. Dr. Stephen Barrett believes that the Nature's Way campaign is illegal and has asked the FDA and FTC to take enforcement action.

"STRESS VITAMIN" MANUFACTURER AGREES TO STOP FALSE AND MISLEADING CLAIMS

On November 25, 1985, E.R. Squibb & Sons, Inc., agreed to pay \$15,000 to New York State and promised to stop making a number of false and misleading claims for its Theragran Stress Formula. New York State Attorney General Robert Abrams had brought prosecution in response to packaging which states: "Stress resulting from work situations, physical activity, smoking and complications of everyday life can increase your body's need for certain vitamins the body cannot store. One Theragran Stress Formula tablet a day can replace B-complex and C vitamins, which are not stored by the body. Theragran Stress Formula also includes Biotin needed to turn carbohydrates into energy."

Theragran Stress Formula contains vitamin C and the B-vitamins in amounts ranging from 15% to 1250% of the Recommended Dietary Allowances (RDAs). Under the settlement, Squibb promised not to state or imply in its advertising or packaging that:

- emotional stress increases the need for water-soluble vitamins
- smoking and ordinary physical activity increase the need for water-soluble vitamins by the amounts contained in Stress Formula
- consumers cannot obtain the water-soluble vitamins lost because of non-severe stress by eating a bal-

anced diet and by increasing food intake when necessary or by taking an ordinary potency (100% RDA) multiple vitamin supplement

- biotin is difficult to obtain in an average diet
- people under emotional or non-severe physical stress are at risk for biotin deficiency
- taking Stress Formula will reduce the effects of psychological stress.

The Attorney General has indicated that he intends to take action against other manufacturers of "stress formulas" who have been making similar or identical claims for their products. The problem was brought to his attention by the Center for Science in the Public Interest.

THE SCIENCE IN OUR FOOD: HOMOGENIZATION

Manfred Kroger, Ph.D.

Homogenization is a prime example of how food technology touches our life in a beneficial way. Yet few consumers know what the process entails.

Practically every milk carton in today's supermarket contains the word "homogenized" on its label. Many other food products have been processed with a homogenizer; and cosmetics and other household products would simply fall apart (separate) if it weren't for homogenization.

Homogenizing means making something homogeneous (the same throughout). This includes making different-looking microscopic components look alike or blending something into a smooth mixture. From a physical standpoint, homogenization is the reduction of particles so that they are uniformly small and evenly distributed. With regard to milk, it is the fat globules that are made homogeneous.

The milk we buy in stores is cows' milk that has been processed in a dairy plant. Packaged whole milk usually has a fat content of 3.25%. Low-fat milk contains 0.5%, 1%, 1.5% or 2% milk fat, as noted on the label, and skim milk (also called nonfat milk) contains less than 0.5% fat. They are all pasteurized and (except for skim milk) processed by a homogenizer. Unpasteurized milk is referred to as raw milk.

Milk fat, also called butterfat, is suspended in milk in perfectly round globules so small that one drop of whole milk contains about 100 million of them. When they emerge from the cow's udder, they range from about 1 to 15 micrometers in diameter.

It is a physical law that particles greater than 5 micrometers in diameter must either settle to the bottom or move to the surface. Being lighter (lower in specific gravity) than the surrounding skim milk, fat globules rise slowly to the top. That explains why non-homogenized milk will develop a visible layer of cream on top when left standing for 10-20 hours. Throughout the 1920s, '30s and '40s, consumers were able to purchase "cream line" milk. It was sold in bottles and had a 1- to 2-inch layer of yellowish cream on top. It looked interesting and would provide cream for one's coffee. The cream layer would get tough like rubber after prolonged standing, and milk bottles with hardened left-over cream in them were difficult to clean. Much milk

fat must have been lost merely because it clung tenaciously to the container.

Because dairies wished to sell milk as fresh as possible, it was often marketed before creaming was complete. This led to some confusion among consumers because most people thought that a thick cream layer was desirable. The dairy industry had difficulty explaining that it took at least 24 hours for a good cream line to form and that its thickness did not indicate the exact fat content or overall quality.

Liquids are homogenized by forcing them through a nozzle under high pressure until all particles contained in them are broken up—made so small that colloidal suspensions are formed. This method was discovered by French scientists in 1899. Homogenizers found rapid acceptance by makers of ice cream, salad dressings and many other products. It wasn't until 1927 in Canada and 1932 in the U.S.A. that homogenization was applied to market milk. Modern milk homogenizers are simply stainless steel pumps that force whole milk through nozzles under pressures of up to 3000 pounds per square inch. Depending on the size of the homogenizer, thousands of gallons can be processed per hour.

Since homogenization does away with creamability, it also did away with cream-line milk. But nobody really bemoaned its disappearance. Early commercials for homogenized milk pointed out its "soft-curd" nature. It turned out that high-pressure treatment not only reduces the size of fat globules but also destabilizes the milk protein micelles (tiny packets 10-100 times smaller yet than fat globules). As a result, claims were made that homogenized milk was more easily digested. It was also observed that homogenized milk curdles more readily than unhomogenized milk when used in preparing such foods as scalloped potatoes and cream of tomato soup.

Homogenization has guaranteed that market milk is creamy white, pours well, contains no unsightly clumps of butterfat, looks the same whether purchased in Maine or California, and whether one day old or ten. Most important, it has a smooth taste.

Dr. Kroger is Professor of Food Science at The Pennsylvania State University.

DIETARY GUIDELINES REVISED

On September 24, 1985, the second edition of *Nutrition and Your Health: Dietary Guidelines for Americans* was released jointly by the U.S. Departments of Agriculture (USDA) and Health and Human Services (HHS). The guidelines were prepared with the help of a nine-person advisory committee led by Bernard S. Schweigert, Ph.D., chairman of the Department of Food Science and Technology of the University of California/Davis. The others were Henry Kamin, Ph.D., David Kritchevsky, Ph.D., Robert Levy, M.D., Sanford Miller, Ph.D., Robert E. Olson, M.D., Ph.D., Lester Salans, M.D., Fredrick J. Stare, M.D., Ph.D., and Judith S. Stern, Sc.D. The committee recommended review and possible revision every 5-10 years.

The guidelines are intended for Americans who are already healthy and want to decrease their chances of developing certain chronic diseases. They are recommended especially for people who have risk factors such as a family history of obesity, diabetes, high blood pressure, high blood cholesterol or heart disease early in life. Rather than recommending specific quantities of foods or nutrients as ideal or optimal, they attempt to suggest a direction of dietary change that seems sensible. There are seven guidelines:

1. *Eat a variety of foods.* To assure variety—and with it a well balanced diet, the guidelines recommend choosing foods each day from five food groups: fruits; vegetables; cereals and other foods made from grains; dairy products; and meats, fish, poultry, eggs, and dry beans and peas. These groups are identical to the “Basic Four” except that fruits and vegetables are categorized separately to make five groups. The guidelines state that vitamin or mineral supplements are rarely needed except by women who menstruate, are pregnant or are breast-feeding. For babies, the guidelines suggest: breast-feeding unless there are special problems; delay of solid foods until the age of 4-6 months; and no addition of salt or sugar to baby foods.

2. *Maintain desirable weight.* Noting that obesity is associated with many serious illnesses, the guidelines suggest that the weight of adults should usually be not much more than it was at about 25 years of age. For those who are overweight, loss of 1-2 pounds a week should be accomplished by increasing physical activity and eating low-calorie, nutrient-dense foods—more fruits, vegetables and grains, less fat and fatty foods, less sugar and sweets, and less alcoholic beverages. Since diets below 800 calories can be hazardous, they should be followed only under medical supervision.

3. *Avoid too much fat, saturated fat, and cholesterol.* Acknowledging that controversy exists about what recommendations are appropriate for healthy Americans, the guidelines state that “for the U.S. population as a whole, it is sensible to reduce daily consump-

tion of fat. This suggestion is especially appropriate for individuals who have other cardiovascular risk factors such as cigarette smoking, high blood pressure, diabetes, or a family history of premature heart disease.” To avoid too much fat, saturated fat and cholesterol, the guidelines recommend: choosing lean meat, fish, poultry and dry beans and peas as protein sources; using skim or low-fat milk and milk products; limiting intake of fats and oils, especially those high in saturated fat; trimming fat off meats; broiling, baking or boiling instead of frying; and moderate use of fat-containing foods such as breaded or deep-fried foods.

4. *Eat foods with adequate starch and fiber.* Because foods differ in the kinds of fiber they contain, it is best to include a variety of fiber-rich foods such as grains, breads, cereals, fruits and vegetables. Adding fiber to foods that do not contain it is not recommended.

5. *Avoid too much sugar.* It is neither necessary nor possible to avoid eating simple sugars. The major health concern with excess sugar consumption is tooth decay. But the guidelines indicate that the risk does not depend simply on how much sugar and sugar-containing foods are consumed but on how often and whether they are eaten between meals and stick to the teeth. Brushing after consuming sugary foods is recommended, as are adequate fluoride intake and use of fluoridated toothpaste.

6. *Avoid too much sodium.* Noting that high sodium intake is often a factor in high blood pressure, the guidelines suggest that consideration be given to reducing sodium intake. This can be accomplished by learning to enjoy the flavors of unsalted foods; adding little or no salt during cooking or at the table; flavoring foods with herbs, spices or lemon juice; and limiting intake of foods that are obviously salty or contain significant amounts of hidden salt.

7. *If you drink alcoholic beverages, do so in moderation.* Since many alcoholic beverages are high in calories and almost all are low in nutrients, even moderate drinkers will need to drink less if they are overweight and wish to reduce. Since the level of consumption at which there is risk of birth defects to unborn children has not been established, pregnant women are advised to abstain completely from alcohol.

The report cautions: “Food alone cannot make you healthy. But good eating habits based on moderation and variety can help keep you healthy and even improve your health.”

In the November/December *Food & Nutrition News*, Dr. Schweigert indicated that the “key guideline” (a combination of Guidelines 1 and 2) is: “Consume a variety of foods providing adequate quantities of nutrients at a caloric level to maintain reasonable body weight.” He also noted that although specific individuals

at risk might benefit from quantitative advice about dietary composition, the advisory committee decided that the data were not extensive or clear-cut enough to make quantitative recommendations for the general public.

USDA's Human Nutrition Information Service is preparing a series of 14 bulletins to help Americans put the guidelines into practice. The first seven bulletins will offer information about each guideline, and the second seven will show how to use the guidelines for shopping, meal planning, eating out, making bag lunches,

preparing quick meals, and choosing snacks.

USDA is making one million copies of the 24-page booklet (Home and Garden Bulletin #232) available free. To obtain one, write to Consumer Information Center, Pueblo, CO 81009. Copies are also obtainable from county extension offices, the National Health Information Clearinghouse (800-336-4947), and the FDA Public Affairs Office. Multiple copies can be requested from the Food and Drug Administration, HFI-40, 5600 Fishers Lane, Rockville, MD 20857.

BRIEFS

Chelation therapy pamphlet. Calling it both unproven and unsafe, the American Heart Association has issued a hard-hitting 12-page pamphlet called "Questions and Answers About Chelation Therapy." (Proponents claim that intravenous administration of EDTA, vitamins and various other substances can remedy heart disease and other conditions by increasing the circulation of blood through arteries narrowed by atherosclerosis.) A free copy can be obtained by contacting any local AHA affiliate or sending a stamped, self-addressed 4"x9½" envelope to the national office at 7320 Greenville Avenue, Dallas, TX 75231.

Quackery brochure. The FDA, FTC, Postal Service and Pharmaceutical Council have jointly produced a brochure to help consumers identify health fraud and guard against worthless health products and services. A free copy in either English or Spanish is available from Quackery, HFE-88, Food and Drug Administration, 5600 Fishers Lane, Rockville, MD 20857.

Pritikin's arteries. Nathan Pritikin's autopsy report, which described his coronary arteries as free of atherosclerosis, is being cited as evidence that his dietary program is effective in reversing coronary artery disease. Reviewing this claim in the November 6th *Medical Tribune*, contributing editor Richard S. Gubner, M.D., notes that Pritikin's cholesterol level dropped from 280 in 1955 to 122 in 1958 and remained in the range of 102-120 in annual tests thereafter, hitting a low of 94 in November 1984. However, Dr. Gubner points out that unusually low cholesterol levels can occur in a number of severe illnesses, including cancer, and that people who die after lengthy illnesses, including cancer, and that people who die after lengthy illnesses that produce cachexia (wasting away) are often relatively free of coronary atherosclerosis. Pritikin was diagnosed as leukemic in 1958 [see NF 2:21].

FDA sued. The U.S. Food and Drug Administration is being sued for \$500,000 by a Kentucky couple who allege that their daughter, Jennifer Leann Frye, suffered liver damage from injections of E-Ferol, a vitamin E solution administered after her premature birth. In 1984, following the death of 30 premature infants treated with E-Ferol, the FDA labeled the product an unapproved new drug and its manufacturer removed it from the marketplace. Last year, the agency proposed new regulations to reduce the likelihood of similar disasters [see NF 1:1 and 2:54]. But the suit alleges that FDA inaction was a factor in Jennifer's case.

New ethical ruling. The American Medical Association's Judicial Council has ruled that it would be ethical for doctors to withhold all means of life-prolonging medical treatment, including artificially or technologically supplied food and water, from patients in irreversible coma, even if death is not imminent.

Yellow page "nutritionists." A study by the National Council Against Health Fraud has found that few "nutritionists" who advertised in the Yellow Pages are apparently qualified. Based on information in the ads, the practitioners were categorized into four groups: 1) "clearly spurious" (advertising hair analysis, cytotoxic testing, mail-order credentials, etc.); 2) "suspicious" (chiropractors, dentists and others suspected of practicing outside the scope of their expertise); 3) "undeterminable"; or 4) "apparently qualified" (Registered Dietitians). Of 439 whose ads were reviewed, 24% appeared clearly spurious, 31% were suspicious, 31% were undeterminable, and only 13% were apparently qualified. Eleven out of 24 physicians listed under the nutrition subsection of "Physicians and Surgeons" were judged "clearly spurious" because they listed such practices as chelation therapy and orthomolecular medicine. And four individuals listed under "Dietitians" were judged spurious.

Fluoride shortage. In mid-February, fluoridation was halted in Cincinnati, San Francisco, and several other cities because of a shortage of fluoride chemicals produced as by-products in the manufacture of phosphate fertilizers. Authorities expect the problem to be resolved within a few months as fertilizer production increases to meet farmers' needs for spring planting.

Alcohol labeling may be modified. The Bureau of Alcohol, Tobacco and Firearms has proposed that labeling and advertising of alcoholic beverages be required to indicate the percent of alcohol by volume rather than the "proof" (the percent of volume multiplied by two). Stating the proof value would be optional.

Health food store sales. *Health Foods Business'* estimates that 40.1% of sales in health food stores last year were for vitamins and other supplements. Based on its annual survey, the magazine reported that 6,800 stores grossed \$670.2 million for these products, up 27.3% from 1984. Other estimates were: books, \$33.4 (down 47.7%); herb teas, \$46.8 (down 6%); other herb products, \$143.7 (up 3%); and macrobiotic foods, \$16.7 (down 58.6%). The number of stores has fallen gradually from a high of 7,900 in 1982.

Microwave oven safety. A new report by the American Council on Science and Health concludes that radiation leakage from microwave ovens is not a significant problem. The real hazards, says ACSH, are electrical shock, fires and burns, most of which can be prevented by proper safety precautions. Shocks can be prevented by proper installation and periodic inspection to ensure that the electric plug and cord are not damaged. The risk of fire can be reduced by not overcooking foods and making sure that oven exhaust outlets are never blocked. And burns can be avoided by remembering that although dishes tend to stay cool, foods within them can get very hot. A free copy of the report can be obtained by sending a self-addressed 4"x9½" envelope stamped with 39¢ postage to Microwave Oven Report, ACSH, 47 Maple St., Summit, NJ 07901.

Nestle boycott report. A 24-page analysis of the Nestle boycott from the company's perspective is available free of charge from Nestle Coordination Center for Nutrition, Inc., 1120 Connecticut Avenue, N.W., Suite 310, Washington, DC 20036. The boycott began in 1977 to protest marketing of infant formula as a substitute for breast-feeding in developing countries. It was ended in 1984 after Nestle agreed to: 1) limit free distribution of formula in these countries to hospitals and health centers; 2) end gifts to physicians who promote formula; 3) add warning labels to packages; and 4) add warnings to promotional material.

Annual vegetarian protest. The second annual Great American Meatout was held on March 20 with protests in more than 25 cities. The event, patterned after the American Cancer Society's Great American Smokeout, is designed to encourage reducing the national consumption of meat. Its principal sponsor, the Farm Animal Reform Movement (FARM), of Washington, D.C., states that 1.5 million Americans are stricken annually with chronic diseases linked to excessive consumption of animal products. FARM also claims that raising animals for food uses up 90% of our agricultural resources, depletes topsoil and groundwater, destroys forest and wildlife habitats, and causes water pollution.

Pressure on McDonald's. Since 1983, the McDonald's Boycott Coalition has been trying to persuade the restaurant chain to add a soy, nut or veggie burger to its menu. According to *Vegetarian Times*, more than 430 groups have joined the coalition and about 100 restaurants have been subjected to demonstrations and leafleting.

PPA diet pills to undergo safety tests. The FDA has asked several drug companies to conduct clinical trials to determine the effect of increasing doses of phenylpropanolamine (PPA) in healthy persons. (PPA is a decongestant that can temporarily depress appetite.) The FDA currently limits the amount in diet products to 75 mg, but cold preparations may contain up to 150 mg. California neurologist Patrick Lyden, M.D., suspects that PPA may increase the incidence of strokes in persons under 40. Recently he reported that a healthy 20-year-old woman died of a PPA-induced stroke after three weeks of PPA taken at appropriate dosage. In response to a proposal by Dr. Lyden, the American Medical Association's House of Delegates has voted to follow the situation closely and may take further action in June at its next meeting.

Plant preservationists. The Seed Savers Exchange is a nonprofit group of more than 500 vegetable gardeners working to save thousands of endangered garden seeds from extinction. Some are "heirloom seeds" that have been passed down from generation to generation within families for well over 100 years. Others are commercial varieties that have been dropped from seed catalogues because they were not sufficiently popular. Membership (\$10/year) includes publications listing the seeds available and how to obtain them free of charge or for nominal cost. For additional information, send a self-addressed stamped 4"x9½" envelope to Seed Savers Exchange, 203 Rural Avenue, Decorah, IA 52101.

“TRAINING” FOR HEALTH FOOD RETAILERS

Odom Fanning

One way “health food” retailers get information is by attending national and regional trade shows where manufacturers display their wares and various spokespeople deliver the industry viewpoint on food and nutrition issues.

Natural Foods Expo '85 East, held October 25-28, 1985, at the Washington, DC, Convention Center, attracted some 4,000 retailers, mostly from the eastern United States. More than 200 exhibits were staffed by friendly sales personnel who passed out literature and abundant samples of foods and food supplements. The exhibitors came from all over the country and included many regulars from the established sister show, Natural Foods Expo West, held each Spring in Anaheim, California. These shows are sponsored by New Hope Communications, of New Hope, Pennsylvania, publisher of *Natural Foods Merchandiser* and *Delicious!* magazines.

Expo '85 East featured 40 seminars and workshops covering all aspects of merchandising, store management and industry trends. One of the most popular seminars—which filled three hours on the final morning—was “Nutritional Selling: A Powerful Customer Service.” Attended by more than 150 health food store operators, it was led by Jeffrey S. Bland, Ph.D., whom many of the participants held in obvious awe.

Dr. Bland, who is on leave from his biochemistry professorship at the University of Puget Sound, Tacoma, Washington, has a B.S. in biology from the University of California at Irvine and a Ph.D. in chemistry from the University of Oregon. But much of his aura stems from his current position as research associate and director of the Laboratory for Nutrient Analysis at the Linus Pauling Institute of Medicine, Palo Alto, California [see NF 2:33-36]. Bland is also president of JSB & Associates, Gig Harbor, Washington, which “specializes in wellness program development and delivery.”

Bland is undoubtedly the health food industry's most prolific publicist and interpreter of nutrition-related scientific developments. In addition to appearing

frequently at trade shows, he writes and edits books, edits and publishes a magazine (*Complementary Medicine*), produces audio and video tapes, conducts courses for professionals, and serves as a consultant to several organizations which share the industry's views.

Expo's nutritional selling seminar included several skits in which Bland played storekeeper and customers were played by three retailers: Kay Peterson, of Hazelwood, Missouri; Dale Bennett, of Winter Park, Florida; and Peter Brodhead, of Savannah, Georgia. Members of the audience were also invited to act as customers and ask their “toughest question” to the four panelists acting as clerks. The quotes throughout this article were taken from *Nutrition Forum's* tape-recorded transcript, edited to remove some of the grammatical errors, repetitious words and other minor artifacts of speaking.

How to avoid “overtly prescribing”

Much of the seminar concerned how product information might be communicated without “prescribing” (which would be practicing medicine without a license). One skit was set at an “information center” located near the vitamin department of a health food store. A 69-year-old man who is a fairly regular customer comes in, walking considerably more slowly than usual. He explains that he has developed arthritis and asks what he could take to help it.

After inquiring about common symptoms such as headaches, joint problems, intestinal problems and stuffiness of the nose, Bland suggested that “food hypersensitivity” was a factor and that milk, wheat and red meat might be contributing to the man's arthritis by “aggravating his immune system.” Bland then proposed that intake of these foods be reduced and consumption of complex carbohydrates be increased. “Fortunately,” he added, “there are some emergent bodies of literature and good medical studies that indicate that things like fish oil . . . the product on our shelves over here . . . have

been shown to help stabilize the immune system in people that may have a tendency toward arthritis." Bland also directed the customer's attention to literature in the store so he could read about these matters and possibly discuss them with his doctor.

Bland's reference to "emergent" studies was typical of his presentation throughout the seminar. His delivery is rapid-fire, with frequent use of biochemical concepts and research findings (usually preliminary in nature) which he considers relevant and encouraging.

In the ensuing discussion, Ms. Peterson remarked that although "the arthritis association categorically says that food has nothing to do with arthritis," doctors may still be receptive to information from retailers. Bland said he would try to make it clear to customers that he is concerned about their medical management, that they have been seeking good care, and that he was not practicing medicine but "trying to support them with nutritional information adjunct to traditional medical care." He also warned that requests for specific product information should be handled cautiously to avoid being "nailed for prescribing."

With a customer who says he read about a product for relieving arthritis pain but doesn't remember its name, Bland suggested this approach: "I'm not sure exactly what you're talking about, but I have seen a couple of articles on amino acids like dl-phenylalanine. Could that have been what you were referring to?"

"If he says yes, it is an easy lead-in to reiterate what you learned in the article. But never say 'that's what you can take.' If he says no, you can say, 'Let me give you the gist of what I read.' Then you can say, 'Dl-phenylalanine was suggested as being a modulator of a substance called enkephalin which is the body's own native pain-deadening process and that this is a part of the endorphin family. Have you ever heard of endorphins?' The person would say yes or no, and you can take the conversation on like that, making it educational and informational. That, to me, is the real position this industry should be in. It is not diagnostic, it is not treatment, because product sales are based on that individual's considered interest and belief system. You'll sell more products by providing information with less legal jeopardy than going right out and saying, 'Here's what you really should be taking on the following dose schedule,' which is certainly overtly prescribing."

Mr. Bennett agreed: "Keep in mind that there is a very fine line in what you can and can't say . . . Once you attach a claim to a product, you are prescribing. So, you must teach your salespeople that very, very carefully. Because today you don't know who you are talking to in your stores . . . When we talk about nutrition I don't really think we can get into too many problems . . . We're not just selling a bottle of vitamins, what we're selling is the concept of good health. And we can keep hammering away at the diet."

Commenting on the abundance of helpful literature available, Ms. Peterson said: "We must make the

most of what is in the public's mind. We're riding a wave of the education that's out there. And we're providing a product . . . There's so much printed information available. A few years ago, there was practically none. Every manufacturer puts information forward. Never suggest the number of tablets the customer should take . . . Simply read the label instructions. Say, 'The manufacturers have recommended this. Through their laboratory analysis, they have found this.' Divert the information from your spoken word to some written piece of information that you have."

The right place for advice?

The audience was then asked to act as customers and present difficult or frequently asked questions to the panel. Here are some excerpts:

Customer: I've been going to a doctor and have discovered, much to my alarm, that I have a fibrocystic lump in my breast. I heard somewhere that vitamin E is good for helping this, and also recently I read something about a macrobiotic diet, and I am wondering if this is some kind of a curative diet for my problem. I don't think the cyst is malignant. I'd like to find some kind of way to help myself without having some doctor cut me up.

Peterson: How recently have you been to your doctor?

Customer: Two weeks ago. I've had some time to think about this.

Peterson: Did they do a complete mammogram? How did they diagnose it?

Customer: No, it was just a manual diagnosis. They told me it was the size of a small lima bean.

Peterson: You are seeking additional information, and certainly we would like to tell you that you have come to the right place . . . If you would be interested in changing your lifestyle—on the basis that the way you have lived to date has not been conducive to keeping your body free from that growth—I can show you information. We have classes on the macrobiotic way of living, and we work with people who teach it. The information you have come across on vitamin E has probably come from Dr. Carlton Fredericks' book. I'd very much encourage you to read that so that you can also prevent further growth. And there's a lot of information we work with that the government has issued.

Nutrition Forum ISSN 0748 8165 is published monthly by the George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106. Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES: \$30/yr., \$57/2 yrs., \$81/3 yrs., prepaid; VISA and Mastercard acceptable; foreign postage by airmail add \$18.00. Manuscripts, books for review, and other editorial correspondence should be sent to Dr. Stephen Barrett, P.O. Box 1747, Allentown, PA 18105. Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

One, for instance, is diet, nutrition and cancer prevention. There is an 800 number to get it: 1-800-4-CANCER.

Customer: Are you saying that vitamin E does prevent further growth of this?

Peterson: Dr. Fredericks' book addresses that issue, and I would very much encourage you to read that.

Bland then commented: "Kay, that was a nice job. I would have probably done one thing myself. Because there are two types of fibrocystic conditions—one of which is more discomfiting than it is a warning sign of cancer—I would have tried to get some quick information. Is this a long-term problem? Does it come close to your menstrual cycle? Have you had it come and go, or is it just in the last few months? Because if it has just come on—a lump that is not inflamed and tender—it would be of higher-order-risk for malignancy. If, however, it's been associated with the menses, been with her for many years, then it's probably the kind of thing Bob London talks about in his work with vitamin E and fibrocystic disease, lower-fat diet, and so forth. You want to be very cautious that you don't alarm the person about having cancer if there is no need to alarm them. But you don't want to miss the possibility that it's not a menstrual cycle-related, long-term cystic mastitis, that it's a recent one and there is some concern about its pathology."

When another "customer" asked whether taking 50 mg of zinc might deplete his body copper level and possibly lead to high levels of uric acid and triglycerides, Bland said probably not, and offered to look at the product's label to determine whether the zinc-to-copper ratio was appropriate. He also suggested that the customer read more about "ways diet relates to triglycerides and uric acid from other avenues, such as a higher-protein diet." To another questioner he advised that sustained-release vitamins might be advantageous because they maintain higher blood levels.

Dealing with resistance

Several members of the audience pretended to be skeptical customers:

Skeptic #1: Last week I kind of got carried away with your enthusiasm and I bought an entire vitamin program that you recommended. Then after I got home I really started thinking about it. I started reading some publications that neighbors gave me when they saw these vitamins that you recommended. Even such reputable magazines as *Consumer Reports* said that our diet is entirely adequate, and that they tested McDonald's

and other fast foods and found that, based on the numbers of the RDA, that B-vitamins were at best useless and at worst can do some harm. So my question is, how do you know what I need and can you test me? Or is there a place I go to get tested, because I don't want to take something without knowing exactly what my needs are.

Bennett: I can understand what you're saying because there is a lot of confusion in the marketplace. I remember my clerk talking to me about you when you had left because you had an awful lot of good questions. I understand that you're an athlete, a triathlon competitor. Well, your needs probably might be greater than a lot of other people's needs. You're talking about some of the high-potency vitamins that you are maybe a little afraid of. They said that you didn't think you were getting the proper diet, that you get up early in the morning and don't eat breakfast. What you may want to do is just gradually work into some of these. Don't take ten vitamins all at one time because maybe your system is not ready for them. You may want to start with multiple vitamins today and possibly additional C and additional E that you have here. And after two days, maybe add this amino acid to it along with it and try to build up. Just don't jump into it all at once. Does that make sense?

Skeptic #1: Yes, it does. It's just a little different than the advice I was given initially . . . The main question about it all is basically how do I tell what exactly my nutrition needs are.

Peterson: There are many tests. We can channel you to some doctors that we work with, or we have a clinical lab where you can have evaluations done for blood, hair analysis, and we have two doctors' offices that work with us. We'd be glad to refer you to them.

Skeptic #2: My friends take vitamins, but I don't think I need them. I eat well, exercise and get enough rest every night. I have some stress on the job site, but I cope with everything. Do I need to take vitamins?

Peterson: Do your friends eat as well as you do?

Skeptic #2: I think so.

Peterson: Since your friends' indication that they feel better when taking vitamins has raised the question in your mind, perhaps you should try a B-complex when you have a stress situation arising and see if that helps you cope better. Then you would have your own proof. You could also read some of the books related to stress.

Mr. Bennett said he tells customers: "Genetics is very important . . . stress is very important, pregnancy is

Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Linda K. DeBruyne, M.S., R.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Suzanne Pelican, M.S., R.D.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.

very important. Now these are all reasons that we need supplements. We need probably 60 nutrients every day in our diet to totally feed ourselves properly. Very few diets out there are accomplishing that."

Bland added that customers who question the need for supplements can be steered toward nutrient-dense foods in the store by saying, "That's wonderful. Do you realize we have a whole series of good foods that can support you in your quest towards healthy living and high nutrient intake? You're doing a great job, and we want to reinforce it. Over here is a whole section of organic foods. If later you have some concerns about vitamins and minerals, we can talk about it."

When a customer asked why natural C and B-vitamins cost more, Brodhead replied that the vitamin C in his products is made from corn by an enzymatic process—"the same process that is taking place internally in animals when they convert vitamin C from blood levels of glucose." He claimed that drugstore products may contain talc, shellac, artificial coloring, flavoring and preservatives, and may be coated so heavily with carnauba wax that they "completely pass through the body without being absorbed."

A retailer from the audience said she tells customers that "perhaps that good diet was true in their

grandparents' time when foods were grown in soil that was nutrient-rich and they had fewer environmental assaults. I tell them about a study on a pig fed corn grown in Iowa 30 or 50 years ago that did well. That same pig today would die."

When asked how to handle a customer whose interest seems to have flagged, Bland suggested giving the customer a health appraisal form with questions about lots of symptoms that may surface and bring him back after he has had time to think further.

When asked whether research by Linus Pauling may show that vitamin C can build up the immune system and make it more difficult to get AIDS, Bland replied that Dr. Ewan Cameron and others at the Pauling Institute are collaborating with an AIDS specialist at San Francisco General Hospital to explore the role of vitamin C and carnitine in AIDS. "The studies are not yet completed," Bland said, "but the testimonial anecdotes that we're getting from some of the participants are quite encouraging. In fact, the hospital doctor himself commented off-the-record recently that he was quite interested in the vitamin C connection with AIDS. So, I do believe it is well worthy of continued study and may offer an immunochemical supporting regime towards immune deficiency conditions."

(continued on page 37)

EDITOR'S NOTE

JEFFREY BLAND'S SALES AIDS

"Hesitant to answer questions your customers may have about their nutritional concerns? For \$79.95, add a doctor to your sales staff." So begins a recent ad in *Natural Foods Merchandiser* for four items produced by Jeffrey S. Bland, Ph.D.:

- *Why Nutrient Supplementation?* (\$79.95), a 20-minute videotape or 35mm slide/audiocassette program, is intended for in-store customer viewing. In it Bland claims that: 1) "marginal deficiencies" are common in the United States; 2) many people who are under the presumption that they are healthy because they are not diseased would actually benefit from higher levels of health if they were taking a regular nutritional supplement; 3) if you eat a balanced diet, the need for supplementation may be reduced; and 4) "prudent nutritional supplementation" can "optimize nutrient quality" to help augment health and prevent disease. Bland also lists ten situations where supplements are supposedly needed, but says nothing about how individuals can determine whether they fit these supposed categories. (Presumably, those listening to the tape will

either "play it safe" by buying a supplement or ask the retailer for advice on "optimization.")

- *Introductory Nutrition* (\$120), a 12-hour audiocassette home-study course, "reviews the contemporary information concerning nutritional therapeutics including the use of vitamin and mineral supplements . . . for the serious student of nutritional biochemistry."

- *Immunity and Nutrition* (\$100), a 12-hour audiocassette course, "presents the latest nutritional implications in such conditions as AIDS, Epstein-Barr virus, hepatitis, herpes, food allergy and hypersensitivity, arthritis and other autoimmune diseases, inflammatory bowel disorder, and chronic candidiasis" and examines the supposed role in "normalizing the immune system" of vitamin C, zinc, iron, copper, manganese, vitamin E, gammalinoleic acid, folic acid, vitamin B₁₂, arginine, EPA, DHA, selenium and lysine.

- *Complementary Medicine Magazine* (\$30/year), published bimonthly by Dr. Bland, is "dedicated to providing you with the information you need to stay at the leading edge of preventive medicine." It is also said to be aimed at "wellness-oriented physicians." Each issue contains articles and ads promoting unproven practices and products.

—Stephen Barrett, M.D.

Regarding questions about stress, Bland commented: "I would say, 'What does the word stress mean to you,' because it's a very personalized definition. They could say, 'It means buzzing in my ears, or high blood pressure, or I can't cope, or I get stomach upset, or I get diarrhea or feel confused.' These are interesting ways of using that patient's/client's own identification system. Then say, 'You've identified stress as insomnia. Let's talk about the things that we know about sleep disturbances. Are you getting regular exercise? Are you staying away from excessive sugar in your diet? Are you getting adequate B-complex nutrients—because the brain which represents only 6% of our body weight consumes about 20% of our energy, and it's a very nutrient-dense part of our body. If you're not properly nourished, the brain is probably the first part of the body that is adversely affected. That's why you can get changes in behavior and perception and sleep disturbances. Therefore, we want to concern ourselves with the B-complex nutrients. And we want to look at magnesium because that's another nutrient extremely important for normalizing proper nervous system function.' So using their own symptoms of stress, you can work down into the holistic approach towards stress management."

"High-tech" information

When asked what else retailers should become knowledgeable about, Bland rattled off a long list of biochemical terms and tidbits, including: therapeutic uses of serotonin, phenylalanine, and catecholamines; use of tyrosine as a supposed brown fat activator substance because of its supposed noradrenalin relationship; and use of lysine and arginine in balance—lysine as an antiviral substance, arginine as an inotropic agent which tends to stimulate the thymus gland output of thymosin which is an immune-activating hormone. "These are all exciting areas that require some technical competency on dose, how they work, their route of administration and dose schedule—things you should have in the back of your mind even though you're not going to prescribe for treatment."

Bland also mentioned chromium, selenium, manganese, copper and zinc. "All of these have their own specific types of physiological functions. What you have to have at your fingertips or memory tips is some little vignette on each of those minerals, their bio-availability, the foods that they come in, why they are commonly the most deficient elements in the standard American diet. Eighty percent of them are lost by processing whole grains to white flour products. In the high-sugar, high-fat diets, where two-thirds of the calories come as sweet fats, there are very few trace elements. So there is a major area that the nutrition products industry can say something very well substantiated about the quality of the American diet."

He also listed fish oils, linseed oil, antioxidants, free radical pathology, antioxidants, chain-breaking

antioxidants, lipid peroxides, rancidity factors, glutathione, coenzyme Q, superoxide dismutase, betaine hydrochloride, intestinal ecology, toxic bowel, and high-fiber foods.

Bland advised that adding "high-tech" in the form of journals, topical literature files, slides and audio tapes "would show people you are really looking at the science of nutrition." But he warned: "It is very easy to give up the high-touch type of format that makes this industry unique. It's extremely important not to compromise personal attention for technical expertise. A person really wants to have their needs dealt with by a caring, humanistic salesperson who has some level of competency, but I would say the competency is second to the personal concerns. If we trade off technology for concern then we've made a real bad mistake about the direction of this industry."

"A few well informed, highly motivated consumers are your best advertising and sales force. My mother, who is a tremendously zealous advocate of nutritional products, has virtually made one of our health food store's business. She goes to all of her clubs and her social events. She is a missionary, saying 'You ought to be down there talking to the local health food place.' Because they have confidence in my mother, that kind of word-of-mouth confidence-builder then comes back to you. It is like training hundreds of salespeople to go out in the community."

When asked about the value of hair analysis, Bland replied: "Nutritional assessment is certainly justified on the basis of nutrition education and information either by computer, diet scan, or whatever diet technology you use. This is a valuable part of your service that customers may not be getting anywhere else, probably not from a doctor, for very few doctors are doing nutritional scans or evaluations. Hair analysis and similar diagnostic or prognostic screening tools have no place in a standard health food store. If you are into education or community service, the last thing you need is to be stigmatized as a quack or repository of cultist information. So by staying away from hair analysis and putting that into the hands of professionals who are licensed to do so, you can do your job best: education transfer, information, and nutritional counseling."

Another retailer asked about the limits of advice: "A lot of people come into the store seeking alternative medical answers. For example, two weeks ago, a friend of mine came in and said he had gallstones. I told him my wife's father had had gallstones, had refused surgery, and went through a specific treatment that worked. It wasn't a wives' tale. It worked. Do you have any comment on how far legally we should or shouldn't go in sharing things like this with customers?"

Bland replied: "If a client asks a question that specific, you need to decide whether he is a client or a friend, and how well you know him. If he is a friend, then I would take him out to lunch, away from your

store and talk to him as a friend. Don't talk as the store proprietor because that would be diagnosis and treatment. No matter what you think you are offering as a service, you are really, by the letter of the law, doing things that could be interpreted as diagnosis and treatment. However, if, as a friend, you anecdotally talk about your experience as a human being, there's no law that prevents freedom of speech."

Ominous implications?

What are the implications of this seminar? What does it tell us about the attitudes of the health food industry? Do retailers really benefit from exposure to a long list of preliminary research findings? What do they do with this information? Are they qualified to understand it, or do they merely absorb clichés for use in selling supplement products? How much do retailers think about their limitations? Do seminars of this sort encourage them to go beyond their limitations? Is there really a difference between giving advice ("prescribing") and steering a customer to a piece of literature that gives

the advice? Does anyone in the health food industry ever suggest that retailers faced with anecdotal evidence try to distinguish between cause-and-effect and coincidence?

And what of Bland? Has he considered that retailers might lack sufficient background to utilize what he talks about? Does he really think they should form opinions and advise customers about types of breast lumps? What is his purpose in mentioning preliminary studies (pertaining to products in their stores) and then saying don't use them yet as a basis for recommending products? Many of his ideas about nutrient needs run counter to those of the scientific nutrition community. Does he deliberately slant his presentations to promote sales of the health food industry's products?

Mr. Fanning is a freelance science writer who produces the nationally syndicated consumer action column, "Help-Mate," and is *Nutrition Forum's* Washington correspondent. He has also been editor and publisher of *Consumer New\$weekly*.

GNC'S DIFFICULTIES CONTINUE

In a strongly worded decision, Federal Trade Commission administrative law judge Montgomery K. Hyun has ruled that advertisements for General Nutrition Inc.'s Healthy Greens were deliberately misleading. The product, a pill containing dehydrated vegetables, vitamins and minerals, had been claimed to reduce the chances of contracting cancer. About 24,000 bottles were sold at prices ranging from \$8.99 to \$12.99. Judge Hyun's order prohibits the company from falsely claiming that the National Academy of Sciences/National Research Council or other research group has found that the use of Healthy Greens or similar products reduces the risk of cancer in humans.

General Nutrition had based some of its ad claims on the 1982 NAS/NRC report *Diet, Nutrition and Cancer*, which recommended that people include adequate amounts of vegetables, fruits and whole-grain cereal products in their diet. But, noted Judge Hyun, the report "specifically states that its recommendations apply only to foods and not to nutrients or supplements." He also concluded that "General Nutrition's unconscionable, false and misleading advertising found in this case is not an isolated incident but in fact part of a continuing pattern." He pointed out that the record contains 14 consent agreements the company entered into with the Postal Service and one with California authorities to settle charges of false advertising of food supplements [see NF 47]. Criminal charges are still pending against GNC for

marketing an evening primrose oil product with illegal claims that it was effective against high blood pressure, arthritis, multiple sclerosis and other ailments [see NF 1:20].

Last year, according to *Health Foods Business*, the company settled two expensive lawsuits brought by other supplement manufacturers. In one case, \$14 million was paid to the William T. Thompson Co. to settle a 7-year-old suit which had accused GNC of advertising Thompson products at a 20% discount in order to drive independent retailers out of business. In the other, GNC paid Nature Food Centers \$3.5 million to settle another antitrust suit. *Health Foods Business* has also reported that General Nutrition closed 20 unprofitable stores last year and plans to shut down more this year. Now able to manufacture more products than it can sell, the company plans to enter the private label market through its subsidiary, General Nutrition Products, Inc.

GNC's difficulties with enforcement agencies appear to have some impact on its marketing practices. Its flyers still exaggerate the need for "nutrition insurance" and falsely suggest that the stress of "traffic jams, arguments, meeting fast-approaching deadlines, or simply trying to decide what to wear at a party" are reasons to supplement with vitamin C and B-vitamins [see *Consumer Reports*, March 1986]. But recent visitors to GNC stores have found no evidence that illegal therapeutic claims are still being made for supplement products.

BRIEFS

Final rules for food irradiation. Health and Human Services Secretary Otis R. Bowen, M.D., has signed final regulations to permit low-level irradiation of fruits and vegetables and increasing the amount of radiation that can be used on dried herbs and spices. Irradiated foods must be labeled "treated with radiation" and contain the international logo of a stylized rose with two petals [see NF 3:23]. Bowen's predecessor, Margaret M. Heckler, had tentatively approved use of the word "picowaved" on the theory that consumers might mistakenly think the food might be radioactive. But critics of this measure thought it was unfair to conceal the fact of irradiation. Low-level radiation can reduce the need for pesticides and inhibit ripening and spoilage, thus extending shelf life and possibly making some foods more available or less expensive [see NF 2:25-27]. Under the new rules, the purpose of the irradiation can be included in the labeling statement. For example, a product label could state: "Treated with irradiation instead of pesticide chemicals to control insect infestation." Bowen urged the FDA and the food processing industry to study further uses of radiation on food.

Kellogg ends factory tours. The Kellogg Company has discontinued tours of its cereal production facilities, which have been open to the public since 1906. The reasons cited were: 1) foreign cereal producers have been trying to copy Kellogg's manufacturing techniques; and 2) the company wishes to reduce the possibility of sabotage like that involving Tylenol tablets.

Doctor sentenced for cancer fraud. Bruce W. Halstead, M.D., has been sentenced to four years in prison and fined \$10,000 after conviction on 24 counts of cancer fraud and grand theft. The sentencing judge indicated that the prison term might be shortened if Halstead ceased all medical activities and abandoned the title of doctor. Press reports indicate that Halstead charged cancer patients \$125 to \$150 per liter for an herbal tea called ADS. Although he maintained that ADS was a "nutritional supplement," analysis revealed it to be 99.4% water and a brown sludge composed mainly of coliform bacteria (the type found in human feces). Halstead, who operated the Halstead Preventive Medical Clinic in Colton, California, has been a leading promoter of laetrile, chelation therapy, and many other questionable practices. Following the trial, which lasted five months, Los Angeles County Deputy District Attorney Hyatt Seligman called him "a crook selling swamp oil." The four-year sentence is probably the longest ever issued to a physician convicted of health fraud. Halstead is appealing it and remains free on \$100,000 bail.

Food prices stable! According to the Food Institute, foods in the nation's grocery stores cost only 1% more in February 1986 than they did in February 1985. But non-food items such as cigarettes, cleaning supplies and health and beauty aids rose an average of 4.1%.

Cigarette company acquisitions. The American Council on Science and Health believes that the main reason that R.J. Reynolds bought Nabisco and Philip Morris bought General Foods last year (the price for each was more than three times book value) was to increase their political power. According to an article in the March/April *ACSH News & Views*, "Television stations and networks which have not been amenable to tobacco industry blackmail since the government banished cigarette advertisements from the airwaves in 1971 could now see heavily advertised products such as BirdsEye frozen food or Fleischmann's margarine used as threats in case they dare report on the health hazards of cigarettes . . . If we see an increase in casual smoking in commercials for products like canned fruit or cookies, it will be because the advertising professionals will have become aware that their ultimate clients are cigarette makers."

Data on food ingredients. Food and beverage companies and manufacturers of food ingredients have formed the International Food Information Council (IFIC) to provide scientists, media personnel and consumers with information about food ingredients. Thomas E. Stenzel, its executive director, has been director of public relations for the National Soft Drink Association. IFIC plans to approach food ingredient issues individually, starting with aspartame. Its address is Suite 300, 1250 Eye St., N.W., Washington, DC 20005 (telephone 202-289-2005).

Mismanaged yeast infection. Two doctors from UCLA medical center have reported the case of a 2-year-old boy who was inappropriately treated by a proponent of "candidiasis hypersensitivity," a concept recently denounced as speculative and unproven by the American Academy of Allergy and Immunology [see NF 3:14-15]. The treatment had been sought because the child had been suffering from fatigue, crankiness, a runny nose and other symptoms supposedly found in this condition as described in the March 1985 issue of *Omni* magazine. Although the youngster actually had chronic candidiasis (a yeast infection), treatment as recommended by leading candidiasis hypersensitivity proponents was ineffective. His infection was subsequently cured by correct anti-fungal treatment administered by the reporting doctors [*New England Journal of Medicine*, March 27, 1986].

Chelation therapy. The American Heart Association has released the following summary statement: "The American Heart Association's Task Force on New and Unestablished therapies has reviewed the available literature on the use of chelation (EDTA) in the treatment of arteriosclerotic heart disease and finds no scientific evidence to demonstrate any benefit of this form of therapy. The Task Force recognizes that there have been no adequate trials using currently approved scientific methodology to support this therapy. Furthermore, employment of this form of unproven treatment may deprive patients of the well established benefits attendant to the many other valuable methods of treating these diseases."

New Pauling book contains dangerous advice! *How to Live Longer and Feel Better* (\$7.95) has been published by W.H. Freeman and Company with an initial printing of 100,000 and publicity that included interviews by Phil Donahue and Merv Griffin. Unlike Pauling's previous books, it recommends chelation therapy for cardiovascular disease and advises adults to supplement their diets with 25,000 IU of vitamin A (an amount that can build up to toxic levels after months or years). Professionals who wish to be prepared for public inquiries about the book can obtain copies for \$7 each plus \$1 postage per order from LVCAHF, Inc., P.O. Box 1747, Allentown, PA 18105. Payment must accompany all orders.

Antiquackery idea. Dr. John Renner, Chairman of the Kansas City Council Against Nutrition Fraud and Abuse, believes that many people will be protected from nutrition quackery by passage of state laws making it illegal for practitioners to sell vitamins and other supplements in their offices. Virtually all practitioners who do this are promoting unscientific practices. Typically they sell the supplements for two or three times their cost—considerably more than they would cost at a drugstore.

Health food retailer group folds. The Natural Foods Network, begun in June 1984 to provide members with news and scientific information via computer hookup [see *NF* 1-16], has ended operations. Membership had peaked at 165.

Fluoridation promotion. The American Dental Association has decided to set up a demonstration project to promote fluoridation in selected cities. It is hoped that the project will spark renewed national interest in fluoridation and provide a model for other communities wishing to set up a fluoridation campaign.

Notable quote. "The scientific debunker's job may be compared to that of a trash collector. The fact that the garbage truck goes by today does not mean that there will not be another load tomorrow. But if garbage were not collected at all, the results would be much worse."—L. Sprague de Camp [*Skeptical Inquirer*, Spring 1986].

New fluoride regulations. On March 17 the U.S. Environmental Protection Agency (EPA) announced final standards for naturally fluoridated drinking water supplies. The upper limit is now 4 parts per million (ppm), approximately double the previous allowable level. (In areas where fluoride is added to drinking water to prevent tooth decay, the usual concentration is 1 ppm.) Communities with naturally high concentrations of fluoride—most of which are in Texas and South Carolina—had asked EPA to raise the upper limit because fluoride removal is costly. Levels above 2 ppm can cause mottling, discoloration and pitting of the teeth. However, the U.S. Surgeon General has concluded that these are cosmetic rather than health problems. The American Dental Association, which agrees with this position, had urged EPA to set no standards at all. Some 280 small towns with a total population of about 200,000 will now be exempted from having to reduce the concentrations of fluoride found naturally in their water. However, suppliers whose level is 2 ppm or higher will be required to notify customers of this fact. Antifluoridation groups have opposed raising the standard and claim that higher fluoride levels can cause serious health problems. The National Resources Defense Council, an environmental group which also opposes higher levels, has asked the U.S. Appeals Court in Washington to review the new standard. South Carolina is suing EPA to have the standards eliminated.

Instant beer? A small French brewery claims to have developed an instant beer—made by adding water to a special syrup—that tastes identical to conventionally brewed beers. According to *Business Week*, the brewery plans to test-market the product in Great Britain and possibly in Saudi Arabia, where alcohol is forbidden.

Free "health food" magazine. *Health Today*, described in recent ads as "the life extension magazine," is claimed to reveal "Nature's way to improve your looks, protect your heart, be more slender, look younger than your years, and be vitally alive." Edited by Lelord Kordel, it contains articles and ads about the supposed wonders of foods and food supplements. Free 3-year subscriptions can be obtained by sending your name and address on a postcard to Health Today, Redford-Box 19268-B, Detroit, MI 48219.

THE IMPACT OF NUTRITION LABELING

Wayne Ellefson

Detailed nutrition labeling made its nationwide debut in grocery stores in 1975 after publication of the FDA's labeling requirements. Its introduction stemmed naturally from growing public interest in diet and health, and from several studies showing that consumers would welcome nutrition information on product labels. Labeling was based partly on the notion that consumers wanted such information to make better purchasing decisions and thus improve their diet. The regulations were designed to satisfy this desire and also to protect consumers from misleading nutrition claims.

Following recommendations of the 1969 White House Conference on Food, Nutrition and Health, the FDA took specific steps to establish regulations with help from many industry and government organizations. As part of the planning process, three label formats were pretested: expressed percentages of U.S. RDA values; stars and color codes; and adjectival descriptions. The final format was based on consumers' clear preference for numerical data.

Since their introduction, labeling regulations have changed little in substance. Infant formula regulations were added following passage of the Infant Formula Act of 1980. Sodium labeling is being required in light of research on sodium's role in hypertension, as well as pressure by medical associations and consumer groups. And cholesterol labeling is under consideration.

Table 1 summarizes key components of the FDA's current labeling regulations for reporting nutrition content. This format is required whenever foods are fortified or carry a nutrition claim on their label. If nutrition labels are used when not required, they must still comply with these regulations. For most packaged foods, ingredients must also be listed. The ingredient used in the largest amount must be listed first, followed by the others in descending order of amount contained. However, the actual amounts do not have to be listed.

After nutrition labels began appearing, researchers from academia, industry and government be-

gan evaluating their impact on consumer behavior. They studied shopping habits, attitudes, and how individuals processed the information.

Many people—particularly those who are health-conscious or on a restricted (low-calorie, low-fat or low-sodium) diet—deliberately seek out nutrition labels, use them to choose products, and fully understand the information they read. The proportion of American shoppers claiming to utilize nutrition labels has increased steadily from less than 10% in 1972 to over 90% in 1981. However, although most people have a positive attitude toward nutrition information, both laboratory and field experiments show that the number of consumers actually using it to make purchase choices is not as large. Many reasons for this discrepancy have emerged from the various studies:

- Although awareness of labels is high, comprehension of the data is not as high.
- Brand loyalty and price can interfere with consumers selecting a product based on nutritional value alone. Price is an issue with lower income buyers, who often do not factor nutrition into their decisions. Also, studies have shown that many food buyers consider nutrition data of less importance than ingredient listings and taste.
- There exists an apparent threshold effect: if nutrition is perceived to be similar among similar products, consumers are less likely to use nutrition information. For example, if consumers perceive all orange juice brands to be similar, then nutrition information is not so important.
- Consumers may use the label to learn initial information about a product. For individuals who use information such as calories in planning their daily diet, the label information may be equally important after the purchase.
- Other aspects of product labeling, such as descriptive terms, can be equally influential. One study

showed that consumers considered such phrases as "sweet and succulent" to be indicators of nutritional quality.

- Nutritional value is not equally important across product classes. For example, nutrition labels may be used more for cereals, which are often purchased for their nutritional value. Candy bars, however, are generally purchased as a snack food, so nutritional value is less frequently an issue.

- Effective use of nutrition information is more likely to effect changes in purchase behavior than individual product labels. In one controlled study, marketing researchers placed placards containing the comparative information in food aisles so they were easily visible when consumers were considering the items listed. In-store purchases of several products were

monitored. When this information was present, products were selected for nutrient reasons 52% of the time and the market share of nutritionally better foods increased up to 8%. The researcher concluded that direct brand comparisons through comparative tables are easier than a comparison of individual labels, because they reduce cognitive effort and memory stress.

A similar but larger 2-year study was run by Giant Foods. Called the "Special Diet Alert," it compared purchases of certain products in 10 stores that utilized shelf placards to flag nutrition and 10 stores that did not. The same information was available in the control stores (or on the products themselves), but was not displayed in a conspicuous manner. The market shares of the products on the placards increased 4-8%.

These two studies indicate that the actual

TABLE 1: Summary of Nutrition Labeling Requirements¹

Description	Reporting Requirement
Mandatory Items	
Serving size	Varies
Servings per container	Varies
Calorie content	0-20 calories to the nearest 2 calories 21-50 calories to the nearest 5 calories 51 + calories to the nearest 10 calories
Protein content	For 1 gram or more, grams per serving to the nearest gram
Carbohydrates	For 1 gram or more, grams per serving to the nearest gram
Fat	For 1 gram or more, grams per serving to the nearest gram
Sodium ²	Milligrams per serving
Percentage of U.S. RDA ³ for protein, vitamin A, vitamin C, thiamine, riboflavin, niacin, calcium, iron	In 2% increments to 10% level 5% increments to 50% level 10% increments above 50% < 2%, indicate by "0" or other appropriate notation
Optional Nutrients (If Naturally Occurring)⁴	
Percentage of U.S. RDA for vitamins D, E, and B ₆ , folic acid, vitamin B ₁₂ , phosphorous, iodine, magnesium, zinc, copper, biotin, pantothenic acid	In 2% increments to 10% level 5% increments to 50% level 10% increments above 50% < 2%, indicate by "0" or other appropriate notation

¹Nutrition information must be presented in this order.

²Sodium content will be mandatory as of July 1, 1986.

³United States Recommended Daily Allowance.

⁴Information on potassium, cholesterol, and fatty acids may also be presented, but if so, it must be included with data on fat.

Source: Code of Federal Regulations, Title 21, Part 101.9 (1985).

method of presenting nutrition data appears to affect consumer behavior. In situations in which the information was made prominent, purchase patterns were altered. Thus it seems that promotional programs are effective with people interested in nutrition but not deliberately seeking information.

Placing nutrition information on packages and labels and in advertisements has improved company and store images. For example, one study showed that nutrition signs placed in the produce section of a West Coast grocery chain gave the store a better overall image. Recognizing this benefit, many producers and retailers use nutrition labels for a marketing advantage:

- The Produce Marketing Association has been involved in the development of programs to allow labeling of fresh produce in grocery stores.

- The McDonald's Corporation regularly tests its products for nutritional value and publishes comparative product and meal information for distribution to consumers.

- Campbell's "Soup is good food" advertising campaign is based on this philosophy.

- Companies such as Del Monte are publishing pamphlets that provide nutrition information on their

products and include recipes and meal suggestions.

- The Potato Board conducted a series of nutrition studies designed to promote the image and value of the potato by showing that it is one of the best vegetables nutritionally. This endeavor has gone a long way in correcting the potato's image as a high-calorie starchy food. The Potato Chip/Snack Food Association is using this approach to promote potato chips.

- The Kroger Company has developed recipes based on nutritional value and uses these recipes to promote products.

Ten years ago, there was a question about whether consumers wanted and needed nutrition labels. Today we ask how they can be most effectively used. From a regulatory standpoint, labels will most likely be modified in response to specific health issues. Regulations should continue to reflect the need to provide information and protect consumers from misleading claims.

Mr. Ellefson is an account executive with Hazelton Laboratories America, Inc., Madison, Wisconsin, one of the world's largest and most respected food testing laboratories.

DR. STARE CRITICIZES DIETARY GUIDELINES

Fredrick J. Stare, M.D., Ph.D., has criticized the 1985 Dietary Guidelines for Americans, issued jointly by the U.S. Departments of Agriculture and Health and Human Services [see NF 3:30-31]. Dr. Stare, who served on the Guidelines' advisory committee, believes that the following would be more precise and comprehensive:

1. Eat a variety of foods from within each of the Basic Four Food Groups, including foods with adequate starch and fiber.

2. Adjust total caloric intake, particularly from fats, to caloric output, so as to reach a reasonable body weight.

3. Whenever possible, drink fluoridated water and beverages made with it.

4. Be prudent in sodium (salt) intake and gener-

ous in calcium intake, particularly after 35-40 years of age.

5. If you drink alcohol, do so in moderation. DON'T DRINK AND DRIVE.

6. Physical activity (exercise) is not a part of diet, but it is the only way to expend the extra calories that are so pleasant to consume—hence moderate, frequent exercise is highly recommended.

7. Enjoy what you eat because eating is one of the pleasures of life and stop worrying about the safety of foods. They are safe.

In the January/February issue of *Nutrition Today*, Dr. Stare revealed that his guidelines had been proposed to the advisory committee but were rejected by a majority.

EDITORIAL BOARD

EDITOR: Stephen Barrett, M.D. **SENIOR ASSOCIATE EDITOR:** Manfred Kroger, Ph.D. **ASSOCIATE EDITORS:** Denise Ferko-Adams, R.D., Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. BRIEFS

Raw milk report. A comprehensive 2½-year study funded by the raw milk industry has concluded that certified raw milk can contain harmful bacteria capable of causing serious infection and death in infants, cancer patients and other individuals with weakened immune systems. The study, performed by public health specialists from the University of California at Los Angeles, included a comprehensive literature review and interviews with staff members of the California Department of Health Services and officials of the Alta-Dena Dairy (the nation's largest producer of certified raw milk). The researchers have proposed that strong warning labels be required on raw milk cartons and that the effectiveness of the labels be evaluated.

FDA's magazine price halved. FDA Consumer, the agency's outstanding magazine on health, nutrition, safety and law enforcement, now costs only \$9.50/year for 10 issues. Orders should be sent to the Supt. of Documents, Government Printing Office, Washington, DC 20402.

Cooking contest announced. Amateur and professional chefs can compete with their peers for cash prizes in a nationwide cooking contest to be held in over 150 cities early next year. The entry fee is \$100 for professionals and \$50 for others. Applications can be obtained by writing to: U.S. Chefs Open, 150 Second Avenue North, Suite 1700, St. Petersburg, FL 33701.

Procter & Gamble merges with Richardson-Vicks. Procter & Gamble (13.5 billion annual sales) has entered the "natural foods" marketplace by merging with \$1.2 billion Richardson-Vicks. The latter, best known for Vicks, Oil of Olay and Clearasil, also owns California Sun (bodycare products), Mill Creek Natural Care Products, Inc., and Tiger's Milk (candy and snack bars whose formulation has been attributed to Adelle Davis).

 Nutrition Forum ISSN 0748 8165 is published monthly by the George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106. Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES: \$30/yr., \$57/2 yrs., \$81/3 yrs., prepaid; VISA and Mastercard acceptable; foreign postage by airmail add \$18.00. Manuscripts, books for review, and other editorial correspondence should be sent to Dr. Stephen Barrett, P.O. Box 1747, Allentown, PA 18105. Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

New Zealand girlcott. *Vegetarian Times* reports that peace groups are calling for a "girlcott" to protect New Zealand from possible economic retaliation for banning nuclear-armed warships in its ports. Under the girlcott (the opposite of a boycott), peace-minded consumers are being urged to buy kiwi fruit and other products produced in New Zealand. According to the magazine's editor, Paul B. Obis, Jr.: "Vegetarianism means eating lower on the food chain, better use of the land, more potential food, more healthful foods, an end to slaughter."

Sugar report. The American Council on Science and Health has concluded that "sugars do not pose a threat to health when consumed in the amounts customary in the United States for the past 50 years, with the exception of the role that sugars and other carbohydrates play in promoting tooth decay." For a free copy of the 24-page report, send a self-addressed, stamped (56¢ postage) 4"x9¼" envelope to Sugar Report, ACSH, 47 Maple St., Summit, NJ 07901.

"Clinical ecology" blasted. Practitioners of "clinical ecology" maintain that a broad range of common physical and psychological disorders can be triggered in susceptible persons by low-level exposure to foods, environmental chemicals and natural inhalants. After reviewing evidence submitted by practitioners to support their claims, a California Medical Association task force has concluded that clinical ecology does not constitute a valid medical discipline [*Western Journal of Medicine* 144:239-245, 1986]. The task force also concluded: 1) no convincing evidence supports the hypotheses on which clinical ecology is based; 2) clinical ecologists have not identified specific, recognizable diseases caused by exposure to low-level environmental stressors; 3) their methods of diagnosing and treating such undefined conditions as "cerebral allergy" have not been shown effective; and 4) it would be misleading to consider clinical ecology's methods "experimental" unless its practitioners begin to adhere to scientifically sound research protocols. The task force report notes that because the medical community is unwilling to accept their concepts, many practitioners of clinical ecology are now identifying themselves as specialists in "allergy and environmental medicine." Reprints of the CMA report can be obtained from Linda Ramsey, Director, Division of Scientific and Educational Activities, California Medical Association, P.O. Box 7690, San Francisco, CA 94120.

BOOK REVIEWS

Weight-reduction camps. According to the April Money Magazine, many summer camps now specialize in weight-reduction programs for children and adolescents. Such programs, which include low-calorie diets, exercise and behavior modification, cost over \$3,000 for an 8-week period. Eleven such camps are operated by Weight Watchers, 183 Madison Avenue, New York, NY 10016.

New labeling bill. S. 1699 has been introduced to require food labels to provide more information on the fat and salt content of food products. Called the Nutritional Information Labeling Act of 1985, the bill would amend the Food, Drug and Cosmetic Act to require that labels contain: 1) the specific or common name of each fat or oil; 2) the number of ounces and calories per serving; 3) the total number of grams and calories of fat per serving; 4) the amounts and calories per serving of saturated, polyunsaturated and monounsaturated fat; 5) the amount of cholesterol per serving; and 6) the amount of sodium or potassium if either exceeds 35 mg per serving. The bill's sponsors, Senators Howard Metzenbaum (D-OH) and Paula Hawkins (R-FL), believe that this information will help consumers reduce their incidence of heart disease and cancer.

Turkey facts. Single copies of "Turkey . . . A Naturally Lite Meat" are free to food and nutrition professionals who indicate their title and affiliation and send a self-addressed, stamped (56¢ postage) envelope 6½" x 9½" or larger to: Department of Consumer Affairs, National Turkey Federation, 11319 Sunset Hills Road, Reston, VA 22090. The 20-page booklet illustrates turkey meat cuts and provides cooking tips and cost comparisons with other meats.

Homeopath's license revoked. The North Carolina Board of Medical Examiners has determined that the practice of homeopathy by a licensed medical doctor constitutes unprofessional conduct and justifies revocation of a physician's license to practice medicine. At the same time, it revoked the license of the state's only homeopathic practitioner, George A. Guess, M.D., unless he stopped practicing homeopathy. Homeopathy is based on the unscientific theory that infinitesimal doses of substances which can cause symptoms in healthy individuals can cure sick individuals who have such symptoms. Many health food stores sell homeopathic remedies. The North Carolina State Court has granted Dr. Guess a temporary stay of the medical board's ruling so he can continue to practice until his appeal can be decided by the courts.

Title: The Best Medicine
Authors: Kurt Butler and Lynn Rayner, M.D.
Publisher: Harper & Row, San Francisco
Price: \$32.95 hardcover, \$16.95 softcover

Mr. Butler, who holds a bachelor's degree in physiology and a master's degree in food and nutritional sciences, is co-founder of the Quackery Action Council, a National Council Against Health Fraud affiliate group. Dr. Rayner, a board-certified internist, is assistant professor of medicine at the University of Hawaii's medical school. Together they have crafted an extraordinary 770-page work intended to help people make choices not only for themselves but for their communities as well.

The book has seven main sections: exercise and fitness; nutrition science and mythology; healthy sex and reproduction; common disorders—a prevention approach; drugs and health; controversial alternatives; and consulting a physician. Laypersons will find the authors' approach highly practical. Professionals may find the lucid explanations useful in talking with patients. Those interested in quackery will find a surprising amount of information that is hard to come by.

Title: Abuse of the Scientific Literature in an Anti-fluoridation Pamphlet (1985)
Editors: Colleen Wulf, R.D.H., M.P.H., Karen F. Hughes, R.D.H., M.P.H., Kathleen G. Smith, R.D.H., M.S., and Michael Easley, D.D.S., M.P.H.
Publisher: American Oral Health Institute, P.O. Box 151528, Columbus, OH 43215.
Price: \$13.50

This 210-page report will be useful to anyone interested in promoting fluoridation. It discusses the principal criticisms of fluoridation and examines the references cited to support them in the writings of John Yiamouyiannis, Ph.D., the nation's most active anti-fluoridationist. His pamphlet, "Lifesavers Guide to Fluoridation," which is invariably distributed wherever community fluoridation is being considered, cites 250 references that supposedly back up his claims. However, public health experts who traced the references found that almost half had no relevance to community water fluoridation and that many others actually support fluoridation but were selectively quoted and misrepresented.

AN IRREVERENT LOOK AT THE VITAMIN BIBLE AND ITS AUTHOR

James A. Lowell, Ph.D.

According to the advertisements in the newspapers, I was going to learn "How to Live to Be 100 Plus!"

"It's free," said one ad, "and if you are less than a century old, what have you got to lose?" So, since I am not quite that old, off I went, pen and notebook in hand, to a lecture in Tucson conducted by Earl Mindell, R.Ph., Ph.D., "noted nutritionist, pharmacist, lecturer . . . and author of the best selling *Earl Mindell's Vitamin Bible*."

The lecture was sponsored by two Great Earth Vitamin Stores located in the Tucson area. Mindell helped found the Great Earth chain of health food stores, numbering about 200, which is now the nation's second largest. He has also written *Earl Mindell's Vitamin Bible for Your Kids*, *Earl Mindell's Pill Bible*, *Earl Mindell's Quick & Easy Guide to Better Health*, and *Earl Mindell's Shaping Up with Vitamins*—books whose total sales are in the millions.

Mindell claims to hold valid credentials in nutrition. Although he does have a bachelor's degree in pharmacy from the University of North Dakota, his Ph.D. is from the University of Beverly Hills, an unaccredited school which lacks a campus or laboratory facilities. During his speech, Mindell also said that he studied at Rutgers University, but representatives in Rutgers' records office whom I contacted could find no record of this.

Mindell's *Vitamin Bible* was written while he was working toward his Ph.D. His adjunct faculty adviser for the project was James Kenney, Ph.D., R.D., who is currently a nutritionist at the Pritikin Longevity Center in Santa Monica, California. Kenney reviewed the manuscript while tutoring Mindell and told him that it contained over 400 errors, more than 100 of which were important. Kenney told me that most of the errors remain in the published edition. The acknowledgments section of the book recognizes Dr. Kenney for his help and also thanks the American Medical Association, the National Academy of Sciences, the National Dairy Council, the American Academy of Pediatrics, and the Nutrition Foundation, "without whom a project of this scope could never have been completed." However, the fact that all of these prestigious organizations would strenuously disagree with information in the book is not mentioned.

In a section entitled "The Whole Truth," *Vitamin Bible* tells what each vitamin and mineral can supposedly do for you and gives advice for self-treatment with supplements of many of them. For example, it suggests pantothenic acid for tingling hands and feet, vi-

tamin D for conjunctivitis, and calcium for menstrual cramps. This section also promotes substances which Mindell calls "vitamins" B₁₀, B₁₁, B₁₃, B₁₅, B₁₇, P, T, and U. There is no evidence that any of these substances are essential to humans or that supplements of any of them are beneficial. Furthermore, B₁₅ (pangamic acid) and B₁₇ (laetrile) pose health risks. Another section of the book recommends self-treatment with supplements for more than 50 ailments and conditions including acne, bad breath, baldness, headaches, measles, mumps, prostatitis, syphilis, gonorrhea and warts.

In *Vitamin Bible for Kids*, Mindell advises parents who suspect that their child is deficient in any nutrient to consult a "nutritionally oriented doctor" or (if mineral deficiency is suspected) to obtain a hair analysis. Among other things, the book recommends vitamin supplements for acne, bronchitis, athlete's foot, canker sores, chickenpox, clumsiness, colitis, dandruff, diabetes, forgetfulness, impetigo, insect bites, prickly heat, poison ivy, stomachaches, tonsillitis, and warts. For multiple sclerosis, it recommends orotic acid, which Mindell refers to as vitamin B₁₃. And for children "whose little white lies are growing darker," he recommends eliminating sugars, refined starches, and junk foods from the diet and supplementing with B-complex vitamins.

Mindell is co-editor of Keats Publishing Company's "Good Health Guides," a large series of booklets promoting dozens of questionable supplements. His fellow editor is Richard A. Passwater, whose "Ph.D." is from Bernadean University, an unaccredited correspondence school that was never legally authorized to grant any degrees.

Mindell has also written information sheets that are distributed as educational material in health food stores. Although all of them warn that the information they contain "is not intended as medical advice but only as a guide in working with your doctor," it is clear that health food stores are using them to boost product sales by making claims that would be illegal on product labels.

The Lehigh Valley Committee Against Health Fraud has collected more than 60 of these articles dated between 1980 and 1984. Some of them describe how various vitamins, minerals and amino acids function in the body and provide tidbits on research involving these substances. Others promote such products as ginseng, bee pollen, chelated minerals, kelp (to help the thyroid gland), yucca extract tablets (for arthritis), papaya (to help digestion), octacosonol ("the amazing energy sus-

tainer"), and golden seal root (for stomach and liver troubles).

Most of the information sheets are misleading, and many contain errors. In #63, for example, Mindell states that research done at Temple University in Philadelphia found that rats fed dehydroepiandrosterone (DHEA) lost weight. What actually happened was that rats who received dosages 50 times greater than those marketed for humans did not lose weight but merely gained less than expected. Great Earth was one of many companies selling DHEA pills as a "fat fighter" until the FDA ordered all DHEA products off the market in the spring of 1985 [see NF 2:30, 2:46, 2:47].

Flyer #44B suggests that supplements of glucomannan (a plant fiber) are an effective appetite suppressant—which they are not. A previous version of this flyer claimed that studies conducted by Judith Stern, D.Sc., of the University of California at Davis, showed that subjects taking glucomannan lost more weight than control subjects. Actually, no significant differences were found between the two groups, and mention of Dr. Stern was deleted after she threatened to take legal action.

Flyer #4B suggests that supplementation with lecithin can prevent heart disease, aid anemia, strengthen weak muscles, reverse psoriasis, improve memory and balance, and even "appears to help multiple sclerosis." (Mindell sometimes calls lecithin "the Roto-Rooter of the nutritional world" because "it cleans out blood vessel walls.")

Flyer #31 claims that superoxide dismutase (SOD) is an "anti-aging enzyme" which may be effective against arthritis, atherosclerosis, cancer and senility. Even if this were true, SOD in pill form could not possibly be effective. Tests on animals have shown that oral supplementation does not affect tissue SOD activity—a finding easily predictable from the fact that SOD, like all other proteins, would be digested rather than absorbed intact into the body.

Flyers #9A and #9B endorse the theory of Dr. Benjamin Frank that increasing intake of RNA and DNA through dietary measures or supplements will "reverse the aging process." [Dr. Frank's *No-Aging Diet*, popular a decade ago, recommended eating sardines, yeast and other foods rich in these nucleic acids.] Nucleic acids, found in all living matter, are basic to cell reproduction. Like SOD, however, those that are eaten are digested and never reach the cells intact. Moreover, nucleic acids are like specific blueprints. If DNA and RNA from yeasts or sardines could actually work in humans, they would turn them into young yeasts or baby sardines.

Mindell says that everyone should take supplements. He claims that foods from the grocery store are depleted of vitamins and minerals and therefore are nu-

tritionally inadequate. He says that smokers need extra vitamin C, those who drink alcohol need extra B-vitamins, and that women taking birth control pills need extra B₆. During his talk in Tucson, Mindell said he personally takes "20-odd" supplements twice daily. He also said that "natural" vitamins like natural vitamin C with rose hips are better than synthetic ones. Even Linus Pauling, whom Mindell frequently quotes, has pointed out that there is no difference between the two in nutritional value.

Mindell's lecture included advice that is potentially dangerous. He said, for example, that vitamin A is safe in amounts up to 100,000 IU per day and that any potentially toxic doses carry warnings. Neither of these statements is true. Cases have been reported in which daily dosage with 25,000 IU of vitamin A has caused toxic levels to build up in the body over periods of months or years. And supplements of this strength do not contain warning labels.

Mindell also recommended exclusive use of whole grains, saying these cannot be harmful unless massive amounts are eaten. Whole-grain foods are perfectly fine for people who are healthy as long as they don't eat too many of them. However, whole grains contain phytates, which can prevent mineral absorption. Americans with borderline intakes of some minerals could become mineral-deficient by consuming excessive amounts of whole cereal grains and fiber.

Mindell told the audience that 300 milligrams daily of zinc supplementation is safe, but research reported in the *Journal of the American Medical Association* [246:2188, 1978] shows that dosages of more than 150 milligrams daily may cause serious copper loss. According to Dr. Harold Sandstead, a major zinc researcher, people who take more than 50 milligrams of zinc a day should have their copper levels monitored. In fact, it has been reported that supplements of only 15 milligrams per day can cause above-normal copper loss [*Journal of Nutrition* 108:1449, 1976].

At one point during his talk, Mindell tried to persuade a member of the audience to follow his advice rather than that of his doctor by claiming that medical doctors are ignorant about vitamins.

Now retired from active management of his stores, Mindell spends much of his time writing, lecturing and appearing on talk shows. Despite the astonishing number of inaccuracies he has been promoting, his ideas are rarely questioned in encounters with members of the media.

Dr. Lowell, a board member of the National Council Against Health Fraud, is Professor of Life Sciences at Pima Community College, Tucson, Arizona, and writes occasionally for *The Arizona Daily Star*.

MORE HERB RESEARCH NEEDED

Varro E. Tyler, Ph. D.

When experts are asked whether a particular herb is really good for such things as upset stomach, insomnia or headache, the answer is usually, "We honestly don't know," or somewhat less frequently, "It depends." Such responses are necessary because, in most cases, the botanical, chemical, pharmacological, and therapeutic research needed to permit a definitive response has never been carried out. Still, with the popularity which the use of herbal medications has now attained, this kind of research is urgently needed.

The reasons why it is not being done already are complex but basically involve money. Before drugs can be marketed in the United States, they must be proven both safe and effective in human beings. This lengthy, complicated procedure now costs an estimated \$75 million for a single medication. Because most herbs have been around for a long time, the chance of obtaining patent protection on new findings concerning one of them is slight; therefore, the discovery cannot remain the exclusive property of the organization conducting the costly research. This reduces the incentive to conduct such research to nearly zero.

Some research is being carried out, but mainly in developing nations where herbal medicine is an accepted form of treatment. Unfortunately, the studies are often poorly designed and do not yield scientifically valid results.

There are some exceptions. A few technologically advanced nations, such as the German Federal Republic (West Germany), which have a long tradition of using plant-derived drugs, have capable scientists who do produce new and useful answers to some of our longstanding questions about herbs. Let's look at two examples.

Calamus, or sweet flag, the aromatic rhizome (underground stem) of *Acorus calamus* L., has been used since biblical times, primarily as a digestive aid and flavoring agent. Tests conducted in 1967 showed that the volatile oil of Jammu (Indian) calamus produced malignant tumors in rats. This activity, resulting from a high concentration (ca. 75%) of β -asarone in the oil, caused the U.S. Food and Drug Administration to ban calamus for human use in 1974.

Studies carried out since that time in Germany and The Netherlands have revealed that the matter is not as simple as first thought. The oil of a North American variety of *A. calamus* contains no carcinogenic β -asarone; the European type contains relatively little.

and Asian types contain large to very large amounts. So oil from the North American calamus can be used to produce a useful antispasmodic product devoid of any hazard to human health.

For years, a sedative action has been attributed to hops, the scaly, cone-like fruits of *Humulus lupulus* L. Hop pickers working in the field seemed to tire easily; mothers filled small pillows with hops and placed them under their children's heads to encourage sleep. Until recently, no active principle capable of producing this effect had been identified in hops, so the reported activity was thought to result from a placebo effect.

But in 1982, German scientists reported that hops contains a volatile, unsaturated alcohol identified as 2-methyl-3-butene-2-ol. Although it existed only in traces in the fresh plant material, its concentration increased during storage at room temperature until it reached a level of about 0.15% after two years. In rat studies this compound showed a definite sedative/hypnotic effect and, being volatile, could account for the effectiveness of hops pillows. The active principle of hops is also closely related chemically to 3-methyl-1-pentene-3-ol, a hypnotic drug now sold in Europe under the trade name Allotropal.

These are just two examples of potentially fruitful results that can be obtained by applying modern research methods to ancient herbal drugs. Additional studies of this sort are urgently needed to provide definitive answers to questions about these interesting and potentially useful remedies. Much of the advice in this field is simply copied from the writings of the 16th century English herbalist John Gerard or the 17th century English apothecary-astrologer Nicholas Culpeper. Instead of relying on such outdated information, herbal advocates would be well advised to encourage competent researchers to undertake studies in this area. Preliminary work could be carried out with relatively modest financing. If initial findings prove promising, more substantial support might become available from governmental, industrial or private sources, including foundations.

Dr. Tyler, Dean of Purdue University's School of Pharmacy, Nursing, and Health Sciences, is an expert in pharmacognosy (the science of medicines from natural sources) and author of *The Honest Herbal*, an evaluation of popular herbs.

NUTRITION FORUM

VOL. 3 NUMBER 7

JULY 1986

ISSN 0748-8165

THE AMERICAN ASSOCIATION OF NUTRITIONAL CONSULTANTS: WHO AND WHAT DOES IT REPRESENT?

Stephen Barrett, M.D.

"... Whatever your specialty, one thing is certain. If you offer nutrition or dietary counseling as part of your service, you should proclaim your professional status by joining the American Association of Nutritional Consultants. When you display the prestigious A.A.N.C. Membership Certificate on your wall, you make your clients, patients, and professional colleagues aware of your commitment to high standards and professional competence in Nutrition Counseling. And you demonstrate your dedication to the cause of good health through nutrition by supporting your Professional Association."

So states "An Open Letter To All Health Professionals" in recent issues of *The Nutrition & Dietary Consultant*, the monthly publication of the American Association of Nutritional Consultants (AANC), 2375 East Tropicana, Suite 270, Las Vegas, NV 89109. The certificate—printed on imitation parchment paper and complete with gold seal and red ribbon—does indeed look attractive and professional. But those who encounter it would be wise to look closely at what it signifies.

AANC's roots

According to AANC's founder, Henry Holcomb, the group began operations in 1981 as the American Association of Nutrition & Dietary Consultants (AANDC). During 1983, AANDC assumed its current name and absorbed a similar group, the International Academy of Nutritional Consultants (IANC).

IANC was formed in 1979 by Kurt Donsbach, D.C., founder and president of Donsbach University School of Nutrition, an unaccredited correspondence school. Donsbach, dubbed "the vitamin king" by the *Los Angeles Times*, is also board chairman of the National Health Federation, a group which promotes the gamut of unorthodox health practices. In 1970, while Donsbach operated a health food store, agents of the Fraud Division of the California Bureau of Food and Drug observed

him representing that vitamins, minerals and herbal tea would control cancer, cure emphysema (a chronic lung disease), and the like. Charged with nine counts of such illegal activity, Donsbach pleaded guilty to practicing medicine without a license and agreed to cease "nutritional consultation." Currently he is therapy director of the Biogenesis Institute, a Mexican clinic offering "aging rejuvenation," "immune stimulation," and "guaranteed" treatment of arthritis, cancer, cardiovascular disease, multiple sclerosis and other ailments.

Regular IANC membership, which was open to anyone, cost \$10 per year (later raised to \$12/year) and included a subscription to its journal, "Professional membership," which cost \$50 per year, included a directory listing plus a "beautiful certificate for your office." Sustaining membership, \$150 a year, entitled members to a 15% discount on advertising in the journal. Most of the 50 or so sustaining members had commercial interests in methods promoted by the journal. Applicants for professional or sustaining membership were asked to name their professional degree and specialty. However, no questions were asked about the origin of the degree, and no effort was made to check the credentials or reputation of any applicant.

In 1979, IANC began publishing *The Journal of the International Academy of Nutritional Consultants* with a press run of 25,000 copies, most of which were sent free-of-charge to chiropractors. Its first editor was Alan Nittler, M.D., a California physician who had lost his license to practice medicine in 1975 as a result of using unproven "nutritional therapies." After three issues he was replaced by Hans Kugler, Ph.D., president of the International Academy of Wholistic Health and Medicine, and author of *Seven Keys to a Longer Life*. In 1981, the journal was renamed *Health Express*, Donsbach took over as editor-in-chief, and marketing was begun through health food stores and newsstands. During most of 1982, Holcomb served as editor, general manager, and director of sales, while Donsbach was listed on

the masthead either as editorial director or as editor-in-chief.

AANC's membership structure is similar to that of IANC: associate membership costs \$30, professional membership costs \$50, sustaining membership costs \$100, and lifetime membership is \$250. In June 1986, it listed 111 lifetime members. During most of AANC's existence, membership applications have asked nothing about qualifications but noted that "degree initials, if any" would appear on the certificate if included on the application.

AANC's monthly publication

AANC's "journal" has been published under various names and in several formats. It began in 1983 as a tabloid newspaper called *The Nutrition and Dietary Consultant* and was renamed *The Nutritional Consultant* later that year. When IANC and AANC merged, their publications merged to become *The Nutritional Consultant & Health Express* ("The Magazine People Read For Nutritional Advice"). Toward the end of 1984, it was called *Your Nutritional Consultant* ("The Magazine America Reads for Nutritional Advice"). In 1985 it again became *The Nutrition & Dietary Consultant* ("America's Only Journal For The Practicing Professional").

Until recently, Henry Holcomb was designated as publisher and Myra E. Holcomb, who was also AANC's executive secretary, was listed as editor and general manager. The Statement of Ownership, Management and Circulation submitted to the Postal Service in October 1985 listed the two of them as owners and declared a paid circulation of 8,196, down from 12,685 in 1984. In March 1986, however, Henry's name disappeared without explanation from AANC publications and Myra was designated as publisher and editor. At the same time, the journal reverted to tabloid newspaper format in order to save money.

For the first few issues after the merger that formed AANC, its national board of counselors was listed on the journal's masthead with Donsbach as chairman. But a few months later, this listing was dropped and Donsbach's name appeared as one of six contributing editors. At various times, AANC's letterhead has listed seven, eight or nine members on its national board of counselors, one of whom, until recently, was Gary Pace, of Garden City, New York. In July 1985, Pace, who holds a "Ph.D." from Donsbach University, was accused by the New York State Attorney General of misrepresenting his credentials, practicing medicine without a license, and defrauding more than 250 clients. Actions were also begun to stop Donsbach University from marketing its courses to New York State residents [see NF 2:70-71].

Shortly after the attorney general took action, Holcomb notified AANC members in Northeastern states that Pace had temporarily obtained permission to

solicit funds to set up New York and North East chapters of AANC. The notice stated that Pace had announced his election as president of the New York Chapter without actually holding elections, that he had refused to render a financial accounting to AANC headquarters, that he was "illegally circulating a letter on AANC stationery soliciting funds in the name of AANC." Pace was then removed from the AANC board, and Donsbach's name disappeared from the masthead of *The Nutrition and Dietary Consultant*.

AANC says its journal is "edited specifically for you who do now, or plan in the future, to earn all or part of your income through counseling on good health or proper nutrition, and for those of you who offer nutritional advice as part of your overall professional services." Each issue contains articles promoting unproven and unscientific practices as well as ads for questionable products, some of which have been subjected to government enforcement action for misbranding. At various times, AANC members have been promised two monthly journals (each with various names), one geared to professionals and the other to "knowledgeable" laypersons. But as noted above, only one has been published so far.

AANC's directory

AANC's 1986 *National Profile Directory of Nutritional Consultants* lists 686 practicing "professional nutritionists," but states that since listing requires a written request, the list "in no way represents the total membership of AANC which at press time stood at 5,618." (This number is probably inaccurate because it is identical with the number listed in the 1985 directory.) The directory is intended to facilitate member-to-member referrals and is to be distributed free at health shows, seminars, conventions, and other distribution points where it can reach potential clients. Listings include the consultant's name, address, telephone number, tests utilized, modalities offered, and areas of specialization. Nineteen percent of those cited are chiropractors. Nine percent have no listed degree, 12% a B.A. or B.S., 10% an M.A. or M.S., 23% a Ph.D., and 3% a medical degree. The rest displayed one or more of some 40 sets of initials, many of which I could not recognize.

Copyright © 1986 by the GEORGE F. STICKLEY COMPANY
Nutrition Forum ISSN 0748 8165 is published monthly by the George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106. Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES: \$30/yr., \$57/2 yrs., \$81/3 yrs., prepaid; VISA and Mastercard acceptable: foreign postage by airmail add \$18.00. Manuscripts, books for review, and other editorial correspondence should be sent to Dr. Stephen Barrett, P.O. Box 1747, Allentown, PA 18105. Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

"Tests utilized" include complete workup by a medical doctor, hair analysis, herbal crystallization, urine analysis, blood analysis, a test to determine metabolic type, a saliva test, iridology, kinesiography, computerized questionnaires, diet analysis, and cytotoxic testing.

"Modalities offered" include acupuncture, acupressure, intravenous chelation therapy, oral chelation therapy, general medicine, detoxification, herbology, homeopathy, hypnosis, naturopathy, nursing, optometry, osteopathy, reflexology, colonic irrigation, chiropractic, dentistry, biofeedback, hydrotherapy, massage, yoga and megavitamin and mineral therapy.

The "nutritional support specialties" are allergies, cancer, diabetic nutrition, drug rehabilitation, endocrine disturbances, general nutrition, geriatric nutrition, hypoglycemia, pediatric nutrition, skin conditions, smoking cessation, sports nutrition, stress management, temporomandibular joint dysfunction, weight control, premenstrual syndrome, prenatal nutrition, heart and blood conditions, digestive problems, and spines, bones, joints.

AANC's directories contain ads similar to those in its journal. The 1985 directory included ads for homeopathic remedies, pau d'arco [a supposed cancer remedy described in *NF* 2:8], amino acid products, two "oral chelation" products that were subsequently ordered off the market, a colonic irrigator, and hair analysis (for which AANC members receive a 36% discount). The current directory includes ads for food supplements and a Mexican hospital where laetrile and other quack treatments are administered.

Anyone can join

It is clear that membership in AANC and its predecessors has been open to anyone. In 1983, Sassafras Herbert (a poodle) became a professional member of AANDC and Charlie Herbert (a cat) secured professional membership in IANC. Both were household pets of Victor Herbert, M.D., J.D., a prominent nutrition scientist. All Dr. Herbert did was submit their name and address plus \$50. According to a story in *The Washington Post*, when a reporter asked Henry Holcomb how Sassafras Herbert could have gained admission to AANDC, he replied that a "membership profile" should have been sent for completion.

The article also quoted Kurt Donsbach as saying that professional members in IANC were required to have "adequate professional background . . . either a degree in the healing arts or a graduate of Donsbach University." The IANC application had asked four questions on professional background, but "Charlie" had left them blank. Despite widespread publicity of the pets' entry into the world of nutritional consultation, their memberships were not cancelled. After the AANDC membership year was up, Dr. Herbert obtained a new "professional membership" in AANC by sending \$50

plus the name and address of another dog.

In January 1985, ads in *The Nutrition & Dietary Consultant* began inviting readers to send for a "Member Application and Qualifications Questionnaire." The application asks for name, address, phone number, school attended, major, degree and year earned, how long the applicant has been involved professionally in the field of nutrition, names of other health associations to which the applicant belongs, and the names of two nutrition-oriented health care professionals who can provide references. After this process began, an individual known to me completed an application under an assumed name, listing a degree from a nutrition diploma mill and providing appropriate references. Membership was granted as soon as the application was received. AANC did write to the persons listed as references—not for information about the applicant, but to ask them to join AANC! Another person I know bypassed the application process and simply sent a \$50 check and the name and address of her pet hamster. She too was notified of acceptance within a few days. The last few issues of *The Nutrition and Dietary Consultant* contain a coupon application for membership which, as in previous years, asks only the applicant's name, address, and "degree initials, if any."

The application for AANC's malpractice insurance policy is also curious. AANC's professional members are eligible for a \$1,000,000/\$3,000,000 policy. The premium varies from \$52 to \$138 according to the number of hours worked per week. But the application asks nothing about the applicant's training, credentials, or type of practice!

"Certification"

AANC's professional members are also invited to become "Certified Nutrition Consultants." According to AANC, "The trademark designation CNC after a Nutritional Consultant's name testifies to the world that the practitioner's qualifications have been certified by his or her Professional Association—that he or she has met professional requirements in addition to, and beyond, normal academic studies and/or professional experience." Some AANC literature refers to an "RNC" designation for "Registered Nutritional Consultant." In June 1986, AANC listed 85 "Certified Nutritional Consultants."

According to an article by Myra Holcomb, CNC applicants must be professional members in good standing in AANC "and have met the high eligibility requirements for membership." However, the CNC application form asks nothing about training, experience or qualifications, but merely requests the names of three professional references (which are not contacted). Applicants must pay a \$150 fee, demonstrate knowledge of practice management and the laws pertaining to nutritional consulting, and pass a self-administered 2,000-question test on general and applied nutrition. They

must acknowledge in writing that information presented in the certification program "is not intended as a substitute for licensed medical care, and is offered for educational purposes only." And they must release AANC "from any damages, claims, or liabilities whatsoever resulting from the information presented." Successful applicants receive an attractive certificate.

The CNC nutrition exam is divided into sections on basic anatomy, principles of nutrition, vitamin therapy, nutrition and common ailments, biochemical individuality, higher nutrition, orthomolecular nutrition, nutrition against disease, diet and disease, child nutrition, geriatrics, acquired body toxins and their elimination, and psychodietetics. Candidates are required to submit a notarized statement that no "second party" helped with the test, but they are given a list of books, purchasable from AANC, each of which can help answer the questions in one section of the test.

The test questions are divided about equally into multiple choice and true/false types. Candidates are

asked to choose "the most accurate" answer even though in some cases, "if the candidate is real sharp and wants to get tricky, he or she might be able to point to special cases or circumstances where none of the choices is correct." Nutrition experts who reviewed portions of the exam at my request have noted that many questions have no correct answer and that the test contains many misspelled words. The clinical significance of some questions—like one about whether whole wheat flour can support the life of weevils—is rather obscure.

"Nutritionist" licensing

As noted in the May 1985 *Nutrition Forum*, dietitians have been spearheading bills to restrict use of the word "nutritionist" to individuals with recognized credentials. Some of the bills also define "nutrition practice" and restrict it to licensed practitioners. This drive was stimulated largely by the rise of unaccredited nutri-

MORE CREDENTIALS, ANYONE?

- The American Nutrition Consultants Association (ANCA), 700 East Green St., Pasadena, CA 91101, established in 1977, is open to "anyone interested in the fields of nutritional science and nutritional consultation, and in developing, perfecting and updating one's scope of nutritional knowledge." ANCA's only requirements for membership are payment of \$35 and completion of an application form which asks for one's name, address, telephone number, gender, age (optional), and spouse's name. Years ago there was an optional question about professional activities; but forms distributed recently no longer have this. Members receive a certificate suitable for framing and a monthly newsletter called *Life Lines*.

ANCA's brochure suggests that "every normal, healthy man, woman and child should seek the advice of a nutritionist for evaluation of his/her nutritional needs." So should people involved in active sports, children, teenagers, pregnant women, persons suffering from chronic diseases such as arthritis and multiple sclerosis, individuals on medication, people with weight problems, people over 60, and people in job or life-related stress situations.

The catalogue for ANCA's unaccredited School of Nutritional Science defines a nutrition consultant as: "one who is trained in the science of dietetics and nutrition for the purpose of providing information to the public as a consultant in the matters of achieving proper dietary regimens for maintaining a state of optimal health. The profession is often practiced in conjunction with the distribution of health foods and food

supplements."

ANCA's president, James D. Flaherty, Ph.D., is administrator and sole faculty member of the school. According to him, "The world is waiting for people knowledgeable in nutrition for the purpose of maintaining a state of optimal health . . . These people have the opportunity of becoming a part of the biggest boon to humanity since time began." His 60-lesson correspondence course, which costs \$495 and must be completed within six months, is composed of material he has written. According to the catalogue, "a Diploma is awarded for satisfactory completion of the course, or a Certificate of Completion for unsatisfactory completion of the course." Flaherty's "doctoral degree" in nutrition is from unaccredited Donsbach University.

All ANCA members and graduates of its school are offered free listing in ANCA's *Registry of Nutrition Consultants*. According to ANCA, "the fact of registration establishes you as a Registered Nutrition Consultant."

- The American Nutritional Medical Association (ANMA), 1326 Dearborn St., Gary, IN 46403, was founded in 1982 to promote increased public understanding and legal recognition of "nutritional medicine and alternative holistic health care." Its manifesto defines nutritional medicine as "that branch of alternative health care which deals with the treatment or prevention of disease through the use of vitamins, minerals, herbs, amino acids, homeopathy, and natural health care education and counseling. This is NOT a branch of

tion schools and organizations such as AANC. The dietitians believe—as I do—that government should try to protect the public against individuals who misrepresent their credentials.

AANC is one of the groups fighting against these bills. It has urged formation of state chapters and has even drafted a model “Nutritional Counselors Licensing Act” of its own. The bill defines “Nutrition Counselor” as someone who charges money for nutrition counseling, nutrition care service, or nutrition education. “Nutrition counseling” includes “assessment of nutritional needs and food patterns . . . and the recommending of appropriate nutritional intake, for both normal and therapeutic needs.”

Section 5(h) of the bill states: “An applicant’s method of study, or educational preparation for the examination, or schools, or colleges, or universities attended shall not be a concern of the [licensing] Board. Such considerations shall be considered discriminatory. Determination of the applicant’s knowledge of nutrition shall be based solely upon results of the written examination.”

What examination? “To facilitate and assist the Board in the writing of the examination,” says Section 6(i), “the Board shall base the examination questions upon the examination (consisting of 2,000 questions) currently in use by The American Association of Nutritional Consultants in its Member Certification program, and upon such tests offered by other nutrition-oriented professional or trade associations, deleting or adding any question the Board deems appropriate.” In other words, the questions are to be supplied by AANC and like groups whose members would presumably have access to them before taking the test.

Section 6(a) states that, “Until such date as the First Board shall provide a written and approved examination . . . any person applying for licensure, who meets all the other requirements as set down in this act and upon the payment of \$100.00 application fee shall be granted a temporary license.” (The “other requirements” are met by being at least 18 years of age, a high school graduate, and of good moral character.) Section 7(c)

(Continued on next page)

allopathic medicine, and practitioners of NUTRIMEDICAL ARTS and SCIENCES should never let their patients think so!”

ANMA offers its members “registration and/or certification in various “alternative health care specialties.” Its members may become Fellows of such august bodies as the American Board of Family Nutrimecists, the American College of Naturopathy, the American College of Otolaryngology, the American Board of Homeopathy, and the American Board of Nutrimecical Obstetricians and Gynecologists. Certification is also available as a chiropractic therapist, massage therapy technician, nutritional medical counselor, nutrimecist, and naturodermacist. (None of these “credentials” is recognized by the scientific community.)

Regular ANMA membership is \$100 for the first year and \$50 per year thereafter, but discounts are sometimes offered. Associate membership costs \$60 for the first year and \$40 thereafter. Although the application asks for education and professional affiliations, these are not verified. Members who recruit new members receive a \$5 commission. The 1986 ANMA Directory indicates that there are about 200 members in the United States. Among those listed are Linus Pauling, Ph.D., Bruce W. Halstead, M.D., and Robert Mendelsohn, M.D. For an additional \$25, ANMA members can join the United Natural Health Association, from which they receive a Certificate of Fellowship.

ANMA operates John F. Kennedy College of Nutrimecical Arts & Sciences (American Nutrimecical

University), which offers a variety of degrees and certificates through correspondence courses. Its 1-year Doctor of Nutritional Medicine (N.M.D.) course costs \$1,895, but ANMA publications indicate that “nonacademic N.M.D. degrees” have been awarded to members who already held a doctoral degree or qualified through other experience. About half of those listed in ANMA’s directory have “NMD” after their name. The 1½-year Doctor of Chiropractic (D.C.M.) course costs \$2,400. The Nutritional Medical Counselor (N.M.C.) course costs \$800. ANMA members receive a 10% discount. Students who pass with lower than a C average are issued a certificate of completion rather than a diploma.

• *The American Holistic Health Sciences Association*, 1766 Cumberland Green, Suite 208, St. Charles, IL 60174, formed in 1979, charges \$70 for first-year membership and \$40 per year thereafter. Upon acceptance, members receive a hand-calligraphed certificate stating that they have “been elected by the A.H.H.S.A. board of examiners as a Fellow of the Society of Nutrition and Preventive Medicine in recognition of the contributions made towards the promotion and advancement of scientific nutrition and preventive healthcare.” Each also receives a certificate from AHSA’s National Board of Registration and Examination stating that he has “completed all required prerequisites . . . and is hereby recorded as a Registered Holistic Practitioner.” Members also receive a free copy of the book *How To Practice Nutritional Counseling Legally Without Being Guilty Of Practicing Medicine Without A License*, by Chester P. Yozwick, C.N.A., N.D., P.M.D.

states that persons employed and supervised by a licensed nutritional counselor do not have to be licensed.

The proposed seven-person board, chosen by the state governor, is to be composed of two licensed nutritional counselors and two public members. Professional members of the first board are to have been practicing nutrition counseling for at least five years. Section 3(k) states that they may not have been officers of "a professional society or trade association of nutritionists or dietitians" during the year prior to appointment. But Section 3(l) states that they cannot have "a financial interest in, or be engaged in, any business or company or employed in such interests involved in the sale of nutrition related products such as food or food supplements." Since most AANC members appear to sell food

supplements, it is unclear who the group expects to be eligible.

Several things are clear, however. AANC is promoting a wide variety of unscientific nutrition theories and practices. Its application process and credentials are a sham. Its members are not required to have any legitimate training. And it wants state governments to allow them to practice as they please.

In my opinion, AANC does have a potentially valuable aspect. Membership in the group is a reliable sign of someone NOT to consult for advice.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 20 books including *Vitamins and "Health" Foods: The Great American Hustle*.

BRIEFS

Amway fine expected. Under a proposed consent decree, Amway Corporation will pay a \$100,000 civil penalty to settle Federal Trade Commission charges that in 1983 the company violated a previous Commission order by making earnings claims for its distributors without disclosing actual average gross income figures. In 1979, the Commission had ordered that whenever the company makes above-average earnings or sales claims, it must disclose clearly and conspicuously either the average earnings of all distributors or the percent of distributors who actually earned the amount claimed. Amway manufactures and markets food supplements and various other products through a multilevel organization in which distributors resell to other distributors or sell directly to consumers. The proposed consent decree is subject to federal court approval.

Aspartame update. Opponents of aspartame lost another round in their efforts to force the FDA to hold new hearings on aspartame's safety when the U.S. Supreme Court refused without comment to hear an appeal by the Community Nutrition Institute and other critics. Last September, a U.S. Circuit Court of Appeals ruled that the FDA had followed proper procedure in approving the sweetener [see NF 2:85]. According to *American Medical News*, recent claims by Dr. Richard Wurtman that 86 aspartame users had experienced seizures have not persuaded the FDA that aspartame is unsafe, but the agency has offered to help set up a controlled study involving some or all of the alleged victims. Meanwhile, however, Dr. Andrew Kulczycki, Jr., of Washington University School of Medicine, St. Louis, has reported confirmation by double-blind studies of allergic reactions to aspartame in five women whose symptoms included hives, itching, rashes and swelling.

The next Herbalife? United Sciences of America (USA), a multilevel company with many prominent scientists on its advisory board, appears to be growing rapidly. According to one of its leading distributors, the company acquired more than 40,000 distributors and had sales in the tens of millions during its first five months of operation. It is selling four products: an antioxidant formula, a fish oil formula, a fiber candy bar, and a powdered meal substitute. The company's introductory videotape, which refers to cancer and heart disease, states (falsely) that USA's products are "a complete nutritional program to protect us from the growing dangers that are threatening the health of our nation."

Meat consumption trends. According to The Food Institute, per capita consumption of poultry advanced nearly 43% since 1970, while red meat consumption fell more than 8% during the same period. Due to slumping demand, prices for all beef cattle in 1985 were at their lowest average in seven years.

Fast foods in hospitals. At least three hospitals have entered joint ventures with fast-food restaurants on their premises. The Children's Hospital of Philadelphia has replaced its visitors' cafeteria with a McDonald's restaurant in its lobby. Abington Hospital, in a northern Philadelphia suburb, has done the same with a Friendly's restaurant. Miami Valley Hospital in Dayton, Ohio, rents space to a Wendy's restaurant under a profit-sharing agreement. Because such arrangements enable hospitals to serve larger numbers of visitors and are also popular with employees and ambulatory patients, hospital administrators predict that they will become increasingly common.

General Nutrition trial. On May 27, the U.S. District Court in Buffalo, New York, denied a motion by General Nutrition, Inc., to dismiss criminal charges against the company and several of its employees. The defendants are charged with violating the federal Food Drug and Cosmetic Act by marketing an evening primrose oil product with claims that it is effective against high blood pressure, arthritis and other diseases [see NF 1:20]. The defendants had claimed that their product is a "food," not a drug, and that claims made for it are protected by the right to free speech. But the court ruled that therapeutic claims made in marketing a product make it a drug under the law and that such claims are illegal unless a product has FDA approval as safe and effective. The trial is scheduled to begin November 3.

Airline meals. A survey of 15 airlines reported in the June 1986 *Nutrition Action Healthletter* found that virtually all offer vegetarian, fruit platter, seafood, low-fat/cholesterol, low- or no-salt, and kosher meals. Some also serve Hindi, Muslim, Oriental, bland, and low-fiber meals. Special meals cost nothing extra but should be requested at least 24 hours before flight time.

Food safety on cruise ships. According to an article in *American Medical News*, outbreaks of gastrointestinal illness have become uncommon as a result of cooperation between the cruise ship industry and the U.S. Centers for Disease Control (CDC), which in 1976 began an inspection program to correct deficiencies in the sanitation systems of cruise ships sailing from U.S. ports. Travel agents can be put on the CDC "Blue Card" mailing list which notes how ships have done on their most recent inspection. To investigate failing scores, agents or prospective passengers can obtain inspection summaries or full reports by specifying ship names and contacting: Office of the Chief, Sanitation and Vector Control Activity, Division of Quarantine, 1015 N. American Way, Room 107, Miami, FL 33132.

International symposium. A symposium on diet and health will take place on October 19-22, 1986 in Alvor, Portugal. Sponsored by the International Life Sciences Institute (ILSI), its purpose is to review the scientific basis of dietary recommendations and the extent to which they may be quantified. The American Dietetic Association is a cosponsor. ILSI is a nonprofit foundation established in 1978 to promote understanding and resolution of major health, nutrition and safety issues worldwide. Its membership includes more than 100 industrial and professional groups. Further information about the symposium can be obtained from Mrs. Gretchen Bretsch, International Life Sciences Institute, 1126 16th St., N.W., Washington, DC 20036.

Beta-carotene supplements. More than 20,000 physicians are still enrolled in an 8-year study to determine whether supplementation with beta-carotene capsules can prevent cancer [see NF 1:7, 1:23, 2:46]. The project's director, Charles H. Hennekens, M.D., of Harvard Medical School, stated recently that no other study in progress or planned is addressing this issue. In a letter to the project's participants, he noted that a positive result would lead to prevention of many deaths, while a conclusive negative result would also be valuable because research energy could then be shifted to more promising issues. He also warned that although no proof of effectiveness exists, beta carotene supplements are being promoted intensively through lay publications and other channels.

QUESTION BOX

Q. Is there any danger in allowing children to drink small amounts of coffee, such as half a cup two or three times a week? Would it be better for them to drink decaffeinated rather than regular coffee?

A. Although there is no conclusive evidence linking moderate coffee or caffeine intake with ill health, it may be sensible to keep coffee out of children's diets rather than displace important foods such as milk and juice. If parents allow their children to drink coffee, a decaffeinated variety is probably better. Because of their low weight, children are more affected by a caffeine dose than are adults. Parents may also be interested to know that of all population segments, children between ages one and five have the highest caffeine intake per kilogram of body weight. Soft drinks are the sole or primary source of this caffeine.

Q. How is coffee decaffeinated? Does the method leave harmful residues?

A. Coffee manufacturers in the United States use chemical solvents to remove caffeine from coffee beans. The most common method involves steaming the beans so that the caffeine is drawn to the surface. They are then repeatedly washed with a chemical solvent to remove the caffeine. The solvent residue is then removed by steaming the beans a second time. Methylene chloride is the solvent most often used in this process. In large amounts, this chemical would be objectionable or even hazardous in the diet. But because no or only insignificant traces of methylene chloride remain on the coffee beans after the second steaming, the FDA approves its commercial use. Ethyl acetate, a chemical found naturally in some fruits, is another solvent used in the decaffeination process. It, too, is harmless in very small amounts.

CONSENSUS ON DIETARY GOALS HOPED FOR

A committee of the National Research Council's Food and Nutrition Board (FNB) is evaluating the health effects of diets and dietary constituents such as fiber, fats and protein. The study's goal is to determine what dietary guidelines for maintaining health and reducing the risk of chronic disease can be formulated on the basis of current scientific evidence, both published and unpublished. In addition, the committee may propose strategies for implementing the guidelines and will identify areas for further research. It is hoped that a detailed scientific report will be available in the Fall of 1988.

On May 13, a public meeting of the committee was held at the National Academy of Sciences to receive comments from a number of invited individuals and groups. Some highlights:

- Lloyd J. Filer, M.D., Ph.D., the new Executive Director of the International Life Sciences Institute—Nutrition Foundation, urged that contributions of genetic background and environmental factors be integrated into the study. He also urged that the study take into account the sensory properties of food, the social aspects of eating, and the effect of food choice on quality of life.

- A. Harold Lubin, M.D., Director of the American Medical Association's Department of Foods/Nutrition and Personal Health, expressed hope that in addition to delineating areas of agreement, the new study would identify research needed to resolve existing controversies. Since exercise is closely related to nutrition and health status, he also suggested that this relationship should receive major emphasis in formulating "preventive nutrition policies."

- Donald J. McNamara, Ph.D., Professor of Nutrition and Food Science at the University of Arizona, cautioned: 1) research on dietary cholesterol requires very careful interpretation because individuals vary greatly in their response to dietary cholesterol; 2) the way cholesterol is lowered may be as important as the blood levels themselves; 3) the common idea that cholesterol-containing foods are "bad" and cholesterol-free foods are "good" does little to educate high-risk patients in effective dietary changes to lower an elevated blood cholesterol level; and 4) individuals who choose a hydrogenated vegetable oil product because it has no cholesterol are not making an effective dietary change.

- Claire M. Wilson, of the Vegetarian Society of the District of Columbia, stated that although 10 million Americans eat meat-free diets, "data on meat abstinence are sparse in relation to the population that requires such information."

- Dr. Suzanne S. Harris, Deputy Assistant Secretary for Food and Consumer Services, U.S. Department of Agriculture, expressed concern that conflicting recommendations given to the public can lead to a loss of credibility in the genuine benefits of a good diet. For this reason, she cautioned that criteria for acceptance of evidence should be stringent, and only conclusions that are clearly sound and have potential for being permanent should form the basis for guidelines for the public. Referring to the 1985 USDA/HHS *Dietary Guidelines for Americans* [see NF 3:30-31 and 3:43], she expressed hope that the new FNB committee would coordinate with other agencies so that public and governmental agencies "speak with one voice" to avoid confusing consumers. She also noted that USDA's Human Nutrition Information Service has gathered valuable information on food composition, nutrient content of the U.S. per capita food supply, eating patterns and food costs.

Data on American eating patterns are gathered mainly through USDA's Nationwide Food Consumption Survey which is conducted every ten years. The next survey, scheduled for 1987-88, will be the largest and most comprehensive ever done by the agency. It will document the eating habits of 15,000 to 17,000 individuals in 6,000 "basic" households, and an additional 10,000 to 11,000 individuals in 3,600 low-income households. Interviewers will utilize portable computers to enter data on age, income and education as well as food consumption. Twenty-eight common nutrients will be tracked.

As part of the government's new Joint Implementation Plan for a Comprehensive National Nutritional Monitoring System, the resulting data will be coordinated for the first time with surveys done by other agencies, including the Department of Health and Human Services' Health and Nutrition Examination Survey (HANES-III). This survey, scheduled to begin in 1988, will include health histories, physical and dental examinations, body measurements, and blood tests to measure vitamin and mineral contents.

FIT FOR LIFE

SOME NOTES ON THE BOOK AND ITS ROOTS

JAMES J. KENNEY, PH.D., R.D.

In 1982, in an article in the National Council Against Health Fraud's newsletter, I attacked some of the fallacies of Harvey Diamond's faddish approach to nutrition. At the time, he was touting "food combining" in seminars called the "Diamond Method." I concluded by stating that from a scientific viewpoint this method was "pure zirconium crystal." Little did I suspect that Diamond and his wife, Marilyn, would later produce the fastest-selling diet book in U.S. history: *Fit for Life* [Warner Books, 1985], which reportedly has 1.8 million copies in print.

Since my little exposé was published, the Diamonds have polished their act enough to become stars of the TV talk show circuit. Perhaps to enhance their brilliance, Harvey obtained a "doctorate in nutrition science" and Marilyn obtained "certification in nutrition counseling" from the American College of Health Science (also called the American College of Life Science). This is an unaccredited correspondence school in Austin, Texas, which teaches a naturopathic philosophy called "Natural Hygiene."

Environmental Nutrition Newsletter calls *Fit for Life* "typical of the new wave of books that intertwine scientific detail with pure nonsense." Other best sellers of this type include *Life Extension* by Durk Pearson and Sandy Shaw, *Dr. Berger's Immune Power Diet* by Stuart Berger, M.D., and *Eat to Win* by Robert Haas. All of these books have made millions for their authors and their irresponsible publishers, largely as a result of appearances on the Donahue and Merv Griffin shows.

Fit for Life's central premise is that nutrition depends more on when and how you eat rather than what or how much you eat. The book has two sections. The first, written in Harvey's "voice," covers the principles upon which the book is based. The second, written in Marilyn's "voice," describes their dietary program and provides recipes and sample menus.

In Part I, Harvey maintains that *Fit for Life* is not a diet but "a way of eating that can be incorporated into your life-style as a way of life, not as a dogmatic regimen." But he promises that those who are "sick and tired of hassling with their weight" can learn to "eat and enjoy it, always feeling satisfied and not deprived, always looking forward to meals, and most important, *always* maintaining a comfortable body weight." Moreover, he offers "permanent results" and claims that he lost 50 pounds within a month of being introduced to Natural Hygiene. In Part II, Marilyn presents her testimonial:

"At the age of 31 . . . I spent much of my time in tears, wondering how I was ever going to feel well enough to get on with my life. No amount of drugs, treatment, or therapy that I had had over the years had done anything to change or improve my situation. In all that time . . . no one ever asked me what I was eating! Harvey did! Natural Hygiene, as Harvey was teaching it, supplied me with answers about my health that I had all but given up on finding . . . I learned that I was in pain and out of energy because I had been overtaxing my system with the *wrong kinds of foods* . . . When I put into practice the principles Harvey recommended, I lost twenty pounds! In a matter of only six weeks, and for the first time in my adult life, I was proud of and comfortable with the shape of my body."

Harvey Diamond says his interest in Natural Hygiene was aroused in 1970 by a man who "explained in a most concise way why I was fat and why I was having such a struggle losing weight and keeping it off. It all made such sense to me that I was dumbfounded at its obvious simplicity." After 3½ years of study with this man (who wishes to remain anonymous), Harvey determined that the teaching and practice of Natural Hygiene would be his life's work.

According to Diamond, Natural Hygiene has ancient roots, but its modern movement began in the

United States in about 1850 with the work of Sylvester Graham and three other medical doctors. During the 20th century, the most prominent promoter was Herbert M. Shelton, D.P., N.D., IN.T., D.N.Sc., who from 1928 to 1981 ran a "health school" which included a clinic, laboratory and teaching program in San Antonio, Texas. In *An Introduction to Natural Hygiene* (1922, 1954, 1963), Shelton said that all medicines are "poisons" and that "any patient who can get well in spite of drugs can get well much sooner and more satisfactorily Hygienically." He advised that eating more than one type of food at a meal is undesirable. He claimed that when people are ill, the food they eat will putrify and ferment instead of being digested. And he claimed that fasting is a safe and valuable method of ridding the intestines of putrified and fermented foods. Shelton died on January 1, 1985, at the age of 89.

Like other cults, Natural Hygiene offers simple solutions to life's complex health problems. In *Fit for Life*, the main problem addressed is unwanted pounds and the simplistic answer is food combining. The book's food plan calls for eating only fruit in the morning and mostly vegetables during the rest of the day. This could lead some people to make a desirable increase in their intake of vegetables. But according to an analysis by Katherine Mulgrave, a nutrition professor at the University of Maine, the *Fit for Life* diet is low in calcium, zinc, iron, and vitamins B₁₂ and D. Readers inspired to embrace Natural Hygiene by abandoning modern medical care will, of course, be at even greater risk.

On September 21, 1982, the *Los Angeles Daily Journal* reported that a federal court jury had awarded \$873,000 to the survivors of William Carlton, a Los Altos man who died after being on a diet of distilled water for 30 days at Shelton's Health School. According to the article, Carlton had died of bronchial pneumonia resulting from a weakened condition that also caused him to lose 50 pounds during his last month of life. The article also stated that he had been the sixth person in five years to die while undergoing treatment at the school, which closed in 1981.

Fit for Life is also based on the ideas of John H. Tilden, M.D., author of *Toxemia Explained* (1926). According to Harvey Diamond, "Tilden's book is considered the tour de force in the field of Natural Hygiene" and explains how "toxemia lays the foundation for putting on excess weight." According to Tilden's theories: 1) toxic waste material is retained if the body does not have sufficient energy to excrete it; 2) common cooking practices create food that is incompletely digested and leaves a toxic residue; and 3) accumulated toxic waste causes overweight. Diamond also explains how: 1) eating foods in the wrong combinations causes them to rot so they cannot be assimilated; 2) combinations such as meat and potatoes, eggs and toast, bread and cheese, or chicken and noodles are "a contributing factor to why

people in this country are dying at age 50"; 3) some foods "cleanse" the body while others "clog" it; 4) eggs rot in the body; 5) refined sugars also ferment and produce acids even when consumed alone because refining strips "every vestige of life" from the sugar; and 6) fruits and vegetables, being high in water content can wash and cleanse the body of toxins—but when fruit is eaten at the end of a meal, its absorption is blocked and it ferments.

Actually, all sugars, whether refined or present in fruit, are almost entirely absorbed in the small intestine. But Diamond declares that "fruit should never be eaten with or immediately following anything"—a rule he calls "unquestionably the most important aspect of *Fit for Life*." Actually, fruits contain pectin, which is fermented. If the Diamonds' theory that fermentation products cause obesity were correct, eating fruit would increase obesity rather than cure it!

Like most advocates of "natural" methods, Diamond repeats a number of "nature-is-best" myths. For example, he claims that "animals in nature are magnificently healthy in comparison to the health that we humans experience." but that pets and zoo animals develop "many of the problems of humans." The fact is that most animals in nature are infested with parasites and succumb to infections and malnutrition. It is only because predators usually kill sick animals that we don't see them stumbling across the plains and through the jungles. Perhaps it has never occurred to Harvey Diamond that the average American lives much longer than any mammal in the wild. The reason pets and zoo animals develop debilitating diseases is because they live much longer than their wild "cousins."

Diamond also claims that many people live well past 100 in various remote areas of the world because they eat "high-water" foods. As evidence for this supposed longevity, he cites a 1973 *National Geographic* article in which Alexander Leaf, M.D., was interviewed following trips to three such areas. (Dr. Leaf is chairman of Harvard Medical School's Department of Preventive Medicine and Epidemiology.) However, in an editorial in the August 1982 *Journal of the American Geriatric Society*, Dr. Leaf explained how further investigation had revealed that many individuals had been

Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

exaggerating their age in order to enhance their social status or to promote tourism.

The American College of Life Science, where Diamond got his "doctoral" degree, was formed in 1982 by its current president, T.C. Fry, whom Harvey calls "today's most eminent, active proponent of Natural Hygiene . . . a most brilliant spokesperson for health." Although Fry obviously has high native intelligence, he admitted in a recent radio debate that he was a high school dropout. He also told me that viruses do not exist and that it was just coincidence that smallpox and polio epidemics ceased when people were immunized against the viruses that cause these diseases.

According to the Life Science catalog (a booklet called *Careers in Health*), "Whereas medical practitioners look to drugs . . . Life Science presents an entirely different approach. We hold that exuberant and radiant health is normal and natural. We hold that suffering and ailments are abnormal, unnatural and unnecessary . . . Cease to indulge in the causes of disease and disease will not occur." The catalog also claims "you can become an expert nutritionist in less than a year" by taking the school's 111-lesson correspondence course. Students can acquire a certificate of proficiency after 32

lessons, a "bachelor of science degree" after 58 lessons, a "master of science degree" after 84 lessons, and a "doctor of philosophy degree" in nutrition science at the end.

Presumably flushed with the success of his star pupils, Fry announced this year that tuition for his nutrition course would rise from \$875 to \$1,250 and that graduates could expect to earn \$500 to \$1,000 per month from home on a part-time basis. But the future of his school is uncertain. In 1982, the Texas Commissioner of Higher Education ordered Fry to "cease and desist advertising or otherwise offering degree programs without a Certificate of Authority from this agency." Fry replied that his school was exempt from the law because it was a religious institution but later said that it had left the state. In 1986, when it became clear that the school was still operating in Texas and would not stop voluntarily, a temporary injunction was obtained forbidding Fry, the College of Life Science, and the American College of Life Science from using the word "College" or granting academic credits or degrees.

Dr. Kenney is a nutritionist at the Pritikin Longevity Center in Santa Monica, California.

BRIEFS

Notable quote: "Fit for Life seems unprecedented in the amount of misinformation contained. It is appalling that such a book can become a best seller in the latter half of the 20th century. Its only socially redeeming feature is that its popularity may alert American educators of their failure to impart the most fundamental knowledge about health and nutrition to students entrusted to their care."—William T. Jarvis, Ph.D., President, National Council Against Health Fraud, Inc.

Book review newsletter. The Chicago Nutrition Association, which has produced several anthologies of recommended and nonrecommended nutrition books, has begun publishing *Guide to Nutritious Reading* to provide current reviews by professional nutritionists. Issues so far have contained 4-6 reviews. Subscriptions are \$5/year for three issues from CNA, P.O. Box 181, Winnetka, IL 60093.

Shelf-life of tea. According to a Lipton spokesperson, teabags can keep for 1½ years. But for peak flavor, they should be stored in an airtight container and used within a year after purchase. In hot, humid climates, or if the tea becomes damp, disease-causing molds can grow on it.

Court supports treatment standards. In a unanimous decision, the Arkansas Supreme Court has upheld the right of a private hospital to prohibit doctors from using megavitamin therapy and other unscientific procedures within the hospital [*Brandt v. St. Vincent Infirmary*, 287 Ark. 431 (1985)]. The judges reasoned that "a hospital's own medical staff can guarantee reasonableness more capably than the courts."

Health fraud team formed. On April 10 a regional health fraud team representing Connecticut, New York, New Jersey, Pennsylvania, Delaware, Virginia, Maryland and the District of Columbia was established by the Central Atlantic States Association of Food and Drug Officials. (AFDO is the national professional organization of state and local government officials whose local work is similar to that of the FDA.) The new team includes FDA officials as well. Its objectives are to educate consumers, collect and share information about health fraud products, prevent duplication of investigatory efforts, develop coordinated strategies against confirmed frauds, advise the news media about proposed ads for health frauds, and encourage the development of local health fraud groups. It is expected that each regional AFDO association will form a similar team.

Free catalogues. A catalogue listing 937 publications sold by the U.S. Government Printing office can be obtained from: New Catalogue, P.O. Box 37000, Washington, DC 20013. Included are 19 publications on food and nutrition and 35 on other health topics. The quarterly *Consumer Information Catalogue* of free and inexpensive publications is available from: M.B. Woods, Consumer Information Center, Pueblo, CO 81009.

Licensing update. Since 1982, 14 states have enacted nutrition licensing laws. While some make it illegal for unqualified persons to call themselves dietitians and/or nutritionists, others define nutrition practice and who is eligible to do it. According to an American Dietetic Association spokesperson, "The speed with which these laws have passed in today's laissez-faire political climate indicates recognition by many legislators that spurious nutritionists are dangerous."

Quackery victim registry. The American Dietetic Association is interested in documenting reports of people harmed by fraudulent nutrition services. The ADA expects that computerizing this information will generate data useful in educating legislators and reporters about the need for greater public protection from unqualified "nutritionists." Professionals interested in providing data should contact: Michele Mathieu, Manager, Licensure Communications, American Dietetic Association, 430 N. Michigan Ave., Chicago, IL 60611 (telephone 312-280-5020).

Supermarkets responsive. According to USDA's *Food News for Consumers*, supermarkets are generally responsive to customer suggestions. Kroger, for example, stopped wrapping its fruits and vegetables when it learned that customers prefer to pick up and feel them before buying. And protests from embattled parents have prompted many supermarkets to eliminate candy displays from checkout aisles.

Fluoride pamphlets. Sample copies of new pamphlets on water fluoridation can be obtained by writing to FLUORIDE, Dental Health Division, Massachusetts Department of Dental Health, 150 Tremont St., Boston, MA 02111 and also to the American Association of Public Health Dentistry, 10619 Jousting Lane, Richmond, VA 23235. Leaders of local fluoridation campaigns can apply for supplies of free educational literature by writing to the American Dental Association Council on Dental Health, 211 East Chicago Avenue, Chicago, IL 60611. The request should state the types of materials, the quantities needed, and how the materials will be used.

Public opinion on fluoridation. The 1985 National Health Interview Survey conducted by the National Center for Health Statistics found strong support for water fluoridation among persons 18 and older in 17,000 households. Eighty percent said it was important to drink fluoridated water from early childhood to prevent tooth decay, and two-thirds even said that long-term consumption of fluoridated drinking water was important for preventing gum disease.

Fluoridation votes. The U.S. Centers for Disease Control has reported that fluoridation referenda were successful in six out of ten U.S. communities during 1985. Although San Antonio citizens voted 42,141 to 39,048 against fluoridation, proponents believe the groundwork has been laid for a successful vote in the future. Following a 2-year educational campaign, a citywide poll of 24,000 voters found that 73% favored fluoridation. But only 19% of those registered actually voted in a special referendum last November. Meanwhile, the British Parliament passed a bill allowing water suppliers to adjust the levels of fluoride when requested to do so by local health authorities.

Organic farm bill update. The Agricultural Productivity Act, passed last year as part of an overall farm bill, calls for \$2 million a year for research into alternative farming methods [see NF 1-6]. However, actual funding will require passage of an appropriations bill which, as of mid-April, was under review by the House Appropriations Committee.

Health fraud surveys. The FDA has asked Louis Harris and Associates to conduct a telephone poll to determine the prevalence and reasons for use of questionable or fraudulent health products. The main interview will involve 1,500 households. Additional questions will be posed to individuals who have used a questionable product during the past year and to individuals with cancer or arthritis. In another survey just completed by C/J Research, Inc., 10,000 randomly selected individuals were sent questionnaires asking about recent experiences with questionable products. Eighty-two percent of respondents said they had encountered an ad during the past year for a fraudulent product or service, and 49% said they or a family member had purchased a product or service that didn't work. Twenty-nine percent said they believe there is a conspiracy among the medical profession to hold back truly effective cures. However, since only 7.2% of those who were sent the questionnaire returned it, the results may not be representative of the population as a whole.

FEDERAL JUDGE BANS SALE OF BLUE-GREEN MANNA

During the past few years, hundreds of products composed of vitamins, minerals, enzymes, plant extracts and/or related substances have been marketed with unproven claims that they can prevent and treat disease. Under federal laws, all products sold with therapeutic claims are considered drugs and must have FDA approval as safe and effective before they are marketed. Since it is illegal to market an unapproved drug, sellers of such products commonly claim that they are foods or food supplements.

One of the most brazen and outlandish promotions of this type has been carried out by K.C. Laboratories of Klamath Falls, Oregon, and its president, Victor H. Kollman. Since 1982, Kollman and the company have operated a multilevel marketing scheme to sell Blue-Green Manna and related products with claims that they are effective against a wide range of health problems.

In 1983, the FDA began a series of legal actions to stop the scheme, but marketing of the products did not stop. Finally, on February 21, 1986, at the agency's request, U.S. District Court Judge Gus J. Solomon issued a permanent injunction ordering all parties involved to stop manufacturing, distributing and selling blue-green algae (spirulina) harvested from Klamath Lake, Oregon. Explaining his decision, the judge said:

"At the trial on January 9, 1986, the government introduced additional evidence of the widespread use of blue-green algae Manna products, and of the therapeutic claims that were made for these products. Victor Kollman denied that he had made therapeutic claims . . . Nevertheless he continued to claim his product has a beneficial effect on the human body . . . as a food, and not a drug. The government showed that taken at the recommended dosage of 1.5 grams, its value as a nutrient is negligible. Further, the cost of the defendant's products, which exceeds \$300 per pound, is so high as compared to other sources of the same nutrients that it is apparent that these products are not and are not intended to be used as a food."

In November 1985, the judge had ruled that the products were misbranded and unapproved new drugs, and had issued a preliminary injunction against their sale. In his recent order, he cited evidence that more than 2,500 persons had been distributing Manna products and making therapeutic claims for them in defiance of the injunction. He also reported that since the injunction was issued, hundreds of distributors had written or telephoned with claims that Manna products have cured them or members of their families of such problems as Alzheimer's disease, heart trouble, skin disturbances, allergies, prostate problems, lack of sex drive, emotional problems, and alcoholism.

At the January trial, the defendants had argued

that because other algae products are sold as foods or food supplements, they too should be allowed to sell blue-green algae as food—changing the packaging, trade name and distribution system if necessary. But the judge ruled that "the demand can no longer be controlled, even if the defendants have a desire to do it."

Stating that Kollman had attempted to mislead not only the court but also purchasers of the products, the judge concluded that a permanent injunction was necessary to prevent the defendants from "benefiting from their past violations by meeting the demand they had created for their products." (In other words, even if unproven claims were stopped, people who believed the previously made claims would still buy the products.) The defendants have appealed their case but will undoubtedly lose again.

Judge Solomon's ruling is important because it supports the FDA's long-held position that "supplement" products for which therapeutic claims are made are subject to agency jurisdiction as drugs even though their promoters call them foods or food supplements. But it also illustrates how an imaginative promoter may remain in business for a few years despite non-criminal enforcement action by the FDA.

Commenting on the case in the *Kansas City Star*, John H. Renner, M.D., noted that "spirulina has a respectable enough history. It was used as a food source by the Aztecs in Mexico and still is consumed in parts of Africa." But in recent years, "natural-food enthusiasts have viewed spirulina as a wonder food because it contains a high percentage of protein and several vitamins and minerals . . . Spirulina is 65% protein, which is quite high when compared with other sources of protein. However, this doesn't mean much because protein varies greatly in quality and digestibility. It turns out that only a small part of spirulina is usable. Moreover, spirulina costs much more than protein from beef, eggs, skim milk and chicken. The vitamins and minerals it contains can also be obtained more economically from other food sources." Claims that spirulina can suppress appetite, provide unusual energy and stamina, and cure numerous illnesses are simply untrue.

INFORMATION WANTED

If you find any newsworthy items, such as a published article or news report, or have a personal experience that might be of interest to our readers, please send it to Stephen Barrett, M.D., P.O. Box 1747, Allentown, PA 18105.

MOCK BEVERAGES ARE BECOMING MORE POPULAR

John R. Dienhart
G. Stewart Eidel

Healthier eating habits, an aging population, alcohol awareness, and crackdowns on drunk driving have greatly increased the market for nonalcoholic beverages. A recent Louis Harris poll for *Business Week* magazine found that 45% of those surveyed were consuming less alcohol than they did five years ago. Many beverage retailers are encouraging the use of non-alcoholic or low-alcoholic beverages as well as responsible drinking, designated driver programs, and the like.

Sparkling water sales have increased 600% in the last 10 years, and sales of other "old-time" nonalcoholic drinks have been rising. Cider is being sold as sparkling cider. Ginger ale is being blended with orange juice and garnished with fresh flowers to make gingemosa. And "virgin" drinks (virgin mary, coherent colada, and mockarita) are becoming more popular.

Beverage manufacturers have been working at a furious pace to develop "mocktails" and mock beers which taste like their alcoholic counterparts. Seagrams spent over five years and \$30 million to develop St. Regis, the first dealcoholic wine to be mass-marketed in the United States. A nonalcoholic, low-calorie wine cooler was introduced to the Florida beverage market by Paradise Fruit Company. The alcohol was removed from a grape wine and combined with fruit juices, NutraSweet, water and carbonation to create an alcohol-free wine cooler with only 18 calories per 12-ounce bottle. More than 30 nonalcoholic versions of imported and domestic beers, labeled as nonalcoholic malt beverages, are currently available.

The hospitality industry is also involved. Holiday Inns has developed a mocktail program that has enjoyed an excellent response. Red Lobster has introduced "thirst-quencher nonalcoholic beverages" to its menu. And Chi Chi's cleverly markets margaritas and coladas as "nada" beverages. The trend is apparent: the American consumer has an increasing desire for healthier beverages with fresh ingredients, attractive appearance, more flavor and less or no alcohol.

Our experience at Purdue University makes it clear that the mocktail market for young adults is quite large. Last year, 102 participants filled out questionnaires while dining in the John Purdue Room, a student laboratory offering formal dining. The survey found that 34% preferred mocktails over cocktails, but 60% would rather dine in a restaurant that offers both nonalcoholic

and alcoholic drinks. Eighty-one percent said the price of a drink does not affect their choice between non-alcoholic and alcoholic drinks. The John Purdue Room began offering mocktails during the summer of 1985. According to its director, Jeffrey Graves, "the response has been excellent—80-90% of the guests enjoy a mocktail."

These figures should really not be surprising, because many people drink in the presence of others for "social" reasons rather than a desire to ingest alcohol. Drinks provide something to do with one's hands, and a way to look busy when conversation lapses.

The health-care industry may also be affected by the increased attention to nonalcoholic beverages. Non-alcoholic specialty beverages have been available for patients for many years. For example, egg-nogs and protein drinks have provided nutrition for the gastrointestinally disabled. However, most of these drinks have been bland, unpalatable and unattractive. This need not be the case in any food service setting if imagination is added to the drink. Improvements can range from nutritious milkshakes for breakfast to sparkling nectar mocktails at afternoon social gatherings. Beverages can be made more appealing through creative uses of glassware, garnishes and service techniques.

Garnishes of fruits and vegetables can add eye appeal and nutrients to any beverage. Garnishing ideas range from vegetable sticks and slices to chunks of frozen fruits. Ideas are available from ordinary cookbooks and pamphlets developed by major suppliers of the food service industry. LeGout has developed mocktail recipes using Equal (aspartame), non-dairy creamer and LeGout drink bases. Perrier has mocktail recipes for cooling drinks served the natural way. V-8 Juice is a ready-to-serve mocktail enjoyed by today's light drinker. A six-ounce portion has only 36 calories and is high in Vitamins A and C.

The mocktail is not a new concept; however, the expanding market for alternatives to alcoholic beverages is new. Party hosts, restaurateurs, bar owners, health professionals, and others involved in providing food or drink to others would be wise to recognize this trend and be prepared to satisfy the growing number of individuals interested in alcohol-free beverages.

RECIPES

Strawberry Squirt (from Perrier)

Fresh Strawberries	6
Vanilla yogurt	1 cup
Chilled Perrier	6½ ounces

Directions: Blend berries and yogurt at high speed until smooth. Stir in chilled Perrier and garnish with a fresh strawberry and serve. To make Strawberry Squirtsicles, pour the Strawberry Squirt drink into a 4 oz. paper cup. Insert a wooden stick in center and freeze. When frozen, peel off paper cup and eat as a frozen pop.

Yield: 2 servings

Breakfast Shake (from Perrier)

Ripe bananas	2
Eggs	2
Papayas, peeled and seeded	2
Honey	2 tbsp.
Low-fat milk	1 cup
Chilled Perrier	6½ ounces
Nutmeg	pinch

Directions: Place first five ingredients in blender and blend on high speed until smooth. Stir in Perrier until frothy and add nutmeg.

Yield: 2 servings

New York Deli (from Campbell Soup, a prizewinning recipe by Marie Fattore of New York)

V-8 juice	8 ounces
Dill pickle juice	1 tsp.
Coarse mustard	1 tsp.
Prepared horseradish	½ tsp.
Worcestershire sauce	dash
Salt & pepper	to taste

Directions: Shake ingredients together and pour over crushed ice. Serve with a pickle spear.

Yield: 1 serving

Chocolate Cinnamon Coffee (a LeGout mocktail)

Hot strong coffee	7 ounces
Non-dairy creamer	1 ounce
Cinnamon powder	¼ teaspoon
Unsweetened cocoa powder	1 teaspoon
Equal low-calorie sweetener	2 packets
Garnish: Cinnamon stick	1 stick
Whipped topping	1 dollop
Cinnamon powder	1 sprinkle

Directions: Combine all ingredients and stir well. Pour into a coffee mug, garnish and serve.

Yield: 8 ounce drink

Calories per serving: 54

BULK FOODS MAY HAVE DOUBTFUL FUTURE

Mark A. Kantor, Ph.D.

The bulk food section of the supermarket faces an uncertain future. Although some stores have been successful in selling these loose, unpackaged foods, other retailers report a decline in consumer interest and are cutting back or eliminating their bulk departments.

Large supermarkets may offer over a hundred bulk food items including breakfast cereals, cookies, pasta, beans, dried fruits, flour, spices, and candy. Snacks and candy are among the best selling items, especially jelly beans, nuts, and fruit/nut mixes. Spices and pet foods are also popular. There is less consumer demand for flour and whole-grain foods. Many supermarkets that used to carry liquid bulk items such as syrup, soy sauce, honey, jam and peanut butter, have dropped them because they were too messy.

Some shoppers like bulk foods because they consider fancy packages and plastics unnecessary. Many are "natural" and "health" food enthusiasts who are used to open bins, since food co-ops and "natural food" stores have been selling products that way for years. But when bulk foods were introduced into supermarkets about five years ago, most shoppers considered them a novelty. Some people hailed buying them as an innovative way to shop. For others, obtaining food from open bins made them think of the "good old days" when life was simpler and the pace was slower.

Ask a dozen people their opinion of bulk foods and you will likely get a dozen answers, from "terrific" to "immoral." Some like the convenience while others say bulk foods are not convenient at all. Lack of sanitation is the number one reason given by shoppers who don't buy them. In a recent survey, more than half the people felt that bulk foods pose a potential health problem and are unsafe. Among this group, 13% said that bulk foods should be banned outright. Another criticism of bulk foods is the lack of proper containers to put them in at home.

Is sanitation really a cause for concern? A recent study conducted in California found that customers usually behave responsibly around the bulk food bins. The researchers observed 857 trips to bins by shoppers in 14 supermarkets. No one dropped a scoop onto the floor, put any foreign material into the food, or coughed into the bin. However, shoppers used their hands instead of the scoop 20% of the time and tasted foods from the bins 15% of the time. Most of the tasters were men.

Children in the bin section do appear to pose a problem. Nearly 3 out of 10 children either play with the food in the bins or insert their hands for a sample to taste. Sometimes children taste food after watching a

parent do it.

Some supermarket executives actually encourage customers to taste food from bins. They view this as similar to a store demonstration. Other managers are opposed to tasting, both because of loss of food and because customers who observe the tasting may decide not to buy from bulk bins.

The success of a bulk food section in a supermarket depends to a large extent on how well the section is managed and where it is located in the store. The more successful ones are kept clean and are well supervised. They are located where there is good pedestrian traffic, since the presence of other customers tends to deter tampering.

The FDA has developed guidelines for marketing bulk food which include provisions for self-closing lids and scoops with attached cords that are kept outside the bins in separate sleeves. This arrangement creates a problem because shoppers may have to struggle to keep the lids open while filling their bags. Bins would be easier to use if they had lids with a latch or magnetic fastener to enable them to stay open. The FDA code also requires bin openings to be 30 inches above the floor to prevent children from reaching their contents. But many children are still able to do so.

Bulk foods appeal to traditional consumer values: the ability to see what is being purchased and select whatever quantity is desired. Consumers also hope that less packaging means lower prices.

Do people really save money by buying bulk foods? Sometimes, but not always. The best savings are usually with herbs and spices and with other purchases weighing one pound or less. Bulk items weighing five pounds or more are usually more expensive than the equivalent amount in a package.

Although many supermarkets are phasing out or discontinuing their bulk food sections because of limited success, Giant Foods of Washington, D.C., is not. This retail chain carries bulk foods in about half of its existing stores in the Washington area and plans to sell them in all of its new stores. The company has reported that buyers of bulk foods are usually "highly educated, wealthy, innovative" shoppers, and not necessarily people with large families looking for bargains.

Dr. Kantor is an assistant professor and food and nutrition specialist with the University of Maryland's Cooperative Extension Service. His monthly column, "Food and Nutrition Update" is distributed to 50 newspapers throughout Maryland.

TWENTY-ONE WAYS TO SPOT A QUACK

Victor Herbert, M.D., J.D.
Stephen Barrett, M.D.

Most people think that quackery is easy to spot. It is not! The modern health quack wears a cloak of science. He talks in "scientific" terms and writes with scientific references. He is introduced on talk shows as a "scientist ahead of his time." He may indeed appear to be knowledgeable. The very word "quack" helps his camouflage by making us think of an outlandish character selling snake oil from the back of a covered wagon—and of course intelligent people wouldn't buy snake oil nowadays, would they?

Well, snake oil isn't selling so well lately. But vitamins? Minerals? "Organic" foods? Stress formulas? Tonics? Oral enzymes? The latest diet book? Bust developers? Devices to increase manhood? Herbal remedies? Bee pollen? Ginseng? B₁₅? Laetrile? Homeopathic remedies? Cytotoxic testing for supposed allergies? Systems to "balance body chemistry"? Megavitamins for mental illness? Business is booming for the health quack. His annual take is in the *billions*!

What sells is not the quality of his products but the quack's ability to influence his audience. To those in pain, he promises relief. To the incurable, he offers hope. To the nutrition-conscious, he says, "Make sure you have enough." To a public worried about pollution, he says, "Buy natural." To one and all, he promises better health and longer life.

How can you tell the difference between an expert and a quack? Here are 21 tips to help you spot the quack.

1. *He uses anecdotes and testimonials to support his claims.*

We all tend to believe what others tell us about their personal experiences. But separating cause and effect from coincidence can be difficult. When someone tells you that product X has cured his cancer, arthritis or whatever, be skeptical. He may not have actually had the condition he names. If he did, his recovery most likely would have occurred without the help of product X. Most single episodes of disease recover simply with the passage of time, and most chronic ailments have

symptom-free periods. Establishing medical truths requires careful and repeated investigation—with well designed experiments, not reports of what people *imagine* might have taken place. That's why testimonial evidence is forbidden in scientific articles and is usually inadmissible in court.

Never underestimate the extent to which people can be fooled by a worthless remedy. During the early 1940s, many thousands of people became convinced that "glyoxylide" could cure cancer. Yet analysis showed it was merely distilled water!

Symptoms which are psychosomatic (bodily reactions to tension) are often relieved by any product taken with a suggestion that it will work. Tiredness and other minor aches and pains will often respond to any enthusiastically recommended nostrum. For these problems, even physicians may prescribe a placebo. A placebo is a substance which has no pharmacological effect, but is given to satisfy a patient who supposes it to be a medicine. Sugar tablets and vitamins are commonly used in this way.

2. *He promises quick, dramatic, miraculous cures.*

The promises are usually subtle or couched in doubletalk—so he can deny making them when the feds close in. Such promises are the quack's most immoral practice. He does not want to know how many people have been broken financially or in spirit—by the elation over his claims of quick cure followed by deep depression when the claims prove false. Nor do quacks keep count of how many people they lure away from proper medical care.

3. *He uses disclaimers couched in pseudomedical jargon.*

Instead of promising to cure your disease, some quacks will promise to "detoxify" your body, "balance" its chemistry, release its "nerve energy," bring it in harmony with nature, or "strengthen your immune system." (Of course he never makes before-and-after measurements of any of these things.) This type of disclaimer serves two purposes. Since it is impossible to measure

the process the quack describes, it is difficult to prove him wrong. Moreover, if the quack is not a physician, the use of nonmedical terminology may help him avoid practicing medicine without a license.

4. *He displays credentials not recognized by responsible scientists or educators.*

The backbone of educational integrity in America is a system of accreditation by agencies recognized by the U.S. Secretary of Education or the Council on Postsecondary Accreditation. "Degrees" from unaccredited schools are rarely worth the paper they are printed on. In the health field, there is no such thing as a reliable school that is not accredited. Since quacks operate outside of the scientific community, they also tend to form their own "professional" organizations. Don't assume that all groups with scientific-sounding names are respectable. Find out whether their views are scientifically based.

5. *He encourages patients to lend political support to his treatment methods.*

A century ago, valid new ideas were hard to evaluate and were sometimes rejected by the medical community. But today, effective treatments are welcomed by scientific practitioners and do not need a group to crusade for them. Quacks place political endorsement ahead of scientific acceptance. Despite lack of evidence that their methods work, the quacks may seek to legalize their treatment and force insurance companies to pay for it.

6. *He says that most disease is due to faulty diet and can be treated with "nutritional" methods.*

This is not so. Ask your doctor or inspect any medical school textbook of medicine. They will tell you that most diseases have nothing to do with diet. Common symptoms like malaise (feeling poorly), tiredness, lack of pep, aches (including headaches) or pains, insomnia and similar complaints, are usually the body's reaction to emotional stress. The persistence of such symptoms is a signal to see a doctor to be evaluated for possible physical illness. It is not a reason to take vitamins.

Some quacks seem to specialize in the diagnosis and treatment of problems considered rare or even nonexistent by responsible practitioners. Years ago hypothyroidism and adrenal insufficiency were in vogue. Today's "fad" diagnoses are "mercury amalgam toxicity" and "candidiasis hypersensitivity." Quacks are also jumping on the allergy bandwagon, falsely claiming that huge numbers of Americans are suffering from undiagnosed food allergies and "diagnosing" them with worthless but lucrative tests.

7. *He recommends a wide variety of substances similar to those found in your body.*

The underlying idea—like the wishful thinking of primitive tribes—is that taking these substances will strengthen or rejuvenate body processes that involve similar substances. For example, "raw glandular therapy" ("cellular therapy") involves substances from

animals that supposedly correspond to the "weakened" areas of the human body. Raw pancreas is given for your pancreas, raw heart for your heart, etc. The quack doesn't tell you that these substances are digested and destroyed by the human stomach and intestines—so they can't possibly do you any good.

8. *When talking about nutrients, he tells only part of the story.*

He tells you all the wonderful things that vitamins and minerals do in your body and all the horrible things that can happen if you don't get enough. But he conveniently neglects to tell you that a balanced diet can provide all the nutrients you need, and that the "Basic Four" system makes balancing your diet simple. All it takes for adults is a daily average of four servings of grains, four servings of fruits and vegetables, two of milk products, and two of meat, fish, poultry, eggs, nuts or legumes. (See NF 2:44-45 for further details on the Basic Four Food Groups.)

9. *He claims that most Americans are poorly nourished.*

This is an appeal to fear which is not only untrue, but ignores the fact that the main forms of bad nourishment in the United States are undernourishment among the poverty-stricken and overweight in the population at large, particularly the poor. Poor people can ill afford to waste money on unnecessary supplements. Their food money should be spent for nourishing food.

It is being alleged that Americans are so addicted to "junk" foods, that a well-rounded diet is exceptional rather than usual. It is true that some snack foods are mainly "naked calories" (sugars and/or fats without other nutrients). But it is not necessary for every morsel of food we eat to be loaded with nutrients. The small amounts of vitamins and minerals that our bodies require are easily obtained by eating a variety of foods, and most "fast foods" contain substantial amounts of vitamins and minerals. No normal person eating a balanced diet each day is in any danger of vitamin deficiency.

Don't be surprised if one of your friends or neighbors suggests that you buy "nutrition insurance." More than one million Americans have signed up as distributors for companies that sell supplements person-to-person. A typical sales pitch goes like this: "How would you like to look better, feel better and have more energy? Try my vitamins for a few weeks." People nor-

mally have ups and downs, and a friend's interest or suggestion, or the thought of taking a positive step, may actually make a person feel better. Many who try the vitamins will mistakenly think they have been helped—and continue to buy them, usually at exorbitant prices.

10. *He claims that fluoridation is dangerous.*

Curiously, quacks are not always interested in real deficiencies. Fluoride is necessary to build decay-resistant teeth and strong bones. The best way to obtain adequate amounts of this essential nutrient is to adjust community water supplies so that the fluoride concentration is about one part fluoride for every million parts of water. But quacks are usually opposed to water fluoridation. It seems that if they cannot profit from an idea, they won't support it.

11. *He claims that modern processing methods and storage remove all nutritive value from our food.*

It is true that food processing can change the nutrient content of foods. But the changes are not so drastic as the quack, who wants you to buy his supplements, would like you to believe. While some processing methods destroy some nutrients, others add them. A balanced variety of foods will provide all the nourishment you need.

12. *He claims that soil depletion and the use of "chemical" fertilizers result in less nourishing food.*

This claim is used to promote the sale of so-called "organically grown" foods. If a nutrient is missing from the soil, a plant just does not grow. Chemical fertilizers counteract the effects of soil depletion. Plants do vary in mineral content, but this is rarely significant in the diet. The quack is also wrong when he claims that plants grown with natural fertilizers (such as manure) are nutritionally superior to those grown with synthetic fertilizers. Before they can use them, plants convert natural fertilizers into the same chemicals that synthetic fertilizers supply.

13. *He claims that under stress, and in certain diseases, your need for nutrients is increased.*

While it is true that the need for vitamins may rise slightly under physical stress and in certain diseases, the need almost never rises above the Recommended Dietary Allowance (RDA)—which can be met by proper eating. Someone who was really in danger of deficiency as a result of illness would be a very ill person who needs medical care, probably in a hospital. Although ads for "stress vitamins" imply that they are helpful against emotional stress, that is absolutely untrue.

Many vitamin pushers suggest that smokers need extra vitamin C. While it is true that smokers have somewhat lower blood levels of this vitamin, these levels are still far above deficiency levels. In America, cigarette smoking is the leading cause of death preventable by self-discipline. Rather than seeking false comfort by taking vitamin C, smokers who are concerned about their health should stop smoking. Moreover, since doses

of vitamin C high enough to acidify the urine speed up excretion of nicotine, they may even cause some smokers to smoke more to avoid symptoms of nicotine withdrawal.

14. *He claims that you are in danger of being "poisoned" by food additives and preservatives.*

This is a scare tactic designed to undermine your confidence in food scientists and government protection agencies. The quack wants you to think that he is out to protect you. He hopes that if you trust him, you will buy what he recommends. The fact is that the tiny amounts of additives used to protect our food pose no threat to human health.

15. *He claims that "natural" vitamins are better than "synthetic" ones.*

This claim is a flat lie. Each vitamin is a chain of atoms strung together as a molecule. Molecules made in the "factories" of nature are identical to those made in the factories of chemical companies. Does it make sense to pay extra for vitamins extracted from foods when you can get all you need from the foods themselves?

16. *He claims that sugar is a deadly poison.*

Many recent books and magazine articles would have us believe that sugar is "the killer on the breakfast table" and is the underlying cause of everything from heart disease to hypoglycemia. The fact is, however, that when sugar is used in moderation as part of a normal, balanced diet, it is perfectly safe. In fact, if you ate no sugar, your liver would make it because your brain needs it.

17. *He recommends that everybody take vitamins or "health foods" or both.*

Food quacks belittle normal foods and ridicule the "Basic Four" of good nutrition. They may not tell you how they earn their living from such pronouncements—via public appearance fees, product endorsements, sale of publications, or financial interests in vitamin companies, health food stores or organic farms.

The very term "health food" is deceptive. All food is health food in moderation; any food is junk food in excess. Did you ever stop to think that your corner grocery, fruit market, meat market and supermarket are also health food stores? They are—and they usually charge less for food that is identical or superior to that provided by "health food" stores.

By the way, have you ever wondered why people who eat lots of "health foods" still feel they must load themselves up with vitamin supplements?

18. *He recommends hair analysis for everyone.*

"Health food" stores, mail-order labs and a variety of practitioners suggest this test. For \$25 to \$40 plus a lock of your hair, you can get an elaborate computer printout of vitamins and minerals you supposedly need. Although hair analysis has limited value in the diagnosis of heavy metal poisoning, it is worthless as a screening device to detect nutritional problems. If a hair analysis laboratory recommends supplements, you can

be sure that its computers are programmed to recommend them to everyone.

19. He tells you it is easy to lose weight.

Diet quacks would like you to believe that special pills or food combinations can be of great help to dieters. But the only way to lose weight is to burn off more calories than you eat. This requires self-discipline: eating less, exercising more, or preferably doing both. There are 3,500 calories in a pound of human fat. To lose one pound a week, you must eat an average of 500 fewer calories per day than you burn up. The most sensible diet for losing weight is one that is nutritionally balanced in carbohydrates, fats and proteins. Most fad diets "work" by producing temporary weight loss—as a result of calorie restriction. But they are invariably too monotonous and are often too dangerous for long-term use. Unless a dieter develops better eating habits, weight lost on a fad diet will soon return.

20. He tells you not to trust your doctor.

Doctors, like everyone else, can make mistakes. But the quack, who wants you to trust him, suggests that most doctors are "butchers" and "poisoners."

21. He claims he is being persecuted by orthodox medicine and that his work is being suppressed because it's controversial.

He may also claim that the American Medical Association is against him because his cures would cut into the incomes that doctors make by keeping people sick. Don't fall for such nonsense! Reputable physicians are plenty busy. Moreover, many doctors engaged in pre-paid health plans, group practice, full-time teaching, and government service receive the same salary

whether or not their patients are sick—so keeping their patients healthy reduces their workload, not their incomes.

Any physician who found a vitamin or other preparation which could cure sterility, heart disease, arthritis, cancer or the like, could make an enormous fortune from such a discovery. Not only would patients flock to him (as they now do toward anyone who falsely claims to cure such problems), but his colleagues would shower him with prizes—including the \$190,000 + Nobel Prize! And don't forget, doctors and their families get sick, too. Do you believe that legitimate doctors would conspire to suppress cures for diseases which also afflict themselves and their loved ones?

We don't mean to imply in this article that everyone who promotes quack ideas is deliberately trying to mislead people. One reason why quackery is so difficult to spot is that most people who spread health misinformation are quite sincere in their beliefs. But where health is concerned, sincerity is not enough!

Dr. Barrett practices psychiatry in Allentown, Pennsylvania, and is a nationally renowned consumer advocate. Dr. Herbert is professor of medicine and chairman of the Committee to Strengthen Nutrition at Mount Sinai School of Medicine, and chief of the hematology and nutrition laboratory at the Bronx VA Medical Center in New York City. He is the author of *Nutrition Cultism* and co-author with Dr. Barrett of *Vitamins and "Health" Foods: The Great American Hustle*. In 1984 both of them received the FDA Commissioner's Special Citation Award for Public Service in fighting nutrition quackery.

BRIEFS

Alcohol labeling defeated. A federal appeals court has overturned a lower court decision and ruled that beer, wine and liquor bottles do not have to carry labels listing all ingredients. According to an Associated Press report, a labeling regulation had been scheduled to take effect in 1983 but was held up by Reagan administration attempts to repeal it and a resulting tangle of legislation. The chief proponent of labeling has been the Center for Science in the Public Interest.

Agricultural breakthrough. Paul Williams, a horticulturist at the University of Wisconsin, has developed strains of broccoli, cabbage, mustard and kale that mature, set seed and die within one month. These fast-growing plants can help increase world food supplies and reduce the time needed to carry out genetic experiments.

New interdisciplinary group. The Association for Food and Society (AFS) has been organized to address a broad spectrum of scientific and political issues related to food and nutrition. Among these are world hunger, malnutrition, food policy, population control, diet and health, food as a social statement, ritual uses of food, changing food styles, eating disorders, changing ideal body images, and the food purchasing habits of consumers. The group hopes to bring together the disciplines of nutrition, sociology, anthropology, medicine, psychology, and political science to study these issues. Its projects will include networking, an interdisciplinary textbook, and a professional journal. Its first annual meeting is scheduled for April 3-5, 1987, at Aquinas College. Anyone interested in joining the Society, attending the meeting or presenting a paper at the meeting can get further information from AFS president, William C. Whit, Ph.D., Professor and Chairperson of Sociology, Aquinas College, Grand Rapids, MI 49506.

Quackery report. Dr. James Lowell has updated, referenced and indexed 81 of his columns from the *Arizona Daily Star* and published them as a softcover anthology called *Health Hoaxes and Hazards*. Dr. Lowell, an NF associate editor, is Professor of Life Sciences at Pima Community College and a board member of the National Council Against Health Fraud. Many of the articles are unique because they include quotes from interviews he conducted with quackery promoters. His topics include questionable weight-loss products, cancer quackery, vitamin and mineral supplements, diet and behavior, phony nutrition assessment tests, and dangerous "health" products. Copies are \$12.50 postpaid from James A. Lowell, Ph.D., 5003 E. Cooper, Tucson, AZ 85711.

Food expenditures rise slightly. According to Food Institute reports, Americans spent \$1,182 per capita at U.S. food stores in 1985, up \$39 (3.4%) from 1984. They also spent \$549 per capita at eating and drinking places, up \$22 (4.2%).

Responsibility for drunken acts shifted. Colorado's new tort reform law, which took effect on July 1st, includes a provision placing the responsibility for sobriety in the hands of the drinker and freeing restaurants and party hosts from being liable for the drunken behavior of their patrons and guests. The law was passed in response to skyrocketing liability insurance premiums faced by professionals, businesses, nonprofit organizations, and local governments.

FDA bans sulfites in salad bars. Sulfiting agents have been used to control microorganisms and to delay spoilage in many foods and drugs. They have also been used to keep vegetables looking fresh in salad bars [see NF 2:49-51]. However, the FDA has determined that a small percentage of individuals can experience asthmatic attacks, hives, diarrhea or other symptoms when exposed to sulfites. Most reactions have been mild, but a few deaths from anaphylactic shock have been reported. In July, the agency published regulations banning their use on raw fruits and vegetables. Warning labels are already required when sulfites are added as preservatives in many packaged foods. But labeling will now be required for smaller amounts of sulfites sometimes used in baking and other processes, if the final product contains detectable levels of sulfites (10 parts per million). The new regulations are scheduled to take effect next January. The Bureau of Alcohol, Tobacco and Firearms has proposed that sulfite use in wines and beers be disclosed.

Prevention supports nutritionist licensing. In an article by its editorial staff, the September 1986 issue of *Prevention* magazine has recommended that nutritionists be licensed "to help assure that the nutritionist you consult is well qualified." The article also tells where to get qualified advice.

Fit for Life update. An article in the September 1986 *Vegetarian Times* states that Harvey and Marilyn Diamond, authors of *Fit for Life*, have begun videotaping their methods and are working on another book scheduled for publication next June. They also expect to establish a restaurant in Los Angeles and to open similar ones throughout the nation. The article also says that as a result of the book's publicity, the American College of Health Science (from which Harvey acquired his unaccredited degree) had gained 200 students, bringing its total to 1,800. However, T.C. Fry, the school's dean, has agreed to a permanent injunction barring him from representing his school as a college or granting any more "degrees" or "academic credits" unless he acquires a certificate of authority from the Texas Department of Higher Education. (For further details, see NF 57-59.) He has renamed his operation Life Science Institute ("A Nonprofit Educational Organization") and begun to produce instructional videotapes. In a recent flyer, he said that the Diamonds have been advanced \$1,000,000 for their next book and that he is slated to edit and help document it.

New nutrition center. The National Center for Nutrition and Dietetics has been launched by the American Dietetic Association Foundation (ADAF). Its activities will include a research library, computerized information services, continuing education programs, a nutrition hotline, a speakers referral bureau, professional review of nutrition-related materials, and development of food industry study panels. ADAF was founded in 1967 to carry out the charitable and educational activities of the American Dietetic Association.

Dubious award. Robert S. Mendelsohn, M.D., has received the National Nutritional Foods Association's 1986 Rachel Carson Memorial Award for his "concerns for the protection of the American consumer and health freedoms." (NNFA is the major organization of health food industry retailers, wholesalers and suppliers.) Mendelsohn, a vicious critic of the medical profession, has been active against nutritionist licensure, water fluoridation, and compulsory immunization of children. Previous Carson award winners have included Gloria Swanson, Lendon Smith and Linus Pauling.

Vitamin packs. *Health Foods Business* reports an industry trend toward marketing groups of supplements in plastic packs for daily use. "No longer is it necessary for a person to be well versed in nutrition to select a combination of nutrients from the hundreds of possibilities available. There are now packs tailored to many specific nutritional needs—from arthritis to athletic endurance," the magazine said. Packs commonly cost three or four times as much as ordinary multiple vitamins. Their primary appeal is to serious athletes, but products like "Brain Power Pack" and "Longevity Pack" also sell well.

QUESTION BOX

Q. Does bran supply calories?

A. Bran, the outermost layer of cells of the cereal grains, consists mostly of two types of fiber, cellulose and hemicellulose, which are digested to a large degree by the bacteria that inhabit the large intestine. The bacteria break down the fiber to varying degrees and release products that can be absorbed and utilized by humans for energy. Researchers disagree, however, over how much is absorbed. Absorption depends on different factors such as the types of bacteria inhabiting an individual's intestine and the length of time the material remains in the intestine. So although the breakdown products of fiber may serve as potential energy sources for humans, it is difficult to say how many calories are supplied to any given individual.

Q. What are "free-range" eggs?

A. An article in the January 1986 *Vegetarian Times* states that these come from chickens which are allowed to roam about in an indoor barn rather than being caged. Also marketed as "organically grown" eggs, they are claimed by proponents to be more nutritious and better-tasting. The chickens that produce them are also said to be under less stress. Farmers who agree to follow the guidelines of the Chicago-based Farm Animals Care Trust (F.A.C.T.) are permitted to market their eggs under F.A.C.T.'s "Nest Eggs" label, which signifies that their hens eat a diet free from chemical additives and pesticides. According to the article, free-range eggs cost 2-3 times as much as factory-farmed eggs, but "a growing number of people are willing to back their ethical beliefs with their purchasing dollars—even if it only benefits some chicken in a barn somewhere."

"Twinkie" case #2? The widow of James Huberty, who killed 21 people and wounded 19 others two years ago in a shooting spree at a McDonald's restaurant in San Ysidro, California, has sued the fast-food chain. According to a UPI story, the suit claims that monosodium glutamate (MSG), routinely added to McDonald's foods, was a contributing factor to Huberty's rage. The suit also alleges that Huberty had been poisoned by high levels of lead and cadmium to which he had been exposed while welding metals for an Ohio company which was named as co-defendant in the suit.

Free report on low-calorie sweeteners. The American Council on Science and Health has updated its position paper on aspartame, saccharin and cyclamate, all of which it considers safe. For a free copy of the 44-page booklet, send a self-addressed 4"x9½" envelope with 56¢ postage to Low-Calorie Sweetener Report, ACSH, 47 Maple St., Summit, NJ 07901.

New antiquackery groups. Chapters of the National Council Against Health Fraud have been formed in New York and Florida. Information on their activities can be obtained by writing to NCAHF New York Chapter, 86-39 Woodhaven Blvd., New York, NY 11421 and NCAHF Florida Division, P.O. Box 160, New Port Richey, FL 33552.

New method to identify irradiated foods. Scientists at the National Bureau of Standards (NBS) have developed an extremely sensitive procedure to detect whether or not a sample of meat has received radiation processing. Previously, no reliable method has been available to tell whether a foodstuff other than dried spices has been irradiated. The new technique is expected to work with vegetable matter and seafood as well. In addition, it should be possible to develop a scale to determine how much radiation has been administered. Although food itself does not become radioactive, the total dose of radiation must be carefully controlled to produce the desired effect without damaging the food. The FDA sets maximum exposure limits for the lifetime of food products. These limits present a problem for regulators and food importers who may need to determine whether a shipment has ever been irradiated. While further experiments are needed, NBS researchers are optimistic that their procedure will provide a useful, accurate test. At acceptable levels, irradiation kills harmful microorganisms and insects and extends the shelf life of food by retarding spoilage.

NEW HELP FOR LACTOSE INTOLERANCE

Mark A. Kantor, Ph.D.

For the millions of Americans who have trouble consuming milk because they can't digest lactose, help has arrived. Low-lactose milk products are now available in many supermarkets, and oral lactase tablets have been developed which permit lactose-containing foods to be comfortably eaten.

Lactose ("milk sugar") is a disaccharide (double sugar) found in milk products. It is broken down into its component monosaccharides (single sugars), glucose and galactose, by the intestinal enzyme lactase. These simple sugars are readily absorbed into the bloodstream.

Children usually have adequate amounts of lactase and are able to drink milk without too much difficulty. The main exception are infants who are allergic to the protein in cows' milk and therefore must drink soy-based products or goats' milk. Children may also refuse milk if they don't like its taste, but parents can disguise the milk with flavored syrups or by making it into puddings.

As people grow older, the amount of lactase in the small intestine gradually declines. If the lactase level becomes excessively depleted, some dietary lactose remains undigested in the intestines, causing water to be drawn in from the body. The undigested lactose is also fermented by gas-producing bacteria naturally present in the colon. These conditions result in the characteristic symptoms of bloating, diarrhea, and stomach cramps.

The decline in lactase that occurs with aging is technically known as "lactase nonpersistence" but is commonly called "lactose intolerance." It is probably an evolutionary adaptation which arose because milk was not as necessary for adults as it was for infants.

The age of onset of lactose intolerance varies. Symptoms may begin during late childhood, early adolescence, or not until adulthood. Because the condition is a genetically programmed event, the amount of milk that one drinks during childhood does not influence whether or not the problem eventually develops or its degree of severity.

Worldwide, about 70% of people have some degree of lactose intolerance. In the United States, it is most common among Blacks, American Indians and people of Asian, Middle-Eastern, and East-European Jewish background. It is much less common among people of Scandinavian and Western European ancestry.

The inability to drink milk can create a significant problem for adults because the need for calcium continues throughout life. The adult RDA of 800 mg is difficult to obtain without supplements if dairy products

are excluded from the diet, and experts now advise women to consume even more. Moreover, in addition to its established role in metabolism, calcium is important in helping to prevent osteoporosis and may have a role in preventing high blood pressure and colon cancer in certain individuals.

Fortunately, a low-lactose commercial milk product is available in most supermarkets. The product, called LactAid, is low in fat as well as 70% lactose-reduced. It also comes in a high-calcium version (500 mg/cup) called CalciMilk.

These lactose-reduced milk products contain a lactase enzyme derived from the yeast *Kluyveromyces fragilis*. The enzyme hydrolyzes the lactose of the milk into glucose and galactose which are readily digested. These simple sugars, however, impart a slightly sweet taste to the milk. All the other properties of low-lactose milk are the same as those of ordinary low-fat milk.

LactAid, Inc., also manufactures liquid and tablet forms of lactase enzyme which are sold in some pharmacies. Consumers can produce their own lactose-reduced milk by adding 4-5 drops of liquid enzyme to a carton of regular milk, shaking gently, and letting the carton remain in the refrigerator for 24 hours. Lactase tablets can also be swallowed just prior to eating a lactose-containing food, which enables the enzyme to break down the lactose during the initial stages of digestion in the stomach.

Lactose intolerance is not an all-or-nothing condition. Some people are able to drink one glass of milk with no problems, but develop symptoms if they have a second glass. Most lactose-intolerant people can eat hard or soft cheeses and ice cream without too much difficulty because they contain little or no lactose.

Yogurt is somewhat higher in lactose than milk because milk solids are added to it, but it can usually be consumed by lactose-intolerant people. During the manufacture of yogurt, the lactic acid starter culture produces lactase, which pre-digests some of the lactose. In addition, after yogurt is eaten, the bacteria multiply in the small intestine and produce lactase which digests much of the remaining lactose. In contrast to yogurt bacteria, those in buttermilk and unfermented ("sweet") acidophilus milk do not help lactose-intolerant individuals.

Dr. Kantor is an assistant professor and food and nutrition specialist with the University of Maryland's Cooperative Extension Service. His monthly column, "Food and Nutrition Update," is distributed to newspapers throughout Maryland.

SWEET ACIDOPHILUS MILK

Manfred Kroger, Ph.D.

Sweet acidophilus milk may have quietly appeared in the dairy case of your supermarket. Contrary to what its name may suggest, it tastes neither sweet nor acidic. It is simply a low-fat milk to which bacteria called *Lactobacillus acidophilus* have been added. The dairy probably has also added vitamins A and D to the milk and most certainly will have pasteurized and homogenized it.

Why would anyone want another milk product? Is the dairy industry going the way of its soft drink competitors who offer a bewildering number of choices? Not really. There has always been acidophilus milk. But because of its intensely sour and often astringent taste, it did not become popular outside of pockets in Europe and the Near East where it originated.

There is a big difference between acidophilus milk, which has been fermented by bacteria, and sweet acidophilus milk, to which bacteria are added without subsequent fermentation. True acidophilus milk resembles cultured buttermilk and yogurt, and people who love these products may also consume acidophilus milk.

The human digestive system requires the presence of certain bacteria for proper functioning and the owner's well-being. Intestinal bacteria are an important part of the body's immunological defense system and also help prevent colonization by disease-causing microorganisms. Benign bacteria on the inner surface of the intestinal wall produce antigens that stimulate the body's defense system after absorption. We provide the bacteria with a place to live, and they help us stay well. Some bacteria, such as those in yogurt, also generate enzymes that are useful in our digestive processes, especially lactose utilization. Biologists call this mutually beneficial live-and-let-live arrangement *symbiosis*. Loss of the normal intestinal flora, which often occurs after treatment with certain antibiotics, can lead to diarrhea caused by organisms that normally would not thrive.

Decades ago it was established that lactobacilli, bifidobacteria, and certain streptococcal bacteria are

the ones which normally inhabit the human intestine. They also thrive in milk. The process of deliberately growing them in a medium such as milk is called *culturing*. Yogurt, cultured buttermilk and the sour kind of acidophilus milk are true bacterial cultures; they are sold around the world as cultured or fermented milk products.

The reason why cultured acidophilus milk has never conquered the American market is probably its bad taste. But Yankee ingenuity has found a way to bring us the benefit of acidophilus bacteria without the taste problem. About ten years ago, food scientists at North Carolina State University developed a process which allows *Lactobacillus acidophilus* bacteria to be precultured and added to cold milk where they remain viable until the milk is consumed days later. This, of course, enables consumers to ingest the culture without any unpleasant taste. In fact, sweet acidophilus milk tastes like any other low-fat milk. It's called sweet because it isn't sour. No sweetener has been added. The name will mislead some people, but informed consumers look beyond a product's name and learn what's in it and what it does.

Although no specific health claims are made by the producers of sweet acidophilus milk, scientific evidence is accumulating that there may be beneficial effects. It has been found, for example, that *Lactobacillus acidophilus* is capable of lowering the activity of intestinal enzymes responsible for the production of cancer-causing chemicals. However, until more research is done, it is premature to recommend sweet acidophilus milk for the prevention or treatment of any disease. It should simply be recognized as another good dairy product whose consumption in the United States has increased dramatically during the past decade.

Dr. Kroger is Professor of Food Science at The Pennsylvania State University.

LIFE EXTENSION PART I: THEORIES OF AGING

Jack Z. Yetiv, M.D., Ph.D.

Some people try to achieve immortality through their offspring or their works. I prefer to achieve immortality by not dying.

—Woody Allen

During the past few years, hopes for extending life have been discussed increasingly in both scientific circles and the popular press. This article evaluates scientific theories and some of the strategies they suggest. Part II of this article discusses life-extension books and questionable supplement products being promoted to the public.

Although the terms *life expectancy* and *life span* are often used interchangeably, they mean different things. Life expectancy is the average number of years that people of a certain age are likely to live. In the United States, for example, life expectancy at birth is now 73 for males and 78 for females. Life span is defined as the average length of life of a species, and maximum life span is the maximal age obtainable by a member of a species. Although it has been claimed that some humans have lived more than 150 years, the maximum documented age for humans is about 115 years. Average life expectancy has increased dramatically from about 45 years at the turn of the century to about 75 years today as a result of improved sanitation, nutrition, and medical care. But maximum life span, which appears to be characteristic for each species, has changed little—if at all—over thousands of years.

Theories of aging

Although many theories have been trumpeted as the cause of aging, it is most likely that several mechanisms working together are responsible for the overall process. The leading theories are:

- *Progressive damage to DNA.* Deoxyribonucleic acid (DNA), located in cell nuclei, provide the molecular basis of heredity. From the time cells are created, their

DNA is subjected to damaging environmental influences as well as intrinsic errors in DNA replication. Environmental factors include solar radiation, x-rays, and chemical mutagens and carcinogens. Although animals and humans have mechanisms to repair this DNA damage, the rate of damage is slightly greater than the rate of repair.

This theory holds that aging is the result of multiple DNA defects which exceed recuperative capabilities. It is supported by the fact that cells from people with progeria or Down's syndrome (mongolism) are less able to repair artificially induced DNA damage. Progeria is a condition in which children become aged and die during their teens. Down's syndrome victims live longer, but still have a shorter-than-normal life expectancy. In both conditions, the cells divide fewer times than normal cells do. Cancer cells, on the other hand, appear able to reproduce themselves indefinitely. Perhaps they "know" how to escape or completely repair the random damage discussed above. Proponents of the damaged DNA theory suggest that if the DNA repair mechanisms could be perfected, aging would be forestalled and immortality within reach.

- *Free radical damage.* Free radicals are by-products of many chemical reactions in the body. They are highly reactive and can attack many important cellular components. Unlike DNA damage, free radical damage appears irreversible. Fortunately, however, enzymes such as superoxide dismutase (SOD), glutathione peroxidase, and catalase deactivate free radicals and render them harmless. It has been hypothesized that when these mechanisms are insufficient, tissues in the vicinity of the free radicals are permanently damaged. If this actually happens, it is likely that free radical damage is responsible for only a small part of the aging process.

- *Programmed limit to number of cell divisions.* Unlike the random damage theories above, this theory

and those below relate to the DNA genetic "program" contained within every cell of all animals. This genetic blueprint determines such characteristics as the sex, hair color, height, intelligence, and probably the life span of the individual and the species.

During the early 1960s, Leonard Hayflick observed that human fibroblasts (connective tissue cells) would only divide about 50 times in tissue culture. He concluded that the DNA blueprint allowed only 50 divisions. The fact that fibroblasts from older people undergo fewer divisions than do those from younger persons supports Hayflick's hypothesis of a built-in quota of cell divisions. This hypothesis holds that aging and death occur as the maximum number of all divisions is approached.

- **Immunologic obsolescence.** It is known that immune system function declines as people age. The thymus gland, which was important in the development of certain immune cells (T-cells), shrinks from adolescence onward. Infections become somewhat more difficult to fight and antibody responses to vaccinations are diminished. The immune system also has more difficulty differentiating "self" from "foreign" proteins. When this happens, the body has more difficulty in attacking invading organisms and has a greater tendency to turn upon its own "self" proteins, resulting in autoimmune diseases.

- **Aging clock.** This theory holds that all major events in life, including growth, maturation and aging, are coded in the DNA "tape." A species-specific, chronologically organized script calls out the steps of life like the caller at a square dance. One of these steps is the aging process. This orderly destruction contrasts with the random damage theories described above. However, it does seem logical that nature provides built-in obsolescence for older adults who have already served their primary evolutionary purpose of reproduction.

Life extension strategies

The May 2, 1985 issue of *The New England Journal of Medicine* contains an excellent evaluation of life extension strategies by Edward L. Schneider, M.D., and John D. Reed, Jr., B.S., of the National Institute of Aging. (Reprints of this article, which cites 194 references, can be obtained by writing to Dr. Schneider at the National Institute of Aging, National Institutes of Health, 9000 Rockville Pike, Bethesda, MD 20205.) Here is a summary of the authors' views plus my own:

- **Caloric restriction.** Several studies in animals have shown that cutting their caloric intake by 50-60% can significantly increase maximum lifespan. However, this action also retards their growth and development, so it is not practical for humans. Milder forms of food restriction begun early in life can produce moderate life extension in rats but still result in slight retardation of

growth. Research in humans suggests that being lean is advantageous, but further research is needed to determine whether there is an optimal weight favoring life extension.

Caloric restriction has received almost no attention from promoters of so-called life-extension products. Perhaps this is because "starvation" cannot be sold at a profit and would be quite unpopular as well.

- **Exercise.** It is widely accepted that regular exercise will prolong life. Exercise has beneficial effects on several aging processes as well as on cardiovascular disease. People who exercise regularly tend to be more health-conscious, to weigh less and to be nonsmokers. However, it appears that although exercise is beneficial to health and well-being, it is not clearly related to longevity. Increased life span has been demonstrated in laboratory rodents who began regular exercise programs early in life. So far no studies of this type have been reported with humans.

- **Antioxidants.** Some proponents of the free radical theory recommend supplements of selenium, vitamins C and E, BHT and other free radical "scavengers." Supposedly these substances will delay aging by "soaking up" errant free radicals that have escaped capture by the body's own free radical patrols. Although antioxidants can deactivate free radicals in the test tube, there is no credible evidence that taking them as supplements will extend human life span. No scientific studies have been done in humans, and animal studies so far have been contradictory—a point seldom mentioned by life-extension promoters. It is also significant that the animals in these studies usually lost weight, which means that their increased longevity may have been caused by low weight rather than antioxidant treatment. No studies so far support a recommendation to take megadose antioxidants, especially since any compound can be toxic in large doses.

Several years ago a study of readers of *Prevention* magazine showed no decrease in mortality among individuals taking large amounts of vitamins [*Proceedings of the National Academy of Sciences* 79:6023-27, 1982]. In fact, increased mortality was seen in those consuming more than 1000 IU of vitamin E daily. However, the latter observation could be due to the fact that sicker peo-

ple may have greater attraction to vitamin supplementation.

- *Superoxide dismutase (SOD)*. Noting that the amount of SOD in the tissues of various animal species appears related to their life span, proponents suggest that consuming SOD supplements may enhance longevity. However, SOD is a protein which, like other proteins, is broken down by the enzymes of the digestive tract. Thus SOD taken by mouth is digested to amino acids and cannot even reach the tissues as intact SOD. Furthermore, it has not been shown that increasing tissue SOD levels is of value; this has actually been demonstrated in mice [American Journal of Clinical Nutrition 37:5-7, 1983].

- *Levodopa*. This drug, commonly used with good results in the treatment of Parkinson's disease, has also been proposed as useful for the aging process in general. Mice treated with near-toxic levels of levodopa have experienced increased survival, but they also had substantial weight loss. Lower doses of the drug had no effect on survival. Thus it is possible that the decrease in weight was responsible for the improved survival. Some studies have found that patients with Parkinson's disease treated with levodopa lived longer than did untreated patients. Yet they still died earlier than the average for their age.

- *Immunologic manipulation*. Many immunologic treatments have been proposed, including the transplantation of immune cells from young animals into old and the administration of thymic hormones. But no such approach has been tested in human beings. Coenzymes Q are another group of compounds proposed as immune stimulators. Part of the rationale is the observation that the levels of these coenzymes in several organs decline with age. There is some evidence that they may enhance the immune response when injected into mice. However, they cannot be recommended for humans because they may also cause organ damage, especially in tissues with poor circulation.

- *Gerovital H-3*. This is one of the most widely promoted "life-extending" nostrums. It is a preparation of procaine hydrochloride (a substance used as a local anesthetic), with benzoic acid and metabisulfite added as preservatives. The only documented effect of Gerovital is a slight antidepressant property. While its Rumanian promoter, Dr. Ana Aslan, has reported life-extending capabilities in rodents, others have been unable to demonstrate such effects. According to an article in the April 1986 *FDA Consumer*, buyers of Gerovital may not even be getting what they pay for. When the FDA analyzed a sample purchased from Peak Health International, a Colorado firm, it contained no procaine hydrochloride.

- *Centrophenoxine*. This drug has been hypothesized to delay aging by decreasing the accumulation of lipofuscin, often referred to as "age pigment." Although

life-extenders theorize that preventing the accumulation of this pigment may prevent the aging process, there is little evidence to support this. In fact, human nerve cells can accumulate large amounts of lipofuscin without any apparent decrease in their function. Thus, although lipofuscin accumulation may accompany aging, it is probably functionally unimportant. An analogy can be made to the skin wrinkling that occurs with aging. Curing this wrinkling (if it could be done) would be unlikely to reverse the aging process.

- *Dehydroepiandrosterone (DHEA)*. This hormone is another compound whose level declines with aging. This fact has led to the speculation that DHEA supplementation will reverse the aging process. Again, just because something changes as one ages does not prove that it plays a role in the process. Although DHEA is a weak male sex hormone, its exact role in the body is unclear. Some animal studies suggest that DHEA administration causes decreased food intake. But blood levels of DHEA in rodents are quite different from those of humans, and DHEA's role in these animals may also differ from that in humans. There are no human studies of DHEA supplementation. Since it is a hormone whose potential side effects are unknown, its intake by "life-extenders" seems inadvisable.

Dr. Yetiv, whose Ph.D. is in pharmacology, is the author of *Popular Nutritional Practices*, reviewed on page 80 of this issue.

QUESTION BOX

Q. What is UHT milk?

A. The term UHT refers to a sterilization process known as Ultra-High-Temperature treatment. This process involves heating the milk to approximately 140°C (285°F) for 1-3 seconds followed by cooling and immediate sealing in germ-free containers. The containers can be held unopened at room temperature for 3-6 months (and thus cost less to store), but refrigeration is essential after opening. Even though the heat treatment is more severe, vitamin losses in UHT milk are not much greater than with conventional pasteurization and still are insignificant. UHT milk can be convenient for picnickers, campers, and people living in remote areas or with limited refrigerator space. It has an acceptable taste, although some people perceive a "cooked" flavor. UHT milk is not yet widely available in American markets, but it is popular in Europe where its cost is the same as for pasteurized milk. Only one processing facility is now operating in the United States.

IF YOU MUST GET RIPPED OFF, AARP WILL SELL IT TO YOU CHEAPER

Stephen Barrett, M.D.

The American Association of Retired Persons (AARP), which prides itself on educating its members and saving them money, has been involved in important antiquackery activities. At the same time, despite warnings from me, its pharmacy service has been selling questionable supplement products and promoting some of them with misleading advertisements and books.

AARP, which currently has 21 million members and over 3,000 chapters, is open to anyone 50 or over who pays \$5 dues. In return for this modest sum, members receive *Modern Maturity* (a well-written bimonthly magazine) and *AARP News Bulletin* (a newspaper published 11 times a year), and are eligible for a wide variety of other services, including group insurance plans. AARP produces syndicated radio and television programs, and newspaper columns. It also produces books and pamphlets, many of which cover health topics.

AARP Pharmacy Service, which was founded in 1959 and reportedly has millions of customers, is the largest private nonprofit mail-service pharmacy in the world. It fills prescriptions and sells hundreds of products through a catalog that is updated about twice a year. The two most recent issues devote about 25 of their 144 pages to vitamins, minerals and other "food supplements," many of which have the same ingredients as popular national brands but are sold at lower prices. Catalogs issued during the previous three years have contained fewer pages, with about 25% of their space covering these products.

AARP's 1985 balance sheet lists operating revenues of \$150,675,000. Its pharmacy service is operated by Retired Persons Services (RPS), Inc., a separate corporation sponsored by AARP. RPS pays a royalty to AARP, but the amount involved, its gross sales, and the percentage of "supplement" sales are not public information.

In September 1985, I sent a lengthy letter to AARP's executive director, Cyril F. Brickfield, complaining that at least 30 supplement products listed in AARP's February 1985 catalog were useless, irrationally formulated, or misrepresented. Among other things, I pointed out:

- AARP's Stress Formula with biotin and folic acid was recommended because "a busy lifestyle puts extra demands on your body." But people with "busy lifestyles" do not need more vitamins than do those who are less busy. The catalog lists other "stress formulas" without saying what type of stress they are supposedly for. Most people buy "stress formulas" because they mis-

takenly think that these products help with emotional stress or other stresses of everyday life. Even the nutrition director of Lederle Laboratories (makers of Stresstabs) has stated publicly that vitamins are useless against emotional stress and that no one eating a balanced diet needs Stresstabs.

- The catalog claims to offer "proven formulations suited for most every lifestyle." Dietary supplementation may be advisable if people don't eat properly, but vitamin needs do not vary significantly with their "lifestyle."

- AARP's Activitamins was recommended "if you play tennis or golf, or like to bike, jog or walk." Engaging in these activities does not create any special vitamin needs.

- AARP's VitamInsurance is an irrational and overpriced combination of ingredients. A person who wants to take a supplement for "insurance" should take one that contains no more than the Recommended Dietary Allowance (RDA) for any ingredient. VitamInsurance contains considerably more and costs 36½¢/day, about ten times the cost of AARP's RDA formulation.

- AARP Energy Formula is irrationally formulated and deceptively named. Vitamins and minerals do not supply energy. Only calories supply energy. The formula is suggested "for those who want a combination of B-Complex vitamins plus iron, Minerals and Vitamin C." Anyone who wants such a formula is confused.

- AARP's Megavitamin Formula is not appropriate for anyone. Some of the dosages it contains should not be taken without medical advice. Two of its ingredients, PABA and choline, are not vitamins for humans and serve no useful purpose as supplements. Another megavitamin product in the catalog contains 25,000 International Units of vitamin A, an amount that can build up to toxic levels in susceptible persons.

- AARP's rutin tablets are a complete waste of money since rutin is not a nutrient and has no therapeutic value. The same is true of AARP's biotin tablets. Biotin deficiency is virtually nonexistent, and there is no reason to take biotin for any other reason.

- AARP sells 1000 I.U. capsules of vitamin E. There is no reason for anyone to take this amount, which can cause fatigue and other problems.

- AARP carries a dozen vitamin C products with dosages ranging from 100 to 1000 milligrams. A note on the same page suggests falsely that vitamin C helps prevent colds and many other viral infections.

• AARP's Antipollutant Formula is claimed to protect people from "pollution." I believe this claim is illegal as well as false.

• Various minerals are offered without a warning that no one should take them without medical advice. Chelated minerals are also offered. These cost twice as much as regular minerals but have no proven advantage.

• Amino acids are offered even though there is no rational reason to buy them. Use of single-ingredient amino acid supplements has not been proven safe.

• AARP's Bee Pollen Plus Royal Jelly may be good for bees, but it is a ripoff for humans and can cause allergic reactions.

• Garlic capsules are another product with no proven usefulness.

• Alfalfa tablets are offered with a note that alfalfa is called "the great healer." However, it has no proven healing ability.

• Another note suggests that lecithin supplements can help prevent arteriosclerosis. There is no scientific evidence for this.

My letter to Mr. Brickfield suggested that AARP inform its members that: 1) nutrient needs can easily be met by proper eating; 2) vitamin and mineral intake should be limited; 3) dosages over the RDA are seldom needed and should not be taken without medical advice; 4) "natural" vitamins—which cost more—are neither better nor different from ordinary vitamins; and 5) "stress" vitamins are fraudulently represented in ads to the public. At the same time, it could teach its members how to evaluate whether their regular daily diet is adequate and whether any supplementation is appropriate.

Within a week, Paul R. Bergeron, II, marketing vice president of AARP Pharmacy Service, replied that: "Vitamin supplementation is as controversial today as it was 30 years ago when I began my career as a pharmacist. The points you raised in your letter . . . are well taken, and I appreciate you taking the time to state your opinions. But I also receive sound comments and opinions that tend to disagree with yours. My dilemma results . . . What vitamin supplements do we offer? At this time, I choose to supply quality, low cost products that our members want and buy. When the evidence is strong that doses or formulations are not in our members' best interest—we discontinue the products involved . . . Currently, we are considering changes in

some of the products you discussed. That's why your comments were appreciated. Our main concern is for the health care costs of AARP members. I think our changing product mix properly addresses the needs and wants of our members."

A few weeks later I wrote again to Mr. Brickfield, asking whether AARP is really interested in trying to protect its members from wasting money on vitamins they don't need. If it is, AARP could easily consult experts of its own choosing to resolve Mr. Bergeron's "dilemma" of not knowing what to believe. I also asked whether AARP would be willing to publish advice in its catalog even though it might decrease vitamin sales. (Such action, of course, would be one of the most important and newsworthy events in the history of consumer protection.)

Brickfield replied by assuring me that AARP is "indeed interested in trying to protect its members from wasting money on vitamins they don't need" but "recognizes that there is no clear and compelling consensus on the question of vitamin supplementation." He also said that future editions of the pharmacy service catalog "will present all sides of the vitamin supplementation question."

When the February 1986 catalog arrived, some of the misleading statements I had complained about were gone, but most of the questionable products were still there. The catalog contained two articles about supplementation. One, from the National Institute on Aging, advised against taking supplements without determining whether they are needed. The other, attributed to the Vitamin Nutrition Information Service (VNIS), claimed that vitamin and mineral deficiencies are common among older Americans and suggests taking a supplement "just to be sure." (Though not identified in the catalog, VNIS is a subsidiary of Hoffmann-La Roche, which wholesales most of the vitamin ingredients used by other manufacturers.) Neither article warned that amounts higher than the RDAs should not be taken without medical advice.

This catalog also offered for sale *The Healthy Heart Book*, by Richard P. Huemer, M.D., past-president of the Orthomolecular Medical Society, an organization of physicians who believe in megavitamin therapy. Although the book contains some sound advice, it also suggests that everyone take supplements of vitamins, minerals, antioxidants, choline and inositol to protect

EDITORIAL BOARD

Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

their heart. (Many of the claims made for these products would be illegal advertising or labeling.)

The August 1986 catalog eliminated the articles on vitamins and also dropped the book. But it included another called *Vitamins and Minerals*, which is part of a series of health books published by Springhouse Corporation, Springhouse, Pennsylvania, under the guidance of the American Family Health Institute, whose medical board includes some well credentialed professionals. However, although the book states that the best way to meet dietary needs is through foods, it contains many false and misleading passages that promote unnecessary supplements. For example, it says that water-soluble vitamins must be replaced daily, which is untrue. Although storage is limited, they are stored in sufficient amounts that missing any of them for days or even weeks is unlikely to cause any trouble whatsoever. The book says that smokers can benefit from extra vitamin C, which is also untrue. It also says that PABA, choline and inositol are vitamins.

AARP Pharmacy Service occasionally engages in misleading advertising outside of its regular catalog. Ads in *AARP News Bulletin* have suggested using AARP's Stress Formula for "a busy lifestyle" and that stocking up on vitamin C tablets is a good way to "prepare for the cold season." And an ad in the AARP Pharmacy Service Bonus Book warned against "harmful free radicals" and suggested supplements of "the protector vitamins" (C, E and beta-carotene) to "ensure added protection."

What makes all of this puzzling is the fact that AARP is significantly involved in fighting quackery on other fronts and has published many outstanding publications on other health topics. Most notably, its Health

Advocacy Service has developed an outstanding slide-and-lecture program warning that "today's quacks combine alluring promises with sophisticated marketing techniques to rake in billions of dollars each year."

Curiously, one of the program's messages is: "There is enough wholesome and appetizing food in our supermarkets so that most of us can easily obtain the nutrition we require. The only person who should determine if you need a vitamin, mineral or other food supplement is your doctor or a professional nutritionist."

This month's *Consumer Reports* magazine contains a brief article criticizing AARP's promotion of Activitamins and its willingness to sell such products as bee pollen and royal jelly, rutin, alfalfa and biotin. The article quotes Mr. Bergeron to the effect that if AARP didn't carry such products, its members would buy them somewhere else.

In my opinion, AARP and its pharmacy service have been acting unethically. If AARP can advise consumers properly on dozens of other issues, why can't it do so about supplements? A clear and compelling scientific consensus certainly does exist on the points I have raised. AARP surely has the resources to identify it. If AARP believes that to satisfy its members it must carry questionable products, why can't it discourage their purchase? After all, AARP and its pharmacy service are supposedly nonprofit.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 21 books including *Vitamins and "Health" Foods: The Great American Hustle*. In 1984 he received the FDA Commissioner's Special Citation Award for Public Service in fighting nutrition quackery.

BRIEFS

Diet and behavior report. In November 1984, the American Medical Association and the International Life Sciences Institute-Nutrition Foundation held an interdisciplinary symposium on diet and behavior [see *NF* 2:11-13]. Participants at the meeting generally agreed that: 1) although diet does affect behavior, the effects are subtle; 2) diet has not been established as a significant causative factor or as having therapeutic potential in the management of abnormal behavior; and 3) based on existing evidence, it is premature to utilize information on the effect of diet on behavior to influence health policy. A special 256-page supplement to *Nutrition Reviews* containing all of the papers presented at the meeting is now available for \$12.00 from the International Life Sciences Institute, Suite 111-N, 1126 16th St., N.W., Washington, DC 20036.

Hair analysis lab fined. On May 2nd, Analytical Research Laboratories (ARL), Inc., of Phoenix, Arizona, signed a consent agreement with the New York State Attorney General to stop "soliciting or accepting hair specimens for laboratory examination where the purpose is to determine possible excesses or deficiencies in nutrient mineral levels or toxic metal levels in the body." The agreement also directed the company to pay a \$1,000 penalty plus \$1,000 for court costs, and to make restitution to any New York customer who filed a claim within 90 days. The Attorney General acted because a health food store proprietor had been using hair analysis as the basis for recommending vitamin and mineral supplements. ARL was never licensed to operate within New York State, and hair analysis for the purpose of determining nutrient levels is not legal there.

USDA information guide. *How to Get Information from the United States Department of Agriculture* is a 16-page booklet which tells how to get information from the Department and its various agencies. For a free copy, telephone 202-447-7454.

Health claims for light attacked. FDA's August 27th *Enforcement Report* contains a "Health Fraud Notice" calling the Vita-Lite Fluorescent Lamp a "gross deception of the consumer" because of its labeled claims. The product, made by the Duro-Test Corporation, North Bergen, N.J., and sold through health food stores, is a full-spectrum fluorescent lamp designed to simulate sunlight. In advertising and store displays, Vita-Lite was claimed to improve visual acuity, reduce fatigue, help fight "winter blues," and help fight osteoporosis by increasing intestinal absorption of calcium; but the FDA said these claims were unsubstantiated. On August 28, New Jersey's District Court refused Duro-Test's request to restrain distribution of the FDA report. The company then agreed to discuss labeling revisions with the agency in an attempt to resolve the matter without further litigation.

New meat labeling rules. The U.S. Department of Agriculture has given producers of meat and poultry products until March 1987 to meet stricter labeling requirements for "lite" or "lean" meat and poultry products. "Extra lean" will be reserved for products containing no more than 5% fat, and the actual amount of fat must appear on the label. "Lean" and "low fat" claims can be used on those containing no more than 10% fat. "Light," "lite," "leaner" and "lower fat" can be used on those containing at least 25% less fat than the majority of such products on the market. But the comparison must be explained on the label. The new policy resulted from a petition by the Center for Science in the Public Interest.

Doctors being pressured. Claiming that doctors pay too little attention to nutrition, the Center for Science in the Public Interest has asked its members to send form letters "anonymously (or not)" urging their doctors to obtain free educational materials from various organizations on dietary strategies for preventing heart disease and cancer.

FOOD IRRADIATION UNDER ATTACK

Irradiation is a valuable way to kill harmful microorganisms and insects, and to extend the shelf life of certain foods by retarding spoilage [see NF 2:25-27]. But the health food industry is urging its followers to oppose it. To stimulate political activity, opponents are suggesting that irradiated foods are dangerous. Health food industry publications have been publishing articles and/or letters to the editor asking their readers to take action.

Some of the propaganda involved resembles that of opponents of fluoridation. For example, the National Coalition to Stop Food Irradiation (NCSFI), P.O. Box 590488, San Francisco, CA 94159, calls irradiation "food fascism." It claims that gamma radiation "destroys essential nutrients in foods" and "produces toxic chemical by-products in foods which are scientifically documented to cause latent diseases." It also claims that "irradiation with cobalt-60 or cesium-137 provides an apparent social justification for recycling radioactive wastes from nuclear weapons production and nuclear power plants." One of NCSFI's aims is to pass municipal and county legislation requiring labeling of all irradiated foods sold

to retail customers. Bumper stickers have been distributed with the message: "Don't Nuke My Food!"

Rep. Douglas Bosco (D-CA) has introduced the Food Irradiation Safety and Labeling Requirement Act of 1986 (H.R. 4762), which already has more than 30 sponsors. This bill would: 1) stop the FDA from implementing regulations that allow food producers to irradiate pork and fresh produce [NF 3:33, 3:39]; 2) impose a 2-year moratorium on use of food irradiation; and 3) require the Secretary of Health and Human Services to arrange for studies on the safety and nutritional value of irradiated foods.

H.R. 4762 would also extend labeling requirements to foods whose components have been irradiated and to irradiated foods sold at restaurants. In a recent fundraising appeal, the People's Medical Society [NF 2:81-83] asked members to sign form letters to Congress and the FDA supporting this provision and asking that labels also be required to disclose the presence of "fumigants, pesticides, waxes and dyes that are added to foodstuffs *after* they are harvested."

BOOK REVIEWS

Title: Popular Nutrition Practices: A Scientific Appraisal (1986)
Author: Jack Z. Yetiv, M.D., Ph.D.
Publisher: Popular Medicine Press, P.O. Box 12607-N, Toledo, OH 43606
Price: \$23.95 hardcover, \$17.95 softcover
Reviewed by: Stephen Barrett, M.D.

To produce this outstanding volume, Dr. Yetiv spent four years collecting and distilling scientific articles on more than 100 nutrition topics of current concern. Included in its 318 pages are such subjects as dietary balance, diet and heart disease, dietary fiber, osteoporosis, weight control, diet and hypertension, diet and cancer, diet and behavior, carbohydrate metabolism, diabetic diets, food allergies, food additives, vegetarianism, and rational usage of vitamins and minerals. Many types of nutrition quackery are discussed, some in detail and others briefly. An appendix tells how the scientific method is used to determine today's truths. The material is detailed enough for professionals yet lucid enough for laypersons. More than 1,000 references are cited so that readers wishing to delve more deeply will find it easy to do so. [*Nutrition Forum* subscribers can obtain softcover copies for \$16 each from LVCAHF, P.O. Box 1747, Allentown, PA 18105. Payment must accompany order.]

Title: Nutrition in Oral Health and Disease (1985)
Editors: Robert L. Pollack, Ph.D., and Edward Kravitz, D.Sc.
Publisher: Lea and Febiger, 600 Washington Sq., Philadelphia PA 19106
Price: \$29.95
Reviewed by: John E. Dodes, D.D.S.

This textbook is excellent for a course on nutrition at a dental school. Dentists, dental hygienists and dietitians who deal with patients undergoing extensive dentistry will also find it valuable, particularly the last section on general nutrition information. The book is 474 pages long, contains an accurate index, and is printed in an easy-to-read typeface. Understanding it requires a solid background in health sciences, especially biochemistry and physiology.

Written by 30 prominent contributors, the book thoroughly covers the role of diet and nutrition in health and disease at each stage of life plus various other topics such as food preservation and setting up nutrition education programs for professionals. An outstanding chapter on food fads and fallacies, written by Dr. Kravitz and National Council Against Health Fraud president William T. Jarvis, Ph.D., is particularly important because dentists and hygienists need to be able to educate their patients in this area. Many chapters end with a list of recommended readings in addition to references. Most of the authors don't overstate the role of nutrition in dental disease. The symptoms of vitamin and mineral deficiency are amply discussed, as are the problems caused by overdosing on supplements.

Typical of first editions, some chapters are far superior to others and there is considerable repetition. The book's major defect is that some of its authors seem overeager to connect nutrition and disease. Some advance unsupportable assumptions about food supplements benefiting the general population, which in this country is mostly overfed and free of deficiency diseases. For example, assumptions are made that periodontal disease may be partly due to "end organ deficiency." No research has demonstrated such a mechanism or that periodontal disease can be improved through vitamin supplementation alone.

The text's perspective of fluoridation is also flawed. It is stated several times that daily fluoride intake of as little as 2 ppm (about twice the optimum level for public water supplies) can cause "overdosage." This is described as a "narrow safety margin," despite the fact that the only adverse effect of fluoride at 2 ppm is whitish opaque areas—detectable only by trained observers—on the teeth of a very small segment of the population. The minimum fatal dose for an adult is approximately 2 grams of fluoride—hundreds of times what people consume daily in water and food supplies combined. Until a better protectant against cavities is found, it is unfair and misleading to denigrate fluoride. But these are minor flaws in a basically excellent book.

Dr. Dodes, a dentist in Woodhaven, New York, is director of the New York Chapter of the National Council Against Health Fraud.

LIVE CELL ANALYSIS: HIGH-TECH HOKUM

James A. Lowell, Ph.D.

NutriScreen Live Blood Analysis is a simple procedure for obtaining a quick and accurate assessment of your blood. With only a sample, taken virtually without pain from your finger, NutriScreen is able to provide a composite of over 25 aspects from your live blood. Darkfield microscopy now allows us to observe multiple vitamin and mineral deficiencies, toxicity, tendencies toward allergic reaction, excess fat circulation, liver weakness and arteriosclerosis. Through new, improved technology in video, patients are able to view their own drop of blood on television while they simultaneously receive their analysis.

So reads a flyer from a Los Angeles chiropractor who uses live cell analysis, the latest in a seemingly endless succession of questionable tests used as the basis for prescribing food supplements. This procedure is carried out by placing a drop of blood from the patient's fingertip on a microscope slide under a glass coverslip to keep it from drying out. The slide is then viewed with a dark-field microscope to which a television monitor has been attached. Both practitioner and patient can then see the blood cells, which appear as dark bodies outlined in white. The practitioner may also take polaroid photographs of the television picture for himself and the patient.

Dark-field microscopy is a valid scientific tool in which special lighting is used to examine specimens of cells and tissues. The objects being viewed stand out against a dark background—the opposite of what occurs during regular microscopy. This allows the observer to see things which might not be visible with standard lighting. Connecting a television monitor to a microscope for diagnostic purposes is also a legitimate practice. Called telepathology, the technique was little used until recently because it was assumed that the quality of video transmission could not provide adequate detail for accurate pathologic diagnoses. Improved technology has resulted in the development of practical applications,

but live cell analysis of the type described in this article is not one of them.

Three companies are selling equipment and protocols for live cell analysis: Livcell Analysis, Inc., of Laguna Hills, California; NutriScreen Live Blood Analysis, of Covina, California; and Physicians Cyto Laboratories, of Fort Lauderdale, Florida. These companies claim that live cell analysis can be used to identify a wide variety of health problems by examining characteristics of blood cells and other matter visible on the screen. (The chart which follows examines this claim.)

The Livcell system, which costs practitioners \$10,300, includes a dark-field microscope, television camera and monitor, patient education packets and brochures, wall charts, a "technical manual," a "nutrition manual," and a four-day training seminar. The equipment can also be leased for \$5,000 a year. Those who pass a test are "certified" by the company. Once a year, meetings are held to keep owners apprised of new developments. Prospective customers for the system are given a sales packet which includes a description of the equipment, testimonial letters and a profitability projection.

Most of the testimonials in the promotion packet are from chiropractors, but one is from Jeffrey Bland, Ph.D., who speaks frequently at health food industry meetings about how to promote supplements [see NF2:33-36 and 3:33-38]. Bland's letter, dated February 7, 1986, states:

"It is clear that the dark-field microscope examination of whole blood is a useful tool in visualizing aspects of the end products of metabolism . . . It appears as if this tool could be extremely useful in promoting better acceptance and personal commitment to nutrition and lifestyle modification."

Livcell's profitability projection is based on using the test to modify the behavior of one new patient per day, five days per week, 50 weeks per year. Committed

patients would pay \$50 for their initial test and \$30 each for two retests. Each initial test, the projection states, will generate sales of about \$60 worth of food supplements on which the practitioner makes 50% profit. With all tests, retests, and supplement sales, a practitioner who owns the equipment would net \$61,000 per year. NutriScreen also includes a profitability projection

in its packet for prospective customers. With five new patients a day (22 days a month) paying \$30 for the test and \$50 for supplements, practitioners would gross over \$100,000 per year just on initial visits.

Livcell's *Technical Manual* describes the appearance of normal blood and 24 "blood indicators" which supposedly signify specific diseases or deficiencies.

CLAIMS VS. FACTS

This chart lists some of the "blood indicators" which live cell proponents claim are useful in diagnosing health problems.

"Blood indicator"	Proponents' interpretation
Separation of red blood cells	Too little separation means oxygen delivery and carbon dioxide removal are reduced, typically caused by too much dietary fat.
Shape of red blood cells	Non-round red cells, caused by toxins entering the body, do not perform or survive well.
Size of red blood cells	They may be too small due to iron deficiency anemia or too big due to B-12 deficiency or rarer conditions.
Rouleaux (red cells that appear stacked like coins)	Caused by "acute phase protein" in the blood. If the condition doesn't respond to nutritional therapy in seven days, additional testing should be performed to rule out arthritis, diabetes, gallbladder disease, rheumatic heart, hepatitis and many other serious conditions.
Red cell clumping	Indicates about the same problems as rouleaux, but may be more serious.
White blood cell count	If too high or low, it tells about bacteria, viruses and use of medication.
Hypersegmentation of neutrophils (a type of white blood cell whose nucleus has several lobes)	Extra lobes mean that the person is deficient in iron, folic acid, or vitamin B-12.
Vitality of white blood cells	Lack of movement or round shape of neutrophils indicates decreased immunity.
Allergy cell count	High eosinophil count indicates possible allergy, food sensitivity or presence of parasites.
Waste (non-blood material) in the blood stream	Immune system or organs of elimination are ineffective.
Spicules (small, slender sharp-pointed pieces)	May signify liver or bowel toxicity.
Fat (chylous material) in blood	Results from a diet high in fats or simple sugars.
Platelet clumping	Can lead to cardiovascular consequences but can be corrected by dietary adjustments, nutritional supplements and smoking cessation. May also indicate marijuana or cocaine use.
Parasitized red blood cells	Bacteria and viruses are present because the body's immunity is low.
Protoplasts	Large germs whose presence may indicate weakness of the body's immune system.

cies. The book is referenced, although few of the references have anything to do with observation or analysis of blood under a dark-field microscope. Once identified, the indicators can be looked up in the *Nutrition Manual* which recommends supplements and additional tests.

A practitioner using these manuals might, for example, determine that a patient has an excess of

eosinophils, a type of white cell which normally makes up 1-3% of the white blood cells. According to the *Technical Manual*, counts over 4% may be related to about 50 diseases, including Addison's disease, scarlet fever, cancers of the lung, ovary and stomach, allergic rhinitis, impetigo, Hodgkin's disease and scabies. The *Nutrition Manual* says that too many eosinophils are a reason to

It was prepared with the help of Ronald Spark, M.D., a pathologist at Tucson Medical Center who uses dark-field microscopy on a regular basis for legitimate medical purposes.

Scientific facts

Oxygen and carbon dioxide have nothing to do with the amount of separation. It is actually determined by the method of preparing the slide. Although extremely high blood levels of fat can cause red cell aggregation, dietary fat does not produce this condition in normal individuals.

Unusual shapes can occur with long-term alcohol abuse and a few relatively uncommon hereditary diseases such as sickle cell anemia. Live-cell analysts don't specify what "toxins" they are talking about.

Although this interpretation is correct, most people performing live cell analysis have insufficient training to actually identify or treat any conditions they discover.

Rouleaux and clumping occur when blood is placed under a microscope without first being suspended in proper solutions to control acidity and agglutination. Rouleaux occurring in other tests can be related to the diseases mentioned, but their occurrence during live cell analysis is not.

The white cell count can be affected by infections and a few medications, but live cell analysis is unlikely to produce accurate counts. Automated equipment used in standard laboratory practice is far more accurate than manual counting methods.

Iron deficiency does not affect the appearance of neutrophils. B-12 status can be related to the number of lobes in their nuclei, but only highly skilled technicians using special stains and techniques (not dark-field microscopy) can determine the average number of lobes accurately.

Neutrophils don't propel themselves but simply float in the fluid in which they are suspended. So the amount of "movement" depends upon the viscosity of the blood on the slide. The shape of neutrophils has no relationship to immunity.

So many different conditions can increase the number of eosinophils that it is not valuable as a primary diagnostic tool. Even if it were, the live cell procedure is not suitable for counting eosinophils accurately.

Although the levels of waste products in the blood can be related to the functioning of various organs (such as the kidneys), these chemicals cannot be seen but require chemical tests to measure them.

Spicules are artifacts, the most common causes of which are contamination and drying of the blood sample.

The amount of chylous material (fat coated with protein to make it soluble enough to travel in the blood) in the blood increases after eating. But it is not readily visible under dark-field illumination unless special techniques are used.

Platelets are difficult to judge under dark-field procedures, even for experts.

The organisms live cell promoters claim to be able to find are extremely rare.

Bacterial protoplasts have poorly developed cell walls and are not visible under dark-field illumination.

take supplements of pantothenic acid, vitamin B₆, vitamin C, bioflavonoids, adrenal tissue concentrate, para-aminobenzoic acid (PABA), vitamin B₂, and "mycellized" vitamin A. The manual also recommends a special diet, hair analysis to check selenium and zinc levels, and another live cell test in 30 days.

Physicians Cyto Laboratories is a clinic specializing in allergy and immunology testing. Founded in 1978, it began marketing its "Darkfield Video Analysis" in 1985. Marketing director Stephen Thompson says that the test is used "as a general health screening tool on all of our patients" and that "the blood is a window to an individual's health and can reflect various problems." According to Thompson, the screening reveals nutritional, allergy, or other problems in about 90% of its patients, most of whom sign up for additional testing and "recovery" programs. (Conventional allergists believe that less than 15% of the general population suffers from food allergies.)

I first saw live cell analysis performed at a health food convention in Phoenix in the Fall of 1984. A few months later, to sample the test's efficacy, I attended a convention in California accompanied by a 27-year-old woman who was recovering from a serious motorcycle accident. Following the accident, she had been in a coma and required close monitoring of her nutrition status during a hospital stay in which she received artificial feedings. She still had slurred speech, a tremor of her hands and head, and a limp that necessitated use of a cane. While I watched, she underwent NutriScreen Live Blood Analysis for the special convention price of only \$15.

The woman performing the test billed herself as a nutrition counselor and "metabolic technician" certified by the International Health Institute (IHI) in Dallas, Texas. (IHI was founded by William Donald Kelly, a dentist who claims to be able to cure a wide variety of ills, including cancer, by adjusting nutrient intake according to a person's supposed metabolic type.) The "technician" paid no attention to our patient's medical history or obvious physical problems but merely asked whether she had eaten or ingested alcohol within the past 24 hours. Then she obtained a blood sample by having the patient press a lever attached to a mouse-trap-like device into which she placed her finger. (I assume this device was used because the practitioner, being unlicensed, could not legally draw blood.)

Using the test, the counselor determined that our patient had "+ 2 protein linkage," spicules, red cell and platelet aggregation, "pulsating white cells," and other abnormal cells, which live cell analysts claim indicate iron deficiency, B-vitamin deficiency and other problems. None of these cited factors actually indicates the conditions she diagnosed. If our patient really had been deficient in iron or folic acid (a B-vitamin), many small or large red cells would have been visible on the video screen. But the practitioner failed to report any.

To correct the problems she claimed to find, she

recommended iron chelated with vitamin C, B-complex vitamins, folic acid, hydrochloric acid, lecithin, fish oils, vitamin E, selenium and other antioxidants. Furthermore, she said, our patient needed to have her immune system stimulated and her liver detoxified. (The latter is usually accomplished by a combination of fasting and coffee enemas.)

Since we were from Arizona and the nutritional counselor would not be able to treat our patient herself, she told us to contact the Nutritional Counseling Service in Dallas, Texas, to locate a certified metabolic technician from the Tucson area. When we did, we received literature describing a "metabolic therapy" program that would include hundreds of supplements a day and cost as much as \$1,000 a month for the first year until the patient achieved good health. Since the program was individualized, however, they advised that we attend their 2½-day "Resort to Health Workshop" in Dallas at a special cost of only \$350 plus room and board.

This literature was soon followed by a letter from a Phoenix chiropractor who signed himself as a "Metabolic Doctor" and identified himself as a representative of the Alumni Association of the International Health Institute. He promised that by examining a computer printout which he would prepare, our patient would see "for the first time, an estimate of what's happening in your body, and it is such a relief to be given exact instructions on how to help the imbalances that keep you from experiencing the good health that you seek and so rightfully deserve."

Even if live cell analysis were a valid test, I suspect that most practitioners are performing it improperly. The three I have observed so far didn't always clean their microscope slides carefully between patients. (Dirt and dust which show up under the microscope can then be misinterpreted as components of the blood.) No agents were used to prevent dehydration or clotting or to control salinity, pH or temperature. Factors like these can account for variations in rouleau patterns, red-cell clumping and the formation of "spicules." Some of the patterns one practitioner saw resulted from his microscope being out of focus and disappeared when I adjusted it properly.

Bill Shaddle, general manager of Livcell Analysis, Inc., says that 400 to 500 dark-field units are being used in the United States for nutritional assessment, including about 350 from his company. He told me that his company promotes live cell analysis as a device for patient education. However, its brochure states that the test indicates "the need for specific nutrients to support, strengthen, and rebuild weakened organs and systems." Shaddle also told me that the basic techniques were developed about six years ago by James Privitera, M.D., a California physician, who founded Livcell Analysis but later left to launch NutriScreen.

Privitera has been involved in questionable practices in the past. In 1975, he was convicted and sentenced to six months in jail for conspiring to prescribe and distribute laetrile as a cancer remedy. In 1980, after the appeals process ended, he served 55 days in jail but was pardoned by California Governor Jerry Brown following a letter-writing campaign generated by the National Health Federation (NHF), a group that promotes questionable health methods. Privitera was a member of NHF's board of governors when the letter-writing campaign took place.

Shaddle and two others who helped Privitera promote Livcell Analysis are former employees of Nu

tri-Dyn, an Illinois-based company which sells supplements of ground-up animal organs called "glandulars" which supposedly strengthen corresponding human organs when consumed. Seminars on live cell analysis have been promoted to chiropractors by the company's main distributor. In 1982, an undercover investigator from WBBM-TV, Chicago, recorded Shaddle telling Nutri-Dyn sales trainees that although there was no proof that company products could cure diseases, they should claim they do anyway. "You've got to be able to do it to survive," he said, "so everybody does it."

Clearly, there are serious questions about both the value of live cell analysis and the credibility of those promoting it. As is the case with many questionable procedures, live cell analysts combine a curious mixture of science and pseudoscience. The test itself is useless in diagnosing most of the conditions which the live cell analysts claim to detect.

Dr. Lowell is a professor of life sciences at Pima Community College and is president of the Arizona Council Against Health Fraud. Some of the documents mentioned in this article were supplied by John Renner, M.D., president of the Kansas City Committee on Health and Nutrition Fraud and Abuse.

FALSE ADS FOR VIOBIN WHEAT GERM OIL APPEAR DOOMED

Viobin Corporation has been a subsidiary of the A.H. Robins Company since 1973. A few days before the acquisition, the Pennsylvania Department of Health embargoed a quantity of Viobin Wheat Germ Oil until the manufacturer promised to stop advertising that the product could "relieve heart stress." But the company continued to suggest that its products would improve physical fitness and athletic performance.

Over the years, Viobin has advertised that Viobin Wheat Germ Oil (liquid), Promtabs (tablets), and Prometol (capsules) will increase endurance, stamina, vigor and total body reaction time, and will help overcome fatigue. The company has also claimed that these benefits were backed by "more than 18 years of University research."

During 1984, after the National Advertising Division (NAD) of the Council of Better Business Bureaus asked for substantiation of these claims, Viobin told NAD that it would discontinue them "in a spirit of cooperation" even though it felt the advertising in question could be scientifically supported [see NF 2:14]. However, the claims continued to appear in Viobin ads for at least six months after the agreement with NAD was announced.

Now the Federal Trade Commission (FTC) has charged Viobin and A.H. Robins with false advertising. Under a proposed consent agreement, they would be prohibited from representing that wheat germ oil can help consumers improve endurance, stamina, vigor or other aspects of athletic fitness, or that its active ingredient octacosanol is related in any way to body reaction time, oxygen uptake, oxygen debt or athletic performance. In addition, Viobin must state in any ads within the next year that "earlier studies of the effects of wheat germ oil and octacosanol on endurance, stamina or vigor do not meet the criteria for modern testing" and that the company no longer makes claims that wheat germ oil supplements will improve endurance, stamina or vigor. Within six months following final ratification of the proposed agreement, the company will also have to place one ad including this disclosure in each publication that carried its ads during 1985. According to FTC staff, the purpose of this provision is to remedy false impressions created by Viobin's false and deceptive advertising.

The consent agreement has appeared in the *Federal Register* and is open to public comment until December 9, after which the FTC will decide whether to make it final.

BRIEFS

Welcome support for fluoridation. Prevention Magazine has published an excellent discussion of fluoridation in its November "Ask Prevention" column. Summarizing the favorable viewpoints of major health organizations, the column airs a prominent public health official's view that "a few opponents of fluoridation try to condemn the practice by taking out of context and misrepresenting legitimate pro-fluoride scientific research." Prevention vigorously opposed fluoridation during the lifetime of its founder, J.I. Rodale, who died in 1971. But its current editors believe it is a valuable public health measure.

Cytotoxic lab zapped. The Attorney General of the State of Washington has secured a consent agreement barring Medical Service Center and its owner, Mark Lovendale, from making a large number of false claims about cytotoxic testing. The company, based in Irvine, California, had been claiming that the test can diagnose food allergies and sensitivities that supposedly cause arthritis, epilepsy, multiple sclerosis and many other diseases. A civil penalty of \$300,000 and court costs and attorneys' fees of \$30,000 were suspended provided the company permanently desist from any business in Washington involving cytotoxic testing or related services. (For additional information on cytotoxic testing, see NF 1:17-19, 2:39, 2:62, 2:84, and 2:91.)

QUESTION BOX

Q. Can any foods consumed before bedtime help people fall asleep?

A. Controlled studies suggest that the amino acid tryptophane administered in doses of one gram or more can reduce the time it takes some people to fall asleep. However, self-administration of individual amino acids is not a recommended practice. It is not known whether human sleep patterns are affected by tryptophane normally present in typical meals or snacks. Touted sleep-inducers like milk contain very small amounts of tryptophane (0.12 grams in 8 ounces of milk). A bedtime snack or warm drink (such as soup or decaffeinated tea) may be comforting, but a dull book or warm bath will probably do more to lull people to sleep. Alcoholic beverages can help induce sleep but may cause the sleeper to wake up early when the effect of the alcohol wears off.

NF's editor honored. At its annual meeting, the American Dietetic Association (ADA) awards honorary membership to one or two individuals who have made significant contributions to nutrition and dietetics. On October 27, 1986, Dr. Stephen Barrett was given this award for "tireless work against health fraud" and "leadership in numerous organizations that promote and support nutrition and good health." Later that day he gave tips on fighting nutrition quackery to an audience of 2,500 dietitians and was videotaped for ADA and Cable News Network programs on that subject.

In-store computer terminals. According to an article in the *Washington Post*, computerized devices now being tested in supermarkets can provide store directories, nutrition information, discount coupons, and printed recipes tailored to individual specifications. Although computers have considerable potential for helping shoppers, they can deliver advertising messages and also influence purchasing decisions in subtle ways.

Mail-order diet fraud stopped. The Federal Trade Commission has announced that marketers of several mail-order diet schemes have signed a provisional consent agreement settling charges that they made false, misleading and unsubstantiated claims in advertising their programs and products. In June 1985 the Commission issued an administrative complaint against Buckingham Productions, Inc., and related companies and individuals who marketed the Rotation Diet, "No Frills" Rotation Diet, Freedom Diet, Freedom Plus! Diet, and Rotation-Freedom Diet. The complaint challenged their claims that dieters could eat virtually unlimited quantities of any food for four days each week and still lose weight if they followed a severely restricted low-calorie diet during the rest of the week and took the company's vitamin supplements and wafers. The complaint also challenged claims that the usual monthly loss was 8-20 pounds for women and 12-25 pounds for men. Under the proposed agreement, Buckingham is prohibited from claiming that consumers can eat as much as they want and still lose weight without disclosing that weight loss depends upon the reduction of total caloric intake. Buckingham also agreed that if testimonials from its employees were used in the future, the fact of their employment would be disclosed in the ads. [Note: Buckingham's Rotation Diet is completely unrelated to Dr. Martin Katahn's best-selling book, *The Rotation Diet*.]

New dietary guides. The U.S. Department of Agriculture has issued seven booklets to help people implement its 1985 Dietary Guidelines for Americans [see NF 3:30-31]. Each booklet contains a self-evaluation and practical tips for following one guideline. To order a set, send \$4.50 to U.S. Govt. Printing Office, Supt. of Documents, Washington, DC 20402. Ask for *Dietary Guidelines and Your Diet*, publication #001-000-04467-2, 1986.

Twinkie #3. The Associated Press has reported that assault charges were dropped against Tony Doherty, a 21-year-old Irishman who claimed that allergy to potatoes caused him to try to strangle his father. According to the story, a judge dismissed the charges after concluding that two packages of potato chips had turned Doherty from pleasant and likable into a wild man. The court was told that a clinic in Manchester had discovered that Doherty was allergic to potatoes, beef, onions and strawberries, and that his personality began to change after he moved into a hostel which served mostly potatoes and beef.

AARP agrees to stop two false ads. After discussion with the National Advertising Division (NAD) of the Council of Better Business Bureaus, AARP Pharmacy Service pledged to stop suggesting Activitamins for seniors who "play tennis or golf, or like to bike, jog or walk." AARP also indicated it would discontinue ads suggesting that supplements of "the protector vitamins" (C, E and beta-carotene) would "ensure added protection against harmful free radicals." AARP Pharmacy Service is operated by Retired Persons Services, Inc., a subsidiary of the American Association of Retired Persons. Dr. Stephen Barrett triggered the NAD intervention after AARP officials failed to heed his complaints [see NF 3:76-78]. AARP's Oct-Nov-Dec 1986 catalogue contains no claims for Activitamins but now suggests that members "ask your doctor about the increased need for vitamin C due to aging and smoking." (There is no such increased need.)

Fluoride lesson plans. Lesson plans on water fluoridation for kindergarten through grade 12 have been developed for San Antonio schools. Information about them can be obtained by writing to Linda S. Crossett, R.D.H., Administrator, Texas Fluoridation Project, Bureau of Dental Health, Texas Department of Dental Health, 1100 W. 49th St., Austin, TX 78756.

Book Review

Title: Parents' Guide to Nutrition (1986)

Author: Susan Baker, M.D., and Roberta Henry, R.D.

Publisher: Addison Wesley, Reading, MA 01867

Price: \$10.95

Reviewed by: Melanie R. Polk, M.M.Sc., R.D.

This is a comprehensive and readable primer on nutrition during pregnancy, infancy, childhood and the teen years, with a great deal of information applicable to adults as well. It covers the development of food habits, feeding problems, and nutritional needs for all ages, and gives practical suggestions for meals and snacks for both sick and healthy children. For example, why not add nutrients via bran, wheat germ, whole wheat flour to chocolate chip cookie batter, when we know the kids want the cookies and would trade or discard what we think nutritious but they dislike?

Readers can approximate their "nutrition IQ" via a quiz which contains ample discussion. A glossary and resource list are included along with helpful charts and tables throughout.

Suggestions are given for those who have limited time and/or money. Fad diets are evaluated, and suggestions made for traveling, cooking with kids, and nutrition basics. Most worthy of comment, however, is the reliability of information. In this age of widely distributed nutrition hogwash, it is refreshing to encounter a trustworthy resource for those interested in good nutrition.

Mrs. Polk is an assistant professor at the University of Connecticut's School of Allied Health Professions and is a consulting nutritionist in private practice in West Hartford, Connecticut.

MARGARINE VS. BUTTER

Manfred Kroger, Ph.D.

Butter and margarine are food fats that are generally considered spreads—for bread—although they can be utilized in many other ways. Both are very much alike in composition: 80-81% fat, up to 1% protein, 1-2% salt (if salted), and 16-18% water. The food energy content of both is about 3,300 calories per pound and 100 per tablespoon (14 grams). A well "buttered" slice of bread could easily deliver 20-40 calories through the spread alone.

Even the color, flavor and price of butter and margarine are virtually indistinguishable. That was not always so. Butter used to be much more expensive and its flavor has always been preferred by chefs and homemakers. Many years ago, margarine was pale yellow or even paler and had to be dyed with a dab of food coloring supplied in the package, if one chose to do so. Yes, in the 1950s the butter interests saw to it that this upstart product called oleomargarine pretending to be butter had a rough time competing. For a time, it was actually illegal in some states to sell margarine with the color already worked in so that consumers in these states had to knead the package to blend in the color. Nineteen states had major restrictive margarine laws.

Butter has enjoyed several thousand years of human use and acceptance. It was probably made wherever milk was consumed. Margarine is a relative newcomer, a creation of modern food technology. Responding to a government offer of a prize for the manufacture of a satisfactory butter substitute, the French chemist Hippolyte Mege-Mouriez created a brand-new product which has enjoyed increasing sales for well over 100 years.

Of course, margarine is a vegetable product. The label indicates which oils were used in its manufacture. There are many vegetable oils to choose from, and two margarines are hardly ever made from the same source. Butter is always made from cream obtained from the milk of a domesticated female dairy animal, usually the dairy cow in this part of the world.

When cream is churned—agitated in a special container—it soon "breaks" into buttermilk and butter.

This is not the buttermilk sold to consumers. What North Americans purchase as buttermilk is really "cultured skim milk"—also called "cultured buttermilk"—a product of bacterial fermentation. But that is another story.

Margarine is the result of the creation of a special semi-solid water-in-oil emulsion. Butter is also a water-in-oil emulsion, and physically the two are quite similar. But margarine is far more variable with regard to fat source and far more complex and variable in its manufacture. Three skills must be brought into play when making margarine: establishing the right emulsion from the proper choice of fats, developing the right "buttery" flavor (don't forget that margarine was made to imitate butter), and obtaining the right spreadability or "melt" of the margarine in the mouth. These are the essential margarine qualities. The art of the food technologist is to put them all together in the "right" way.

Butter always contains butterfat (milk fat) and can harden excessively when refrigerated (a definite consumer complaint and drawback to sales). But margarine is made from a mixture of oils and fats, hydrogenated (hardened) oils, or partially hydrogenated oils which maintain just the right consistency, even when refrigerated. Vegetable fats are substantially more polyunsaturated than butter and maintain softness at lower temperatures. Polyunsaturation in food fats has lately been linked to desirable nutrition/dietary qualities and has given margarine sales a further boost.

Annual U.S. per capita margarine consumption has gradually grown to 11 pounds, up from 2 pounds in the 1920s, while butter consumption has decreased from 10 pounds to less than 5 in that 60-year period. It is interesting to speculate on these past consumption trends. What caused the rise and fall? Was it price, health, flavor or spreadability?

Dr. Kroger is Professor of Food Science at The Pennsylvania State University.

FDA CONSIDERING POLICY FOR HEALTH MESSAGES ON FOOD LABELS

Odom Fanning

When Congress is in session, a typical day includes many committee hearings on proposed laws or government regulations. With abundant opportunity for the airing of views, why would a trade association hold a simulated hearing?

In the case of the Food and Drug Administration's proposed policy on health messages for food labels, the Council for Responsible Nutrition (CRN) felt it wasn't getting the attention it deserved. CRN represents about 40 supplement manufacturers and wholesale distributors. Its request to meet with Health and Human Services Secretary Otis R. Bowen, M.D., was turned down. FDA Commissioner Frank E. Young, M.D., Ph.D., did meet with CRN officials but said he would not consider changing FDA's draft document until it was published in the *Federal Register* for public comment.

Controversy had erupted in 1984 over ads suggesting that the high fiber content of Kellogg's All-Bran made it useful in preventing cancer [see NF 2:69 and 3:19-20]. The ads had been designed with help from the National Cancer Institute (NCI) and were acceptable to the Federal Trade Commission. But FDA officials thought that linking a specific food product to NCI's general dietary guidelines might make All-Bran a "drug" subject to premarket proof of effectiveness. Kellogg, CRN, and other industry groups then petitioned the agency to allow certain health claims in food advertising or labeling.

Frustrated by its inability to influence the FDA proposal before it was made public, CRN staged a model Congressional hearing on September 8, 1986, at its annual meeting in Washington, D.C. The meeting's overall theme was "Health Messages—New Directions and New Opportunities." In his opening remarks, CRN president J.B. Cordero called the draft FDA document "one of the worst-kept secrets in Washington." After noting that CRN had gotten its copy by filing a Freedom of Information request with the FDA, Cordero read from the draft's preamble:

"In this notice, the Food and Drug Administration (FDA) discusses a new and innovative initiative concerning the placing of health-related claims or information on food labeling and the criteria it will apply in evaluating the propriety of such labeling.

"The agency also announces its intention to form a Public Health Service committee that will attempt to develop health messages appropriate for use on food labeling.

"FDA recognizes that this new initiative represents a substantive change in past agency policy and, because of the complexity of the matter and the broad public interest, wishes to proceed cautiously and deliberately in its regulatory approach. Consequently, while this notice represents current policy used by FDA to regulate health messages on food labeling, the agency is soliciting public comments on whether the policy is appropriate and reasonable or requires specific revision."

After indicating that CRN's hearing was designed in part "to provide useful comments—as FDA requested—to those who shape public health policy," Cordero observed:

- The FDA proposal represents a significant step forward toward encouraging food manufacturers to make health claims. The document incorporates many of CRN's points and should be viewed favorably by its members.

- Nevertheless, substantial differences remain, especially in FDA's negative attitude about the expected application of this policy to dietary supplements.

- While CRN applauds the progress it has helped bring about, it will not remain silent until the prejudice (real or perceived) against vitamin and mineral products is excised from FDA policy.

Cordero also said, "Until recently, the policy of the FDA seemed to be to prohibit a company from making a health claim for a particular food product. Such a claim used to make the product a drug under the Food, Drug, and Cosmetic Act, and thus subject to the new

drug approval process. Today, this prohibition seems to be changing due to the actions of the Kellogg Company when it launched its All-Bran cereal campaign in October 1984. These advertisements precipitated a nationwide debate that challenged FDA either to conclude that All-Bran was an unapproved new drug or to modify its health message policy position."

Cordero listed seven "social dynamics" he believed had shaped the FDA policy review:

1. Accumulating evidence suggests relationships among certain foods, dietary habits, and health problems and supporting dietary and lifestyle changes.

2. Consumers are becoming increasingly aware of, and interested in, the relationship among diet, health, and costs.

3. Congress, federal agencies, and many health professional groups believe that consumers need more information about the role of nutrition in the maintenance of promotion of health and about the relationship between nutrition and diseases.

4. Food manufacturers want and need a mechanism to provide accurate, truthful, and non-misleading information about the potential role that specific foods may play in improving diet and promoting good health.

5. Wellness and fitness have become "commodities" that are being marketed and have become big business.

6. Every level of our health care system is under pressure to reduce costs.

7. FDA long has believed that it is important to promote general health measures that will improve public understanding, increase self-help toward disease prevention, and lower overall mortality and morbidity statistics.

Cordero said that "affected interests . . . have moved from the argument over whether the public should be informed. Now the focus is on how accurate, truthful and nondeceptive information can be provided while holding at bay 'the jackals of nutritional fraud.'" One question he hoped CRN's hearing would address is whether health messages should be permitted for supplements as well as conventional foods.

For the mock hearing, key Congressional staffers played the roles of members of Congress while FDA officials and others "testified" during a lively 3-hour session. The chair was W. Benjamin Fisherow, counsel, Subcommittee on Oversight and Investigations, House Committee on Energy and Commerce. From the same committee staff came two House colleagues: Edwin H. Allen, associate counsel of the parent committee, and Robert S. Adler, counsel, Subcommittee on Health and the Environment. The participant from the Senate was W. Douglas Campbell, majority (Republican) health counsel, Committee on Labor and Human Resources.

"There is no turning back," said Fisherow in opening remarks. "There will be a policy from the FDA sooner or later. It will try to separate the good claims

from the bad claims, and it will apply to all segments of the food industry . . . to the honest businessman and the knave alike."

He urged food supplement marketers to exercise caution, however. "If there is an early overload of claims, particularly claims at the margin, you may find yourself facing an overreaction from the regulators," he warned. He also suggested that the FDA must be prepared to protect the marketplace by enforcing whatever regulations it establishes, for "if the honest businessman sees competitors getting away with murder, he may feel forced to do the same. Then we have something approaching chaos. We could have an ugly marketplace, and that's no good for anyone."

He also said that "any message significant enough to put on a food product's label is important enough to be featured in its advertising. It's unfortunate that we have two separate regulatory agencies that will be regulating the same information directed to essentially the same audience for essentially the same purposes, but I think we're stuck with it. The Federal Trade Commission is not going to give up its responsibility to regulate advertising. The Food and Drug Administration certainly is not going to give up its responsibility to regulate labeling. So while we have to deal with that, we don't have to deal with the kind of conflict we saw in the All-Bran case between FDA and FTC. The worst thing we can envision is 60 million American consumers seeing a message in advertising on television that would result in misbranding if it appeared on the product's label."

The first to face the panel were two FDA officials: Allan L. Forbes, M.D., director, Office of Nutrition and Food Sciences, Center for Food Safety and Applied Nutrition, and Fred H. Degnan, associate chief counsel for enforcement, Office of General Counsel.

Dr. Forbes pointed out that "this all started with fiber but right at the very beginning it became patently obvious that the whole scope of nutrition science is involved. It's not just non-nutrient components of foods, it's vitamins and minerals, micronutrients, macronutrients, protein, fats, and so on . . . And then there's the related matter of how much of whatever it is you're talking about is biomedically significant . . . One of the most difficult problems to deal with is if you provide a claim, is it specifically related to what's in the package or is it of a more generic nature."

Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

Mr. Degnan cautioned that health-related information on food labeling may produce a distorted impression of the relative value of individual foods. With respect to supplements, he said that although FDA policy permits factual statements on labeling, the support for health messages is based on data relating good health to total dietary pattern rather than to individual supplements.

Following their prepared testimony, Fisherow asked Dr. Forbes whether the staff of the FDA is prejudiced against the dietary supplement industry, feeling that the industry markets products improperly, sells products that are unnecessary in some instances and unsafe in others, and has taken advantage of the FDA through Congressional action.

"It just isn't so," Forbes responded. "We are concerned about nutrient toxicity. Every nutrient in the book is toxic at some given amount over some given period of time. On the other hand, it's not an FDA perspective, it's a national nutritional community perspective that there is a very significant role for dietary supplements, vitamins and minerals—and other components of foods—under very specific sets of circumstances. Whenever there is doubt about the adequacy of a diet, it's perfectly appropriate and very useful for a dietary supplement to be applied: for example, the elderly individual whose total caloric consumption may well be 1,000 to 1,200 calories a day and is accompanied by a lack of physical activity. It is virtually impossible under those circumstances for that individual to receive an adequate supply of vitamins and minerals. A well balanced vitamin and mineral supplement is of immeasurable value to sustain the nutritional health of such an individual.

"Similarly, you have circumstances such as infancy, pregnancy, and a whole host of disease states where the diet is compromised. So there is a very positive foundation at FDA and in my own mind for the acceptance of a major public health role for dietary supplements. That's a simple fact." [A bit too simple for those of us who believe that correction of an inadequate diet is generally preferable to supplementation—Ed.]

More questioning elicited from Dr. Forbes some comments about education: "Nutrition understanding by the general public is poor. The basic problem is absence of solid nutritional education in elementary and secondary schools. That's the core dilemma . . . Food labeling is only a mini-part of all that." Later he added: "There's absolutely no earthly reason why the food label can't be one more vehicle for conveying reasonable information to the general public. But I would not anticipate that its impact would be massive. I hope it would be useful."

Later he was asked whether "in the typical American on the typical American diet there are nutritional deficiencies that ought to be addressed by nutritional supplements?" He responded: "The policy of our government spelled out in the Dietary Guidelines is that

if you eat a well balanced diet, there's rarely a need for supplement . . . The nutritional status of Americans is good . . . There are vulnerable groups with deficits of one nutrient or another . . . but there is no evidence of massive deficits in the general population."

CRN's mock hearing did an excellent job of addressing the complex question facing the FDA: Is there a way to permit health claims for food and supplement products without opening the floodgates to nutritional fraud? No simple answer appears on the horizon.

Mr. Fanning is a freelance writer who produces the nationally syndicated action column, "Help-Mate."

BRIEFS

America's food bill. According to a Food Institute report, sales by food retailers exceeded \$413 billion in 1985, accounting for 30% of all retail trade in the U.S. "Supermarkets are aggressively marketing convenience foods while convenience stores are attacking the fast food business," the report said.

Phony apple juice. Beech-Nut Nutrition Inc., two of its executives, and three of its suppliers have pleaded innocent to criminal charges of marketing millions of bottles of bogus apple juice between 1978 and 1983. According to an Associated Press report, a 470-count indictment charges that the product, labeled as 100% apple juice for babies, was actually made from flavored concentrate. The company and its officers allegedly sold the phony juice to avoid taking a \$3.5 million loss in inventory. The judge presiding over the case, which will be tried in the U.S. District Court in Brooklyn, N.Y., has predicted a lengthy trial. Beech-Nut was also named in a \$10 million class-action lawsuit filed in Philadelphia.

Liquor manufacturers sued. A 24-year-old Chicago man has filed suit against two liquor companies seeking compensation for his seven years of alcoholism. The suit also asks that the companies be required to place warning labels on their products stating that alcohol consumption is addictive. According to *Physicians Financial News*, a recently formed group called the Council for Law and Education on Alcohol Risks plans to file further suits with the hope of gaining money for education and research on alcoholism. The Council's founder, New York lawyer Gary Rubin, says it is looking into the best way to apply product liability law to alcohol-related problems.

HOMEOPATHY: IS IT MEDICINE?

Stephen Barrett, M.D.

During the past few years, increasing numbers of homeopathic remedies have been offered for sale in health food stores and elsewhere. Their promoters suggest that they are safe, effective, natural remedies which have no side effects. This report summarizes a year-long investigation of homeopathy I conducted on behalf of *Consumer Reports* magazine.

Homeopathy's roots

Homeopathy dates back to the late 1700s when Samuel Hahnemann (1755-1843), a German physician, began formulating its basic principles. Hahnemann was justifiably distressed about bloodletting, leeching, purging, and other medical procedures of his day which did far more harm than good. He was also critical of medications like calomel (mercurous chloride) which was given in doses that caused mercury poisoning. Instead, he developed his "law of similars"—that the symptoms of disease can be cured by substances which produce similar symptoms in healthy people. The word "homeopathy" is derived from the Greek words *homeo* (similar) and *pathos* (suffering or disease).

Although ideas like this had been espoused by Hippocrates in the 4th century B.C., and by Paracelsus, a 15th century physician, Hahnemann was the first to use them in a systematic way. He and his early followers conducted "provings" in which they administered herbs, minerals and other substances to healthy people, including themselves, and kept detailed records of what they observed. Later these records were compiled into lengthy reference books called *materia medica*, which are used to match a patient's symptoms with a "corresponding" drug.

Hahnemann believed that diseases represent a disturbance in the body's ability to heal itself and that only a small stimulus is needed to begin the healing process. In line with this—and to avoid toxic side effects—he experimented to see how little medication could be given and still cause a healing response. At first he used small doses of accepted medications. But later he used enormous dilutions and concluded that the

smaller the dose, the more powerful the effect—a principle he called the "law of infinitesimals."

That, of course, is just the opposite of what pharmacologists believe today. As summarized in the 1977 report of an Australian Parliament committee of inquiry: "For each [drug] property, there is a clearly defined dose-response relationship in which increasing the dose increases the effect . . . There is not one example in the whole area of pharmacology in which simple dilution of a drug enhances the response it produces any more than diluting a dye can produce a deeper hue, or adding less sugar can make food sweeter."

Homeopathy's remedies

Homeopathic drugs are prepared as follows: If the medicinal substance is soluble, 1 part is diluted in either 9 or 99 parts of a water and/or alcohol solution and shaken vigorously; if insoluble, it is finely ground and pulverized in similar proportions with powdered lactose (milk sugar). One part of the diluted medicine is diluted, and the process is repeated until the desired concentration is reached. Dilutions of 1 to 10 are designated by the Roman numeral X ($1X = 1/10$, $2X = 1/100$, $3X = 1/1,000$, $6X = 1/1,000,000$). Similarly, dilutions of 1 to 100 are designated by the Roman numeral C ($1C = 1/100$, $2C = 1/10,000$, $3C = 1/1,000,000$, and so on). Most remedies today range from 6X to 30X.

According to the laws of chemistry, there is a limit to the dilution that can be made without losing the original substance altogether. This limit, called Avogadro's number (6.023×10^{23}), corresponds to homeopathic potencies of 12C or 24X (1 part in 10^{24}). Hahnemann himself realized there is virtually no chance that even one molecule of original substance would remain after extreme dilutions. But he believed that the vigorous shaking or pulverizing with each step of dilution leaves behind a spirit-like essence which cures by reviving the body's "vital force." Hahnemann's theories have never been accepted by scientifically oriented physicians, who charge that homeopathic remedies are placebos (inert substances).

Because homeopathic remedies were actually less dangerous than those of 19th-century medical orthodoxy, many medical practitioners began using them. At the turn of the century, homeopathy had some 14,000 practitioners and 22 schools in the United States alone. But as medical science and medical education advanced, homeopathy declined sharply, particularly in America, where its schools either closed or converted to modern methods. The last pure U.S. homeopathic school closed during the 1920s, but Hahnemann Medical College (Philadelphia) continued to offer homeopathic courses on an elective basis until the late 1940s. A few graduates from other modern medical and osteopathic schools later became homeopaths by taking courses here or abroad or by training with a practicing homeopath.

Homeopathic remedies were given legal status by the 1938 Federal Food, Drug, and Cosmetic Act, which was shepherded through Congress by Senator Royal

Copeland (D-NY), a prominent homeopathic physician. One provision of this law recognized as drugs all substances included in the *Homeopathic Pharmacopeia* of the United States. Soon to be in its ninth edition, this book lists more than 1,000 substances and the historical basis for their inclusion: not modern scientific testing, but homeopathic "provings" conducted as long as 150 years ago.

Today's marketplace

The 1985 directory of the National Center for Homeopathy, in Washington, D.C., lists some 300 licensed practitioners, half of them physicians and the rest mostly chiropractors, naturopaths, dentists, veterinarians or nurses. But Jay P. Borneman, of Swarthmore, Pennsylvania, whose family has been marketing homeopathic remedies since 1910, believes that several hundred more consider themselves homeopaths and that many conventional physicians utilize one or a few homeopathic remedies for specific conditions. Larger numbers of homeopaths practice in England, France, India, Germany, the Soviet Union and several other countries where homeopathy is more popular.

Laypersons are also involved in practicing homeopathy. Some operate offices, which may not be legal. A few unaccredited schools have offered correspondence courses leading to certificates or "degrees" in homeopathy. (One of them is Donsbach University, the unaccredited correspondence school whose nutrition "degrees" triggered the current drive by dietitians for nutritionist licensure [see NF 2:40].) Consumers interested in homeopathic self-treatment can obtain guidance through lay study groups, books, and courses sponsored by the National Center for Homeopathy.

Most homeopathic practitioners still rely on materia medica in choosing among the thousands of remedies available. But a few utilize computerized electrical devices which they claim can help match the remedies to the patient's diseased organs. "Classical" homeopaths—who follow Hahnemann's methods closely—take an elaborate history to fit the remedy to the individual (see page 4). They prescribe one substance at a time, while non-classical homeopaths may prescribe several.

Homeopathic remedies are available from practitioners, health food stores and drugstores, as well as manufacturers who sell directly to the public. A few products are sold person-to-person through multilevel marketing companies. Home remedy kits are available from several companies. Jay Borneman believes that U.S. sales of homeopathic products probably total no more than \$15 million a year, with half done by five companies that have been in business for 75 to 150 years.

According to FDA officials, homeopathic remedies used to be marketed on a small scale by these five companies, mainly to serve the needs of licensed practitioners. "These drugs bore little or no labeling for con-

HOMEOPATHIC HOME REMEDY KITS

The National Center for Homeopathy's Homeopathic Household Kit (\$35.00), prepared by Luyties Pharmacal Company, contains 28 remedies and an index-card-sized list of suggested uses. Among the indicated uses are sudden fever, enlarged tonsils, fretfulness, frequent or painful urination, food poisoning, earache, nosebleed, puncture wounds, and delayed menstruation. The price includes a copy of the book *Homeopathic Medicine at Home*. A bumper sticker, "Homeopathy: the safer medicine" is available for \$1.00.

HRI-Dolios' Homeopathic Household Kit (\$34.95) contains 24 remedies, each containing five to nine ingredients and named according to its purpose. Included are: Diarrhea, Glandular for Women, Glandular for Men, Travel Sickness, Trauma, Bed Wetting, and Hepatic Dysfunction. The directions for all are identical: "5 granules under the tongue 3 times a day or as directed by physician."

Boiron-Borneman, Norwood, Pennsylvania, offers a Natural Home Health Care Kit for \$59.95. It contains 40 remedies for a wide range of common ailments including colds, flu, hoarseness, indigestion, bruises, motion sickness, poison ivy, insect bites, menstrual pain, colic, and teething. The kit contains four pages of instructions written in the style of a materia medica. The instructions warn: "None of the medicines listed should be used on a seriously ill individual. A doctor should be consulted immediately. If . . . an individual's condition does not improve rapidly (within one or two days), a physician should be consulted as soon as possible."

sumers because they were intended for use by homeopathic physicians who would make a diagnosis and either compound a prescription, dispense the product, or write a prescription to be filled at a homeopathic pharmacy," says William G. Nychis, the FDA's expert on homeopathy. "The pharmacies also sold a limited number of nonprescription homeopathic products. During the past decade, however, the homeopathic marketplace has changed drastically. New firms have entered the field and sold all sorts of products through health food stores and directly to consumers."

Jay Borneman readily admits that "there is a lot of insanity operating under the name of homeopathy in today's marketplace. Companies not committed to homeopathy's principles have been marketing products that are unproven, untested, not included in the *Homeopathic Pharmacopeia*, and combination products that have no rational or legal basis. Some are simply quack products called homeopathic for marketing purposes."

Perhaps the most blatant promotion was that of Biological Homeopathic Industries, Albuquerque, New

Mexico, which in 1983 sent a 123-page catalogue to almost 200,000 physicians nationwide. Among its products were BHI Anticancer Stimulating, BHI Antivirus, BHI Stroke, and 50 other types of tablets claimed to be effective against serious diseases. In 1984, the FDA forced the company to stop distributing several of the products and to tone down its claims for the rest.

In September 1985, agents of the FDA and Pennsylvania Health Department seized some \$125,000 worth of drugs sold person-to-person by Probiotic, Inc., of Reading, and Homerica, Inc., a subsidiary. The products were labeled Skin Relief, Human Power Recharger, and Pain Control, and did not state what they were for, what was in them, or how to use them. Other questionable products are listed in the chart below.

Homeopathy's legal status

In most states, homeopathy can be practiced by any physician or other practitioner whose license includes the ability to prescribe drugs. Three states—Ari-

QUESTIONABLE HOMEOPATHIC REMEDIES MARKETED AS NONPRESCRIPTION DRUGS DURING THE PAST TWO YEARS

Company	Product Names
Bioforce of America, Ltd. Plainview, N.Y.	Arthritis Formula, Asthma Formula, Circulation Formula, Prostate Formula, Liver & Gall Bladder Formula
Biological Homeopathic Industries Albuquerque, New Mexico	Bleeding, Chest/Pleurisy, Liver, Pancreas
Boericke & Tafel Philadelphia, Pennsylvania	Spasmodic Croup, Suppressed Menses, Hemorrhoids, Simple Kidney Disorders, Dribbling of Urine
Consumer Express* Lakes Charles, Louisiana	Arthritis, Menopause, Allergy, Enzyme (for fatigue)
Dolisos Las Vegas, Nevada	Hepatic Dysfunction Drops, Vermifuge Drops (Children)
Humphreys Pharmacal Incorporated Rutherford, New Jersey	Simple Fevers, Simple Diarrhea, Asthmatic Paroxysms, Irregular or Delayed Menses
Longevity Marina Del Rey, California	BeLite (for weight reduction), Male Essential, Female Essential
Luyties Pharmacal Company St. Louis, Missouri	Whooping Cough, Worms, Insomnia, Enlarged Prostate, Gonorrhoea, Gall-Stones, Heart Tonic
Nutritional Factors (Natra-Bio products) Concord, Calif.	Arthritis, Chest Cold, Flu, Herpes, Exhaustion
Seroyal Brands, Inc. Concord, California	Cardio Forte, Thyro Forte, Renal Forte, Ovarian Forte
Standard Homeopathic Company Los Angeles, California	Hoarse Cough, Hacking Cough, Bronchial Cough, Loose Moist Cough, Dry Cough, Spasmodic Cough, Bedwetting Tablets

*Consumer Express is a multilevel marketing company. One of its distributors has distributed a fact sheet which claimed that the company's Master-Key Formula 1 can lower blood pressure, cleanse the liver, improve memory and act on degeneration of the heart.

zona, Nevada and Connecticut—have separate homeopathic licensing boards. The Nevada situation is notable because some of its practitioners acquired licenses as homeopaths after other states revoked their medical license for cancer quackery.

Arizona's licensing boards are subject to "sunset" review, which means they will be abolished unless reauthorized by the Arizona legislature. Last year, as the expiration date for the homeopathy board drew near, the state's homeopaths joined forces with health food stores to lobby vigorously. To counter the idea that a board might not be needed because there were only a handful of homeopaths in the state, the American Institute of Homeopathy (a group of about 100 classical

homeopathic physicians) urged its members to apply for licensure in Arizona "to show that there are doctors interested in practicing homeopathy today." According to the National Health Federation, a health food industry group which helped with the campaign, close to 2,000 supporters attended hearings and state legislators got hundreds of handwritten letters supporting homeopathic licensing. The reauthorization bill passed unanimously.

Public protection regarding drugs is based on a framework of federal laws and regulations which require that drugs be safe, effective, and properly labeled. But the FDA has not applied this framework to homeopathic remedies. Since most homeopathic remedies

"FITTING THE REMEDY TO THE INDIVIDUAL"

"Do you like your home temperature warm or cold?"

"How is your thirst?"

"Do you drink tap water? Ice water?"

"Do you eat ice?"

"Do you drink a whole glass at a time or just sip it? What's your nature?"

The questioner was David Wember, M.D., who has been practicing classical homeopathy in Falls Church, Virginia, for more than 10 years. His office resembles that of a standard family practitioner except for cabinets and open shelves which contain thousands of remedies in small bottles.

Dr. Wember, one of America's most prominent homeopaths, is a board member of the National Center for Homeopathy and directs its seminars for doctors. His manner is alert and extremely warm. On most days, he sees 10 to 12 patients, new ones for an hour and others for half an hour. ("A bit more time than the average medical doctor," he notes.) On the particular day when I observed, his patients complained of headaches, diarrhea, overweight, chronic tension, and arthritis—symptoms typically seen in any general medical office. Each patient was asked standard medical questions plus many more about such things as emotions, moods, food preferences, and reactions to the weather.

"Homeopathy is based on all of the patient's symptoms, both emotional and physical." Dr. Wember explained. "This includes likes and dislikes, cravings and aversions to foods, and the patient's relationship to the environment. They involve the whole person and are more important than pain in the knee, or something like that, which is a symptom of only part of the person. We try to fit the remedy to the nature of the individual rather than a disease process."

As a patient's answers began to suggest a familiar pattern, Dr. Wember compared them to lists in a homeo-

pathic materia medica and asked questions to confirm his hunches. The remedy arrived at, he removed a few granules from one of his many bottles, placed them on the patient's tongue, and arranged for another appointment.

"I treat with whatever is most natural and least toxic. Most of the time I can use homeopathic remedies, which have no toxicity. But sometimes I will use drugs. For example, penicillin for a strep throat or recurrent ear problem that isn't getting better homeopathically. But most often it's the other way around. They have recurrent problems and keep getting antibiotics. Over a period of time we get them off antibiotics and the problems go away."

When asked how he responds to the charge that homeopathic treatment can delay needed medical care, he replied: "Above all, I'm a doctor. When I believe someone needs drugs or surgery, I refer that person. My approach has the advantage of not rushing in with treatment that might have harmful side effects. Many patients who see me are afraid of doctors and drugs and would not go to a regular doctor. They feel they can trust me because I don't overtreat. If they need medical care, often I can convince them to go for it. So with these patients, homeopathy fosters medical care rather than delaying it."

contain no detectable amount of active ingredient, it is impossible to test whether they contain what their label says. They have been presumed safe, but unlike most other drugs, they have not been proven effective against disease by scientific means such as double-blind testing. If the FDA were to require such proof for homeopathic drugs to remain on the market, the industry would not survive unless it could persuade Congress to change the law.

The American Association of Homeopathic Pharmacists, a group of leading homeopathic manufacturers, has proposed that homeopathic remedies remain marketable without a prescription for minor ailments that do not require complex medical diagnosis or medical monitoring. Traditional homeopathic remedies used for the treatment of serious diseases would be available by prescription only from physicians and others authorized by state laws to prescribe drugs. The FDA is considering this proposal and hopes to issue a policy guide for homeopathic products in the near future.

In January 1986, the North Carolina Board of Medical Examiners revoked the license of George A. Guess, M.D., the state's only licensed homeopathic physician, after concluding that he was "failing to conform to the standards of acceptable and prevailing medical practice." (The decision has been appealed to the courts.) Dr. Guess is a 1973 graduate of the Medical College of Virginia and was board-certified in family practice from 1976 through 1983. But in 1978 he began practicing homeopathy. During the North Carolina proceedings, another family practitioner testified that although Dr. Guess is intelligent and well trained in orthodox medicine, "homeopathy is not medicine. It's something else."

Most pharmacy school educators seem to feel the same way. Last year I sent a questionnaire to the deans of all 72 U.S. pharmacy schools. Faculty members from 49 schools responded. Most said their school either doesn't mention homeopathy at all or considers it of historical interest only. Hahnemann's "law of similars" did not find a single supporter, and all but one respondent said his "law of infinitesimals" was wrong also. Almost all said that homeopathic remedies were neither potent nor effective, except possibly as placebos for mild, self-limited ailments. About half felt that homeopathic remedies should be completely removed from the marketplace.

Homeopathic research

Probably the best review of homeopathic research is the two-part article by A.M. Scofield, Ph.D., a British biochemistry professor. In the *British Homeopathic Journal* [73:161-180 and 73:211-226, 1984], he concludes: "Despite a great deal of experimental and clinical work there is only a little scientific evidence to suggest that homeopathy is effective. This is because of bad design, execution, reporting or failure to repeat promising experimental work and not necessarily because of the inefficacy of the system which has yet to be properly tested on a large enough scale . . . It is hardly surprising in view of the quality of much of the experimental work as well as its philosophical framework, that this system of medicine is not accepted by the medical and scientific community at large."

Scofield cautions against dismissing homeopathy simply because its underlying philosophy does not fit accepted scientific premises. Feeling that "some of the experimental work already done suggests that homeopathy may be of value," he recommends that carefully controlled experiments be done to test homeopathy further.

One apparently well designed study was published in the British journal *Lancet* on October 18, 1986. In this study 56 hay fever patients who received a homeopathic preparation of mixed grass pollens had fewer symptoms than a comparable group of 52 patients who received a placebo. Whether this type of finding can be consistently reproduced remains to be seen.

Overview

During my lengthy investigation, I was impressed by the warmth and sincerity of the homeopathic leaders I met. But the key question is whether homeopathy is effective.

Consumer Reports concluded in its January 1987 issue that, "Unless the laws of chemistry have gone awry, most homeopathic remedies are too diluted to have any physiological effect . . . CU's medical consultants believe that any system of medicine embracing the use of such remedies involves a potential danger to patients whether the prescribers are M.D.'s, other licensed practitioners, or outright quacks. Ineffective drugs are dangerous drugs when used to treat serious or life-threatening disease. Moreover, even though homeo-

EDITORIAL BOARD

Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

pathic drugs are essentially nontoxic, self-medication can still be hazardous. Using them for a serious illness or undiagnosed pain instead of obtaining proper medical attention could prove harmful or even fatal."

Homeopathic leaders insist that their remedies are effective and that studies *do* support this viewpoint. They also suggest that homeopathy's popularity and long survival are evidence that it works. But the only way for homeopathy to gain acceptance by the scientific community would be to demonstrate positive results through repeated experiments designed with the help of critics and carried out with strict safeguards against experimenter bias and fraud.

If the FDA required homeopathic remedies to be proven effective in order to remain on the market, homeopathy would face extinction in the United States. But no indication exists that the agency is considering this. FDA officials regard homeopathy as relatively be-

nign and believe that other problems should get enforcement priority. Moreover, if the FDA attacks homeopathy too vigorously, its proponents might even persuade Congress to rescue them. On the other hand, some level of enforcement is needed to prevent the homeopathic marketplace from getting completely out of hand.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 21 books including *Vitamins and "Health" Foods: The Great American Hustle*. The following homeopathic proponents reviewed drafts of this article and made helpful suggestions: Jay P. Borneman, David G. Wember, M.D.; Jacquelyn Wilson, M.D., president, American Institute of Homeopathy; Julian Winston, editor, *Homeopathy Today*; and Dana Ullman, M.P.H., president, The Foundation for Homeopathic Education and Research.

MY VISIT TO THE NEVADA CLINIC

Stephen Barrett, M.D.

A few physicians who consider themselves homeopaths use "electrodiagnostic" machines to help select the remedies they prescribe. The main proponent of this method in the United States is F. Fuller Royal, M.D., owner and medical director of The Nevada Clinic, Las Vegas, Nevada. Dr. Royal is a member of Nevada's homeopathic licensing board and was its president from 1983 to 1985.

Nevada Clinic publications state that electrodiagnosis is one of the most effective aids for diagnosing illness and that "there are no incurable diseases, only ignorant physicians." The initial clinic visit—which spans a two-day period—commonly costs \$700 to \$800, including \$165 for allergy testing and \$100 for homeopathic remedies. The program also includes lectures on nutrition and allergies.

The clinic is located in a small shopping center near the outskirts of Las Vegas. It has 10,000 feet of floor space with more than 40 rooms. The spacious waiting room is tastefully decorated and seats 18 people. Most staff members wear white uniforms with royal blue jackets. There are four physicians, each of whom sees about 70 patients during a 4½-day work week. Patients are typically asked to return three times during the six months after their first visit and annually thereafter. Most learn of the clinic through word-of-mouth or ads in homeopathic or health food publications. After making an appointment, they are sent medical history forms to complete.

Upon arrival at the clinic, patients are given a name tag and asked to sign an insurance form and a consent form which acknowledges that the clinic spe-

cializes in electrodiagnosis, uses homeopathic methods, has made no guarantees, and will not function as their primary physician for routine examinations or other necessary treatment.

After signing the forms, patients receive a 71-page *Patient's Handbook* and are shown a 20-minute videotape, both of which introduce the staff and explain the clinic's methods. Then they are escorted to the various rooms where examinations and educational programs are carried out. They are weighed, blood pressure is taken by a nurse, and specimens of urine and blood are taken for laboratory analysis. Since overnight fasting is required for some of the blood chemistry tests, a snack of juice, nuts and rice cakes is provided after the blood is drawn. (Some clinic "veterans" bring their own snacks.)

All patients at The Nevada Clinic are diagnosed with a computerized galvanometer called the INTERRO. This is said to measure changes in the skin's electrical resistance which indicate whether the body's organ systems have proper "electromagnetic energy balance."

To use the device, the doctor probes "acupuncture points" on the patient's hands and feet and interprets numbers on the computer's screen. (The less the electrical resistance, the higher the score.) One wire from the computer goes to a brass cylinder covered by moist gauze which the patient holds in one hand. A second wire is connected to a probe which the doctor touches to the patient's other hand or foot. When he does so, it completes a low-voltage circuit and causes a band to rise from 20 to up to 100 on a scale on the

computer screen. Readings over 60 are said to represent "inflammation," readings of 48 to 60 are normal, and readings below 48 represent "degeneration," which may signify cancer or atherosclerosis. The device makes a whining noise resembling that of an electrical motor; the higher the number, the louder the noise.

The INTERRO is programmed so that charts and tables can be placed on the screen to help the doctor select from approximately 1,700 homeopathic remedies. By selecting certain remedies and retesting with the probe, the doctor determines which remedies will balance the disturbed energy flow in the patient's body. (According to the *Patient's Handbook*, "the magnetic blueprint of the homeopathic remedy flows through the body via the electrical current and resonates in harmony with the body, returning an abnormal reading to normal.") One or more remedies may be placed in a tray attached to the computer to receive an energy transfer.

The INTERRO and another device are used to diagnose allergies. During the latter procedure, vials of common allergy-causing substances are placed in the tray so they become part of the circuit.

Mercury dental fillings are probed with another electrodiagnostic device said to measure negative electrical potentials, which, if too great, indicate that toxic amounts of mercury or other metals may spread to surrounding tissues and cause eventual damage to nearby nerves.

Some patients are tested by the clinic nutritionist with a device in which vitamins, minerals and enzymes are placed in a tray connected to a meter that supposedly indicates whether the patient needs them.

Last October, at Dr. Royal's invitation, I underwent all of the electrodiagnostic tests except for vitamin testing. After testing me on the INTERRO, he said I had a number of electromagnetic blockages and had "temporomandibular joint stress, probable subclinical allergies, and possible mild early preclinical arthritis."

After determining what he thought was the most appropriate remedy, he placed a vial of vitamin B₁₂ in the tray and "transferred an electromagnetic blueprint" to it. He explained that it was desirable to overcome "energy blocks" caused by the scars in my skin. Since the energy travels mainly through acupuncture meridians on the surface of the skin, he wanted to remove the blockage by injecting the specially prepared B₁₂ into the points of blockage: my appendectomy scar, the areas inside my throat from which my tonsils had been removed, the skin near my jaw joints, and my vaccination scar. After doing this, he retested and said that most of the blocks were gone, but my jaw showed considerable tension and should be manipulated. After doing that, he prescribed five homeopathic remedies for home use and advised me to have my dentist replace one of my mercury amalgam fillings with another material.

During the testing, I noticed that the harder the probe was pressed to my finger or toe, the higher the reading on the INTERRO screen. Royal readily acknowl-

edged this, but said, "that's why it takes a lot of training to use the equipment properly."

The manufacturer's literature states that if the INTERRO is used for medical diagnosis in the United States, it must bear the label "FOR INVESTIGATION USE ONLY. The performance characteristics of this product have not been established" and that diagnosis must be confirmed with an accepted medical procedure. But Royal told me that no such label was needed.

A sign in the clinic pharmacy warns that homeopathic remedies should be kept away from electrical outlets and appliances and should not be x-rayed at airport entries. The reason for this is that "remedies possess electromagnetic fields [that] become distorted and unpredictable when strongly affected by other magnetic fields."

The nutrition lecture was conducted by a woman who said she had taken correspondence courses through Donsbach University (an unaccredited school) and the American Nutrition Consultants Association. Her main advice was to eat less meat and more fresh fruits, vegetables and other unprocessed foods. She recommended installation of a home water purifier. She also said that aluminum pots can cause Alzheimer's disease, that milk (other than goat's milk) is not good for adults, that microwave cooking "zaps the life force" and changes the molecular structure of foods, and that sunshine beneficially stimulates the pituitary gland.

Royal calls his approach "bioenergetic medicine" and says it is the wave of the future. He was introduced to it by Floyd Weston, a former insurance executive who had investigated its use in Germany. (According to a 1981 article in the National Health Federation's *Public Scrutiny*, Weston learned about electrodiagnosis after organizing a group of businessmen "to conduct a worldwide search for the answer to good health.")

When Weston approached him, Royal was practicing medicine in Oregon and felt that the medical climate would be hostile toward electrodiagnosis. So Weston investigated the situation in Nevada and reported that influential persons were interested in having another type of tourist industry besides gambling and had promised him that Royal would not be bothered there by medical authorities.

In 1979, before Royal could relocate, Oregon's board of medical examiners became concerned about his use of electrodiagnosis and ordered him to take written and oral competency examinations. He passed the written examination, and since he had been planning to move anyway, it was agreed that the oral exam would be dropped and his Oregon license classified as inactive. The Governor of Nevada subsequently appointed Royal to a homeopathic advisory board, and a homeopathic licensing law was passed which included "noninvasive electrodiagnosis" as part of the definition of homeopathy. So this practice is now legal in Nevada.

The Nevada Clinic of Preventive Medicine

opened in 1980, but in 1983 its name was shortened because insurance companies would not honor claims from a "preventive medicine" clinic. ("With the name change," the clinic newsletter notes, "more patients' insurance claims are being paid.") Royal originally directed the clinic's medical aspects and Weston directed its business aspects, but in 1983 they parted company, and in 1984, Royal became sole owner and operator.

Royal struck me as an extremely sincere person who believes in what he is doing and wants very much to help those who consult him. His clinic set-up radiates caring and concern. The atmosphere is unhurried, and the staff is friendly, efficient and energetic. Everything is explained in detail, an aspect of treatment missing from many medical practices. From a marketing standpoint, the clinic set-up is outstanding.

So far 16,000 patients have been seen at The Nevada Clinic. Royal said he plans to double the clinic's size, to add a mini-kitchen and physical therapy department, and to computerize all patient records so that statistical reports will be easy to compile.

Do Royal's methods actually help people? It would be easy to suggest that since electrodiagnosis and homeopathy are outside the realm of accepted medical practice, such treatment is worthless. But Royal says that most of his patients suffer from headaches and/or allergies. These conditions often have an emotional

component that can be influenced by a positive doctor-patient interaction—which most patients who trust The Nevada Clinic are likely to have.

Does the clinic lure people away from effective treatment? My single visit could not determine this, but several patients told me they had not been helped by their previous doctors. Royal said he does not accept cancer patients because "if they get better, physicians will say it was a spontaneous remission or that the patient did not have cancer at all; and if they die, I'll get blamed. It's a no win situation."

Royal said he does not want to treat severe neurological disorders such as amyotrophic lateral sclerosis ("Lou Gehrig's disease") or the late stages of multiple sclerosis. Nor does he wish to treat illnesses severe enough to require hospital care or surgery. Regarding medications prescribed by other doctors, he said, "All medications are to be continued until improvement is noted by the referring doctor and/or the patient. We advise patients to follow the advice of their personal physician and to give us progress reports at specific times."

It would be fascinating to conduct a well designed study to measure what Royal is actually accomplishing. He seems open and self-confident enough to cooperate with such a study if an appropriate person or agency were interested in carrying it out.

BRIEFS

Nutrition programs for computers. *The Journal of Dietetic Software* (P.O. Box 2565, Norman, OK 73070) is now an annual publication with quarterly newsletter updates. The 96-page annual includes over 100 software descriptions, sample printouts, and articles about software applications in nutrition and food service. The newsletter updates cover software programs, conferences, and services for professionals who use software. A one-year subscription costs \$30 (\$35 outside the U.S.).

Diet/breast cancer study. The National Cancer Institute (NCI) has announced plans to study the effect of a low-fat diet on the incidence of breast cancer in 30,000 women at high risk for the disease. According to a recent NCI report, most Americans consume about 40% of their calories from fat. The study will examine the effects of diets with only 20% fat, which is less than the 30% level generally recommended for cancer and heart disease prevention. Peter Greenwald, M.D., Director of NCI's Division of Cancer Prevention and Control, says, "the 20% level is so low that we also will be testing the feasibility of staying on such diets."

Cholesterol education program. The National Heart, Lung and Blood Institute has begun a program to encourage Americans to lower their blood cholesterol levels to lessen their risk of coronary heart disease. Health professionals interested in counseling patients about this can obtain a free information packet from The National Cholesterol Education Program, NHLBI-NIH, C-200, Bethesda, MD 20892.

Grapefruit pillmaker squeezed again. In September 1986, World Communications Inc. filed for bankruptcy, listing liabilities of about \$5 million and assets of \$3 million. Most of the creditors are independent television stations that carried the company's ads for tapes and records as well as its "fat-burning" Grapefruit 45 program. World's president Jay Kholos blamed the company's cash-flow problems on its dispute with the U.S. Postal Service. Postal authorities seized \$4 million in C.O.D. payments after the company violated an injunction against misleading advertising of its diet plan [see NF 2:38]. The authorities are seeking to return the money to customers and may ask for a large civil penalty as well.

THE LEGACIES OF PAAVO AIROLA

J. Darlene Forester, Ph.D., R.D.
Sherée L.T. Thompson

Health Plus Publishers, of Scottsdale, Arizona, a division of Airola, Inc., actively markets its books through health food stores. To encourage them to stock up, one of its recent mailings urged: "Take just one of our books, *How to Get Well*, by Dr. Paavo Airola (800,000 copies sold to date—mostly in health food stores). That book recommends vitamins, minerals and other supplements, herbs, juices, and natural foods for more than 60 common ailments, as well as equipment such as juicers, seed grinders, and flour mills."

"For example: for osteoporosis . . . you have the potential of selling: 14 vitamins and supplements, modestly estimated at \$5.00/product; 5 herbal products @ \$3.00 each; groceries . . . \$20; possibly a piece or two of equipment such as a juicer or seed grinder (\$200). TOTAL: \$305.00 . . . And your customer will most likely return for replenishment of supplements and foods."

"These figures might not be accurate, but you get the picture. Now multiply these figures times hundreds of customers and 60+ ailments, and you can see what far-reaching effects one book such as *How to Get Well* can have on your overall sales volume."

The book's jacket states that Paavo Airola, Ph.D., N.D., was "an internationally recognized nutritionist, naturopathic physician, award-winning author, and renowned lecturer. He studied nutrition, biochemistry and biological medicine in Europe, then spent many years studying ancient, herbal, and alternative healing methods during his world-wide travels. His clinical experience was acquired while directing various biological medical clinics in Europe and Mexico. Because of his pioneering work and extensive knowledge, Dr. Airola is looked upon as a world-leading authority on nutrition and holistic medicine." Several of his other publications label him "America's foremost nutritionist" and "America's #1 bestselling health author." But none of them provides details of his educational background.

Airola's books are similar to each other, and a few simply duplicate chapters of other works with new titles. Overall, he touts a diet that stresses fresh, raw, organically grown fruits, vegetables, and grains. Animal proteins are out, except for farm-fresh-fertilized eggs, and unpasteurized cows' or goats' milk. Airola claims that meat causes cancer and that protein requirements can be met from plant sources if they are eaten raw. Enzymes, he says, make the protein in these foods complete. His recommendations also include a regimen of vitamin, mineral, and herbal supplements, fermented foods, and a collection of health and beauty "secrets" from countries all over the world.

Airola died in 1983, but 11 of his 14 books and booklets are still sold by Health Plus Publishers:

- *Stop Hair Loss* (1965), a 32-page booklet, suggests methods for preventing baldness and for restoring hair to bald heads. Airola recommends headstands and a scalp operation to increase scalp circulation, and various dietary rules and food supplements such as kelp (dried seaweed) to "feed your hair from within."

- *How to Keep Slim, Healthy, and Young with Juice Fasting* (1971), an 80-page book said to have 500,000 copies in print, describes how to fast for up to 40 days on juices made from raw fruits and vegetables. Included are stories of how Airola supposedly cured patients of arthritis, cancer, asthma, obesity, diabetes, and abnormal heart rhythms, all with juice fasting. Prolonged fasting is dangerous because it causes breakdown of proteins in vital organs such as the heart and kidneys. But Airola claims (incorrectly) that the body decomposes only dead, dying and damaged cells, tumors and abscesses, and that all vital organs are spared. He says raw juices are "youthifying" and calls juice fasting "the oldest and most effective healing method known to man." His recommendations include string bean skin tea for diabetes, carrot juice for emphysema, and apple

juice for nervousness. But he also attempts to disclaim responsibility by stating (in boldface type): "The information in this book is not intended as diagnosing or prescribing; it should be used in cooperation with your doctor to solve your health problems. In the event you use the information yourself, you are prescribing for yourself, which is your constitutional right, but the author and publisher assume no responsibility."

- *Swedish Beauty Secrets* (1971), a 32-page booklet, claims that "Sweden, a little, far-away Scandinavian country, has produced more internationally known beauties than any other country in the world." Airola attributes this to use of "certain elements in their daily diet and beauty care which the latest scientific research has proven to be miraculous beauty aids." He considers rose hips the "number one beauty aid" because their vitamin C prevents wrinkles from collagen breakdown due to vitamin C deficiency. He also states that they will keep the complexion "velvety fresh" by combating bacterial putrefaction and preventing constipation, which he considers "the enemy of beauty."

- *Are You Confused?* (1971), a 224-page book said to have over 700,000 copies in print, covers his basic philosophy with each of his health "secrets" described at length. To help readers decide what information is "absolutely reliable, objective and scientifically correct," he suggests that "laboratory research and animal tests are only of limited value as compared to the thousands of years of actual human experience with nutrition capable of producing superior health."

- *How to Get Well* (1974), a 304-page book, offers "a complete therapeutic program" for more than 60 health problems, including arthritis, bladder infection, cataracts, diabetes, emphysema, heart disease, impotence, multiple sclerosis, paralysis (from a stroke) and stomach ulcers. For each of these conditions, he recommends "foods, vitamins, food supplements, juices, herbs, fasting, baths and other ancient and modern nutritional and biological modalities." The vitamin guide lists 23 "vitamins" although the scientific community recognizes only 13.

Occasionally he includes some facts. His discussion of heart disease, for example, correctly identifies smoking, high blood pressure, diabetes, lack of exercise, high blood cholesterol and other "risk factors." But for treating heart disease he advises a diet that contains no salt, sugar, coffee, meat, distilled water or refined carbohydrates. He also states: "Do not drink chlorinated water. Chlorine destroys vitamin E in the body, which is absolutely essential for the health of the heart. This is extremely important."

- *The Miracle of Garlic* (1978), a 48-page booklet, claims that garlic can help or correct high blood pressure, heart disease, diabetes, arthritis, cancer, emphysema, digestive disorders, intestinal worms, insomnia, colds, allergies, asthma and many other conditions. Al-

though recent research suggests that garlic may have some health benefits, Airola's claims were premature and go far beyond what is possible.

- *Everywoman's Book* (1979), a 640-page book, covers women's health issues, including childbirth, adjusted to his philosophy. The book begins with a disclaimer that its information is offered "purely for educational or experimental purposes" and that the author and the publisher "assume no responsibility in regard to the effectiveness of, or possible harm incurred from correct or incorrect application of therapeutic approaches described within." Airola's questionable ideas include: 1) headstands might make the breasts firmer; 2) sugar should be completely excluded during pregnancy or lactation; 3) immunizations generally do more harm than good, but if you want your child to get them anyway, administer large daily doses of vitamin C for one to two weeks beforehand; 4) eating lots of salty foods prior to conception will increase the odds of having a boy, while eating calcium-rich foods will increase the odds of having a girl.

- *The Airola Diet and Cookbook* (1981), a 288-page book, contains a weight-loss diet, a "complete vitamin guide," a "complete mineral guide," and over 200 recipes developed and tested by Airola's daughter, Anni Airola Lines, who is a registered dietitian. The diet is based on what he calls "three basic food groups": 1) grains, legumes, beans, seeds and nuts; 2) vegetables; and 3) fruits. Though his advice to consume ^{new} amounts of fresh fruits, vegetables, and whole ~~grains~~ is commendable, Airola's diet is almost devoid of complete protein sources. He makes no attempt to complement vegetable protein sources because he believes raw vegetables, buckwheat, and millet provide complete proteins—which they do not. Like many strict vegetarian diets, his "optimum diet" tends to be low in calories as well. The "vitamin guide" lists 22 vitamins. Although this book is the most conservative of Airola's works, it still displays ignorance of many basic food and nutrition concepts.

- *Hypoglycemia: A Better Approach* (1977), a 192-page book, is Airola's basic three-food-group diet with emphasis on curing "low blood sugar," which he claims affects over 20 million Americans.

Copyright © 1987 by the GEORGE F. STICKLEY COMPANY
Nutrition Forum ISSN 0748 8165 is published monthly by the George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106. Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES: \$30/yr., \$57/2 yrs., \$81/3 yrs., prepaid: VISA and Mastercard acceptable; foreign postage by airmail add \$18.00. Manuscripts, books for review, and other editorial correspondence should be sent to Dr. Stephen Barrett, P.O. Box 1747, Allentown, PA 18105. Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

• **Cancer: Causes, Prevention, and Treatment—The Total Approach** (1972), a 48-page booklet, begins: "I want to make it perfectly clear that I do not offer a cure for cancer. I only report how cancer is successfully treated in several of the biological clinics in Europe." In a footnote, he explains that this disclaimer was made "mainly to protect myself against persecution by overzealous government agencies, who, in the name of the public, mercilessly attack anyone who not only dares to advise but even to report on unorthodox cancer therapies."

The booklet gives Airola's personal list of 22 causes of cancer, including animal protein, salt, and heated vegetable oils. His "anti-cancer diet" excludes meat, fowl, eggs, fish and cows' milk, and includes juice fasting, and systematic undereating, which he described as a low-protein diet eaten as several small meals per day. His "anti-cancer supplements" include: up to 150,000 International Units (I.U.) of vitamin A per day (an amount likely to build up to toxic levels); pangamate and laetrile (which he calls vitamins B-15 and B-17 even though they are not vitamins); 5,000 mg of vitamin C; 1,000 I.U. of vitamin E; and digestive enzyme supplements "to help the body better utilize nutrients, particularly proteins." He concludes by advocating laetrile and other "non-toxic unorthodox treatments."

Curiously, Airola's daughter acknowledges that pangamate and laetrile are incorrectly referred to as vitamins and omits them from her own Health Plus

book, *Vitamins and Minerals: The Health Connection* (1985), in which she claims there are 17 vitamins.

• *Worldwide Secrets for Staying Young* (1982), a 208-page book, covers "proven and effective ways to halt and reverse the aging processes and live a long and healthy life." Each of the first 13 chapters covers "health and longevity secrets" from one part of the world. For example: rose-hip tea and whey (Sweden); rye (Finland); fermented foods, mineral water, and juice fasting (Germany); soured milk (Bulgaria); pollen-rich honey, garlic and onions, and buckwheat (Russia); ginseng and gotu kola (China); and skipping breakfast, except for a piece of fruit (Pitcairn Islands). Claiming that "one of the true fountains of youth is optimum nutrition," Airola recommends an "optimum diet" composed mainly of seeds, nut and grains, vegetables, and fruits, supplemented with "special super-foods" and food supplements. He also claims that humans should live to the age of 120 unless they "kill themselves prematurely by violating the basic laws of health and life."

Despite all this, Airola was only 64 when he suffered a fatal stroke.

Dr. Forester is State Extension Specialist and Associate Extension Professor of Foods and Nutrition at the University of Kentucky College of Agriculture, and Sherée L.T. Thompson is a dietetics student at the University of Kentucky College of Home Economics.

BRIEFS

Free report on sugar. *Sugar: Fact and Fiction*, a well written booklet about controversies involving sugars, is available from The Sugar Association, 1511 15th Street, N.W., Washington, DC 20005.

Sugar safety supported. An FDA task force on the health aspects of sugars has concluded that except for tooth decay, no evidence exists that sugars are hazardous to the general public at current consumption levels. Eleven staff members of the FDA Center for Food Safety and Nutrition participated in the project, with some focusing on sugar intake while others abstracted and reviewed the scientific literature. The task force report—152 pages of text with more than 900 references—concluded that sugar consumption does not cause diabetes, high blood pressure, heart disease, gallstones, cancer or behavioral changes in children or adults. Furthermore, sugars do not play a unique role in causing obesity or dietary imbalance. Similar conclusions were reached by the Federation of American Societies for Biology when it reviewed sugar for the FDA ten years ago.

Notable quote. "The key word in quackery is promotion. Quacks quack. Legitimate researchers also work with unproven methods . . . The difference is they do it in a guarded, responsible fashion—they don't promote unproven methods publicly or commercially."—William T. Jarvis, Ph.D., *U.S. News & World Report*, December 8, 1986.

FTC attacks Agricultural Commissioner. Federal Trade Commission Chairman Dan Oliver has initiated a National Consumer Fleece Award to be given annually to "those who use government powers to deprive consumers of the benefits of competition." The first award was given to New York State Agricultural Commissioner Joseph Gerace. According to the January 12th *FTC News Notes*, New York City has the highest milk prices in the United States because the New York Milk Cartel enjoys an "anti-consumer monopoly." Last year, when Farmland Dairies of New Jersey was permitted to sell milk in Staten Island, prices immediately fell. But Commissioner Gerace refused to license Farmland for the rest of the city. A few days after the "award," Gerace left office.

Hospitals marketing frozen dinners. Metropolitan Medical Center of Minneapolis and United Hospital of St. Paul have developed new types of frozen dinners called "Nutritious Cuisine." The dinners, which are targeted to senior citizens, are nutritionally balanced and have reduced levels of fat, sugar and sodium. The hospitals saw a need for such products when a survey revealed that 91% of home health service patients had a special dietary requirement and half had to cook for themselves. Marketing rights have been sold to North Star food company of Minnesota.

Resources for dietitians. Consulting Nutritionists, a Dietetic Practice Group of the American Dietetic Association, has published its 1986-1987 Resource List of 41 practice aids developed by registered dietitians. The list includes such items as videotaped cooking classes for special diets, a hand-held computer for nutritional assessments, and a body image questionnaire to help treat eating disorders. For a free copy, send a stamped (39¢ postage), self-addressed 4"x9 1/2" envelope to Candace Mattson, R.D., 9545 Delphi Road, S.W., Olympia, WA 98502.

Court orders raw milk ban. U.S. District Judge Norma Holloway Johnson has ordered the U.S. Department of Health and Human Services (HHS) to ban interstate shipment of raw (unpasteurized) milk and raw-milk products. The judge ruled that unpasteurized milk is unsafe and that agency officials have been arbitrary and capricious in refusing to ban its sale. The FDA stayed a proposed ban in 1973 and began drafting regulations again in 1982, but stalled until prodded by Public Citizen's Health Research Group (HRG), an organization founded by Ralph Nader. HRG petitioned the agency in April 1984, and together with the American Public Health Association (APHA), filed suit in September 1984 to force a response. After public hearings in October 1984 [See NF 2:1-4 and 2:20], FDA Commissioner Frank Young, M.D., Ph.D., suggested a ban in a memo to HHS Secretary Margaret Heckler. But she rejected this idea and ordered Dr. Young to deny HRG's petition [NF 2:28]. HRG and APHA then sued again [NF 2:62], and the American Academy of Pediatrics filed a supporting brief. Noting that HHS had spent more than 13 years studying the raw milk issue, Judge Johnson concluded, "It is undisputed that all types of raw milk are unsafe for human consumption and pose a significant health risk. The appropriate remedy in this case is, therefore, an order compelling the agency to promulgate a regulation prohibiting interstate sale." She also said that HHS can prohibit intrastate sales if an interstate ban is not effective. The main producer of raw milk in the United States is the Alta-Dena Certified Dairy of City of Industry, California.

Pauling Institute criticized. A fundraising appeal by the Linus Pauling Institute of Science and Medicine was sharply criticized in an article in *The Washington Post*. The appeal, dated October 6, 1985, began, "If you are worried about the spreading of the AIDS epidemic, then I have important news for you. There is growing evidence that vitamin C is effective in the treatment of AIDS . . . That's exactly why the Linus Pauling Institute needs your support today." The letter was signed by G. Richard Hicks, executive vice president, who claimed in an interview that Donald Abrams, M.D., assistant director of the AIDS clinic at San Francisco General Hospital, "has told us that of the AIDS patients he has treated, those who survive the longest are the ones who take large amounts of vitamin C." But Abrams denied making such a remark and said he has not tested vitamin C efficacy in AIDS. Thomas H. Jukes, Ph.D., Professor of Space Sciences at the University of California/Berkeley, said that using fear of AIDS to raise funds for an unproven treatment is "exploiting the public."

Comatose patient allowed to die. Paul Brophy, a 49-year-old former Boston firefighter became the first comatose patient allowed by a state supreme court to have artificial feeding removed while he was still alive. Brophy, who suffered profound brain damage in 1983, had been comatose for three years but could have been maintained indefinitely on life-support systems. His wife won the right to have his feeding disconnected when the Supreme Judicial Court of Massachusetts reversed a lower court decision [see NF 3:7]. Testimony in the case showed that Brophy would not have wanted to be kept alive by artificial means in a hopeless state. The high court ruled that artificial life support could be terminated if it is clear that the patient would not have consented to such treatment. Brophy died eight days after the feeding was stopped.

Force-feeding dispute rages on. Elizabeth Bouvia, a 29-year-old Los Angeles quadriplegic who was fed through a nasogastric tube against her wishes, has sued a county hospital and its ethics committee which recommended the feedings. Ms. Bouvia attracted nationwide attention in 1983 when she petitioned a California court to order her doctors to stop tube-feeding her and give her painkillers so she might die. After the court ruled against her, she transferred to the county hospital where she professed no suicidal thoughts and began eating without the tube. However, her weight dropped considerably and tube-feeding was resumed. She then returned to court and won a ruling that her right to be left alone outweighed the hospital's desire to see her gain weight and remain healthy. Now in another hospital, she is eating voluntarily but has lost more weight.

Sulfite labeling for alcoholic beverages. The Bureau of Alcohol, Tobacco and Firearms has issued regulations requiring labeling of alcoholic beverages that contain sulfur dioxide levels of 10 parts per million or more. By January 8, 1988, a sulfite declaration must appear in the labeling of such beverages before they leave domestic bottling plants or the custody of U.S. Customs.

Cash for losing weight. U.S. Healthcare, a Pennsylvania-based Health Maintenance Organization (HMO), is offering to reward members who lose weight through its Healthy Eating Program. Members can enroll by paying \$35 for a program guidebook and being assigned a weight goal by their primary HMO physician. Participants are awarded \$25 for reaching goal weight, \$50 for maintaining it six months, and \$100 for maintaining it a year. They can also earn a sweatsuit, a bathroom scale, exercise equipment and other incentives.

Magazine survey. The American Council on Science and Health has again rated nutrition advice given in popular magazines. The survey covered articles published during the past 2½ years in 25 magazines. A 3-person panel did the scoring, awarding points for both accuracy and readability. Five magazines were rated excellent: *Consumer Reports* (95% of possible points), *Better Homes & Gardens* (94%), *Changing Times* (93%), *Consumers Digest* (86%), and *Parents* (86%). Fourteen were rated generally reliable: *Glamour* (85%), *Good Housekeeping* (85%), *Essence* (82%), *McCall's* (82%), *Self* (82%), *Vogue* (82%), *Family Circle* (81%), *Modern Maturity* (81%), *American Health* (79%), *Seventeen* (79%), *Health* (78%), *Reader's Digest* (76%), *Woman's Day* (76%), and *Gentlemen's Quarterly* (73%). Three were rated inconsistent: *Mademoiselle* (70%), *Redbook* (69%), and *Prevention* (64%). Three were judged unreliable: *Cosmopolitan* (62%), *Ladies' Home Journal* (62%), and *Harper's Bazaar* (42%). The survey report is available for \$2 from ACSH, 47 Maple St., Summit, NJ 07901.

GENERAL NUTRITION PLEADS GUILTY

In 1984, General Nutrition, Inc., three of its officers and two of its store managers were charged with criminal violations of the Federal Food, Drug, and Cosmetic Act. The indictment accused them of conspiring to promote and sell an evening primrose oil product (Gammaprim) with claims that it is effective against high blood pressure, arthritis, multiple sclerosis and other diseases [see NF 1-20]. Gammaprim had been promoted with newspaper and magazine articles, radio talk show discussions, flyers, and claims made by salespersons to customers. Although the company termed the product a "food supplement," the promotional claims made it a drug that could not be legally marketed without FDA approval, which it lacked. The indictment also contained six counts of misbranding related to Gammaprim purchases made by undercover FDA investigators at GNC stores in western New York State.

In motions to stop the prosecution, the defendants had claimed that 1) their right to free speech was being violated; 2) the prosecution was unfair because many other companies making health claims in advertising have not been prosecuted; 3) Gammaprim should not be considered a drug because it is not inherently toxic; and 4) the laws under which they are being prosecuted are too vague. In May 1986 these motions were dismissed by a federal judge who noted that the defendants were aware, or should have been aware, that they were breaking the law.

In October, the company pleaded guilty to four counts of misbranding a drug and agreed to pay \$10,000 to the government as reimbursement for costs of prosecution. Its former president, Gary Daum, and a current vice president, David E. Walsh, each pleaded guilty to one of the misbranding counts. The remaining counts of the indictment and all charges against other employees were dismissed. In December, Daum was sentenced to pay a \$1,000 fine.

General Nutrition, Inc., with more than 1,000 outlets, is the largest chain of health food stores in the United States and Canada. Settlement of this case climaxed a series of federal enforcement actions that began several years ago. In 1985, the company signed consent agreements with the U.S. Postal Service to stop making unsubstantiated claims for 14 of its products sold by mail [NF 2:7 and 2:47]. In 1986, an FTC administrative law judge ruled that ads for another product were deliberately misleading and concluded that "General Nutrition's unconscionable, false and misleading advertising found in this case is not an isolated incident but part of a continuing pattern" [NF 3:38].

Although these enforcement actions have involved small penalties, they have had a dramatic effect on General Nutrition's marketing practices. During the past six months, it has not used flamboyant ads or made illegal therapeutic claims for any products.

SUGAR SUBSTITUTE IN FDA'S LIMBO

James A. Lowell, Ph.D.

Last summer Nichole Walker, a former Cayone del Oro math teacher and mother of four, won a red ribbon at the Pima County (Arizona) Fair for her recipe for sugarless whole-wheat orange-pecan muffins. While winning a ribbon is not so unusual, there was something different about her recipe: she used the finely ground leaves of an herb called Stevia. Since the word got out about Walker's recipe, the stores that carry Stevia haven't been able to get enough of the plant to fill the demand.

Stevia sells for 80¢ to \$3 an ounce. There is a problem with its sale, however. According to Blondell Anderson of the FDA's division of food and color additives, Stevia is illegal to sell because it is not on the "GRAS" list of foods or food additives — those "generally recognized as safe." But it is available at health food stores and the FDA has made no attempt to remove it.

Stevia rebaudiana is the botanical name for this member of the sunflower family which originated in Paraguay and Brazil. There, where it is widely used as a sweetener, it is known by various names such as Caa-hee-hee, Caa-enhem and Azuca-caa, all of which mean "sweet herb."

Although Stevia lacks FDA approval for sale in the United States, it is commonly used in other parts of the world. The plant parts themselves and various compounds derived from them are also approved as food additives in Japan, where they have been used as low-calorie sweetening agents and sugar substitutes since the mid-1970s. In fact, 11 Japanese firms have formed a consortium known as the Stevia Konwakai to study the effects and uses of the sweetener.

Dozens of chemical compounds are found in the leaves and stems of Stevia. The major ones responsible for the sweet taste are known as steviosides and rebaudiosides. These ingredients make Stevia about 300 times sweeter than sugar, and make the number of calories per gram insignificant. It is so sweet, says Walker, that she only needs half a teaspoon to sweeten 1½ dozen of her muffins.

Pure stevioside has a very bitter and persistent aftertaste, but when it is diluted it is comparable to products such as cyclamates and aspartame. Unlike aspartame, it doesn't break down under high temperatures, so it can be used for baking.

Over the years, questions have been raised about Stevia's safety. A report in the August 1960 *Endocrinology*, for example, indicated that the action of male sex hormones might be blocked by large intakes of the

herb. This could explain the effects discussed by other researchers in an article in *Science* [Nov. 29, 1968, p. 1007] which described how the Paraguayan Matto Grosso Indians used Stevia as a contraceptive. Moreover, laboratory experiments on rats indicated that an extract of its leaves and stems added to their water might have an anti-fertility effect.

Additional concerns were raised by two pharmaceutical researchers at the University of Illinois in Chicago who found that some of the compounds formed from the digestion and breakdown of the sweetener could cause genetic mutations in bacteria. Since other chemicals which cause similar effects in bacteria may also cause mutations and cancer in humans, they recommend that further tests be carried out to be sure that Stevia is safe. Other experiments indicated that Stevia might act as a respiratory poison, although no toxic effects were noted when the sweetener was given to laboratory animals over extended periods of time.

However, since the 1960s, numerous follow-up studies have failed to confirm that Stevia causes any harm or has any contraceptive effect. And in Japan, where it has been used for years, no harm has been reported in humans who used either the herb or sweeteners derived from it.

Walker said the only trouble she had with Stevia was that it turned her tapioca green.

Dr. Lowell is a professor of life sciences at Pima Community College and is president of the Arizona Council Against Health Fraud.

QUESTION BOX

Q. What is durum wheat?

A. It is one of the three wheat species that are commercially important. The others are bread wheat and club wheat (used mainly for biscuits and pastries). The two varieties of durum wheat—red and white—are hard spring wheats grown primarily in North Dakota. The flour of durum wheat (called "semolina") is used to make pasta products. Semolina, when mixed with water, yields a very elastic paste that can be extruded to create the many different pasta shapes that we have come to enjoy.

HERBALIFE AGREES TO PAY \$850,000 PENALTY

Herbalife International, Inc., and its president Mark Hughes, have agreed to pay \$850,000 to settle charges by the California Attorney General that the company made false medical claims and engaged in an illegal pyramid-style marketing scheme. Herbalife has been selling its products through a multilevel marketing program in which the amount of money received by its distributors depended upon the amounts purchased by them and by those whom they recruit as distributors.

The Attorney General's suit, filed in 1985, cited the following questionable claims made for Herbalife products:

- Slim and Trim Formulas comprise an effective weight loss program which can produce a typical weight loss of 10-29 excess pounds a month.

- Cell-U-Loss can attack "cellulite," eliminate inches, suppress appetite, improve circulation, and help many other conditions.

- Herbal-Aloe can aid digestion, "heal" and "cleanse the system."

- N.R.G. can increase energy, increase mental alertness, and provide a "nutritional lift." (The fact that caffeine is one of its active ingredients was not disclosed.)

- Lifeline aids the cardiovascular system.

- Schizandra Plus can combat damage that leads to premature aging.

- Tang Kuei is effective against hot flashes and can help the regularity of the menstrual system and relieve menstrual disorders.

- Flora-Fiber "scrubs and cleanses" the intestine with fiber and prevents disease.

- K-8 stops "induced depression" and "elevates your mood so you can handle stress."

The suit also charged:

- Early editions of the *Herbalife Official Career Handbook* made illegal claims that various herbal ingredients were effective against more than 70 diseases and conditions. Although most of these claims were deleted in subsequent editions of the handbook, the company had not replaced the original pages sent to distributors with the revised pages or asked these distributors to destroy them.

- Similar testimonial claims were made in com-

pany broadcasts over cable television.

- To attract new distributors, the TV programs and company magazine contained stories of individuals who made large amounts of money by building large networks of Herbalife distributors. These representations are misleading because there is no reasonable basis to assert that most people who become distributors will earn large sums.

- Although the company offered a "full warranty" on all of its products, customers who tried to invoke the warranty were often thwarted in their efforts by the defendants.

The court order settling the case, dated October 14, 1986, forbids representations without reasonable basis that:

- Herbalife products contain herbs that can curb appetite, burn off calories, or cleanse the system.

- Product users can lose weight without reducing caloric intake.

- Cell-U-Loss can eliminate "cellulite."

- Other products or their ingredients are effective as specified in the Attorney General's complaint.

The court ordered strict limits on testimonials and said that the caffeine content of N.R.G. should be disclosed in the career book and on the product's label. It also ordered Herbalife to change its marketing program so that distributors can profit only from retail sales and are discouraged from maintaining (and possibly becoming stuck with) large product inventories in order to qualify for bonuses.

The \$850,000 penalty—payable over a five-year period—was assessed to reimburse the state for costs, attorneys' fees, expenses of investigation, and other expenses. Mark Hughes was ordered to post a \$400,000 security deposit to cover possible default by the company.

On December 3, 1986, *The Wall Street Journal* reported that Herbalife merged with a Utah-based shell corporation and plans to raise \$14 million with a public stock offering. The company netted \$7.6 million on sales of \$115.7 million during the first half of 1986 and \$12.4 million on \$462.9 million of sales in 1985. (For additional information about Herbalife, see *NF* 2:65-68 and 2:73-77.)

THE RISE OF THE HUMBLE POTATO

Howard D. Lerner

Foods have long been victims of superstition and ignorance. Because an evil witch in a certain fairy tale decided to use "poison mushrooms" as her brew base, many otherwise adventurous eaters balk when they see a dish featuring mushrooms. Even the familiar peanut was snubbed until the turn of the century when George Washington Carver demonstrated its versatility by inventing peanut butter.

The potato, like the peanut and the mushroom, has also had public relations problems. Scottish clergymen of the 18th century preached against eating potatoes because they're not mentioned in the Bible. Even modern-day children are occasionally told that their ears will sprout spuds if not cleaned regularly.

The potato (*Solanum tuberosum*) had been cultivated by the Incas for thousands of years before Francisco Pizarro and his Spanish Conquistadores encountered it during their invasion of Peru. Europe did not, however, share Pizarro's enthusiasm over the spud. As late as 1774, potatoes were refused in Germany. Only after King Louis XVI and Marie Antoinette of France declared them fashionable in 1785 did the potato receive its due. Today it ranks fourth in the world in importance behind wheat, rice and corn as a staple crop.

The potato, heartiest of vegetables, survives in the torrid deserts of Africa and even under the frozen tundra of Alaska. Its resistance to harsh conditions so appealed to Irish farmers that by 1845, the "prat" was Ireland's sole crop. When the Late Potato Blight fungus hit Ireland in 1845, the resulting "Potato Famine" killed one million Irish people over a six-year period. Another million escaped the famine by sailing to America. As a result, the Irish are now one of the largest ethnic groups in America.

The potato may again be on the verge of changing world history—this time by feeding millions of starving people. Scientists at the International Potato Center in Lima, Peru, are developing strains of potatoes more resistant to pests. Hearty hybrids with meshed skins, impervious to infestation, are now available.

Unlike corn or wheat, the potato does not produce seeds suitable for planting. To obtain a good yield from a thousand acres of land, a farmer must plant a thousand tons of mature potatoes. An equal harvest of corn requires only a hundred pounds of seed. Scientists have succeeded in producing "potato seeds" from the tiny berries that grow on the potato plant, a method that can save poor countries millions of dollars in equipment costs and storage. Before long, it is hoped, potatoes will supply the world with an abundant food source.

Virtually all the world loves potatoes, and the United States is no exception. According to The Snack Food Association, potato chips alone grossed more than \$3 billion for manufacturers last year. Yet the big potato

money-maker is the "French fry." Once served by Thomas Jefferson in the White House, this European snack was popularized here by the J.R. Simplot Company of Boise, Idaho. Simplot began producing French fries after World War II. Today, the company processes 100,000 raw potatoes every hour of the day and night. McDonald's claims the largest portion of them in frozen form. Fast food restaurants sell most of the five billion pounds of French fries produced each year in the U.S.

Our taste for the potato, however, is not limited to French fries and potato chips. Today, the versatility of the potato is being hailed. Baked potatoes are still popular, and potato skins, long thought to be inedible leftovers, are now rivaling hamburgers on the tables of many American eateries. Even restaurants that solely feature potatoes are popping up—and staying.

"The potato is the perfect food," says Kevin Braun, manager of Potatoes Etc. "It's a meal contained in itself." Braun's small restaurant boasts 19 varieties of stuffed potatoes, with hot Cheddar and bacon the most popular. For something with a bit more pizzazz, you can try a potato stuffed with sirloin tips in wine sauce. Or smothered with seafood Newburg.

Many people cling to a misconception that potatoes are undesirable because they're high in starch (a complex carbohydrate). But complex carbohydrates are considered "good guys" by today's nutritionists. Moreover, an average potato contains enough vitamin C to supply an adult with half the Recommended Dietary Allowance. Although several other foods are richer in vitamin C, the potato is actually the world's leading food source of this vitamin because of its widespread use.

"A man could live for months on five pounds of potatoes and a quart of milk daily," says Mary Ellen Beindorff, a nutritionist at Barnes Hospital in St. Louis. She sees a wide range of patients every day, from compulsive overeaters to those suffering from malnutrition. "I recommend that people eat potatoes in every case," she says.

Potatoes are smart eating for other reasons too. For the dieter, they are a filling, low-calorie choice. A 12-ounce potato has only 90 calories. What you put on it, though, can pile on more.

The potato is 99.9% fat-free, and will remain so if baked rather than fried. Topping it with low-calorie margarine instead of butter will constrain calories without altering the flavor too much. Or try a spoonful of stewed tomatoes and some grated Parmesan cheese instead of the usual sour cream. They're lower in calories and might even taste better.

Mr. Lerner, a senior majoring in English at Washington University in St. Louis, has been involved in Oxfam and other humanitarian outreach programs.

NEW GROUPS PRESSING FOR "HEALTH FREEDOM"

Stephen Barrett, M.D.
Grace P. Monaco, J.D.

Promoters of unscientific methods have organized three more groups to promote their methods and end government regulation of health care practitioners. The Health Alternatives Legal Foundation, led by attorneys, is working primarily through the courts. The American Quack Association is a network of "holistic" practitioners. The Coalition for Alternatives in Nutrition and Health Care is organized for grass-roots lobbying. All three use the words "alternative," and "freedom" to suit their own purposes.

The Health Alternatives Legal Foundation (HALF), 105 N. Foster St., Dothan, AL 36303, is described in its literature as a "nonprofit public interest law center." It was formed in 1986 to defend "alternative" health care practitioners and to file suits challenging medical practice laws.

HALF's newsletter, *Alternatives*, describes the group's philosophy and reports news (mostly legal troubles) involving promoters of unproven methods. According to the newsletter, "Powerful elements of organized allopathic medicine, led by the American Medical Association, have been waging an expensive, well-orchestrated political and economic campaign designed to stifle competition from alternative health care providers. This campaign has been advanced by advocates of the medical establishment who, for financial or philosophical reasons, seek . . . to eliminate the ability of alternative health care providers to practice in the American marketplace. Maverick doctors, chiropractors, osteopaths, homeopaths, acupuncturists, naturopaths, podiatrists, nutritionists, midwives and eclectic physicians have felt the full brunt of this organized attack."

HALF's brochure states that "alternative health care practitioners deserve proper recognition by state legislators, regulation by review boards of their own peers, and reimbursement for services from health in-

surance companies. Our attorneys defend individual health practitioners against charges of operating outside the scope of standard medical practice."

The chairman of HALF's board of directors is Attorney William H. Moore of Savannah, Georgia. In 1984 Moore attempted to intervene in a laetrile case with an action designed to stop virtually all interference with "unorthodox" methods, but he withdrew when the plaintiffs objected [see NF 2:89-90].

HALF's executive director is attorney Michael S. Evers, of Dothan, Alabama, whose adoptive father, H. Ray Evers, M.D., recently had his medical license revoked by the Alabama Medical License Commission. HALF's newsletter states that the grounds included: 1) engaging in the practice of medicine in such a manner as to endanger the health of the patient; 2) using untruthful or deceptive or improbable statements concerning the effects or results of his proposed treatment; 3) demonstrating unprofessional conduct in the treatment; and 4) "gross malpractice." The case involved a breast cancer patient Dr. Evers had treated with an herbal salve. (A circuit judge has blocked the revocation while Evers appeals to state courts.)

The American Quack Association (AQA), P.O. Box 550, Oviedo, FL 33765, has about 300 members, most of whom are health professionals. Founded in 1985, its main purposes appear to be providing emotional support to its members, poking fun at their critics, and stimulating positive public feelings toward unorthodox practitioners. Noting that "Discrimination, legal investigation, persecution, prosecution, and even imprisonment have variously been the fate of those few physicians and others who have publicly counseled alternative means of health care," AQA's "Articles of Health Freedom" demand that "No law or regulations shall be made prohibiting the right of people to freely assemble for healing of any type." They also oppose "any

penalty whatsoever against anyone employing any form of treatment for cancer or any other disease for him or herself or others, except in cases of fraud, deception or the use of force."

AQA's vice president is Roy Kupsinel, M.D., a "holistic" practitioner in Oviedo, Florida. Kupsinel publishes *Health Consciousness*, a bimonthly magazine which contains articles on cosmic philosophy, conservative causes, and the "persecution" of unorthodox practitioners. It also contains ads for unproven products and services. Its last few pages are printed upside down as the *Journal of the American Quack Association*, edited by AQA president Jonathan V. Wright, M.D., of Kent, Washington. AQA's logo depicts a stressed but smiling duck flying through the "Q" of AQA. Dues are \$6.00 a year.

The Coalition for Alternatives in Nutrition and Healthcare (CANAH), P.O. Box B-12, Richlandtown, PA 18955, is a nonprofit corporation established in 1984 "to educate the public in nutrition and alternative healthcare . . . through lobbying, public awareness presentations, and timely presentations." CANAH's founder, president and "legislative advocate" is Catherine J. Frompovitch, Ph.D., who practices "nutritional consultation" in Richlandtown, operates C.J. Frompovich Publications, and edits CANAH's *Health Rights Advocate*, a comprehensive quarterly report on legislative developments. (Her "Ph.D." is from Columbia Pacific University, an unaccredited correspondence school.)

At one point last year CANAH had about 400 members, but no current figure has been publicly released. No officer other than Ms. Frompovich has been identified in the group's publications, but the 28-person advisory board listed on its letterhead includes Moore, Kupsinel, and:

- Jeffrey S. Bland, Ph.D., a biochemistry professor who promotes food supplements through publications and frequently lectures at health food industry conventions [see NF 33-38].
- Dan Clark, M.D., a Florida physician whose license was revoked for unprofessional practice.
- Richard Crews, M.D., President of Columbia Pacific University.
- Alan R. Gaby, M.D., a Maryland physician/author who practices "nutritional therapy"
- Bruce W. Halstead, M.D., a California physician who in 1985 was convicted of cancer fraud and grand theft for selling herbal tea to cancer patients for \$125 to \$150 per quart [NF 1:5]. He has been fined \$10,000 and sentenced to four years in prison but is appealing his conviction.
- Conrad G. Maulfair, Jr., D.O., a Pennsylvania osteopath who practices chelation therapy.
- Robert Mendelsohn, M.D., former president of the National Health Federation, who attacks established medical and public health procedures in lectures and

publications.

- Earl Mindell, R.Ph., Ph.D., author of *Earl Mindell's Vitamin Bible* and numerous other publications promoting questionable use of food supplements [see NF 3:46-47]. His "Ph.D." is from the University of Beverly Hills, an unaccredited school.

- Richard Passwater, Ph.D., author of numerous publications promoting questionable uses of food supplements. His "Ph.D." is from Bernadean University, an unaccredited diploma mill that was not authorized to issue any degrees at the time Passwater obtained his.

- Linus Pauling, Ph.D., who seems willing to ally himself with virtually anyone who supports his questionable ideas about megavitamins [see NF 2:33-7].

- Carl Pfeiffer, M.D., Ph.D., director of the Brain Bio Center, Princeton, New Jersey, which offers "nutritional" treatment for "the schizophrenias and biochemical deficiencies associated with aging, alcoholism, allergies, arthritis, autism, epilepsy, hypertension, hypoglycemia, migraine, depression, learning disability, retardation, mental and metabolic disorders, skin problems, and hyperactivity."

- Barbara Reed, Ph.D., a former probation officer who is now devoted to promoting her theory that criminal behavior can be attributed to poor diet and corrected by dietary reform. Her "Ph.D." is from Donsbach University, an unaccredited correspondence school.

- Michael B. Schachter, M.D., a New York psychiatrist who has been prominently involved in using laetrile and megavitamins to treat cancer.

- Lendon Smith, M.D., a prominent author and pediatrician who was placed on probation by his state board of medical examiners from 1973 to 1981 for "inappropriate prescribing of drugs" to heroin addicts.

CANAH's activities have included support for an unproven cancer treatment (immunoaugmentative therapy) and opposition to food irradiation, water fluoridation, licensing of nutritionists, and other antiquackery legislation. Regular membership costs \$10 per year. News articles and invitations to join have appeared in many health food industry publications. CANAH wants individuals denied access to or insurance coverage for "alternative healthcare" to file antitrust suits and other legal actions to "protect their rights."

Copyright © 1987 by the GEORGE F. STICKLEY COMPANY
 Nutrition Forum ISSN 0748 8165 is published monthly by the George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106. Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES: \$30/yr., \$57/2 yrs., \$81/3 yrs., prepaid: VISA and Mastercard acceptable; foreign postage by airmail add \$18.00. Manuscripts, books for review, and other editorial correspondence should be sent to Dr. Stephen Barrett, P.O. Box 1747, Allentown, PA 18105. Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

CANAH's main goal is enactment of a "Healthcare Rights Amendment," which has two basic provisions:

1. Congress shall make no law which restricts any individual's right to choose and to practice the type of healthcare they shall elect for themselves or their children for the prevention or treatment of any disease, injury, illness or ailment of the body or the mind.

2. Congress shall have the power to enforce, by appropriate legislation, the provisions of this article.

A flyer promoting the amendment claims that "vested interest groups, certain individuals and trade associations, the American Medical Association in particular, have launched legal procedures against medical doctors who employ in their practice such modalities as natural nutrition, chelation therapy, vitamin/mineral supplementation and other means commonly referred to as alternative healthcare modalities which may not be in agreement with orthodox medicine. Practitioner and patient alike have been brought up before the bars of justice and peer review with heretofore unknown medical inquisition-like techniques. WE THE PEOPLE believe this is unconstitutional, and we therefore propose this amendment." Ms. Frompovich hopes to deliver at least 100,000 signatures supporting the amendment to "proper governmental officials" during 1987, which is the 200th anniversary of the Constitution.

CANAH's logo depicts a hummingbird because it has "the freedom of choice and can go from flower to flower to satisfy its needs." The group's brochure quotes the famed philosopher/ethicist John Stuart Mill (1806-1873) as though he would support its aims: "The only freedom which deserves the name, is that of pursuing our own good in our own way, so long as we do not attempt to deprive others of theirs, or impede their efforts to obtain it. Each is the proper guardian of his own health, whether bodily, or mental or spiritual. Mankind are great gainers by suffering each other to live as seems good to themselves, than by compelling each to

live as seems good to the rest." But Mill recognized that where "there is a definite damage, or definite risk of damage, either to an individual or to the public, the case is taken out of the province of liberty and placed in that of morality or law."

Under current laws, our federal and state government can set licensing standards for health practitioners, institute public health measures, and outlaw remedies that are dangerous or ineffective. In *Rutherford v. United States*, in which a patient sued for access to laetrile, the U.S. Supreme Court ruled that "selection of a particular treatment, or at least a medication, is within the area of governmental interest in protecting public health." CANAH wants all restrictions removed. Under its amendment:

- Government agencies could no longer remove unproven or dangerous remedies from the marketplace so long as a single consumer objects.

- Anyone—licensed or not—could engage in any practice labeled "health care" so long as a single consumer wishes it to continue.

- Courts could no longer protect children from parents who deny them access to effective health care, even if such neglect will result in their death.

- Dangerously psychotic individuals could not be compelled to undergo treatment if anyone objected.

- Compulsory immunization would end.

- Community water fluoridation would end if a single person in the community objects.

Although promoted in the name of "freedom," CANAH's health care rights amendment would end protection of consumers from quackery.

Dr. Barrett, a psychiatrist and consumer advocate, is co-author/editor of 21 books including *Vitamins and "Health" Foods: The Great American Hustle*. Mrs. Monaco, a partner of White, Fine and Verville, of Washington, D.C., specializes in health law as it applies to unproven methods of medical management.

BRIEFS

Microwave injuries. *The New England Journal of Medicine* has reported a case of a 10-year-old boy whose eyelids and cornea were burned by steam escaping from a bag of microwave-popped popcorn [315:1359, 1986]. The product's packaging warned, "Handle the bag carefully—It's hot!" But the injury was caused by a rush of steam released when the bag was opened. In 1984, serious burns of the throat were reported in a baby who drank infant formula that had been heated in a microwave oven. [*Journal of Pediatrics* 105:864-7].

Fast food trends. According to the Food Institute, supermarkets and convenience store operators see ready-to-eat foods as a way to capture consumer expenditures that would otherwise go for eating out. Supermarkets, with their advantage of high-volume, heavy-traffic locations, are adding more service delis and hot foods "to go" and are experimenting with everything from breakfast bars to sushi. Since more than half of American homes now have a microwave oven, microwavable products will also be heavily promoted.

Notable quote. "Toxic terrorists and doomsayers who have brought us so much bad news about the quality of our environment, food and life are under closer scrutiny. While there remains a role for the federal government in the promotion of public health . . . much of our fate is in our own hands."—Elizabeth M. Whelan, Sc.D., Executive Director, American Council on Science & Health.

Gastric balloon warning. The manufacturer of the Garren-Edwards Gastric Bubble has warned physicians to limit its use because one patient has died and 80 others have developed serious complications such as blockage of the intestine and ulcers and perforation of the stomach. According to *American Medical News*, 17,000 patients have used the device since it received FDA approval in 1985. It is inserted into the stomach through the mouth and inflated as a temporary measure to curb appetite. In a letter to 2,000 gastroenterologists who were trained to use the device, the company recommended it only as a last resort for patients with life-threatening obesity for whom other treatments have not worked. The letter also warned that if the bubble suddenly deflates (as has happened during the first three months in 2% of patients), surgery may be needed and that delay in removing the bubble could cause death.

Dangerous weight-reduction drug. In March 1986, Nicholas Bachynsky, M.D., who operates a chain of "Physicians Clinics" in Texas and neighboring states, was found guilty of violating the Texas Food, Drug, and Cosmetic Act and ordered to pay \$86,000 in fines and attorney's costs. Action was brought by the Texas Attorney General because Bachynsky was prescribing 2-4-dinitrophenol, a highly toxic drug he dispensed under the name Mictal. The presiding judge also enjoined further use of dinitrophenol without FDA approval. When Bachynsky persisted, he was charged with violating the injunction and fined \$100,000 by the judge. Although dinitrophenol can cause weight loss by speeding up metabolism, the FDA banned it during the 1930s because it also causes severe skin reactions, jaundice, cataracts, disturbances of smell and taste, and agranulocytosis, a potentially fatal disorder in which production of blood cells is impaired. Although Bachynsky was aware of these problems, he claimed the drug was safe and "forces your metabolism to burn thousands more calories." According to an article in the February 1987 *FDA Consumer*, some 14,000 people were treated at Bachynsky's clinics at a cost of approximately \$1,300.

Natural Foods Month? During the past ten years, the health food industry has promoted April as "Natural Foods Month." But according to *Health Foods Business*, it did not spark enough media and public attention to catch on. "In fact," the magazine's editor wrote recently, "were April to pass without anyone making note of 'Natural Foods Month,' it's probably safe—and sad—to say virtually no one would notice." In some years, the Natural Nutritional Foods Association distributed public relations materials and had notables such as Gloria Swanson, Carol Burnett, Gayelord Hauser and Steve Garvey serve as honorary chairpersons. But this year, individual businesses are on their own.

FDA criticized. Lack of FDA enforcement against quackery was sharply criticized in the December 8, 1986 *U.S. News & World Report*. Noting how quackery is rampant, the article revealed that "internal FDA documents show that the agency's policy is to take no action at all against products that are worthless but not dangerous."

Vitamin C and mortality. A 10-year study of 3,119 adult Californians has found no relationship between vitamin C intake and death from cancer, heart disease or other diseases [*American Journal of Public Health* 76:1124-1130, 1986]. In 1973 or 1974, each participant completed a detailed 28-page questionnaire about personal habits, health care patterns, vitamin supplement usage, and other characteristics. Vitamin C consumption was estimated from reported intakes of orange, grapefruit and tomato juice, other fruits and vegetables, and vitamin C pills. Subsequent mortality was determined by checking California death and motor vehicle bureau records. Individuals who smoked or had certain other bad health habits had higher death rates than those with better health habits. But no difference was found between individuals with daily vitamin C intakes under 250 mg (few of whom had been taking supplements) and those who consumed 250 mg or more (almost all of whom had been taking supplements). Reprints of the article can be obtained from James E. Enstrom, Ph.D., School of Public Health, University of California, Los Angeles, CA 90024.

COMING SOON
The Rise and Fall of
United Sciences of America

Cholesterol extraction under study. According to an article in *American Medical News*, food scientists have been able to remove up to 80% of the cholesterol from butter, lard, beef tallow and egg yolks while retaining nutrients, flavor and consistency. The process, called supercritical fluid extraction, is being refined at the University of Wisconsin and the Phasex Corporation of Lawrence, Massachusetts, under a grant from the Wisconsin Milk Marketing Board. The researchers hope to remove additional cholesterol and reduce costs so that commercial use becomes practical within the next year. They also are experimenting with meat, ice cream, cheese and other high-cholesterol foods.

Diet drugs banned at border. In the wake of four deaths, the FDA has asked the U.S. Customs Service to halt importation from Mexico of Redotex, Ponderex and Moduretic, three drugs dispensed at border diet clinics. Before the ban, American citizens who could prove that a physician had prescribed the drugs were allowed to keep them. Now the Customs Service will seize them.

Cholesterol labeling proposal. The FDA has proposed standards for the terms "cholesterol free," "low cholesterol," and "cholesterol reduced" on food labels. When these are used, labels would also have to report the amount of cholesterol and fatty acids (saturated vs. unsaturated) per serving. These standards are intended to help the National Heart, Lung and Blood Institute's National Cholesterol Education Program to help prevent heart disease by lowering blood cholesterol levels. The information can also help people follow the American Heart Association's "Healthy Heart" guidelines for reducing dietary cholesterol and saturated fats. Under the proposal, "cholesterol free" would mean less than 2 mg per serving, "low cholesterol" would mean less than 20 mg per serving, and "cholesterol reduced" would mean processed to lower cholesterol content by 75% or more. Where reductions are significant but less than 75%, labels could make a comparison statement. The proposal has been criticized because it does not require listing the percentages of fats, which would be easier for consumers to interpret than the amounts. The Center for Science in the Public Interest (CSPI) has also pointed out that foods low in cholesterol but high in saturated fat could be marketed with "low-cholesterol" featured on their front label while the undesirable fat content appears in small print on the rear label. CSPI has asked the FDA to define "low in saturated fats" to help consumers moderate their fat intake.

Carbonated milk. Dairy Research Incorporated (DRINC), of Elk Grove Village, Illinois, has developed a way to expand the market for dairy foods: carbonated milk. The unflavored form, which tastes similar to club soda and is nutritionally equivalent to skim milk, contains 302 mg of calcium and 86 calories per 8-ounce serving. Such flavors as strawberry, peach, chocolate, root beer and pina colada are also being developed. Mass production of carbonated milk will take another year or two. Researchers believe that if it captures 6-8% of the soft drink market in the United States, it might eliminate the milk surplus, which was 13 billion pounds in 1985.

Few results from milk carton photos. The Associated Press has reported that the millions of milk cartons with pictures of missing children have helped locate only six children.

Free diabetes treatment. Diabetics who need insulin have been invited to volunteer for a 6-year program of intensive treatment designed to test whether strict control of blood sugar levels can prevent or reverse long-term complications of diabetes. The program will involve severe dietary limitations, insulin injections three times daily (or use of an insulin pump), and considerable attention to exercise. Participants will receive free insulin and supplies, 24-hour phone counseling, and state-of-the-art monitoring and treatment of early complications. Candidates must be between the ages of 13 and 39, have had insulin-dependent diabetes for 1-15 years without serious complication, and agree to extensive recordkeeping. Interested persons can call 1-800-522-3228 for a preliminary screening.

Chiropractors attack cytotoxic testing. The American Chiropractic Association (ACA) has ratified a well written position paper by its Council on Nutrition which concluded that cytotoxic testing "may result in a high number of false positive findings" and "should not be employed in the evaluation of patients suspected of having adverse reactions to foods." In this test, a patient's white blood cells are placed on slides containing dried food extracts and examined under a microscope [see NF 1:17-19]. Since many chiropractors engage in unscientific nutrition practices, the ACA's action represents a major step forward. The ACA Council on Nutrition hopes to develop position papers on many methods of diagnosis and treatment involving nutrition.

THE "SECRET" OF CHEESEMAKING

Manfred Kroger, Ph.D.

Charles deGaulle once said, "How can you govern a country that has 246 kinds of cheese?" This was undoubtedly a wild guess, but France probably does manufacture more than 200 varieties. Worldwide and historically, the number is somewhere between 600 and 800. But many variously named cheeses differ only in minor attributes. Basically, there are only two types of cheese: those made with the enzyme rennet, and those made with bacteria-produced acid. Hard cheeses, like Cheddar and Swiss, are examples of the first, cottage cheese and cream cheese of the latter. Most varieties are rennet-type cheeses because these last longer and may be ripened for weeks or months in many different ways. Most acid-type cheeses are consumed fresh without ripening.

Cheeses can also be categorized as "processed" or "natural." Process (or processed) cheeses, cheese foods and cheese spreads are relative newcomers whose manufacture from "natural" cheeses requires melting down, blending and emulsification into highly standardized products. As a result, such cheeses are uniform throughout in taste, texture and appearance. All other cheeses are called "natural cheeses."

Cheese has been around since before the "invention" of agriculture. When nomadic people, probably around 10,000 years ago, kept milk in pouches made from animal stomachs or when they allowed milk to go sour, they observed that curd and whey were produced, that the whey was a nourishing drink, and that the curd lent itself to many food uses. It could even be stored for prolonged periods during which it changed in flavor and texture into another edible product. People must have valued this outcome because they continued making and eating this cured curd which became cheese as we know it.

Cheesemaking is simply the deliberate conversion of most of the milk's protein (the casein), fat, mineral salts and other nutrients into solid curd. Whey

is the liquid by-product and contains all the milk's carbohydrate (lactose or milk sugar), about 20% of its protein (the whey proteins), traces of the fat, and some of the nutrients. Strictly speaking, cheese is simply concentrated milk, and cheesemaking is a form of food preservation.

The key difference between the two basic types of cheese is the method of curd formation. When casein is exposed to acid it will curdle. To the food scientist, such curd is coagulated casein precipitate. To the consumer, it's something like cottage cheese. The acid used in the manufacture of this type of cheese is not added but is lactic acid developed from the milk's lactose by bacterial action. The bacteria are added at the beginning of the cheesemaking procedure in the form of a "starter culture." This can be frozen, concentrated culture obtained from a commercial supplier or simply a batch of cultured buttermilk.

Making hard cheese is another matter. The main added ingredient here is rennet, an enzyme prepared from the stomach lining of calves. When rennet is added to milk, the milk's casein is chemically disassembled to a minor extent, so much so that a gel is formed. This rennet-coagulated curd is called calcium paracaseinate. In cheesemaking, it is cut into cubes and forced by gentle heating to expel whey until hard curd particles are obtained. These are pressed into particular cheese shapes and moved into a ripening room. What is called "green cheese" at the beginning will eventually cure, age or ripen into one of the many cheeses found in the cheese store.

Cheesemaking isn't really so simple as described here. It is an art, subject to the maker's decisions and interventions, as well as a science that requires adherence to strict processing requirements, such as milk composition, nature and amount of the bacteria and rennet added, specific temperatures, severity and duration of agitation, and dozens of other details. Further

EDITORIAL BOARD

EDITOR: Stephen Barrett, M.D. **SENIOR ASSOCIATE EDITOR:** Manfred Kroger, Ph.D. **ASSOCIATE EDITORS:** Denise Ferko-Adams, R.D., Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

variations including temperature and humidity are introduced during the ripening period.

Despite the initial statement that only acid-type and rennet-type cheeses exist, there is always some rennet added to acid cheeses and bacteria are always utilized when making hard cheeses. During ripening, these specifically selected bacteria and their enzymes gradually convert the casein into what is eventually enjoyed as cheese. Even certain molds can be used for this process. Stilton, Gorgonzola, Roquefort and blue cheese are examples of blue-mold cheeses that are ripened from the inside out.

Proper ripening is as critical to cheesemaking as is the conversion of milk into curd. Some cheeses, including Cheddar, Swiss, Edam, Parmesan, and the blue-mold cheeses, ripen only inside, with or without hole formation, while others, such as Limburger, Trappist and Port Salut, ripen both inside and from the outside in. Considering all of these variables and their permutations in cheesemaking, it is easy to understand why there are so many cheese varieties.

You may want to try your hand at it as my eight-year-old son did the other day. Add a dash of lemon juice to milk. Observe how the casein flocculates. Note how the coagulated white protein separates from a greenish liquid. Like Little Miss Muffit, you have just prepared curds and whey. Stir the mess gently and pour it through filter paper or some fine-meshed cloth. The whey will run through and—*presto*—cheese curd will stay behind. Eat it! You have just become a cheesemaker.

Dr. Kroger is Professor of Food Science at The Pennsylvania State University.

QUESTION BOX

Q. Does hard water supply significant amounts of dietary calcium?

A. The hardness of water depends on the presence of different minerals, primarily calcium carbonate. "Hard water" is found in regions where there is much limestone. Ground water in these areas is enriched with calcium and magnesium. (The softening process replaces these minerals with sodium). The amount of calcium obtained from water varies with the hardness and amount of water a person drinks. Although the amount of calcium obtained from hard water can be significant, it is usually much less than the amount obtained from food. [*Journal of the American Dietetic Association* 86:1192-1195]. Good food sources of calcium include milk and milk products such as cheese and yogurt, and dark green leafy vegetables.

Book Review

Title: Nutrition for the Working Woman (1986)

Author: Audrey Tittle Cross, J.D., M.P.H.

Publisher: Fireside Books, 1230 Avenue of the Americas, New York, NY 10020

Price: \$7.95 softcover

Reviewed by: Melanie R. Polk, M.M.Sc., R.D.

This book is geared toward the busy woman who encourages healthy eating for her family. It is chock full of helpful hints and sensible suggestions. Its style is quite original, viewing the kitchen as a corporation with the woman as corporate executive. This is interesting, although it may not work for many "working women" who may not relate their jobs to the "corporate environment." In fact, the information is hardly "high-level." Concepts are all fairly basic and a great deal of information is not geared specifically to the working woman at all.

The book tells how to cut costs and shopping time, keep calories in check and nutrient content high, plan menus, make meals more elegant and appetizing, use leftovers creatively, and organize and delegate kitchen tasks. Sections are included on meal patterns for vegetarians and restaurant eating. Most of the information is appropriate, although several examples of incorrect information or omissions are apparent. For example: tofutti is not fat-free, as the author suggests; excesses of water-soluble vitamins are not necessarily washed out of our bodies; the 1979 Dietary Guidelines are not updated; and new research on monounsaturated fats and fish oils is not mentioned when it could be. Overall, however, *Nutrition for the Working Woman* could serve as another sensible addition to your health library.

Mrs. Polk is an assistant professor at the University of Connecticut's School of Allied Health Professions and is a consulting nutritionist in private practice in West Hartford, Connecticut.

INFORMATION WANTED

If you find any newsworthy items, such as a published article or news report, or have a personal experience that might be of interest to our readers, please send it to Stephen Barrett, M.D., P.O. Box 1747, Allentown, PA 18105.

CASES SETTLED BY NEW YORK ATTORNEY GENERAL

New York Attorney General Robert Abrams, a vigorous opponent of quackery and health fraud, has entered into consent agreements settling seven complaints filed by his office during the past 2½ years:

- Lederle Laboratories, Pearl River, N.Y., has agreed to alter its advertising and packaging of Stresstabs to stop implying that Stresstabs can reduce the effect of psychological stress and ordinary physical stress. The company paid New York State \$25,000 and agreed not to make any of the following representations unless supportable by competent evidence:

- Emotional stress causes depletion of water-soluble vitamins.

- Ordinary physical activity or ordinary physical stress alone causes depletion of water-soluble vitamins by the amounts contained in Stresstabs.

- Consumers undergoing ordinary physical stress cannot obtain all necessary nutrients by eating a well balanced diet or taking an ordinary potency (100% of the U.S. RDA) multiple vitamin supplement.

- Biotin is a vitamin which is difficult to obtain in an average diet.

- People under severe or non-severe physical stress, without more biotin, are at risk for biotin deficiency.

- Stresstabs will reduce the effect of psychological stress.

- Donsbach University, of Huntington Beach, California, and its president, Kurt Donsbach, promised to disclose in any direct mailings to New York residents or in any nationally distributed publication that Donsbach University degree programs are not registered with the New York Department of Education and are not accredited by any accrediting commission recognized by the U.S. Department of Education. The University also agreed to pay \$500 to New York State.

- Gary Pace, of Garden City, N.Y., a "Ph.D." graduate of Donsbach University, agreed to a permanent injunction against engaging in the unlawful practice of medicine or using "Ph.D." or "Dr." in dealings with the public unless he obtains a degree from an institution recognized by New York State. Pace had been charged in 1984 with illegally diagnosing, treating and prescribing remedies for hundreds of clients who paid him hundreds of dollars each for worthless tests and bogus advice (see NF 2:70-71). He agreed to pay \$2,000 to New York State and to make restitution to former clients who are dissatisfied. He also agreed not to do further "nutrition counseling" unless he either obtains proper creden-

tials or posts a \$150,000 bond.

- Doctors Data, a Chicago-based laboratory that performed hair analyses on Pace's clients, agreed to stop accepting human hair specimens from New York State unless it can obtain a permit from the New York State Department of Health. The company also agreed to pay \$25,000 in costs and penalties over a 4-year period. Pace used the test as a basis for prescribing vitamins, minerals and other supplements, which is not a valid practice.

- Herbal Tracers, Ltd., of Hewlett, N.Y., and its president, David Fishman, agreed to stop soliciting or accepting specimens for laboratory examinations without a laboratory permit. The defendants had been performing a test called Herbal Crystallization Analysis, in which human saliva was examined to determine what dietary supplements or herbs the donor supposedly needed. The defendants agreed to stop representing that the test is valid for use in diagnosis, prevention or treatment of disease. They also agreed to pay \$5,000 for court costs and civil penalties.

- The International Institute of Natural Health Sciences, Huntington Beach, California, and its president, Kurt Donsbach, agreed: 1) to restrict the sale of its Nutrient Deficiency Test to health care professionals legally authorized to practice within New York State; 2) to stop marketing in New York State all current versions of its nutrient deficiency questionnaire and associated computer analysis services; 3) to place conspicuous disclaimers on future versions of the questionnaire to indicate that the test should not be used for the diagnosis or treatment of any disease by either consumers or professionals; and 4) to pay \$1,000 in costs. The test, which lacks scientific validity, is used by questionable practitioners as a basis for prescribing vitamin and mineral supplements.

- The Vitamin Shoppe, Inc., agreed to stop selling Orachel or other "oral chelation" product in New York State labeled with claims or suggestions that it is effective in preventing or treating clogging of the arteries. The company also agreed to pay \$500 in costs. Orachel was a Donsbach formulation of vitamins, minerals, amino acids and other substances marketed by HRG Distributors of Huntington Beach, California. But Donsbach sold HRG several months before the New York Attorney General filed suit and initiated a product seizure (see NF 2:8). The Vitamin Shoppe operates retail stores in New York City and sells by mail at discount prices.

THE RISE AND FALL OF UNITED SCIENCES OF AMERICA

Stephen Barrett, M.D.

United Sciences of America (USA) is a multilevel company based in Dallas, Texas. When it began marketing, its founder predicted gross sales of \$150 million for 1986 and \$1 billion by 1989—which would have made it the fastest growing company in U.S. history. By August 1986, USA claimed over 100,000 distributors and gross sales in line with these predictions. But today the company is bankrupt and under the guns of several government agencies.

USA is similar in concept to Shaklee, Amway, and Herbalife. Its products are food supplements said to represent "state-of-the-art nutrition." Anyone could become a distributor by completing an application and paying \$24.50 for a Success System Kit and Manual. No knowledge of nutrition or medical care was required. Distributors were urged to use and sell the products and to persuade others to become distributors who, in turn, would do the same. When sales volume was sufficient, distributors would get a percentage of the sales in their "downline." The company also set up a research foundation to generate research through grants and office-based studies.

Company management

USA was founded by Robert M. Adler II, a Dallas businessman who became wealthy by developing a computer that dials phone numbers and engages in interactive messages. USA's corporate brochure listed nine co-founders, including:

- Jerris Leonard, a former U.S. Assistant Attorney General, was USA's president.
- Jeffrey A. Fisher, M.D., a pathologist with a master's degree in immunology, was USA's medical director and senior vice president and was president of the USA Research Foundation. USA publications described him as a marathon runner and "a nationally recognized expert on preventive medicine." He hosts "The Life Extension Program," a talk show on radio station WOR, New York City.

- Lawrence J. Muno, USA's vice president for sports communications, is counselor and agent for many prominent athletes and has been president of the Association of Representatives of Professional Athletes.

- Mark Albion, Ph.D., an assistant professor of marketing at Harvard Business School, was an executive consultant to Mr. Adler.

- Haydon Cameron, USA's vice president for marketing, is a former newspaper reporter who was a top sales leader for Cambridge International, marketers of the Cambridge Diet.

- Robert A. Good, M.D., Ph.D., was chairman of USA's Scientific Advisory Board. Former president of Sloan-Kettering Institute for Cancer Research, he is now chairman of the Department of Pediatrics and Professor of Microbiology and Immunology at the University of South Florida College of Medicine.

Scientific Advisory Board

USA's corporate brochure listed 14 scientific advisors in addition to Dr. Good:

- Julius Axelrod, Ph.D., Chief, Section on Pharmacology, Laboratory of Clinical Sciences, National Institute of Mental Health, and winner of the Nobel Prize in Medicine and Physiology in 1970

- Eugene Braunwald, M.D., Professor of Medicine, Harvard Medical School, and Physician-in-Chief, Brigham and Beth Israel Hospitals

- Peter Cerutti, M.D., Ph.D., Director of Carcinogenesis Research, Swiss Institute for Experimental Cancer Research

- Michael DeBakey, M.D., Chairman, Department of Surgery, Baylor College of Medicine

- Philip J. DiSaia, M.D., Professor and Chairman, Department of Obstetrics and Gynecology, University of California, Irvine Medical Center

- Maureen Henderson, M.D., Professor of Epidemiology and Medicine, University of Washington School of Medicine

- Rashida Karmali, Ph.D., Associate Professor of Nutrition, Rutgers University, and Associate Professor, Sloan-Kettering Institute for Cancer Research

- Alexander Leaf, M.D., Chairman, Department of Preventive Medicine and Clinical Epidemiology, Harvard Medical School

- Robert J. Morin, M.D., Professor of Pathology, Harbor-UCLA Medical Center

- Lester Packer, Ph.D., Professor of Physiology and Anatomy, University of California, Berkeley

- William A. Pryor, Ph.D., Professor of Chemistry and Biochemistry, Louisiana State University

- Andrew V. Schally, Ph.D., Chief, Department of Experimental Medicine, Tulane University, and winner of the Nobel Prize in Medicine and Physiology in 1977

- Eli Seifter, Ph.D., Professor of Biochemistry and Surgery, Albert Einstein College of Medicine

- C. Norman Shealy, M.D., Ph.D., Director, Shealy Pain and Health Rehabilitation Institute, and founder and past-president of the American Holistic Medical Association.

Most members of USA's Scientific Advisory Board were attracted by what they perceived as an opportunity to advance the cause of preventive medicine and the promise that more than \$1 million a year in research funds would be made available to the scientific community. However, several members became upset that USA was using their presence on the board for marketing purposes. Between June and December 1986, Drs. Axelrod, Braunwald, Good, Henderson, Karmali, Leaf and Schally resigned. Some were upset about USA's marketing practices, while others were concerned about unfavorable publicity the company was receiving.

According to Dr. Fisher, some of them and most of the remaining board members believed that supplements of the type promoted by USA could have valuable preventive health benefits—and most of them used one or more of the company's products.

Most board members received annual stipends of \$10,000 to \$20,000 in return for attending one meeting a year and furnishing advice when requested. In line with USA's announced intention to generate nutrition-related scientific research, the USA Research Foundation awarded \$100,000 grants for studies involving antioxidants or fish oils. The first 12 grants went to Drs. Leaf, Pryor, Cerutti, Good, Packer, DeBakey, Axelrod, and five other scientists who were not members of USA's Scientific Advisory Board.

USA's products

The company's press packet stated: "At the heart of United Sciences of America, Inc.'s broad-based nutrition program lies its products, four state-of-the-art nutritional formulations that are based on over 50,000 published research and clinical studies interpreted by

some of the world's foremost research scientists . . . to come up with the right amounts of nutrients to promote optimal health without any risk whatsoever of toxicity."

The four products were: 1) the Master Formula consisting of vitamins, minerals, and antioxidants; 2) Formula Plus, a marine lipid concentrate rich in omega-3 fatty acids; 3) Fiber Energy Bar, containing nine grams of fiber; and 4) Calorie Control Formula, a high-fiber protein powder mix for use as a meal substitute. Their ingredients are listed on the following page. A kit containing a month's supply of the four products cost distributors \$100 and "retailed" for \$135.

Early this year, the American Council on Science and Health asked forty-eight of its advisors to examine USA's formulas and to complete a detailed questionnaire about one of them. (Twelve advisors were assigned to each product.) A total of 28 questionnaires were completed: Master Formula (10); Formula Plus (7); Calorie Control Formula (8); and Fiber Energy Bar (3). All twenty-eight respondents stated that USA's marketing materials contained claims for product ingredients that were false, unproven and/or premature. In most cases, the advisors felt that the product formulations were irrational and that it had not been established that long-term use is safe.

Those who reviewed the Master Formula disagreed with the claim that it provides the body with the right nutrients in the right amounts or increases immunity in people whose diets contain the Recommended Dietary Allowances of essential nutrients. Those who reviewed Formula Plus felt that fish oils may turn out to have value in preventing or treating various conditions, but no data exist to recommend supplements for "everyone over 30" as USA recommends. Some who reviewed the Calorie Control Formula felt that "meal substitutes" are useful in weight control programs, while others felt they are not. Two advisors who commented on the fiber energy bar did not believe that daily long-term use would be beneficial, while the other said that insufficient data are available to evaluate the product.

Marketing claims

According to an article in the February 1986 Inc. Magazine, Adler was aware that multilevel marketing had pitfalls and supposedly took steps to avoid them. He enlisted a scientific advisory board to help design USA's products, Mark Albion to design its sales program, and Jerris Leonard to provide legal guidance. And "to eliminate hyperbole on the part of overeager salespeople," USA produced videotapes for presentations to prospective customers.

From a marketing standpoint, the videotapes were awesome. The *Company Introduction Videotape* was narrated by William Shatner (Captain Kirk of *Star Trek*) and included scenes of a space rocket launching, a

USA, INC. PRODUCT INGREDIENTS

Master Formula, Formula Plus, Fiber Energy Bars and Calorie Control Formula contain the highest quality ingredients available today. These ingredients meet the exacting standards established by USA, Inc. in conjunction with the USA, Inc. Scientific Advisory Board.

MASTER FORMULA

Recommended adult use: Take three tablets, three times daily prior to or with meals.

Vitamins	9 Tablets Supply:	% U.S. RDA
Vitamin A (Acetate)	5,000 IU	100
Beta Carotene	25,000 IU	500 ^a
Thiamine (Thiamine-HCl)	50 mg	3333
Riboflavin	20 mg	1176
Niacin	25 mg	125
Niacinamide	100 mg	500
Pantothenic Acid (d-Calcium Pantothenate)	50 mg	500
Vitamin B-6 (Pyridoxine-HCl)	20 mg	1000
Vitamin B-12 (Cobalamin Concentrate)	30 mcg	500
Vitamin C (Ascorbic Acid)	1500 mg	2500
Ascorbyl Palmitate (Lipid Soluble Vitamin C—42 mg as Vit. C)	100 mg	70
Vitamin D-3	200 IU	50
Folic Acid	400 mcg	100
Biotin	150 mcg	50
Vitamin E Complex		
Vitamin E (d-Alpha-Tocopherol Acetate)	400 IU	1333
Mixed Tocopherols (Beta, Gamma, Delta Tocopherols)	100 mg	333 ^b
Amino Acid Anti-Oxidant Complex		
L-Cysteine (L-Cysteine-HCl)	200 mg	**
L-Methionine	50 mg	*
L-Glutathione	15 mg	**
Selenium		
Seleno-Methionine	100 mcg	*
Lipogenic Complex		
Choline (Choline Bitartrate)	250 mg	**
Inositol	250 mg	**
L-Taurine	150 mg	**
Minerals and Chelates		
Calcium (Calcium Carbonate)	1000 mg	100
Magnesium (Magnesium Oxide)	500 mg	125
Potassium (Potassium Chloride)	99 mg	5
Zinc (Zinc Gluconate)	30 mg	200
Copper (Copper Gluconate)	2 mg	100
Manganese (Manganese Gluconate)	2.5 mg	*
Iodine (Potassium Iodide)	50 mcg	33
Molybdenum (Sodium Molybdate)	125 mcg	*
Chromium (Natural Trivalent Chromium)	250 mcg	*
Additional Nutrients		
Bioflavonoids (Hesperidin Complex)	250 mg	**
PABA (Para Amino Benzoic Acid)	25 mg	**
Allium sativum (Pure Gar Co.)	250 mg	**

^a 15mg of beta carotene supplies 25,000 IU of precursor vitamin A activity.

^b Activities of mixed tocopherols vary—level of activity based on 100mg of dl-alpha-tocopherol equivalents.

* Determined to be an essential nutrient but actual requirements have not been established.

** No nutritional requirement established.

*Source: USA product flyer

FORMULA PLUS

Recommended use: Take 3 to 6 capsules once per day with a meal.

Three 1 gram capsules daily supply:

EPA (eicosapentaenoic acid)	540 mg
DHA (docosahexaenoic acid)	360 mg
Allium sativum extract	150 mg*
d-alpha-tocopherol	21 mg**
Ascorbyl palmitate	6 mg

* Contains a certified allicin content of 1 mg determined by measuring levels of enzymatically liberated pyruvic acid.

** Vitamin E activity of 27 IU—equivalent to 88% US RDA. Gelatin capsules colored naturally with carob, and contain no artificial flavors or preservatives.

FIBER ENERGY BAR

Ingredients: UltraProtein Blend (high protein cottonseed flour, calcium/sodium caseinate, Lactose Free whey protein concentrate, surimi, garbanzo bean flour), fructose, Fiber Blend (oat bran, guar gum, cellulose, barley bran, rice bran, pectin, apple fiber, yucca fiber, carrot powder, beet root powder), maltodextrin, lecithin, natural and artificial flavors, carrageenan, tricalcium phosphate, magnesium oxide, potassium chloride, calcium ascorbate, ferrous fumarate, zinc oxide.

This product has no derivatives of soy, yeast or wheat. Sweetened only with fructose. Contains no sucrose, artificial sweeteners, artificial colors or preservatives.

giant computer bank, scientific laboratories, prominent medical institutions, and medical journals. Shatner alleged that "our food, water and air are becoming contaminated" by chemicals ("toxic killers"), that cancer is on the rise, that our soil is being depleted of "vital, life-giving nutrients and important earth minerals," that one out of every three families will be stricken with some form of cancer, and that two out of five people will die of heart disease or stroke. Then he described how Robert Adler had developed a "brain trust of medical and scientific experts who have pioneered one of the most dramatic programs in the history of nutritional science . . . Their mission is clear: to develop a complete nutritional program to protect us from the growing dangers that are threatening the health of our nation." Shatner also suggested that investing in USA's program would result in "looking your best, feeling maximum physical energy and mental well-being, enjoying total health."

The *Business Opportunity Videotape* was combined with the *Company Introduction* into a 26-minute videotape. William Shatner explained multilevel marketing and stated that "the potential profits are staggering because the growth is geometric." Mark Albion suggested that anyone using USA's marketing package properly would be successful, and "with a medical and scientific credibility, United Sciences, Inc., is destined to become the IBM of nutrition." And five prominent athletes—Joe Montana, Gary Carter, Chris Evert Lloyd, Bill Rodgers and Steve Garvey—invited viewers to "join USA's winning team."

The *Medical Library Videotape* was a 90-minute tape in which Dr. Fisher answered about 100 questions about USA's products and the relationship of nutrients to disease. According to the tape's narrator, "Nutritional science is expanding so rapidly that only a company with USA's state-of-the-art computer technology and USA's advisory boards, comprised of world-leading medical doctors and Ph.D. researchers can properly inform the public."

Before the tapes were produced, USA released a 20-page *Company Overview* that described its purposes, scientific advisory board, research base, products, research goals, and marketing strategy. The company was described as "a major new entity with a revolutionary health concept." Its corporate mission was "to provide all Americans with the potential of optimum health and vital energy through state-of-the-art nutrition." The company was said to have established "the world's largest computerized data base in clinical nutrition" in the following manner:

"USA's team of Ph.D. researchers searched and reviewed the collective data of more than 5 million references in 14,200 medical and scientific journals covering 150 countries . . . From this powerful body of clinical

evidence came USA's own in-house index of 30,000 scientific studies covering 250,000 pages of documented research which was condensed to 10,000 pages of categories and studies . . . Never before has a nutritional information base so complex been assembled by a single company."

The *Company Overview* stated that media interviews with scientists and superstar athletes, combined with articles in major publications "are expected to elevate USA Inc.'s extraordinary concept into a new national movement." USA's Profit Plan was "designed to encourage all product-users to go into business for themselves—with a minimal financial investment and without risk." It also offered "a vital new life—and financial freedom for all who become involved."

USA also produced a 2-page flyer describing the company's products and listing its scientific advisory board. According to the flyer, Harvard's Dr. Leaf called USA's products "the most complete nutritional program I have ever analyzed." Similar statements were attributed to him in USA's corporate brochure, sales manual and introductory videotape.

Armed with all of this information, distributors who joined early placed classified ads in *USA Today*, *The New York Times*, *American Health* magazine, and many other publications. A typical ad read: "Achieve optimal health and financial freedom selling nutritional and weight control products endorsed by Nobel Prize winning physicians and world class athletes." People who responded would be asked to invest up to \$25 for an information packet that included the introductory videotape.

During the past year, I spoke with about 20 active USA distributors. All believed strongly that USA's products had been designed and endorsed by the company's Scientific Advisory Board and that the products were effective against a wide range of health problems mentioned in USA's Medical Library tape. Most claimed that the products had made them more energetic, and one was absolutely certain that the Master Formula "removes the toxic pollution stored in your fat cells" and that Formula Plus "cleans the cholesterol from your veins."

Media backlash

USA's marketing program aroused the ire of Fredrick J. Stare, M.D., Ph.D., Emeritus Professor of Nutrition at Harvard University School of Public Health, and John H. Renner, M.D., president of the Kansas City Committee on Health and Nutrition Fraud and Abuse. In the September 1986 *Good Housekeeping*, Dr. Stare accused USA of "peddling unnecessary supplements and calling it a breakthrough," and in the October 9, 1986, *New England Journal of Medicine*, he charged that "USA seems to want to outdo others in person-to-person peddling of unnecessary or unproved diet supplements." In the same journal, Dr. Renner wrote: "I doubt that United Sciences' products are 'a highly effective pro-

USA's corporate brochure shows its vice president of science and data information standing in a room full of giant computers. The brochure doesn't reveal that the computers belong not to USA but to Dialogue Information Service, Palo Alto, California.

gram for optimal health.' As far as I know, they were not tested before marketing. Moreover, an optimal health program should involve more than high-priced food supplements, protein powder, and candy bars."

These criticisms stimulated many other publications to examine what was going on. Invariably, they concluded that USA was making false or misleading claims for its products. This criticism, plus the resignation of several USA advisors, forced the company to announce that it would stop distributing virtually all of its promotional materials.

On October 28, 1986, NBC-TV's 1986 broadcasted a devastating exposé in which Dr. Leaf denied endorsing USA's products. Dr. George Bray, a prominent nutritionist, said he had suffered a near-fatal anaphylactic reaction to the Fiber Energy Bar. A Texas dietitian reported that USA products had made her quite ill. And the program's narrator, Connie Chung, said that USA was being investigated by the Texas Attorney General and the U.S. Food and Drug Administration. Actually, the Texas Attorney General's Office had merely decided to investigate but had not begun to do so. But the TV program produced an avalanche of inquiries that stimulated a full-scale investigation. The program also curtailed USA's sales. Within a month, the company was headed for bankruptcy.

Legal difficulties

On December 12, 1986, the U.S. Food and Drug Administration (FDA) sent USA a strongly worded regulatory letter ordering it to stop suggesting that any of its products are effective in the cure, mitigation, treatment or prevention of disease. The agency said that claims of this type in its videotapes make the products "new drugs" that are illegal to sell in interstate commerce because they lack FDA approval. In addition, all of the product labels were defective in other ways.

On January 21, 1987, USA petitioned in federal court for Chapter 11 bankruptcy, listing total assets of \$7,300,000 and liabilities of \$8,600,000. (The purpose of this type of bankruptcy is to stave off creditors to give the company time to restructure its indebtedness with the hope of remaining in business.) The petition named Robert Adler as sole shareholder and director of USA, Inc., and Jerris Leonard's law firm as its eighth largest unsecured creditor, with \$121,379.69 owed. No official sales figures have been released, but press reports suggested that USA's 1986 gross income totaled \$60 million.

On January 28, the Attorneys General of Texas, New York and California filed suit in their respective states, charging that USA, Inc., had made improper claims for their products and that their sales plan constituted an illegal pyramid scheme. In addition, the Texas suit charged that USA had not properly registered as a manufacturer, and the New York suit demanded

that Chris Evert Lloyd, Joe Montana, Steve Garvey, Gary Carter and Bill Rodgers appear in court to explain their financial relationship with the company. The New York Attorney General's office indicated that many USA distributors were not paid commissions owed them by the company. The California suit, filed by Supervising Deputy Attorney General Albert N. Sheldon, who had successfully prosecuted Herbalife [NF 4:1], demanded civil penalties of at least \$1,000,000 plus the cost of prosecution.

On February 5, the District Court of Dallas County, Texas, issued a temporary injunction based on an agreement between USA and the Texas Attorney General. Its terms barred the company from:

- Marketing any current products without sending a "correction letter" acceptable to the Attorney General to all distributors
- Shipping any products unless accompanied by an acceptable disclosure stating that they are not for the prevention or treatment of disease
- Representing that USA's products have any effect in: infectious and parasitic disease; tumors; endocrine, nutritional and metabolic diseases and immunity disorders (including AIDS); diseases of the blood; mental disorders; diseases of the nervous, circulatory, respiratory, digestive, genitourinary or musculoskeletal systems; complications of pregnancy or childbirth; birth defects; injury or poisoning; or ill-defined conditions
- Manufacturing any food products without being registered as a manufacturer by the Texas Commissioner of Health
- Selling products through a multilevel distributorship

During this period, the company was sold to T.J. Talley, D.D.S., a retired dentist with a special interest in nutrition, and Peter J. Speckman, Jr., an attorney with a background in marketing and sales. On March 5, Speckman notified the FDA that he was sending letters informing USA's active distributors that: 1) he and Dr. Talley had completed purchase of the company; 2) the FDA had issued a regulatory letter; 3) three state attorneys general had filed suit against USA; 4) the company had agreed to an injunction; 5) products would soon be available for sale; 6) the company plans to develop new sales materials and a new marketing plan that do not

violate state laws; and 7) all existing videotapes should either be destroyed or returned to the company for partial credit. Speckman told the FDA he would enclose a copy of the injunction and would warn distributors not to make any claims that USA's products are effective against any disease. He also said that henceforth, all USA products would bear the following disclosure:

IMPORTANT NOTICE

The products you have purchased are a nutritional supplement. They are not intended for the prevention, treatment or cure of any disease, illness or other condition. Please disregard any claims you have been told to the contrary. Thank you for using USA products.

USA is now completely under new management. On March 24, David Lough, its current vice president for marketing, told me that Jerris Leonard had resigned in November (a fact not revealed to most USA employees) and that Dr. Fisher and the rest of USA's original management team had left when the company went bankrupt. It seems likely that adverse publicity and/or lack of payment have driven away the rest of USA's scientific advisors and endorsing athletes. But Mr. Lough said he had no information on this because the company has not had recent contact with them. He estimated that Mr. Speckman's letter of March 5th went to about 5,000 of USA's most active distributors. But in February, USA's top distributor invited his downline to join Ameriplus, another multilevel company with products similar to those of USA.

Overview

Though some of its stated goals were laudable, United Sciences of America promoted its products with enormous exaggeration. Its Scientific Advisory Board, though prestigious, had no monopoly on the ability to analyze scientific data. USA's products were formulated by pooling the opinions of Dr. Fisher and the members of his advisory board who believe that virtually everyone should take dietary supplements. Skeptics were involved minimally if at all.

Within the past two years, the National Academy of Sciences has endured raging controversy over

EDITOR: Stephen Barrett, M.D. **SENIOR ASSOCIATE EDITOR:** Manfred Kroger, Ph.D. **ASSOCIATE EDITORS:** Denise Ferko-Adams, R.D., Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Odom Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

whether it is actually possible to determine "optimal" levels of nutrients at this time [NF 3:1-2]. Even if USA's formulations turn out to be optimal—which is very doubtful—it was extremely presumptuous to represent them as "state-of-the-art nutrition." They were merely a guess by a small group of scientists who espouse minority viewpoints on supplementation.

USA's imagery and puffery certainly didn't reveal this. USA boasted of "analyzing 1,300 new research papers a month" to be sure its product formulations were up-to-date. That statistic might persuade laypersons that emergent scientific data are too voluminous for ordinary mortals (like their personal physician) to keep up with. However, it is doubtful that so many papers are relevant to USA's products. Even if they are, the number of papers entered in one's computer bank is not as important as the data they contain and the logic used to analyze them.

Nor was USA's method of gathering information anything special. Many medical facilities, researchers and practicing physicians have ready access to computerized data bases. And many scientists not only follow the scientific literature but know about important studies before they are published. Significant informa-

tion is spread rapidly throughout the medical community through journals, lectures, informal discussions among doctors, cable television programs, and other channels of communication.

Exaggeration was also involved in recruiting distributors. Although those who sign up during the first few months of a successful multilevel company can make a great deal of money, the later the entry, the less the chance of success.

Although USA stopped distributing all of its questionable promotional materials, the claims they generated may circulate indefinitely by word of mouth.

The fact that USA pledged to support research was laudable, but its approach was backwards. Before asking the American public to spend millions (or billions) of dollars on USA products, they should have been tested for both effectiveness and long-range safety.

It seems unlikely that USA, Inc., can recover from its legal and financial difficulties and remain in business.

BRIEFS

Attack on irradiation continues. According to a report in *Health Foods Business*, the Food Irradiation Safety and Labeling Requirement Act (HR 956) now has 49 cosponsors. This bill would block FDA regulations permitting irradiation of all fresh fruits, vegetables, pork and other foods. Meanwhile, the New Jersey Senate approved a bill (S-2571) to ban the sale of irradiated food. Although radiation is safe, it is being opposed by the health food industry and several small but vocal groups [NF 3:79]. Perceiving this fuss, food companies are worried about consumer acceptance and are hesitant to expand utilization of the process.

Dairy research centers. Six dairy research centers will be funded jointly by the National Dairy Promotion and Research Board (NDB), local industry and dairy groups, and 12 universities the centers will represent. NDB will contribute \$2.7 million per year for five years to the project and will award a similar total to individual scientists and research groups. NDB was established by Congress to strengthen the dairy industry's position in domestic and foreign markets. It began operations in 1983 and is financed by a mandatory assessment of 15¢ per 100 pounds of milk produced and marketed in the continental United States. Its address is 2111 Wilson Boulevard, Suite 600, Arlington, VA 22201.

Research contract. Panlabs, Inc., of Seattle, Washington, and Eastman Pharmaceuticals, a division of Eastman Kodak Company, have entered a multimillion dollar agreement under which Panlabs will screen fermentation broths for new types of pharmacologically active molecules produced by naturally occurring microorganisms.

Supplement use rising? According to a study by Business Communications Company, retail sales of vitamins, minerals and associated products through all outlets totalled \$2.9 billion in 1986. During the year, calcium sales rose from \$18 million to a projected \$240 million, and beta carotene showed signs that it would also rise sharply. Meanwhile, *Health Foods Business's* 1986 annual survey estimated that health food store sales totalled \$2 billion (up 22.5% from 1985), including \$763 million for vitamins and supplements (+ 14%), \$76 million for bulk herbs (- 47%), \$41 million for herb teas (- 12%), \$29 million for macrobiotic foods (+ 72%), \$135 million for grains and cereals (+ 135%), and \$67 million for books (+ 102%).

QUINOA SALES RISING

Stephen M. Voynick

Among the so-called "super" grains, quinoa (pronounced keen'-wah) appears the most likely to move from health food stores to supermarkets. Quinoa's growing popularity is due to taste, kitchen versatility and—most important—high nutritional value. Duane Johnson, Ph.D., a Colorado State University agronomist developing quinoa strains for domestic cultivation, is one of quinoa's nutritional proponents. While emphasizing that no single food can provide all human nutritional requirements, Johnson said in *Newsweek*, "If you had a choice of one food to survive on, this one would be the best."

Quinoa (*Chenopodium quinoa*) is a five-foot-tall herb plant which, at maturity, bears heavy clusters of millet-sized seeds. Botanically, the seed is classified as a fruit; but its physical characteristics, nutritional profile, method of cultivation, and end uses, are nearer to those of the grain family. Quinoa is native to the high Andes of South America, where it has been cultivated since antiquity. Together with maize and potatoes, it was a staple in the highly developed Incan agricultural system. The "mother grain," as quinoa is known, was considered sacred; at planting time, the Incas opened the first quinoa furrow with a ceremonial golden implement. After the Spanish conquest, production of quinoa declined dramatically. Today, it has little popularity among South American urban consumers. However, it remains a dietary staple of rural Andean peasants who grind it into a flour for use in porridge and tortillas.

Quinoa had been introduced to American consumers twice without success, first in the 1880s for its spinach-like leaves, then in 1918 as a breakfast cereal. Later, in 1983 a trio of friends founded Quinoa Corporation in Boulder, Colorado, to import and distribute the grain through health and natural food stores. Initially, they seemed headed for failure; consumers were either unfamiliar with quinoa or put off by its \$3/pound retail price. First year sales were only 1,000 pounds. In 1984, one of the partners was killed by a stray bullet while organizing a quinoa farm supply system in Bolivia. But driven by a sincere belief in their product, the others persisted.

In 1984, sales rose to 12,000 pounds. When sales quadrupled the next year, investment analysts began paying attention to "that offbeat Boulder health food company." In 1986, the company was acquired by a major holding corporation which provided capital for expansion, and sales topped a quarter-million pounds. Today, quinoa is available in all 50 states, and growing consumer interest in its nutritional qualities may drive 1987 sales over one million pounds.

Like most grains, quinoa contains about 100 calo-

ries per ounce. It is a fairly good source of calcium, phosphorus, iron, fiber, vitamin E and several B vitamins. Quinoa is considerably higher in protein and oil and lower in carbohydrate content than other grains. Protein content among quinoa varieties ranges from 10-20% of total seed weight, generally higher than high-protein wheats and several times higher than corn and rice. Oil, primarily unsaturated, amounts to 5½-7% of total seed weight, higher than in oats and 2-6 times higher than in other grains. Carbohydrate content, however, is 10-15% lower than found in most grains. Quinoa protein is of particular interest because it contains an unusual balance of essential amino acids, including high levels of lysine and methionine, putting its overall protein quality on a par with that of milk.

Quinoa's taste, sometimes compared to that of corn or squash, may be described as mellow and grainlike, yet distinctive. The dried quinoa seed keeps indefinitely and cooks like rice, but in half the time. Basic preparation requires simmering in a double volume of water, after which the quinoa expands, becomes nearly transparent and takes on a texture similar to tapioca. The basic preparation may be consumed as breakfast porridge, made into soups or puddings, or served as a side dish with meat or fish. The amino acid balance makes it an excellent main dish substitute for vegetarian platters. Quinoa may also be used in poultry dressings, casseroles and such dishes as stuffed peppers.

Quinoa flour is used to bake light and highly nutritious cookies, cakes and pastries. While its low gluten content makes it unsuitable for yeast-type breads, quinoa and quinoa flour are a dietary alternative for those on gluten-restricted diets.

In 1982, seedstock from six of the hundreds of existing quinoa varieties was selected for experimental U.S. planting in the Rocky Mountains, where the cool, dry climate is similar to that of the Andes. Progress in strain development for domestic cultivation is already apparent. In 1986, Colorado alone produced 50,000 pounds of quinoa for seedstock and domestic consumption. Quinoa is hardy, frost and drought-resistant, tolerant of poor soils, and requires relatively little care. Considering the high retail price, continued acceptance among U.S. consumers could make it a lucrative small farm cash crop, both here and in South America.

Recipes and additional information can be obtained from the Quinoa Corporation, P.O. Box 7114, Boulder, CO 80306.

“NUTRITION INSURANCE”—A SKEPTICAL VIEW

Alfred E. Harper, Ph.D.

Vitamin deficiency diseases have not been encountered in the major health and nutrition surveys done recently in the United States. In fact, such diseases now occur so rarely in this country as to be medical curiosities. Nevertheless, large numbers of apparently healthy people take vitamin supplements. The reasons they give for this are a concern that they are not getting enough vitamins from their diets and the belief that they will be less healthy without supplements. These views are encouraged by nutrition supplement advertisers and others who suggest that dietary inadequacy is common and that many Americans have special nutrient needs for which supplementation is advisable.

Interpretation of surveys

One of the main points used to support recommendations for “insurance” with vitamin supplements is that health and nutrition surveys have found that intakes of some vitamins by some segments of the population are below the Recommended Dietary Allowances (RDA). [The abbreviation RDA is used for both the singular and plural of the term.] It is true that surveys have made such observations. But proper interpretation of these results requires understanding how the RDA are established and how dietary surveys are done.

The RDA are dietary standards: the levels of intake that the Committee on Dietary Allowances of the Food and Nutrition Board of the National Research Council/National Academy of Sciences considers “adequate to meet the nutritional needs of practically all healthy persons.” But they were designed to provide food service personnel who prepare food for large groups of people with a set of values for desirable intakes of key essential nutrients and appropriate intakes of calories. The quantities of these essential nutrients in the food offered each day could then be compared with the RDA to determine whether the key nutrients were being provided in large enough amounts to prevent any nutritional inadequacy.

Because people differ in size and genetic makeup, their nutrient requirements differ; requirements of individuals for essential nutrients range from about 50% below to 50% above the population average. The RDA are therefore set high enough to ensure that, if the quantities of nutrients in the food being served meet this standard, they will meet the needs of individuals with the highest requirements. Thus the amounts of nutrients most people require will be below the RDA, and about half the population should require less than 75% of the RDA. It would require an elaborate probability analysis to determine how likely it is that people consuming less than the RDA have intakes that are not adequate. Using the RDA directly as standards for evaluating the adequacy of individual nutrient intakes is improper; it would be like setting the standard for height at seven feet and concluding that all those under seven feet have suffered growth retardation.

Even when the estimates of nutrient intakes obtained during dietary surveys are compared with the RDA, we find that only two vitamins—A and C—are identified consistently as “problem” nutrients. In interpreting these observations, we encounter two additional problems. The adult RDA for vitamin C is high enough to ensure that an adult who is consuming an amount of vitamin C equal to the RDA will have a store of the vitamin sufficient to prevent signs of deficiency even if no vitamin C is consumed for about two months. This standard, twice that of the World Health Organization, is much higher than necessary. Because of this, one would expect to find problems of “inadequate” intake where none exist—and that is exactly what happens.

With vitamin A, a different problem is encountered. The main sources of vitamin A in the diet are carotenoids, precursors of the vitamin found in dark green and yellow to orange vegetables. These foods are not usually eaten every day. So when the results of dietary surveys are based on measurements of nutrient in-

takes for a single day—as they frequently are—many people have “low” intakes of vitamin A while others have unnecessarily high intakes. Since vitamin A is stored efficiently in the liver, a surplus consumed on one day will provide a reserve that is available on subsequent days. Intakes of vitamin A can probably be estimated accurately only by averaging daily intakes over at least a week.

Thus, because of the nature of the RDA and of dietary surveys, it is not possible to assess nutritional status by comparing estimates of nutrient intakes with the RDA. The only way that vitamin status can be determined reliably is from clinical observations and measurements of blood or tissue concentrations of vitamins or cofactors or the rates of metabolic reactions for which the vitamins are needed. When this has been done, a very small proportion of the population surveyed has been found to have values that are low, but still not low enough to be considered deficient. With such a high proportion of the population showing no evidence of inadequate vitamin intakes, the low values cannot be due to inadequacies of the food supply.

Estimates of the nutrient content of our food supply by the U.S. Department of Agriculture indicate that the amounts of most nutrients available to the consumer have increased during this century. Consumption of fruits, vegetables, cheese, skim milk, fish, poultry and pork—all excellent sources of essential nutrients—have increased during the past ten years more than enough to compensate for declines in the consumption of beef, whole milk, and eggs. Of low-income families studied by the Agriculture Department, 42% were consuming a diet that met the RDA for eleven nutrients. This is incontrovertible evidence that the food supply contains adequate amounts of essential nutrients. Families that were dependent on food stamp allotments were consuming less adequate diets, indicating that as income falls, food choices become more limited and intakes of some essential nutrients decrease. Inadequate intakes of food, and hence usually of nutrients also occur because of neglect, illness, alcoholism and ignorance. Dietary supplements are not an appropriate solution to these problems.

Eating patterns

Another reason given for the use of vitamin supplements is deteriorating or haphazard eating habits. America's eating habits have changed, but whether this represents deterioration is certainly debatable. A pattern of eating three or more substantial meals a day is common in agricultural communities and others in which human energy expenditure is high. This was accepted as the most desirable pattern when our population was largely rural and when mechanization was much less in both the home and the workplace than it is today. One might well ask whether, in a society in

which energy expenditure is low, it may not be preferable to eat several small meals throughout the day and to eat when hungry rather than when the clock says it is mealtime. There is much speculation but little evidence that “irregular” eating patterns result in consumption of inadequate amounts of essential nutrients except when total food intake is low.

Even the claim that many people, especially women, have low caloric intakes, and therefore low intakes of essential nutrients, deserves careful scrutiny. The basis for the RDA for energy (calories) is different from that for essential nutrients. The RDA for energy represent average requirements. Half of the population should thus require less than the RDA. Also, with as much as 20% of the population (especially women) on weight reduction regimens at any one time, the proportion found to have caloric intakes below the RDA in any dietary survey would be expected to exceed 50%. Despite this, underweight is a problem for very few people in this country; hence, the number of dieters who stay on low-calorie diets for very long cannot be high.

Furthermore, dietary surveys usually find that protein intakes meet or exceed the RDA. Since protein tends to make up a relatively constant proportion of calories in most diets, this suggests that caloric intake has been underestimated. Persons with caloric intakes above the RDA are reported to have intakes of most essential nutrients that are well above the RDA. Thus, underestimation of caloric intakes probably accounts for some of the low estimates of micronutrient intakes.

Since there is little evidence that will stand up to scrutiny to suggest that any substantial proportion of the U.S. population is consuming a nutritionally inadequate diet for any length of time, there is little reason to assume that vitamin supplements will benefit a substantial portion of the population. Foods contain important nutrients that are not provided in vitamin supplements; they also contain many constituents whose significance for health is unknown. Learning how to select foods properly to meet nutritional needs, regardless of changing eating patterns or changes in the food supply, is the only reliable way to ensure lifelong nutritional health. Encouraging the use of vitamin supplements as a corrective for poor eating habits defeats the entire purpose of nutrition education, i.e., to learn the nutritional prin-

ciples needed to select a healthful diet instead of accepting nutritional advice on faith.

"Protector Vitamins"

In recent years it has been suggested that above-RDA amounts of vitamins are needed to counteract the effects of various environmental stresses. However, since the human subjects used in experiments which provided the information on which RDA are based were not protected from usual environmental stresses or infections, it is doubtful that vitamin supplements are needed in these conditions. During illness, recovery from illness, and periods of drug therapy, food intake may be so low that it becomes difficult or even impossible to meet nutritional needs from foods. Nutritional supplements can be useful under such conditions, but as part of a comprehensive program of treatment under the guidance of a physician.

Various observations have led to suggestions that certain vitamins—particularly A, E and C—may have some unique value in preventing or reducing adverse effects from environmental hazards. (Hoffmann-La Roche has even designated these three as "Protector Vitamins" in an extensive advertising campaign.) Some of these observations are tantalizing, e.g., that these vitamins may act in some way to protect against certain cancer-inducing agents; and, that vitamins E and C, as antioxidants, may protect against ill effects from certain chemical contaminants. Some studies indicate that vitamin deficiencies can increase susceptibility to toxic agents, but it does not follow from this that extra vitamins provide extra protection. This concept is the subject of much current research, but unless direct evidence is found, it seems unwise to recommend supplementation on this basis.

"Special needs"

Advocates of vitamin supplements have suggested that many people belong to population groups that have special vitamin needs. Probably the most elaborate presentation of this concept is contained in "Personal Health Circumstances Benefited by Nutritional Supplementation," a six-page flyer published recently by the Council for Responsible Nutrition (CRN), a coalition of major food supplement manufacturers and distributors.

According to the flyer: "CRN believes that the analysis of personal nutrition need categories strongly suggests that large groups of people are at risk for a variety of reasons and that their nutritional status, overall quality of health, and consequent mortality and morbidity are affected. Thus it makes good sense to help guide those in these special need categories to take some action that will protect or improve their nutrition status. Nutrition is a dynamic, rapidly evolving science. CRN believes it is foolish for some old-fashioned health, medical and nutrition personnel to automatically exclude supplements as one worthwhile choice. Instead, it is rational for the millions of people in self-identifiable circumstances to investigate and choose from among all appropriate alternatives of proven benefit." In line with these thoughts, the flyer designates 18 "groups with proven nutrient needs" for which "scientific evidence available today suggests that a nutritional supplement as part of total intake will be beneficial."

CRN is correct that individuals in these groups have "proven nutrient needs." In fact, it is a truism that all subgroups of the population have proven nutrient needs. But these needs are taken into account by the scientists who determine the RDA! Here is my analysis of each of the groups listed in CRN's flyer:

- *People taking prescription drug(s): 125 million.*

Although certain drugs are known to increase the requirements for specific vitamins, it is improper to assume that drugs automatically increase nutrient requirements. Problems are most often associated with consumption of marginal diets—and with prolonged use of drugs that cause malabsorption or metabolic impairment. It is important to identify drug-nutrient interactions that can create clinical problems. Individuals taking such drugs need a recommendation from a physician for the appropriate extra amount of any specific nutrient that is needed. General supplementation is not a rational approach because only the nutrient(s) that will correct the problem will be of any value.

- *Dieters: 95.4 million.* Certainly dieters who are consuming less than 1,200 calories per day should consider whether the total amount of food they consume will provide adequate amounts of all of the essential nutrients they require. Many dieters do not consume such low amounts of calories and, if they do, they usually do so for only a short period of time. If caloric intakes are reduced below 1,000 calories a day for longer

EDITOR: Stephen Barrett, M.D. **SENIOR ASSOCIATE EDITOR:** Manfred Kroger, Ph.D. **ASSOCIATE EDITORS:** Denice Ferko-Adams, R.D., Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Odum Fanning (Washington correspondent); Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

than one week, it is probably wise to take a standard one-a-day vitamin-mineral supplement. However, such low-calorie dieting should be done under supervision of a physician with the appropriate supplement being provided as part of the overall diet plan.

- *Premenopausal women of childbearing age: 55 million.* Premenopausal women of childbearing age are part of the population of normal healthy individuals. The RDA for healthy adult women are based on their needs. Many of these women need education about appropriate food use, but if they are eating wisely they should not need supplements except during pregnancy when they may not eat enough total food to build up adequate iron stores. A standard iron supplement is commonly recommended during pregnancy, as are additional milk and milk products to ensure that the RDA for calcium will be met.

- *Smokers: 54 million.* There has been much emphasis on the fact that vitamin C levels in the blood of smokers are lower than those of nonsmokers. However, the suggestion that smokers need high doses of vitamin C seems incongruous when one considers that most of the subjects used in the major experiments that served as the basis for present RDA for vitamin C allowances were reported to be smokers. It would seem much more appropriate to suggest that nonsmokers need less than the RDA. Moreover, smoking is so devastating to health that even if vitamin C did offer slight protection against its ravages, it would be senseless to encourage smokers to believe that they can avoid the consequences of smoking through nutritional measures!

- *People with specific gastrointestinal disorders: 40 million.* Most gastrointestinal disorders last only a few days and require no special nutrient supplements. For chronic or prolonged gastrointestinal disorders, management by a physician is essential and emphasis should be placed on identifying the cause and curing the condition. Supplements may be desirable while nutrient loss is occurring but should be done under medical supervision. In malabsorptive diseases—where absorption of specific vitamins is impaired—specific supplementation is advisable until the condition can be brought under control.

- *Postmenopausal women: 39 million.* The major change in nutrient needs of healthy postmenopausal women is reduced energy requirement. From age 50 on, caloric needs decline steadily while the need for essential nutrients remains the same. The best way to obtain these nutrients while eating less is to select a large proportion of foods that are rich in essential nutrients. It is also wise for postmenopausal women to maintain and possibly increase their physical activity. This will also help prevent loss of calcium from their bones and will decrease their chances of becoming overweight.

- *The elderly: 28 million.* The active elderly who are healthy have no special needs beyond those covered

by the RDA. (Of course, the above comments about declining energy needs and the desirability of increased physical activity apply to the elderly generally.) The elderly who are ill, and a substantial proportion are, need medical advice and not a general recommendation for a nutrient supplement. The older elderly may have unusually low caloric requirements because of low activity as well as low metabolic rate. Here again, attention should be given to maintaining an adequate intake of foods that are highly nutritious. In some circumstances, food intake may be so low that a supplement becomes appropriate.

- *Women taking postmenopausal estrogen: 2.3 million.* Women taking postmenopausal estrogens should be no different from the normal healthy elderly. They should maintain calcium intake in the RDA range because the beneficial effect from estrogens on osteoporosis has been shown most clearly when calcium intake is in that range or somewhat higher.

- *People with osteoporosis: 20 million.* There is no evidence that individuals with osteoporosis have any general need for nutrient supplements. Even the evidence of benefits from high intakes of calcium is inconsistent and controversial. For normal bone maintenance, a calcium intake that meets the RDA is needed throughout adult life. This can be obtained from foods, especially dairy products, but dietary surveys show that many elderly women have low total food and calcium intakes. Increased physical activity will enable them to eat more without gaining weight, and tends to reduce bone mineral loss. It is unclear whether calcium supplements alone are helpful in treating osteoporosis. Combined calcium and estrogen therapy is reportedly beneficial, but of course should be done under medical guidance.

- *Poor people: 33.1 million.* The poor need a support system; they need food programs that provide them with adequate quantities of essential nutrients and energy sources. In other words, they need proper food. Supplements of essential nutrients cannot substitute for basic needs for energy sources and protein, and are expensive in relation to the income of this group of people.

- *People with chronic or infectious disease(s) or under chronic physical stress: unknown millions.* Chronic and infectious diseases generally cannot be assumed to increase nutrient needs. This is an irrational grouping in relation to nutritional requirements. Infectious diseases are individual problems and should be dealt with by appropriate medical care, not by general recommendations for increased intakes of nutrients. If a chronic or degenerative disease results in severely depressed food intake and weight loss, it may be appropriate to provide a supplement with the food during the period of debilitation.

- *Teenagers: 25.9 million.* Teenagers represent an active part of the total healthy population. Students up

to college age are usually physically active and often have caloric intakes that are quite high. They need mainly to learn how to achieve dietary balance by choosing nutritious foods and moderating intake of foods that contain small quantities of essential nutrients. They need nutrition advice, not supplements which tend to distract them from learning about sound food choices.

- *Alcoholics: 25 million.* Supplements are not a solution for alcoholism. Alcoholics need food instead of alcohol and guidance to learn how to control the problem of addiction. If food intake of an alcoholic is extremely low, severe vitamin deficiencies can develop. These need prompt clinical attention and a program of rehabilitation. Inappropriate vitamin supplements may delay the appearance of certain deficiency signs and result in medical treatment being put off until serious deterioration of vital organs has occurred.

- *Women taking estrogen for birth control: 8.8 million.* There have been reports of changes in the metabolism or blood levels of certain essential nutrients in women using birth control pills. However, claims that these provide evidence of nutritional inadequacy have not stood up to rigorous testing. Again the most important dietary advice for women using contraceptive estrogens is to maintain an adequate intake of all nutrients through appropriately balanced diets that meet the recommended allowances.

- *Strict vegetarians: 8.5 million.* I do not believe there are 8.5 million strict vegetarians in the United States. Moreover, vegetarians are often more knowledgeable about nutrition than the average person because they have organizations that offer valid nutrition advice. Most vegetarians consume eggs and dairy products and obtain adequate quantities of all nutrients including vitamin B₁₂, although some may not. For those who are strict vegetarians, a source of vitamin B₁₂ is required. It is also particularly important for vegetarians to select a wide variety of different types of fruits and vegetables and cereal grains because serious malnutrition has been found to occur in individuals who have restricted their intake to a narrow range of foods from plant sources. Supplements are not a substitute for sound diet planning.

- *Pregnant women: 3.6 million.* There are modest increases in needs for essential nutrients during pregnancy. Food consumption usually increases during gestation so the pregnant woman will be eating increased quantities of all nutrients. If food intake declines, a supplement providing about half the RDA for the vitamins most likely to be in short supply, together with iron, would not be inappropriate.

- *Lactating women: 2.16 million.* During lactation, energy needs of women increase substantially. Their increased food intake will normally compensate for the increased quantities of essential nutrients

needed for production of milk. For women who are reducing weight during lactation or who have low food intake, a standard vitamin-mineral supplement may be appropriate, but otherwise essential nutrient needs are readily met by diet.

- *Premature infants: 0.36 million.* Premature infants require medical care; their needs should be determined carefully by the physician to ensure that the essential nutrient supply is adequate. Essential nutrients are usually provided as part of the formula, not as a special supplement.

Appropriate supplementation

The most appropriate use of vitamin supplements is in conditions in which caloric intake is below 1,200 calories per day and particularly if, at the same time, requirements are increased, perhaps as the result of illness. A correctly balanced multivitamin supplement may also be appropriate for pregnant women. Supplements of vitamins A and D of appropriate potency can be justified for young infants as insurance against nutritional inadequacy. And supplementary fluoride is vital to help strengthen the teeth of children growing up in unfluoridated communities—a need that CRN does not address. I see no evidence in the scientific literature that Americans generally require vitamin supplements. Rather, they need accurate nutrition information about food and health to counter the nutrition misinformation to which we are constantly exposed.

Dr. Harper is Professor of Biochemistry and Nutritional Sciences at the University of Wisconsin. He has been chairman of the Food and Nutrition Board of the National Research Council/National Academy of Sciences from 1978 to 1982 and has served on other NRC/NAS committees involved in determining the RDA.

QUESTION BOX

Q. What is sea salt? Is it all right for a low-sodium diet?

A. Sea salt is salt derived from evaporated sea water. The only difference between it and ordinary table salt is dirt, since sea salt contains impurities from sea debris. Sea salt is promoted with the claim that table salt consists of extremely small crystals that dissolve and ionize poorly and which our bodies find hard to digest. This is untrue, since salt crystals, whether large or small, will dissolve when taken by mouth, and when dissolved must ionize. Since sea salt has the same sodium content as table salt, it is not appropriate for a low-sodium diet.

CRN: RESPONSIBLE OR IRRESPONSIBLE?

Stephen Barrett, M.D.

The Council for Responsible Nutrition (CRN), 2100 M St., N.W., Washington, DC 20037, is a trade association for manufacturers and wholesale distributors of vitamin and mineral supplements. Products manufactured by its members are sold in drugstores, supermarkets, convenience outlets, discount chains and health food stores, and are also sold through direct (person-to-person) sales.

CRN's principal purposes are: "1) to create increased public awareness of the safety and benefits of nutritional supplements by compiling and communicating authoritative information about their appropriate role in diet and health; 2) to enhance the credibility of the nutritional supplement industry, including responding to unwarranted, ill-informed criticisms; and 3) to enhance and expand CRN's institutional capabilities to serve the nutritional supplement industry internationally." Its bylaws state that "CRN is dedicated to enhancing the health of the U.S. population through responsible nutrition, including the appropriate use of nutritional supplementation."

CRN has three categories of members. Companies engaged in the manufacture, packaging or labeling of supplements are eligible for voting membership. Suppliers of services or other support to the supplement industry are eligible for associate membership, while foreign companies or affiliates of voting members can become international correspondents. Dues for voting members are based on annual sales and range from \$2,500 for companies with sales up to \$5 million to a maximum of \$25,000 for those with sales of \$50 million or more. Associate members pay \$1,500 and international correspondents pay \$1,000 per year. Currently there are 40 voting members, 10 associate members and 5 international correspondents.

Since 1982, CRN's president has been J.B. Cordero, who previously held senior positions with the Food Safety Council, the U.S. Congress Office of Technology Assessment, and the U.S. Department of State's Agency for International Development. He has a B.S. degree in government, economics and philosophy, and a master's degree in agricultural and nutrition economics. CRN's scientific and technical committee chairman is Joseph L. Kanig, Ph.D., former dean of Columbia University's College of Pharmaceutical Sciences. CRN's vice-president for communications is Bruce M. Brown, a former FDA press officer who drafted many of the agency's news releases and Talk Papers on health frauds and quackery. Annette Dickinson works part-time as

CRN's technical counselor.

CRN was formed in 1973 in response to an FDA attempt to regulate the labeling and dosage of supplement products. In 1972, after lengthy study, the agency had proposed that food products be labeled so that ingredients, nutrient content and other information would be displayed in a standard format. These provisions became regulations with little controversy and are still used today [see NF 3:41-43].

The 1972 FDA proposal also said that labeling could neither state nor imply that a balanced diet of ordinary foods cannot supply adequate amounts of nutrients. Because this struck at the heart of health food industry mythology about "nutrition insurance," the industry responded with a massive letter-writing campaign asking Congress to completely remove FDA jurisdiction over food supplements. This activity was orchestrated by the National Health Federation (NHF), a militant lobbying group, many of whose leaders had been in legal difficulty for questionable health promotions. After CRN joined the fray, it proposed legislation that was enacted in 1976 as the Proxmire Amendment to the Federal Food, Drug, and Cosmetic Act. Though not as restrictive as NHF's proposal, this law prevents the FDA from regulating food supplements unless they are inherently dangerous or are marketed with illegal claims that they can prevent or treat disease.

Most of CRN's original members were manufacturers from the "health food" side of the supplement industry. But since 1979, membership has broadened to include pharmaceutical and food manufacturers and distributors who are active in the nutritional supplement field.

CRN's code of ethics states that its members "recognize their duty to . . . ensure that consumers are provided with the accurate information they need to make informed choices" and that they "avoid making unsubstantiated or false or misleading claims for their products." CRN's members rarely make *therapeutic* claims for their products, but several of them—as well as CRN itself—have exaggerated the need for "nutrition insurance." For example:

- Cernitin America, which sells flower pollen products, has claimed that "most Americans are shamefully lacking in essential nutrients" and that "pollen is nature's most complete food."

- Neo-Life Corporation has suggested that eating "packaged foods" is like "putting used motor oil in a new car."

• Nutrilite (a division of Amway Corporation) has listed "improper food selection, poor eating habits, dislike or intolerance to certain food groups, special diets, and increased eating away-from-home" as "some of the reasons diet may be inadequate in essential vitamins and minerals."

• A Shaklee Corporation sales manual has stated: "Stress can cause the body to use up more nutrients faster. Add alcohol, birth control pills, smoking or medications that alter the unique balance in your body achieved by nature's handiwork and you may need additional nutrients."

• Hoffmann-La Roche has advertised widely that, "If your diet, like that of so many people, is coming up short, consider taking Protector Vitamin E . . . an easy, safe and inexpensive way to ensure added protection." This message is dishonest because vitamin E deficiency on a dietary basis has never been reported in an American adult.

On April 8, 1987, while four national groups were warning about unsafe supplement use [see following story], CRN issued a press release titled "Most Americans are at Nutrition Risk." This release claimed that supplements can benefit most Americans because "their normal food intake doesn't supply all Recommended Dietary Allowances (RDA) of essential nutrients, according to the most recent government surveys." The release also stated, "There is a conservative camp within today's nutrition community . . . These anti-progressives adamantly oppose moderate use of nutritional supplements, even in conjunction with dietary improvements, to optimize intake of protective nutrients. Simply put, these views are out of step—with the rest of the nutrition community, public health experts, and medical professionals."

I disagree. Most nutrition scientists, public health experts and physicians believe that: 1) dietary adequacy can be achieved with a varied and balanced diet; 2) it is easy to do so in this country; 3) most people's diets do not place them at risk for deficiency; 4) amounts over the RDA are rarely advisable; and 5) it is a waste of money to take supplements you don't need.

Having diligently collected the publications of CRN for several years, I have yet to see one suggesting how anyone can tell when supplements are *not* needed. I also find it interesting that CRN accepts the RDA as standards but rejects as "old-fashioned" or "out-of-step" the opinions of those who set them!

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 21 books including *Vitamins and "Health" Foods: The Great American Hustle*. In 1984 he received the FDA Commissioner's Special Citation Award for Public Service in fighting nutrition quackery.

SCIENTIFIC GROUPS WARN AGAINST VITAMIN MISUSE

The American Medical Association Council on Scientific Affairs has issued a lengthy position paper titled "Vitamin Preparations as Dietary Supplements and as Therapeutic Agents." Published in the April 10, 1987 *Journal of the American Medical Association*, it reflects the views of the scientific literature through November 1986. The report covers vitamins (not minerals) and defines dietary supplements as "preparations designed to increase the dietary intake of one or more essential vitamins," ordinarily in amounts 50% to 150% of the RDA. The report concludes:

- Sound dietary practices should eliminate any need for supplemental vitamins after infancy in essentially all healthy children.

- Healthy adult men and women and healthy nonpregnant, nonlactating women consuming a usual, varied diet do not need vitamin supplements. Infants may need dietary supplements at given times, as may women who are pregnant or are breastfeeding.

- Occasionally, vitamin supplements may be useful for people with unusual lifestyles or modified diets, including certain weight-reduction regimens and strict vegetarian diets (that exclude all foods of animal origin).

- Before deciding whether a vitamin supplement should be recommended to an adult, a history regarding the adequacy of dietary intake should be carefully evaluated and an attempt made to correct any inadequacy in food selection or eating pattern.

- Vitamins in therapeutic amounts (2-10 times the RDA) may be appropriate for the treatment of deficiency states, for pathologic conditions in which absorption and utilization of vitamins are reduced or requirements increased, and a few special situations where vitamins are used as drugs.

- Therapeutic amounts should not be used without the advice and supervision of a physician. Therapeutic vitamin mixtures should be so labeled and should not be used as dietary supplements.

- Public health nutrition will be served best by insistence on a scientifically sound basis for vitamin supplementation and therapy. All health practitioners should emphasize repeatedly that properly selected diets are the primary basis for good nutrition.

- Reprints of the report can be obtained by writing to the AMA Council on Scientific Affairs, 535 N. Dearborn St., Chicago, IL 60610.

- On April 8, four other national groups joined forces to warn Americans about the unsafe use of vitamin and mineral supplements. At a press conference in New York City, the American Dietetic Association, American Institute of Nutrition, American Society for

Clinical Nutrition and National Council Against Health Fraud issued the following joint statement covering minerals as well as vitamins:

- Healthy children and adults should obtain adequate nutrient intakes from dietary sources. Meeting nutrient needs by choosing a variety of foods in moderation, rather than by supplementation, reduces the potential risk for both nutrient deficiencies and nutrient excesses. Individual recommendations regarding supplements and diets should come from physicians and registered dietitians.

- Supplement usage may be indicated in some circumstances, including: 1) women with excessive menstrual bleeding may need to take iron supplements; 2) women who are pregnant or are breastfeeding need more of certain nutrients, especially iron, folic acid and calcium; 3) people with very low calorie intakes frequently consume diets that do not meet their needs for all nutrients; 4) some vegetarians may not be receiving adequate calcium, iron, zinc and vitamin B₁₂; and 5) newborns are commonly given, under the direction of a physician, a single dose of vitamin K to prevent abnormal bleeding.

- Certain disorders and some medications may interfere with nutrient intake, digestion, absorption, metabolism or excretion and thus change requirements.

- Nutrients are potentially toxic when ingested in sufficiently large amounts. Safe intake levels vary widely from nutrient to nutrient and may vary with the age and health of the individual. In addition, high-dosage vitamin and mineral supplements can interfere with the normal metabolism of other nutrients and with the therapeutic effects of certain drugs.

- The Recommended Dietary Allowances represent the best currently available assessment of safe and adequate intakes, and serve as the basis for the U.S. Recommended Daily Allowances shown on many product labels. [The USRDA are based mainly on the 1968 RDA.] There are no demonstrated benefits of self-supplementation beyond these allowances.

- The joint statement was developed during the past year by an 11-person task force assembled by the American Dietetic Association. The AMA Council on Scientific Affairs has reviewed the statement and considers it consistent with its own. The press conference was sponsored by the National Dairy Board and National Dairy Council, which last May sponsored a conference on the potential problems of vitamin megadosage. The FDA has urged physicians to report cases of toxicity through its Adverse Reaction Monitoring System, which keeps track of information on adverse drug reactions.

COMMON MISCONCEPTIONS ABOUT QUACKERY

Stephen Barrett, M.D.

Although most Americans are harmed by quackery, few perceive it as a serious problem and even fewer are interested in trying to do anything about it. As a psychiatrist, I have been trained to look for hidden reasons why people act the way they do—especially when they fail to avoid trouble. Applying this technique to quackery, I have identified 17 misconceptions which I believe contribute to this situation:

- *Misconception #1: Quackery is easy to spot.* Quackery is far more difficult to spot than most people realize. Modern promoters use scientific jargon which can fool people not familiar with the concepts being discussed. Even health professionals can have difficulty in separating fact from fiction in fields unrelated to their expertise.

- *Misconception #2: Personal experience is the best way to tell whether something works.* When you feel better after having used a product or procedure, it is natural to give credit to whatever you have done. This can be misleading, however, because most ailments resolve themselves and those that don't can have variable symptoms. Even serious conditions can have sufficient day-to-day variation to enable quack methods to gain large followings. The Freireich Experimental Plan described in the next article explains how this works. In addition, taking action often produces temporary relief of symptoms (a placebo effect). For these reasons, scientific experimentation is usually necessary to establish whether health methods are actually effective.

- *Misconception #3: Most victims of quackery are gullible.* Gullibility implies a wish for magic. Individuals who buy one diet book or "magic" diet pill after another are indeed gullible. And so are many people who follow whatever fads are in vogue. But the majority of quackery's victims are merely unsuspecting. People tend to believe what they hear the most. And quack ideas—particularly regarding nutrition—are everywhere. Another large group of quackery's victims is composed of individuals who have serious or chronic diseases which make them feel desperate enough to try

anything that offers hope. Alienated people—many of whom are paranoid—form another victim group. These people tend to believe that our food supply is unsafe, that drugs do more harm than good, and that doctors, drug companies, large food companies and government agencies are not interested in protecting the public. Such beliefs make them vulnerable to those who offer foods and healing approaches alleged to be "natural."

- *Misconception #4: Quackery's victims deserve what they get.* This is based on the idea that people who are gullible should "know better" and therefore deserve whatever they get. This feeling is a major reason why journalists, enforcement officials, judges and legislators seldom give priority to combatting quackery. Even doctors asked to testify as expert witnesses in quackery cases often refuse to do so because they have no sympathy for the victims. As noted above, however, most victims are not gullible. Nor do people deserve to suffer or die because of ignorance or desperation.

- *Misconception #5: Quacks are frauds and crooks.* Quackery is often discussed as though all of its promoters are engaged in deliberate deception. This is untrue. Promoters of mail-order quackery are almost always hit-and-run artists who know their products are fakes but hope to profit before the Postal Service shuts them down. But most other promoters of quackery sincerely believe in what they do. The FDA defines "health fraud" as "promotion of an unproven product for profit." This also causes confusion because in ordinary usage—and in the courts—the word "fraud" connotes deliberate deception.

- *Misconception #6: Most quackery is promoted by quacks.* Most people think of quackery as being promoted by quacks, charlatans, or others who are deliberately taking advantage of others. Actually, most quackery is promoted by victims of quackery who share their misinformation and personal experiences with others. Many customers of multilevel companies that sell overpriced vitamin supplements are friends, relatives and neighbors of those already using them. Quack-

ery is involved, but no "quacks." Pharmacists also profit from the sale of nutrition supplements which few of their customers need. In most cases pharmacists don't promote them but simply profit from the propaganda of others. Much quackery is involved in telling people something is bad for them (such as food additives) and selling them a substitute (such as "organic" or "natural" food). Quackery is also involved in misleading advertising of nutrition supplements and other nonprescription drugs. Again, no "quack" is involved—just hype from an advertising agency.

To make matters even more complicated, quackery is not all-or-nothing. A practitioner may be scientific in many respects and only minimally involved in unscientific practices. And products can be useful for some purposes but worthless for others.

Dictionaries define quackery as "the practices or pretensions of a quack" and define quack as "a pretender to medical skill." I think it is better to define quackery as "anything with false claims in the field of health." This covers the broadest possible spectrum of quackery and avoids implying that its promoters intend to deceive.

- *Misconception #7: Most quackery is dangerous.* Quackery can seriously harm or kill people by inducing them to abandon or delay effective treatment for serious conditions. Although the number of people harmed in this manner cannot be determined, it is not large enough or obvious enough to arouse a general public outcry. Most victims of quackery are harmed economically rather than physically. Moreover, many people believe that an unscientific method has helped them. In most cases, they have confused cause-and-effect and coincidence. But sometimes an unproven approach actually relieves emotionally related symptoms by lowering the person's tension level.

Statements condemning quackery rarely arouse indignation in people who have not been personally affected. Thus it is probably unrealistic to believe that opposition to quackery will become a high priority issue for the general public. It is perceived as a serious problem by professionals who are offended by the audacity of quacks who defile science and hurt the public. But most professionals feel too busy to get involved.

- *Misconception #8: "Minor" forms of quackery are harmless.* Quackery involving small sums of money

THE FREIREICH EXPERIMENTAL PLAN

The following tongue-in-cheek plan was devised by Emil J Freireich, M.D., of the M.D. Anderson Hospital and Tumor Institute, Houston, Texas. It assures that when proper research methods are not used, any remedy with no obviously harmful side effects can be "proven" effective for virtually all patients with serious disease. Note that "proof" is most evident when the disease has ups and downs—which almost all conditions have at one time or another—but that no possible outcome can disprove effectiveness:

Treatment should be applied only after a period when the disease has been getting progressively worse. If improvement occurs or the condition stabilizes, the treatment is obviously responsible. If the condition continues to worsen, either the dosage needs increasing or the duration of treatment has been too short to produce results. If the patient dies, it is because the treatment was applied too late.

After doing the above, the only remaining patients are those whose disease has either stabilized or worsened after the initial therapy. In all of these patients, either increase the dosage or continue the treatment. Again, improvement or stabilization proves that the treatment is effective, while worsening means that higher dosage or longer duration is needed. Since the treatment is harmless, the dose can be raised as often as necessary.

If this process is repeated enough, all patients will either stabilize or die. Since those who die came too late, their results don't count. This means that all patients who live will wind up in the category of showing improvement.

Of course, if the remedy is really worthless, all periods of temporary improvement will be followed by recurrence of disease. Therefore, once improvement occurs, it is crucial to stop the treatment or lower the dosage before worsening occurs. Then if the disease remains stable or gets worse, stopping the treatment can be blamed. Treatment should then be resumed at the initial dosage, and the cycle repeated as often as necessary. Of course, if the patient does well after treatment is stopped, this also confirms that the treatment was effective.

and no physical harm is often viewed as harmless. Examples are "nutrition insurance" with vitamin pills and wearing a copper bracelet for arthritis. But their use indicates confusion on the part of the user and vulnerability to more serious forms of quackery. There is also harm to society. Money wasted on quackery would be better spent for research, but much of it goes into the pockets of people (such as vitamin pushers) who are spreading misinformation and trying to weaken consumer protection laws.

The Feingold diet is an example of quackery whose potential harm is underestimated. Although the diet itself is harmless, it is probably harmful to teach children that the way they behave depends upon what they eat rather than on what they feel. Also, social development can be jeopardized if eating habits subject children to ridicule or lead them to avoid group activities where forbidden foods are served.

- *Misconception #9: The media are reliable.* Most people seem to think that statements about health issues "wouldn't be allowed" if they weren't true. Some media outlets—most notably *Consumer Reports* magazine—do achieve great accuracy. But most are willing to publish sensational viewpoints which they believe are newsworthy and will increase their audience. Even exposés on questionable methods are often "balanced" by including testimonials from satisfied customers. Money can also affect the flow of health information. General magazines which carry vitamin ads almost never publish articles advising readers not to waste their money on vitamins. Radio and television talk shows abound with promoters of nutrition quackery. Some promoters have their own publications and a few even have their own radio or TV talk shows.

- *Misconception #10: Advertising outlets are ethical.* There is a widespread public belief that if something isn't legitimate, publications and broadcast outlets would not allow it to be advertised. While most outlets have some limitations, most do not limit ads for health products. Standards are quite variable. All bust developers, penis enlargers, sexual enhancers, sauna belts, sauna suits, spot reducers are fakes. But their promoters have little difficulty in obtaining advertising outlets. Publishers and advertising managers sometimes claim they have no practical way to determine whether proposed ads are legitimate and that they must protect freedom of speech. Both positions are baloney. Ads can be checked quickly and easily by consulting a trusted authority; and freedom of speech does not include a right to defraud people.

- *Misconception #11: Education is the answer.* Education can help unsuspecting people learn to recognize quackery. However, those who are desperate, gullible or alienated may be difficult if not impossible to educate. Law enforcement is necessary to protect them.

- *Misconception #12: Government protects us.* Al-

though various government agencies are involved in fighting quackery, most don't give it sufficient priority to be effective. Moreover, the agencies involved do not have a coordinated plan to maximize their effectiveness.

The Postal Service has jurisdiction over misrepresentations that involve the mail. It operates a very aggressive program against mail fraud and can use administrative procedures to stop mail to the perpetrators of a scheme. For many years the Postal Service operated under weak laws which made it easy for those who were stopped to begin anew with a new ad, new product or a new company name. But the Mail-Order Consumer Protection Amendments Act of 1983 now enables the agency to seek penalties of \$10,000/day against repeat offenders. I believe that mail-order quackery is decreasing as a result and will eventually be a minor problem.

The Federal Trade Commission (FTC) has jurisdiction over false advertising of health products and services except for prescription drugs. It has a very powerful law which can result in stopping offenders and assessing huge penalties. However, the agency has taken little interest in quackery. It has prosecuted only a few quackery cases and often takes years to complete its investigations.

The U.S. Food and Drug Administration (FDA) has jurisdiction over food and drug product labels. Any written or oral claim made in the context of a sale is considered part of labeling, and therapeutic claims must be approved prior to marketing. This means the agency doesn't have to prove that quack products don't work in order to remove them from the marketplace. It merely has to show that claims made for them lack FDA approval. When a violation is detected, the agency can issue a warning letter, initiate a seizure of the illegally marketed product, seek an injunction against its sale, or initiate criminal prosecution.

Although the FDA's power is enormous, it has not been applied systematically against quackery. Many violations are ignored, warning letters are sometimes delayed for years, few seizures are made, and few injunctions are sought. Worst of all, since 1963 the FDA has initiated only two criminal prosecutions involving quack products [see NF 1:1-2].

The FDA claims that it lacks the manpower for a more effective program, that criminal prosecutions are too costly, and that the Justice Department is reluctant to prosecute quackery cases. Even if these claims are true—which I doubt—they do not explain why warning letters are issued months or years after the FDA detects violations. Nor does it explain why high-ranking FDA officials keep telling the public all about the agency's antiquackery options without revealing how little they are used.

The FDA does have an outstanding educational program against quackery. During the past three years it has disseminated valuable information to the media,

networked with many voluntary groups, and sponsored important health fraud conferences throughout the country [see NF 2:9-10 and 2:85].

State attorneys-general have jurisdiction over problems within their own states. Action within a single state can sometimes stop a nationally promoted fraud, but sometimes promoters will start anew in another state. New York and California have been most active against quackery [see NF 4:24]. Many states have weak laws that make enforcement action against quackery difficult. It would help if state attorneys-general coordinated their antiquackery activities and developed a central strategy. It would also help if a law were passed to enable them to sue in federal court for injunctions that would have national effect. Federal legislation of this type has been introduced but has not been passed [see NF 2:71].

Much quackery takes place in private between retailers and their customers. Although this could be decreased with appropriate prosecution, such prosecution is not popular with enforcement agencies because it requires undercover work and involves attacks on "ordinary" people, approaches which might not have widespread public support.

State licensing boards, which have jurisdiction over licensed practitioners, seldom take action against those who use unscientific methods.

- *Misconception #13: Quackery's success represents medicine's failure.* It is often suggested that people turn to quacks when doctors are brusque with them, and that if doctors were more attentive, their patients would not turn to quacks. It is true that this sometimes happens, but most quackery does not involve medical care. I recommend that doctors pay attention to the emotions of their patients and make a special effort to explain things to them. But blaming medicine for quackery is like considering the success of astrology the fault of astronomy. Some people have needs that exceed what legitimate medical practice can provide.

- *Misconception #14: Quackery is medicine's responsibility.* Many people think that medical doctors have: 1) special ability to recognize quackery; 2) special ability to combat it; and 3) a special duty to do so. It is true that medical training enables most doctors to identify quackery readily. (Unfortunately, a small percentage are quacks.) But it is clear that the medical profession cannot do the job alone. Effective control of quackery will require concerted effort by educators, writers, editors, publishers, advertising managers, talk show producers, legislators, law enforcement officials, and defrauded victims.

- *Misconception #15: The AMA has the power to stop quackery.* Many people (including some physicians) seem to think that the American Medical Association has some magical power to stop quackery. In fact, the quacks often accuse the AMA of "conspiring to

destroy alternative medicine" even though it is minimally involved. For many years the AMA maintained a department which was active against many types of quackery. But in 1975 it was shut down, and so was the AMA's quackery committee. Quacks cry "conspiracy" in an attempt to gain support by portraying themselves as underdogs.

- *Misconception #16: Fighting quackery is hopeless.* It is often reasoned that: 1) most victims of quackery are gullible; 2) gullible people can't be protected from their own follies; and therefore 3) quackery cannot be controlled. This reasoning has two flaws. First, as explained above, most victims of quackery are not gullible. Second, effective law enforcement can limit quackery's toll.

Alienated individuals who are "true believers" in quack methods can also arouse the feeling that fighting quackery is hopeless. These individuals are usually hopeless, but they constitute only a small proportion of quackery's victims. Effective law enforcement can protect many of them too. The best strategy for professionals confronted by "true believers" is to avoid wasting time with them.

Quackery's persistence causes many people to feel there is no point in trying to combat it. I disagree. Think about death and disease. No matter how much disease is cured, death still comes. But no one suggests that we stop fighting disease. Our goal should be to limit quackery as much as possible. Although the problem can never be eradicated, it can be greatly reduced if more people work on it.

- *Misconception #17: Fighting quackery is risky.* Many people inclined to do something about quackery are afraid they will get hurt by controversy or lawsuits. There are two reasons why these fears are unjustified. First, those who wish to avoid controversy can still take effective private actions like joining an antiquackery group, reporting frauds to law enforcement agencies, and telephoning editors to complain about misinformation in their publications. Second, libel suits are extremely rare and can be avoided by common sense: attack questionable ideas, and don't call anyone a "fraud" or a "quack."

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 21 books including *Vitamins and "Health" Foods: The Great American Hustle*. In 1984 he received the FDA Commissioner's Special Citation Award for Public Service in fighting nutrition quackery.

ANTIQUACKERY GROUP GROWING

The National Council Against Health Fraud, Inc., now has more than 2,100 members and chapters in 13 states. Organized in 1977 as the Southern California Council Against Health Fraud, the group became national in 1984. Its purposes are to: 1) conduct studies and investigations to evaluate claims made for health products and services; 2) educate the public, professionals, legislators, business people, organizations and agencies about untruths and deceptions; 3) provide a center for communication between individuals and organizations concerned about health misinformation, fraud and quackery; 4) support sound consumer health laws and oppose legislation which undermines consumer rights; and 5) encourage and aid in legal actions against consumer health protection law violators.

NCAHF's founder and president is William T. Jarvis, Ph.D., who is Professor of Health Education at Loma Linda University. Six of its board members belong also to *Nutrition Forum's* editorial board. The Council's cur-

rent activities include a speaker's bureau, a media clearinghouse, consumer complaint referral services, legislative advisement, expert testimony, law enforcement assistance, research on unproven methods of health care, and seminars for professionals and the general public. The Council also appoints task forces that conduct extensive investigations and issue position papers.

Membership in NCAHF is open to anyone who supports its beliefs and purposes. Regular membership costs \$15, and professional membership is \$25. Donations are tax-deductible. Members receive a bimonthly newsletter, ready access to printed information on more than 100 topics, and discounts on antiquackery publications. NCAHF's address is P.O. Box 1276, Loma Linda, CA 92354. (Telephone: 714-796-3067) Chapters exist in Arizona, Florida, Illinois, Iowa, Kentucky, Ohio, Michigan, Minnesota, New York, Oregon, Texas, Washington and Wisconsin.

BOOK REVIEW

Title: Contemporary Clinical Nutrition—a Conspectus (1986)

Editor: John J. Cunningham, Ph.D.

Publisher: George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106

Price: \$19.95

Reviewed by: Denice Ferko-Adams, R.D.

This is a valuable 288-page collection of 43 reprints from 22 scientific journals, including *The American Journal of Clinical Nutrition*, *Journal of the American Dietetic Association*, *Journal of the American Medical Association* and *The New England Journal of Medicine*. Suitable for health and nutrition professionals, the articles are organized into two sections and nine subtopics, each preceded by a well written, referenced overview by Dr. Cunningham.

Section I covers the nutritional needs of infants, children, adults and the elderly, with topics including the use of whole milk in infancy and how vitamin D

deficiency affects the development of osteomalacia in the aged. Section II covers the role of diet and nutrition in heart disease, obesity, cancer, carbohydrate metabolism, hypertension, alcoholism, and appetite regulation. Exemplary topics in this section include lactase deficiency, very-low-calorie diets, coffee and cancer, and potassium for hypertension.

The articles were originally published between 1981 and 1984, with most from the latter half of that period. Since nutrition recommendations change rapidly, periodic updates by Dr. Cunningham would be valuable.

Ms. Ferko-Adams is a nutrition consultant in private practice in Allentown, Pennsylvania. She also consults for the YWCA and a Dairy Council affiliate, and is Secretary for Consulting Nutritionists, a Dietetic Practice Group of the American Dietetic Association. In 1986 she won the ADA's Recognized Young Dietitian for the Year award.

EDITORIAL BOARD

EDITOR: Stephen Barrett, M.D. **SENIOR ASSOCIATE EDITOR:** Manfred Kroger, Ph.D. **ASSOCIATE EDITORS:** Denice Ferko-Adams, R.D., Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Mark Fuerst; Kathy King Helm, R.D.; Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

BRIEFS

Antiquackery handbook. A team of California physicians, dietitians and government officials and their respective organizations has produced an outstanding 33-page handbook called *The Professional's Guide to Health and Nutrition Fraud*. Its topics include indentifying quackery, insights into food faddism, counseling of health fraud victims, antiquackery actions, interested agencies, and publications. Single copies are available for \$7.50 from Sutter Publications, California Medical Association, P.O. Box 7690, San Francisco, CA 94120.

New publication. *Nutrition Clinics*, edited by Eleanor N. Whitney, Ph.D., R.D., began publication in June 1986. Each issue covers one topic in 14-30 pages, with references. The first five topics have been Nutrition and Cancer, Diet and Heart Disease, Diet Planning for the Vegetarian, Hypoglycemia and Nonhypoglycemia, and Nutrition and Behavior. Subscriptions are \$24/year (six issues) from the George F. Stickley Co., 210 W. Washington Sq., Philadelphia, PA 19106. Single copies are \$5.00 plus 50¢ postage.

Multivitamin survey. Two New Haven dietitians who surveyed five pharmacies, three groceries and three health food stores have concluded that most of their multivitamin products were irrationally formulated [*Journal of the American Dietetic Association* 87:341-343]. Most people using these products are seeking "nutrition insurance." For this reason, products were considered appropriate if they contained amounts the authors consider suitable for this purpose: 50-200% of the U.S. RDA for the vitamins and minerals for which U.S. RDAs are available, and no more than 100% of others for which Estimated Safe and Adequate Daily Dietary Intakes have been suggested. The authors rated 29 multivitamins (31% judged appropriate), 105 multivitamin/mineral preparations (15% appropriate), 27 stress formulas (none appropriate), 50 B-complex preparations (none appropriate), 40 children's supplements (half appropriate), and 6 prenatal supplements (half appropriate). Most products judged inappropriate had too much of some vitamins and not enough of others. *Editor's note: I would have classified any product with more than 100% of the U.S. RDA as irrational. It would be interesting to compare the percentage of inappropriate products in pharmacies and health food stores.*

News about obesity. The *International Obesity Newsletter*, edited by Francie M. Berg, M.S., and Nancy L. Grade, R.D., interprets obesity research from scientific journals and reports on conferences, books and weight-loss programs. It is written primarily for health and nutrition professionals. Introductory subscriptions are \$24 per year (10 issues) from the Healthy Living Institute, Box 612, Hettinger, ND 58639. Ms. Berg, who also writes a newspaper column, has asked her readers to report any trouble they have had with weight-loss schemes.

Notable quote: "Dentists are victims of their own success. They've been able almost to eliminate dental cavities through fluoridation of the water and better dental care."—John F. Griffith, Georgetown University's executive vice-president for health sciences, explaining to a *Washington Post* reporter why Georgetown's dental school (the nation's second largest) is closing because of a shortage of qualified applicants. Nationwide, a surplus of practicing dentists has led to a 28% drop in first-year dental students.

Media resource center. The Scientists' Institute for Public Information, 355 Lexington Ave., New York, NY 10017, maintains a computerized list of 20,000 experts in science, technology and medicine who have volunteered to help journalists. Members of the working press can be referred for help by calling 1-800-223-1730 (212-661-9110 in New York State). The Institute averages more than 50 calls a week, one-third of which concern health and medical topics.

Calories and cancer. Although overnutrition is known to be a risk factor for cancer, the way in which this works is unclear. In February 1986, the International Life Sciences Institute sponsored a symposium to discuss research on the relationships between caloric intake, dietary fat, energy expenditure, hormones, body weight, and cancer development. A 372-page compendium of the papers presented at this meeting is now available for \$10 from *The American Journal of Clinical Nutrition*, 428 E. Preston St., Baltimore, MD 21202. (Ask for Supplement Volume 45, Number 1.)

Supplement flyer. The American Dietetic Association, 430 N. Michigan Ave., Chicago, IL 60611, has published a new flyer about food choices and supplement misconceptions called "Alphabet Soup: Nutrients from Food and Supplements." Single copies are available for \$1 plus a self-addressed, stamped, 4" x 9½" envelope.

Orange juice taste. Manuel Moshonas, a U.S. Department of Agriculture chemist, has used gas chromatography to isolate what he calls the "flavor code" of fresh orange juice: a unique blend of some 21 chemicals that give fresh orange juice its special tang. Currently, freezing and concentrating adversely affect flavor by upsetting this chemical balance. Moshonas hopes that citrus processors can modify their methods to produce processed orange juice with a nearly-fresh taste.

Nutrition status of problem drinkers. A Finnish study which compared 26 employed men who drank excessively with 49 men who did not found that the drinkers consumed more calories, but otherwise had similar diets [*American Journal of Clinical Nutrition* 45:456-61, 1987]. The drinkers weighed less, but had more body fat. Gross nutritional deficiencies were not found, but there were some subtle differences between the two groups which the authors believe should be studied further.

Protein development lagging. Many researchers have hoped that inexpensive protein sources could be developed to help the world food supply keep pace with population increases. During the past 20 years, much attention has been paid to such high-protein sources as bacteria, yeast, molds, algae, leaves, soybeans, cottonseed and peanuts. According to an article in the February 1986 University of Guelph *Notes on Agriculture*, however, two factors have slowed progress: 1) strict safety requirements make it difficult to gain approval for "new" sources; and 2) production costs have been higher than expected. Soybeans appear to be most promising because regulatory problems are minimal and soy flour can be produced very inexpensively. In this form it is suitable for animal feed, but the additional processing needed to produce human foods such as tofu (soy curd) or hamburger substitute raises the cost to that of ground beef. The article's author predicts that plant proteins will play a greater role in the food supply as people become more interested in lowering the fat content of their diet and scientists find better ways to convert them into acceptable foods.

Health food advocate dies. Betty Lee Morales, a major promoter of questionable health and nutrition methods, died March 27 at age 80 of an apparent heart attack. She marketed food supplements and was founder-president of the Cancer Control Society and a board member of the National Health Federation, groups that promote unproven methods of cancer treatment.

QUESTION BOX

Q. Why are cucumbers waxed? When is the wax applied? What kind is used? Is it edible?

A. Cucumbers and about 15 other vegetables and fruits are waxed for two reasons: 1) to improve appearance and consumer acceptance and 2) to preserve freshness by inhibiting the evaporation of moisture. Although many fruits and vegetables have a natural waxy layer on their surface which seals in moisture, this coating is often lost when produce is washed to remove soil, filth, and pesticide residues. Replacing the natural wax with a commercial one prevents shriveling and wilting of produce due to transpiration, the postharvest loss of water. Packers usually apply the wax before shipping their produce to supermarkets. Waxing is especially useful to prevent moisture loss from slightly injured products. American packers have been using waxes for more than 50 years, but the practice originally dates back to 13th century China.

The FDA has approved a variety of wax compounds for fresh produce. Carnauba wax, derived from palm leaves, and candelilla wax, which comes from a reed-like plant, are commonly used. Others include paraffin (a petroleum derivative), polyethylene (a synthetic made from petroleum products), shellac (derived from insects), sucrose-fatty acid ester (derived from tallow), and oleic acid (usually derived from tallow). The waxes are mixed with water and wetting agents to form an emulsion which provides a thin continuous coating after application by dipping or spraying.

All waxes authorized by FDA for use on food have been tested and are considered safe even if ingested in the daily diet. They are not on the GRAS (generally recognized as safe) list, but are authorized by specific regulations. Although edible, only small amounts are likely to be consumed. Very little wax is used, as one pound covers thousands of pieces of produce, and most people wash or peel fruits and vegetables before eating them.

"RASPBERRY TEA"

Varro E. Tyler, Ph.D.
Michael J. Pcolinski, B.S. Pharm.
Jerry L. McLaughlin, Ph.D.

Among herb enthusiasts, tea prepared from the leaves of the raspberry plant (*Rubus idaeus* L.) has acquired a considerable reputation as "the drink" for expectant mothers. In the popular literature it is praised as a "panacea during pregnancy" and said to do "everything from allaying morning sickness to preventing miscarriage to easing labor pains." Even such a reliable reference as the 28th (1982) edition of Martindale's *The Extra Pharmacopoeia* credits it as a "traditional remedy for painful and profuse menstruation and for use before and during confinement."

Whether raspberry leaf tea can actually help such conditions is not known. Adequate clinical studies of its physiological properties have never been carried out, and the existing chemical analyses have revealed only the presence of relatively common constituents such as tannins, plant acids, flavones and vitamin C. These compounds probably account for the astringent, bitter taste of raspberry leaf tea which some consumers find closely resembles that of ordinary black tea.

Raspberry leaves possess neither the pleasant taste nor the highly aromatic odor of raspberry fruits. Therefore, our curiosity was aroused when we acquired a tea sample which had a strong raspberry odor. Simply labeled "Raspberry," it had been packaged by the Westerley Coffee, Tea & Spice House of Tiburon, California. The product appeared to consist mostly of black leaf fragments which looked like ordinary black tea, plus a much smaller number of tiny particles of green leaves. We suspected that this was a black tea to which a small amount of raspberry leaves had been added, and the mixture was then strongly flavored by adding a volatile oil which smelled like raspberry fruits.

This assumption was verified by examining 2 grams of the mixture for caffeine, using the method described by Tyler and Schwarting in the third edition of *Experimental Pharmacognosy* [Burgess Publishing Co., Minneapolis, 1962]. This procedure yielded 14.07 mg. of a white crystalline solid which, on the basis of its melting point, co-chromatography and infrared spectrometry, was proven to be caffeine. The calculated yield was 0.7%, a figure near the lower portion of the 1-4% range of caffeine found in common black tea. We concluded that the "Raspberry" tea consisted primarily of ordinary black tea flavored with essence of raspberry

fruit but did not contain an appreciable quantity of raspberry leaves.

At least one other tea capitalizes on the popularity of the raspberry name: "Raspberry Patch," marketed by Celestial Seasonings, Inc., of Boulder, Colorado. The list of ingredients on its label does not include raspberry leaves. Dried raspberry fruits are present, but they are listed as a minor ingredient after hibiscus flowers, rose hips, orange peel, and roasted chicory root. Any expected benefits of raspberry leaves would not be obtained from this product.

Tea made from the leaves of the blackberry plant (*Rubus fruticosus* L.) is considered to produce effects similar to those of raspberry tea. Therefore, we also inspected a package of "Blackberry Tea," marketed by Thomas J. Lipton, Inc., of Englewood Cliffs, New Jersey, to see if it contained any quantity of the leaves. According to its ingredient statement, the product contains neither blackberry leaves nor fruit. Instead, it is composed of orange pekoe and pekoe cut black tea and natural flavors. In other words, it is simply black tea to which blackberry fruit flavoring has been added.

This kind of inexact labeling of herbal teas is very common. Although federal laws require that ingredients be correctly listed on product labels, the names by which products are marketed do not necessarily reflect what they contain. Quality control within the herbal products industry is often not good, and some herbal products are potentially toxic. For all of these reasons, it is unwise to use herbal products without an understanding of their ingredients—which, as the above examples indicate, cannot necessarily be gathered from product names.

Dr. Tyler, Dean of Purdue University's Schools of Pharmacy, Nursing, and Health Sciences, is an expert in pharmacognosy (the science of medicines from natural sources) and author of *The Honest Herbal*, an evaluation of popular herbs published by the George F. Stickley Co. Dr. McLaughlin is Professor of Pharmacognosy in Purdue's Department of Medicinal Chemistry and Pharmacognosy. Mr. Pcolinski, a recent Purdue graduate, is currently studying at Ohio State University.

FIGHTING QUACKERY: TIPS FOR ACTIVISTS

Stephen Barrett, M.D.

The crucial step in fighting quackery is to overcome any negative feelings about becoming involved. So before discussing techniques, let's look at the concerns faced by would-be activists.

Almost everyone who thinks about fighting quackery experiences some fear of being sued for libel or slander. The fact is, however, that no one who understands the law and follows commonsense rules faces any significant risk. To be libelous, a statement must be *defamatory, malicious and false*, and must appear in print. Slander is similar, but applies to oral claims and requires proof of actual damages. A defamatory statement is one that accuses someone of being dishonest, criminal, or professionally incompetent. Malicious (done with malice) means done for an improper reason or with knowledge that the statement is false. It is possible for a statement to be false but not defamatory. In any case, truth is a complete defense against libel and slander. It is possible to defame an individual, a small group of individuals, or an organization. But one cannot defame a large class of individuals (such as "all doctors") or an entire industry.

Avoid name-calling

It is never libelous to criticize an *idea*. Therefore it is safe to attack ideas or to list ideas characteristic of quackery. It is legal to mention adverse facts—such as criminal convictions or dubious credentials—about people who place themselves in the public spotlight by claiming to have expert knowledge. But avoid statements about motivation (such as "He's only in it for the money") because they may be impossible to prove. The appearance of malice can usually be avoided by investigating carefully and citing reliable sources of information. Also avoid name-calling. Above all, never call anyone a name (like "quack," "crook" or "fraud") unless you are willing to defend this claim in court.

It should be apparent from the above discussion

that antiquackery actions based on facts and done for legitimate reasons cannot provide the grounds for a successful libel suit. But what about suits whose purpose is intimidation? The National Nutritional Foods Association (NNFA) and some of its leaders tried this approach with Fredrick J. Stare, M.D., Ph.D., Emeritus Professor of Nutrition, Harvard School of Public Health, and Elizabeth M. Whelan, Sc.D., M.P.H., Executive Director of the American Council on Science and Health. Filed in 1979, NNFA's suit charged them with "recklessly, maliciously and knowingly disseminating false and defamatory remarks with respect to plaintiffs and the health food industry" through books and published articles.

It was obvious that the plaintiffs would lose in court. Their names had not even been mentioned in the publications to which they objected. In 1980 the suit was dismissed by a federal judge who warned that "any further suit by plaintiffs against critics of the health food industry should be scrutinized carefully to determine whether it was brought in good faith." (In other words, plaintiffs would be held responsible for defendants' legal bills.)

The suit was actually part of an announced effort to silence critics of the health food industry. Very few such suits have been filed, and all have been against leading critics. As far as I know, none has ever been filed against a critic of quackery who was not nationally prominent unless he called someone a quack. Thus it is very unlikely that anyone who sticks to facts and does not engage in name-calling will be unjustly sued for libel.

Of course, if it makes you more comfortable, you can avoid criticisms of individuals altogether. Just criticize ideas that you disagree with and provide the correct information. For additional safety, you can use the word "questionable" (e.g., "That idea is certainly questionable"), which is not defamatory.

Some people fear that taking a stand against

quackery will embroil them in unpleasant public controversy. That certainly can happen, but many effective actions require no public exposure at all. For example, you can: 1) offer background information to a reporter with a request that you not be quoted; 2) send letters to the media marked "not for publication"; 3) complain about false advertising to appropriate agencies; 4) encourage victims of quackery to file lawsuits; and 5) contact legislators and encourage others to do this too. All of these things can be done privately and without risk.

Lack of confidence can also interfere with taking action. Non-experts often feel that only experts can be effective. Even experts may hesitate when they aren't

sure what action would be most effective. However, although expert knowledge is helpful, the number of people taking action is often more important than the nature of what they do. Moreover, many antiquackery actions require no expertise.

Fighting quackery can be very time-consuming. But keep in mind that many actions (such as reporting illegal ads) take only a few minutes.

Dealing with the media

Much can be done to counter the spread of misinformation through talk shows and publications.

WHERE TO COMPLAIN

Problem	Agency to Contact*
False advertising	Bureau of Consumer Protection, Federal Trade Commission, Washington, DC 20580 Regional FTC office National Advertising Division, National Council of Better Business Bureaus, 845 Third Avenue, New York, NY 10022 Editor or station manager of media outlet where ad appeared
Drug or device marketed with false or exaggerated claims	Health Fraud Branch, Food and Drug Administration, 5600 Fishers Lane, Rockville, MD 20857 Regional RDA office State attorney general Congressional representatives
Phony mail-order promotion	Chief Postal Inspector, U.S. Postal Service, Washington, DC 20260 Editor or station manager of media outlet where ad appeared
Improper treatment by licensed practitioner	Local medical society, if practitioner belongs Local hospital, if practitioner is on staff State licensing board Private attorney for possible lawsuit
Improper treatment by unlicensed individual	Local district attorney State attorney general Local newspaper or TV station Private attorney for possible lawsuit
Advice needed about questionable product or service	National Council Against Health Fraud, Inc., P.O. Box 1276, Loma Linda, CA 92354

*Where more than one agency might be interested, complain to all of them.

If you object to a broadcast, make your objections known by writing or phoning its producer or the station manager. Persist until you learn how those you contact feel about your request. If you encounter resistance, get as many people as you can to make similar contacts. Don't be discouraged if no immediate corrective action is taken. Expressions of protest may still influence what happens in the future.

If you object to a newspaper or magazine article, write a letter to the editor and get others to do the same. If the publication is local, phone calls can also be useful because they insure that the person you are contacting really thinks about your complaint. Contacting the writer may also help prevent future difficulty. If you have expert knowledge and would like to be interviewed or used as a consultant, make your interest known and send story ideas and pertinent background literature to reporters or editors. When accurate information is published, expressions of support will encourage more of the same.

Objections to advertising can be made to advertising managers, editors, publishers, and/or station

managers. Although advertising revenue may count more than your opinion, protests are sometimes effective. If you report a misleading ad to an enforcement agency, tell your local media. Reporters who value the credibility of the press may relish an opportunity to embarrass their own advertising department by publicizing what you did.

The National Advertising Division (NAD) of the Council of Better Business Bureaus can exert pressure against misleading messages in national advertising. NAD is well equipped to handle nutrition issues. Its director, Ronald H. Smithies, Ph.D., J.D., is an attorney with a doctoral degree in biochemistry. The investigative staff includes a registered dietitian.

Reporting illegal activities

Suspicious activities can be reported to state and federal government agencies. Some people hesitate to report suspicious activities for fear they will become embroiled in legal controversy. This fear is unfounded. Enforcement agencies conduct their own investigations and obtain outside experts as needed.

ANTIQUACKERY PUBLICATIONS

Publication	Special Features
Nutrition Forum (\$30/yr.) George F. Stickley Co. 210 W. Washington Sq. Philadelphia, PA 19106	News pertaining to nutrition quackery; includes original investigations
NCAHF Newsletter (\$25/yr.) National Council Against Health Fraud, Inc. P.O. Box 1276 Loma Linda, CA 92354	News pertaining to all types of quackery. Council membership includes newsletter and special reports
FDA Consumer (\$9.50/yr.) Superintendent of Documents Government Printing Office Washington, DC 20402	Reports on nutrition, food safety, government regulations and enforcement actions
ACSH News & Views (\$10/yr.) American Council on Science and Health 1995 Broadway, 18th Floor New York, NY 10023	Analysis of chemical and health controversies. ACSH membership (\$35/yr.) includes newsletter and special reports
Environmental Nutrition (\$24/yr.) 52 Riverside Drive New York, NY 10024	Timely analyses of controversies; book reviews
Consumer Reports (\$16/yr.) Box 51166 Boulder, CO 80321	Occasional in-depth articles relevant to quackery

The U.S. Food and Drug Administration (FDA) has jurisdiction over the labeling of products that enter interstate commerce. Labeling includes not only the actual words on the label but also any claims made through literature or oral claims involved in the sales process. Supplement products or questionable devices claimed to be effective against disease should be reported. Complaints made through FDA regional offices usually get more attention than those made to the agency's central office.

The Federal Trade Commission (FTC) has jurisdiction over advertising of products or services involving interstate commerce. However, the FTC almost never gets involved with the claims made by practitioners who are licensed by the states. Trouble of this type should be reported to state licensing boards. The Postal Service has jurisdiction over products sold through the mails.

When making a complaint, include as much information as possible. If you can, spell out what is wrong, point out why it may be harmful, and suggest what can be done to correct the problem. Where more than one agency may have jurisdiction, complain separately to all of them. Federal violations should also be reported to Congressional representatives with a request that they ask the appropriate federal agency to take action and let you know the outcome. Complaints from lawmakers often get greater attention than those from individuals. If you complain to an agency, please send a copy to *Nutrition Forum*, P.O. Box 1747, Allentown, PA 18105. We may be able to investigate and cover the situation in an article.

Unscrupulous practitioners may be prosecuted by state agencies, but a lawsuit by an injured victim may be more effective. The trick is to find an attorney interested in fighting quackery who will file suit on a contingency basis. Under this arrangement, the attorney gets paid a percentage of the winning but charges no fee if the case is lost.

Individual efforts against quackery can be multiplied greatly when coordinated with those of others. The National Council Against Health Fraud, Inc., has more than 2,100 members and has chapters in 13 states.

Its newsletter alerts members to pending legislation and provides information on current fads and frauds. Other useful publications are listed in the table on page 51.

Remember that in matters of health there should be no tolerance for deception. Your effort in opposing quackery may save many people from being hurt—and may even save a life!

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 21 books including *Vitamins and "Health" Foods: The Great American Hustle*. In 1984 he received the FDA Commissioner's Special Citation Award for Public Service in fighting nutrition quackery.

BOOK REVIEW

Title: *Nutrition, diet and health* (1986)

Editor: Michael J. Gibney

Publisher: Cambridge University Press, 32 East 57th St., New York, NY 10022

Price: \$29.95 hardcover, \$8.95 softcover

Reviewed by: Stephen Barrett, M.D.

Dr. Gibney, a senior lecturer in nutrition at Trinity College (Dublin, Ireland), has produced a lucid 168-page discussion of nutrition basics and current controversies. Three quotations will illustrate his knack for explaining things and his unique writing style:

- Vitamins do not function in a magical manner. They act biologically, each having its own specific function. For a particular biological reaction to proceed at the correct pace, there is a given quantity of the vitamin required. Excess vitamins will not push the pace of biological reactions faster, just as having a full tank will not make a car go faster than its engine capacity will allow.

- If in the manufacture of cars there were a shortage of gearboxes, then there would be a proportionate shortage of cars. One option which might be open to the car manufacturer, but is not open to the body's protein-synthesizing mechanism, is that of building the car to a certain stage to await delivery of the gearbox. In the body it is whole proteins or none at all. There can be no compromise.

- Fashion is not confined to the clothes industry, to holiday resorts or to political belief. There are fashions in most professions, including science. In general, a subject becomes fashionable when scientists see in it an opportunity to make a name for themselves by publishing papers and to secure research grants. This is easiest in a new field or, as in the case of fiber, in an old field which has been revived.

This book is suitable for laypersons wishing to deepen their understanding of nutrition. It can also be valuable to professionals seeking better ways to communicate nutrition information.

BRIEFS

Genetic engineering update. About 2,400 strawberry plants in a small test plot near Brentwood, 40 miles east of San Francisco, have been sprayed with Frostban, which contains altered *Pseudomonas* bacteria. The action was taken after a county court judge ruled there is "no credible evidence" that the test is unsafe and a state appeals court refused to stop the test. After the appeals court ruling, vandals uprooted most of the plants, but scientists in charge of the facility were able to replant them. According to an article in the *Los Angeles Times*, natural *Pseudomonas* contributes to \$1.6 billion per year in frost damage by encouraging frost formation on fruit, nut and vegetable crops. The test was designed to see how well the altered version will colonize the leaves and blossoms of strawberry plants and protect them. A few days later, scientists from the University of California/Berkeley began tests near the Oregon border with potato seeds treated with a solution containing similar bacteria called "ice-minus." The method is based on the discovery that removal of a single gene from the bacteria can transform it from a frost-inducer to a frost-fighter. Opponents of genetic engineering were able to delay field testing of this type for several years by filing lawsuits [see NF 3:5].

"Organic foods" not tax-deductible. A federal tax court has ruled that Warren and Gail Becher of Niagara Falls, N.Y., may not deduct "organic foods" as medical costs of coping with supposed allergic reactions that included "foggy thinking." This case contrasts sharply with a 1977 ruling in which a court held that the extra cost of "organically grown" foods could be deducted as a medical expense by Theron Randolph, M.D. (a leading "clinical ecologist") and his wife, Janet. The Randolphins claimed that Janet experienced mental confusion, crossed eyes, and difficulty in walking when she inhaled or ingested contaminants and that Theron had suffered from loginess, malaise, headaches, nausea and anorexia due to contaminated foods.

Price reduction. The softcover edition of *Popular Nutritional Practices*, by Jack Z. Yetiv, M.D., Ph.D., [Popular Medicine Press, 1986] has been reduced from \$17.95 to \$12.95. The 320-page book, which has received outstanding reviews, covers more than 100 topics of contemporary interest and is suitable for laypersons as well as professionals. *Nutrition Forum* readers can obtain copies for \$14.20 (postage included) from LVCAHF, Inc., P.O. Box 1747-N, Allentown, PA 18105.

Homeopath upheld. A county court judge has overturned the decision of the North Carolina Board of Medical Examiners to revoke the license of the state's only homeopathic physician, George A. Guess, M.D., unless he stops practicing homeopathy [see NF 4:5]. The Board has appealed this ruling to the state court of appeals.

Calcium juice. The American Medical Women's Association (AMWA) has awarded its first seal of approval to Citrus Hill Plus Calcium, a calcium-fortified orange juice product. After scientific review, AMWA's Scientific Evaluation Council concluded that the calcium in this product is more absorbable than that in milk. The seal, which Procter & Gamble can use in ads and on product labels, states: "Citrus Hill Plus Calcium has been shown to be a well-absorbed source of dietary calcium, which, as part of a balanced diet and accompanied by regular exercise, can help build and maintain strong bones.—*American Medical Women's Association.*"

Diet and health report. The *American Journal of Clinical Nutrition* has published all of the scientific papers presented at the October 1986 symposium on diet and health sponsored by the International Life Sciences Institute and other prominent groups. The issues addressed at the conference included: 1) What criteria should be used for making dietary recommendations? 2) Should recommendations be made to groups, individuals at risk, or everyone? 3) How can quantitative recommendations be applied to populations? 4) How should physiological variations such as age, sex, pregnancy and lactation affect quantitative recommendations? 5) What intake levels of nutrients or nonnutrients pose health risks? 6) Which dietary constituents are uniquely essential? 7) Is a multifactorial approach (diet, exercise, behavior and nutrition education) more effective than calorie restriction alone in reducing body weight? 8) How should population studies be carried out? 9) What are the pros and cons of public education vs. modification of the food supply? 10) What is the proper role of the food industry in public education? The 400-page compendium includes 53 papers on energy and obesity, fat and cholesterol, simple and complex carbohydrates, dietary fiber, selected vitamins and minerals, and implementation of dietary guidelines. Copies are available for \$10 from *The American Journal of Clinical Nutrition*, 428 E. Preston St., Baltimore, MD 21202. (Ask for Supplement Volume 45, Number 5.)

Berger blasted again. Tufts University Diet & Nutrition Letter has published a devastating review of *How to Be Your Own Nutritionist*, by Stuart M. Berger, M.D., author of *Dr. Berger's Immune Power Diet*. According to the Tufts' review, the new book: 1) was actually written for Berger by a freelance writer; 2) confuses cholesterol with fat, and saturated fat with total fat; 3) mistakenly claims that riboflavin has no RDA; 4) condemns high-fat foods in one chapter but recommends 400 calories-worth of almonds (80% fat) in another; 5) fails to explain how Berger arrived at his suggested "optimal" doses of vitamins and minerals; and 6) makes unjustified recommendations for using nutrients to treat dozens of problems ranging from sexual impotence to a craving for sweets. On June 30th, the North America Syndicate (a Hearst Corporation subsidiary), stopped publication of Berger's newsletter, *The Berger Report*. Issued twice monthly, it had attracted only 300 subscribers during its 11-month existence.

Suction lipectomy increasing. According to an article in *American Medical News*, suction lipectomy is becoming one of the most popular forms of cosmetic surgery in the United States. A survey of 2,800 members of the American Society of Plastic and Reconstructive Surgery reported 99,330 cases of fat suctioning last year—an increase of 78% over the number reported in 1984—with fees ranging from \$500 to \$4,000. The procedure was developed about ten years ago and introduced in the U.S. about five years ago. At first it was used almost exclusively for body contouring around the thighs, buttocks and abdomen. Now it is often used on the face as well. Critics of the procedure say it can numb nerves and tear blood vessels, causing infections and potentially fatal blood clots. According to Robert Berggren, M.D., professor emeritus of plastic surgery at Ohio State University, the ideal patient is under 40, at ideal weight, but still has collections of fat regarded as abhorrent.

AMAZING CLAIMS FOR CHLOROPHYLL

James A. Lowell, Ph.D.

A few years ago, a student arrived in one of my classes with her teeth and gums dyed bright green. When I inquired about her strange oral hue, she said that her doctor had prescribed chlorophyll for her hereditary gum disease. I had seen ads claiming that the chlorophyll in mints and chewing gum could freshen one's breath, but I had never heard of it being used as a medicine.

Not long afterward, a friend told me that his brother's chiropractor had suggested trying chlorophyll as a remedy for bleeding from the penis, a problem associated with jogging.

These two episodes led me to examine the claims being made for chlorophyll as both a medicine and a deodorizing agent. I began my little research project by picking up literature at several health food stores which sold chlorophyll liquid and tablets. Various pamphlets and ads stated that chlorophyll would do everything from cleaning dirty colons to providing vital life forces to the brain. The most enlightening publication, however, was a booklet written by T. M. Rudolph, D.C., Ph.D., whose claims were nothing short of astounding.

According to Rudolph, chlorophyll can cure, help to cure, or improve burns, leg ulcers, trench mouth, tonsillitis, peptic ulcers, several types of vaginitis, urinary bladder diseases, high blood pressure, colitis, tooth decay, arthritis, athlete's foot, constipation, hay fever,

rectal fissures, anemia, gas and "acidic" bowels, stomach and intestinal problems, laryngitis, ear problems and impetigo. He also says it will help tired feet, soothe gunshot wounds, destroy bacteria, and improve metabolism.

Rudolph asserts that chlorophyll is "the catalyst of the vegetable kingdom which can allow vegetation to produce life and vital energy by feeding on air, water, and sunlight and known and unknown agents and invisible rays of the sun." It does this, he explains, because it "produces oxygen by breaking down poisonous carbon dioxide."

This description is not quite correct. There are thousands of catalysts (chemicals that speed reactions) in the plant kingdom (not the "vegetable kingdom"), but chlorophyll is not one of them. It is the pigment responsible for the green color of plants that enables them to "trap" energy from sunlight. This energy and carbon dioxide are then used to manufacture the carbohydrates that all living things use as food. Oxygen is not produced by the breakdown of carbon dioxide but is a by-product of the splitting of water during photosynthesis.

Chlorophyll's proponents also claim that it is a natural substance equivalent to the "blood of plants." It is true that a small part of the chemical structure of chlorophyll resembles that of blood, but the functions of the two are entirely different. Nor should most products

labeled "chlorophyll" be considered "natural." They are breakdown products produced by exposing plant material to chemicals such as acetone, hexane gas, and copper. The resultant material is no longer chlorophyll.

Most claims that chlorophyll products can heal, kill bacteria, and remove odors are based on research performed early in the 20th century, before antibiotics were available to fight infections. Although many of these studies are considered invalid by modern scientific standards, there is evidence that chlorophyll can kill certain types of bacteria. It is not a practical choice, however, because very high concentrations are needed for any positive effect and modern antibiotics are far more effective anyway. Also, although chlorophyll kills some bacteria, it actually promotes the growth of others.

What about deodorizing properties? Despite the sales hype, in products sold to the public it doesn't have any. According to John D. Kephart, who performed studies at the laboratories of The National Chlorophyll and Chemical Company about 20 years ago, "No deodorant effect can possibly occur from the quantities of chlorophyll put in products such as gum, foot powder, cough drops, etc. To be effective, large doses must be given internally." [*Journal of Ecological Botany* 9:3, 1955]

Not long ago I visited a health food store to augment my collection of questionable nostrums. Because of my chlorophyll study, I selected a small bottle of garlic capsules with chlorophyll. Garlic has been considered to be a healing herb for hundreds of years. Many studies have examined the properties of garlic and its active ingredient, allacin. While some evidence exists that allacin may help lower blood cholesterol levels and effect blood pressure, no published studies demonstrate that health food variety garlic pills are good for anything other than flavoring food or providing bad breath. But literature at the store suggested they can help or cure cancer, diarrhea, dysentery, grippe, sore throat, intestinal disorders, tuberculosis, polio, and many other conditions.

To believers, adding chlorophyll to garlic seems impeccably logical: garlic makes you smell bad, chlorophyll makes you smell good, so the overall effect should be neutral. But since small amounts of chlorophyll do not deodorize, the most probable result from the pills is bad breath and a green tongue.

As I approached the cash register, another product caught my eye. For only \$3.50 I could obtain a bottle of Hoffman's Energol, a wheat germ oil product marketed by the York Barbell Company, of York, Pennsylvania. In 1960, the FDA charged York Barbell with misbranding its Energol Germ Oil Concentrate because literature accompanying the oil claimed falsely that it could prevent or treat more than 120 diseases and conditions. In 1974, the company was prosecuted again for claiming that Energol had special dietary value as a source of vigor and energy. In both cases, products were seized and destroyed under court-approved agreements the company reached with the FDA.

Although York Barbell no longer makes therapeutic claims for Energol, the stuff still retains some reputation for enhancing athletic prowess. When the clerk saw me looking at the bottle, she said, "You know, Energol is great, but it's only half of what you need. Because the Energol is temporarily stored in the liver, you need this or you won't get your energy fast enough. You don't want to wait for your energy, do you?"

"Oh no," I said, looking at the bottle she handed me. The label read Octacosonal, a product marketed by another company. "This seems a bit expensive," I said, looking at the \$5.95 price tag. "According to the label, this whole bottle contains only 30 thousandths of 1 gram of an alcohol taken out of yeast and put into a pill. Couldn't I just eat the yeast?"

"No, no," she replied, "this is different. It is the concentrated vital essence of wheat germ which will unlock the vitalizing powers of the Energol which is going to be stored in your liver. It really is an amazing scientific breakthrough."

What else could I do? The Energol wouldn't work properly without the Octacosonal, and the garlic would make me smell bad without the chlorophyll. So I went to the cash register and bought them all.

Dr. Lowell, who has graduate degrees in botany and genetics, is Professor of Life Sciences at Pima Community College in Tucson, Arizona, and is vice-president of the National Council Against Health Fraud. His recently revised book, *Health Hoaxes and Hazards*, is available for \$13.50 from the Nutrition Information Center, 255 N. Granada, #2058, Tucson, AZ 85701.

LONDON SMITH LOSES LICENSE!

Diane S. Lund

Pediatrician/nutrition guru Lendon Smith, M.D., has voluntarily surrendered his medical license to the Oregon Board of Medical Examiners rather than face an arduous battle with the board. In January 1987, Dr. Smith was brought before the board's investigative committee on charges of having violated two Oregon statutes: "obtaining any fee by fraud or misrepresentation" and "making a fraudulent claim," said John Ulwelling, the board's executive secretary.

Ulwelling said the investigation was initiated because of a complaint and that the board had asked Dr. Smith to retire. Although the board has declined to discuss the specifics of the charges, they apparently involved allegations that he had signed documents authorizing insurance payments for patients he had not seen.

Dr. Smith, who has written ten books and appeared frequently on television talk shows, had in recent years been working in "nutrition-oriented" clinics with chiropractors, homeopaths, and other nontraditional practitioners. He is widely known as a critic of traditional medicine.

"The Board felt that my work was inappropriate and dangerous," Dr. Smith told me during an interview. (He would sign the insurance papers outlining the patient's treatment plan. Insurance companies began questioning the number of addresses Smith had since the clinics were located in three different parts of town.) "The Board said that I wasn't there to see each patient, that I wasn't acting as a proper doctor because I wasn't practicing the way doctors practice, that it wasn't real medicine because I wasn't using drugs. But people were getting well."

"I've been treating things successfully with a different approach and have been going against the mainstream. That bothered the board," said Dr. Smith, who is 65. "I retired before they asked for it. I was about to quit anyway." Smith insisted that his behavior could not be characterized as fraudulent. "If someone has a valid license and is not lying or cheating, why shouldn't he be reimbursed by the insurance company?"

This was not the first time Dr. Smith faced action by the Oregon Board of Medical Examiners. In 1973, he was ordered to surrender his narcotics license and was placed on probation for ten years for prescribing medication that was "not necessary or medically indicated" for six adult patients, one diagnosed as hyperactive and the other five as heroin addicts. He was also ordered to confine his practice to pediatrics.

According to a 1980 article in *The Washington Post*, Dr. Smith, like many pediatricians, had prescribed

Ritalin to calm hyperactive children. After working in a free clinic for drug addicts, he theorized that many heroin addicts had been hyperactive children and prescribed Ritalin for them also. However, trouble arose when some of the addicts sold his prescriptions to buy heroin. Ritalin is a controlled substance, and Smith did not have federal approval to run a program for addicts. In 1974, the Oregon Board agreed to allow Smith to write prescriptions for narcotic drugs under certain conditions, but in 1975, he was again restricted because the Board felt he was prescribing Ritalin for too many children. His probation lasted until 1981.

A native of Portland, Smith graduated third in his class from the University of Oregon Medical School and completed a residency in pediatrics. After entering practice in 1951, he worked as a pediatrician and became a clinical professor of pediatrics at the University of Oregon Medical School. Shortly after the Board's action in 1973, he turned to "nutritional therapy" and allied himself with naturopaths, homeopaths, and chiropractors. Later he became the first physician named to the board of the Portland-based National College of Naturopathic Medicine. He is a frequent speaker at health food industry seminars and has also lectured at dental meetings.

Smith contends that nutrition plays a major role in behavior and that nutritional remedies are helpful in a wide range of diseases and conditions. He claims, for example, that allergies, alcoholism, insomnia, hyperactivity in children, and a variety of other ailments are the result of enzyme disturbances which can be helped by dietary changes. He recommends a variety of food supplements and avoidance of white sugar, white flour, pasteurized milk, and other foods that are not "natural".

His books include *The Children's Doctor, Feed Your Kids Right, Improving Your Child's Behavior Chemistry, Encyclopedia of Baby and Child Care, Feed Yourself Right, Foods for Healthy Kids, Dr. Smith's Low Stress Diet*, and *Dr. Smith's Diet Plan for Teenagers*. Most of them were published by the trade division of McGraw-Hill, a leading publisher of college textbooks.

PREMENSTRUAL SYNDROME: IS IT NUTRITION-RELATED?

Therese Beaudette, M.S., R.D.

Many women experience symptoms preceding their menstrual periods. While some have similar symptoms each month, others report differences in incidence and severity from one cycle to the next. These symptoms are commonly referred to as "premenstrual tension (PMT)" or, more commonly, "premenstrual syndrome (PMS)." Current public concern is reflected by the existence of more than 200 free-standing clinics and information sources directed at PMS within the United States. However, there is considerable scientific debate over the nature of this problem, how it should be treated, and even whether it is actually a clinical entity.

The fact that symptoms occur in cycles related to menstruation has been observed for centuries. PMS was first postulated as a clinical disorder by Robert T. Frank, M.D., in 1931. He defined it as a specific and severe syndrome of "indescribable tension and irritability" with a "desire to find relief by foolish and ill-conceived acts" and relieved by the onset of the menstrual period.

During the 1970s, PMS was even used as a legal argument for diminished responsibility in the trials of three women in Great Britain who were acquitted of murder. However, in 1982 an attempt to use this plea in the United States was unsuccessful.

Definition

The scientific community has not agreed upon an exact definition of PMS. In general terms, however, it can be defined as a combination of physical and/or emotional symptoms that occur before menstruation and disappear or become minimal during menstrual periods. The symptoms can include tension, depression, irritability, fatigue, difficulty in concentration, crying spells, aggression, headaches, abdominal bloating, swelling of the hands and feet, breast tenderness, constipation, acne, abnormal thirst, and cravings for sweets

and/or salty foods [*American Journal of Obstetrics and Gynecology* 153:599-604, 1985]. Usually relief occurs when periods begin, but if periods are delayed, the severity of symptoms increases.

PMS should be differentiated from dysmenorrhea (menstrual distress), which can include crampy lower abdominal pain, headache, nausea, and diarrhea. These complaints begin shortly before the onset of menstrual flow and usually last two or three days. Dysmenorrhea usually starts during early adolescence and diminishes after childbirth, while PMS usually starts during the late twenties and thirties and worsens with age and childbearing. Most women with dysmenorrhea do not experience PMS and vice versa.

Statistics on PMS are related to the criteria used to define it and the method of recording the symptoms. Based on questionnaire data, 70-90% of women in the United States report recurrent premenstrual symptoms, but only a small percentage report changes severe enough to interfere with their functioning. Researchers who have compared women's recall of past PMS symptoms with what they report in a daily symptom diary have found that diary symptoms are generally less severe.

Possible causes

The cause of PMS is unknown, but it seems unlikely that a single cause is responsible for the wide variety of symptoms involved. Hormonal, nutritional and psychological factors have been suggested [*Journal of Reproductive Medicine* 30:113-126, 1985].

The hormonal patterns of the menstrual cycle indicate that PMS symptoms closely follow the secretion of progesterone. Many workers have suggested that progesterone excess or deficiency is a cause of the syndrome. Since progesterone appears to have a sedative

effect on the central nervous system, a deficiency could account for the symptoms of tension and irritability. Excess estrogen has been theorized to cause fluid retention, fullness of the breast, and abnormal carbohydrate metabolism. However, no one has found a hormonal distinction between women who have PMS and those who have not.

Several nutritional theories have been proposed. During the 1940s it was suggested that B-vitamin deficiency might lead to an estrogen excess that caused symptoms. Although the suggestion was based on studies with rats, reports alleging successful treatment in humans soon followed. After it was noted that women with severe vitamin B₆ deficiency actually had normal estrogen metabolism, vitamin B therapy lost its popularity until it was discovered that B₆ is involved in the synthesis of serotonin, a brain chemical related to mood.

Some speculations have centered on low vitamin A levels as a causative factor in PMS. Positive results have been alleged in uncontrolled studies, but no well-designed study has been reported. The possibility that a cyclic vitamin deficiency exists in PMS seems remote.

Some workers have suggested that stress and other symptoms of PMS are related to magnesium deficiency. Guy E. Abraham, M.D., and a colleague have reported that the magnesium level in the red blood cells of 26 women with PMS was lower than in 9 women without PMS. But blood levels were normal in their study, and no controlled study of magnesium administration for PMS has been reported [*Postgraduate Medicine* 77(7):32-37, 1985].

Because some PMS patients complain of increased appetite, cravings for sweets, fatigue, dizziness and "the shakes," it has been speculated that low blood sugar (hypoglycemia) may be responsible. This seems quite unlikely, however, because premenstrual symptoms are rarely confined to those times when hypoglycemia might be expected, such symptoms are not relieved by eating, and hypoglycemia can occur in women without PMS [*Comprehensive Therapy* 11:12-15, 1985].

Extensive research has been done to try to document sodium and fluid retention as a cause for PMS. While premenstrual weight gain has been found in some cases, it has not been consistently noted, even in hospitalized subjects on strictly controlled diets. It is clear that some women experience significant fluid retention before their periods. But voluminous literature on this subject reveals that weight gain and other symptoms don't always occur together, and that symptoms often fail to improve with diuresis alone. Local accumulations of fluid could cause headache, breast pain and gastrointestinal symptoms without a significant increase in body weight. Water may simply shift between various body compartments.

Animal research shows that changes in food consumption during the menstrual cycle are related to hormonal changes. An early human study found that 37% of 249 women reported a craving for sweets during the premenstrual phase, while 23% reported a generalized increase in appetite. Other studies have found that women who reported severe PMS symptoms also recorded higher caloric intakes. However, it is not known whether these events are causally related to each other.

Patients with PMS are sometimes thought to be more neurotic than normal women, but psychological testing has found similar neuroticism scores in women with and without the problem. While some researchers have related PMS to marital discord and other stresses, a purely psychogenic explanation for PMS does not appear possible. More widely accepted is the theory that physiologic factors cause premenstrual symptoms but personality characteristics and stresses of daily living influence their severity. An excellent scientific review of the subject of premenstrual syndrome appears in the *American Journal of Obstetrics and Gynecology* 155:921-936, 1986.

Last year an advisory committee of the American Psychiatric Association proposed a diagnostic category called "late luteal phase dysphoria," which would be applied only if premenstrual symptoms are severe enough to cause marked impairment of social and occupational functioning and have occurred during a majority of menstrual cycles during the past year. However, critics of this proposal felt that evidence of its validity was lacking and that it had such a high potential for misuse, particularly against women, that it should not be included. Because of this controversy, the APA's 1987 *Diagnostic and Statistical Manual of Mental Disorders* lists "late luteal phase dysphoria" in an appendix called "Proposed diagnostic categories needing further study."

Diagnosis

There is no consensus on the number or severity of symptoms needed to establish a diagnosis of PMS. Nor are there clear-cut diagnostic tests that can determine whether or not a woman has it. The diagnosis is suspected from the patient's history and established by doc-

umenting the relationship of symptoms to menstruation using prospective charting. For this procedure, both symptoms and menses must be charted daily for several months. Recording more than three symptoms can make the chart confusing. Therefore, only predominant symptoms should be noted. Charting will clarify whether symptoms actually recur before periods or occur throughout the menstrual cycle.

Medical evaluation may include a discussion of possible sources of stress. Hormonal measurements are expensive and are unnecessary because their significance in diagnosing PMS has not been established.

Self-screening questionnaires are available from PMS clinics and have been published in women's magazines.

Treatment

Although most treatments proposed for PMS have been reported as successful in some women, none has been consistently effective in double-blind studies (studies in which neither the subject nor the researcher knows who receives the experimental treatment and who received a placebo). This is particularly important because the placebo response rate in women with PMS is quite high—perhaps 50%.

The majority of women with PMS do not need treatment. Only those whose symptoms disrupt their life need intervention, and for most of them, symptoms respond to any demonstration of concern. The use of general measures such as simply helping the patient understand what may be occurring within the body often results in significant improvement.

The most commonly recommended treatments for PMS are diet, exercise, vitamins and progesterone [*Journal of Reproductive Medicine* 29:705-711, 1984]. A recent survey indicated that 60% of physicians who treat PMS patients recommend some type of dietary modification or supplement [*Drug Intelligence Clinical Pharmacology* 19:714, 1985].

Dr. Abraham, the leading proponent of dietary therapy for PMS, believes that regulating the intake of certain foods and beverages can help decrease the symptoms of PMS. He recommends a low-sodium "hypoglycemia" diet with limited use of dairy products, despite the fact that low calcium intake increases the risk of osteoporosis.

Although supplementation with vitamin B₆ is commonly recommended, little evidence of effectiveness has been reported. In one double-blind study a daily dose of 100 mg appeared to be more effective than a placebo. In another, it was no more effective. A study of one patient found 50 mg of B₆ more effective than a placebo. Another study showed positive results, but the dosage involved (500 mg/day) is unsafe. Another study using 250 mg doses found no benefit over placebo. Vari-

ous results have been reported in uncontrolled studies.

Vitamin B₆ poses a risk in high doses. In 1983, damage to the nervous system was reported in individuals who took daily doses of 2,000 mg or more for three or more months. (The RDA is 2 mg.) One patient in the first such report was a 27-year-old woman who took vitamin B₆ for PMS symptoms and increased her intake to 5,000 mg a day. Nerve damage has also been reported in a few individuals who took 500 mg doses and in one person whose reported intake was 200 mg/day for three years. Their symptoms, which resembled those of multiple sclerosis, included numbness and tingling of the hands, difficulty in walking, and electric shocks shooting down the spine. Although all the afflicted individuals improved greatly when they stopped taking B₆ supplements, some did not recover completely. The maximum safe dose of B₆ is unknown but probably does not exceed 50 mg daily.

One study found that daily administration of 600 mg of vitamin E to 26 women with fibrocystic disease improved breast tenderness, a symptom seen in PMS. However, subsequent studies with larger numbers of women found no significant difference between women receiving vitamin E and those receiving a placebo.

Other studies have examined the relationship between consumption of caffeine-containing beverage and PMS. One study found that 13 of 20 women who abstained from caffeine had complete resolution of symptoms in one to six months. A survey of 295 college-aged women found that caffeine intake was strongly related to the presence and severity of PMS. However, the author noted that consuming large amounts of any liquid may be related to PMS and also that women who consume large amounts of caffeine and cola may differ from women who do not in ways that are causally related to PMS.

Women with PMS may benefit from avoiding alcohol since it is a mood-altering drug which can cause depression and feelings of hopelessness. Some women have a decreased tolerance for alcohol premenstrually and may become intoxicated from drinking their usual amount. Eliminating caffeine and nicotine can reduce premenstrual anxiety and irritability, and sodium restriction is sometimes recommended to relieve PMS symptoms such as bloating, edema and weight gain.

Daily exercise can decrease PMS symptoms. Women who are physically active tend to suffer less from PMS. This lessening of symptoms may be linked to the rise in endorphins that occurs during exercise (the so-called "runner's high") or perhaps to an adjustment of body fluid status. Regular aerobic exercise can increase one's sense of well being, decrease fluid retention, and help relieve depression.

Progesterone therapy is a controversial issue in the treatment of PMS. Some clinicians enthusiastically

support its use, but others believe that it can worsen the syndrome because PMS occurs when body levels of progesterone are highest. Double-blind controlled studies have failed to indicate that progesterone was better than a placebo. Although progesterone scored better than no therapy, so did a placebo. The use of progesterone for treatment of PMS does not have FDA approval.

Synthetic progestins have also been tried. Patients who responded to one oral preparation did not necessarily respond to another. Well-designed studies with a variety of synthetic and natural progestational agents may clarify the value of this approach.

Studies using synthetic androgens (male hormones) and progesterone/estrogen combinations (oral contraceptives) have been inconclusive. Although some women may improve while taking a particular pill, others show no effect or worsening of such symptoms as depression and abdominal bloating.

Diuretics have been widely used for treating PMS on the premise that it is associated with salt and water retention. However, double-blind studies have yielded various results, with several diuretics performing no better than placebos. Spironolactone (Aldactone), a diuretic which is also an anti-androgen, showed positive results in two double-blind studies.

Another proposed remedy for PMS is evening primrose oil, which contains a fatty acid called gamma linolenic acid (GLA). Its use is based on speculations that PMS involves a deficiency of GLA that causes hormonal imbalance. Primrose oil is available without a prescription because it is marketed as a nutritional supplement. Its leading proponent is Dr. David Horrobin, a former professor of medicine at the University of Montreal who is affiliated with a major manufacturer of primrose oil supplements [see NF 1:20].

Some data suggest that GLA may play a role in PMS, primarily in symptoms related to the breast, but no large, well-designed studies have been performed. Primrose oil also contains vitamin E. The effect of regularly using vitamin E or primrose oil supplements is unknown. However, a recent report by Robert M. London, M.D., and colleagues at Johns Hopkins University suggests a possible role for vitamin E in treating PMS symptoms. In a controlled study of 41 women, they noted significant improvement in those receiving supplemental vitamin E. This study and several others were reported in a symposium on PMS in the June 1987 issue of the *Journal of Reproductive Medicine*.

Dr. Abraham has reported that women with PMS consume more sugar, refined carbohydrates and dairy products, whereas women with no symptoms consume more of certain vitamins and minerals. Based on this information, he formulated and is marketing Optivite, a nutritional supplement which contains 29 ingredients, including high doses of vitamins A, C, E, B₆, other B-

vitamins, magnesium, iron and zinc. During the past few years he has claimed positive results in studies of small numbers of women divided into groups according to symptoms. But research with larger numbers of subjects is needed to clarify the significance of these trials and which if any of Optivite's ingredients may be helpful. This product, which costs \$18-\$21 per 180 tablets, is considerably more expensive than equivalent doses of B₆ alone.

Overview

Publicity has made women very aware of PMS, and an "epidemic" has resulted. But the lack of criteria for definition as well as a paucity of careful studies has led to a situation where publicity of the problem exceeds the science dedicated to researching its causes and treatment. Future research must focus on establishing uniform diagnostic criteria and conducting well-designed studies of proposed treatment regimens, both pharmacologic and nutritional. Meanwhile, for those who suffer from PMS, some commonsense suggestions may help:

- For premenstrual water retention (abdominal bloating and swelling of the hands and feet), refrain from adding salt at meals and restrict sodium-containing foods at that time of the menstrual cycle.

- For breast discomfort or symptoms of anxiety, avoid or limit coffee, tea, cocoa, cola, other foods and medications that contain caffeine or related compounds. Although this may not help, it is harmless and relatively easy to do.

- Try to identify and deal with psychosocial stresses.

- If eating sweets appears to produce symptoms, try to satisfy cravings with complex carbohydrates (starches) rather than simple sugars.

- If vitamin supplementation is used, megadoses should be avoided.

Ms. Beaudette is author/publisher of *Seminars in Nutrition*, a bimonthly publication offering continuing education credits for dietitians. Information about this program can be obtained by writing to her at P.O. Box 3525, Littleton, CO 80161.

 Suma: A Questionable New Herb

NEW HYPE FOR B-VITAMINS

The Food and Drug Administration has expressed concern over Ener-B, a vitamin B₁₂ gel administered inside the nose. On February 26, 1987, the agency sent a regulatory letter to the manufacturer, Nature's Bounty, of Bohemia, New York, stating that Ener-B is an unapproved new drug that is illegal to market without FDA approval.

Full-page ads in *American Health*, *Health, Prevention*, *Bestways*, *Let's Live*, *Vegetarian Times* and *Total Health* state: "Get a BURST of ENER-B . . . Just a tiny dab of ENER-B gel placed inside the nose delivers the B₁₂ boost simply not possible with tablets." Some ads call B₁₂ "the 'hard-to-get' vitamin." Flyers for distribution through health food stores promise, "You'll feel good about it, especially the morning after." Ads in the trade press state: 1) Vitamin B₁₂ is very difficult to absorb; 2) Ener-B delivers ten times more B₁₂ to the blood than tablets; and 3) Ener-B makes vitamin B₁₂ tablets obsolete." A 12-dose package retails for \$11.95.

Ener-B is being marketed with the help of G.S. Schwartz & Co., Inc., a Madison Avenue public relations firm. Materials distributed to the press described the dangers of pernicious anemia ("one of the few vitamin deficiencies that still kills Americans") and noted that the body's ability to absorb B₁₂ decreases with age. They also stated that "Nutritional authorities have described Vitamin B₁₂ as having the ability to restore or increase energy levels." Media outlets were notified that Earl Mindell, author of *Earl Mindell's Vitamin Bible*, was available for interviews about the product. Mindell also spoke to retailers at Natural Foods Expo '87 West, held in March. Among other things, he claims that "chronic low-grade shortages plague many individuals who have otherwise balanced diets."

Ener-B attracted considerable attention through an article in *People Magazine* which began, "They claim it can give an instant energy high, that lasts for 48 hours . . . Snorting it has great appeal for those who used to inhale unhealthy stuff, and now they can still practice the ritual." Company officials think this article may have triggered the FDA action.

Interviewed by *Natural Foods Merchandizer*, a company official claimed that Ener-B is "a food supplement taken exclusively for its nutritional value." But FDA nutritionist Marilyn Stephenson responded, "There is no scientific evidence to support the need to sniff vitamins in a healthy, normal population. Generally people get all the B₁₂ they need in their diet. The only people who don't get enough are those with problems like pernicious anemia. They can't absorb the vitamin, so they get B₁₂ injections. That's a drug use and these people are treated by physicians."

Nature's Bounty has petitioned the FDA to issue a regulation or guideline relating to food classification and methods of consumption and to refrain from taking enforcement action until such regulation or guideline has been promulgated and made effective. According to the petitioners, Ener-B should be classified as a food substance even though it is consumed through the nose.

An alternate route and B₁₂ hype are involved in another new product: Total B, a mixture of the eight B-vitamins ("including 250% of the RDA of the hard-to-get vitamin B₁₂") plus vitamin C. This product is a liquid administered under the tongue with a dropper. According to its manufacturer, Real Life Research, of Shanton, California, "Total B was originally developed to give professional athletes a competitive edge by allowing them to increase their stamina and resistance to disease." The company also claims (falsely) that B-vitamins and vitamin C are not stored in the body and therefore must be taken daily, and that "B Complex helps reduce stress, build stronger immune systems and increase energy."

Literature from the company's public relations firm states that Total B is endorsed by Bernd Friedlander, D.C., who was "a pioneer in the research and use of free-form amino acids for improving athletic performance" and is "a godsend to dozens of Los Angeles area elite athletes, including members of the Rams and Raiders teams, as well as the entire UCLA women's crew team."

Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

BRIEFS

Nevada naturopaths delicensed. The Nevada legislature has repealed a 1981 law under which naturopaths were licensed. According to an article in the *Las Vegas Review-Journal*, only three naturopaths were practicing in Nevada and serious questions had been raised about their credentials. The board had no record of an application from one of the practitioners. Another claimed to have a degree from a school that does not exist. And the third claimed to have a degree from a school that was closed during the years he said he was a student.

Verdict in raw milk suit. A jury has awarded \$40,000 to the family of a man whose death they believe was caused by bacteria in Alta-Dena Certified Dairy's raw milk. According to testimony during the 2½-week trial, the victim, Paul B. Telford of El Monte, California, drank the milk several weeks before his death in 1982 when he was undergoing radiation therapy for lung cancer. Dairy officials, who blame the cancer for Telford's death, are appealing the verdict. Alta-Dena is the nation's leading producer of raw milk products, selling 10,000 gallons a day, mostly in Southern California. The FDA is currently formulating a ban on interstate shipments of raw milk under a federal court order.

Alcohol and breast cancer. Two research groups reported in the May 7 *New England Journal of Medicine* that drinking alcoholic beverages several times a week is associated with an increased risk of developing breast cancer. Analyzing these reports, the July *Harvard Medical School Health Letter* concluded that "alcohol intake is in some way associated with the probability of developing breast cancer." However, the newsletter points out: 1) the findings do not prove cause-and-effect; 2) no one has devised a biological model to explain how alcohol exposure might lead to breast cancer; 3) the studies are being widely misinterpreted to mean that moderate alcohol intake as much as doubles the risk of breast cancer; 4) the increased risk is greatest in women below 50, in whom breast cancer is not common, so that their overall risk is still low; 5) if the studies are accurate, drinking might be responsible for 1-2% of all cases of breast cancer in the United States; 6) the studies were not designed to help predict what benefit might result from abstinence; and 7) the situation provides "a suitable occasion for women to reassess the amount they drink and the reasons they drink. But it should not be an occasion for terror and guilt."

Diet and health report. The Council for Agricultural Science and Technology (CAST) has published an excellent report on nutrition-related health issues. Prepared by a task force of prominent scientists, its 62 pages cover obesity, diabetes, heart disease, high blood pressure, cancer, osteoporosis, tooth decay, food allergies, diet and behavior, diet and senile dementia, and additives and toxic chemicals in foods. Though the report was written primarily for professionals, most of it can be understood by laypersons. Copies are available for \$5 from CAST, 137 Lynn Avenue, Ames, IA 50010.

Free dietitian list. Consulting Nutritionists in Private Practice, a practice group of the American Dietetic Association, has compiled a list of Registered Dietitians in private practice in all 50 states. A free copy can be obtained by sending a stamped, self-addressed 4" x 9½" envelope to Aviva E. Croll, R.D., M. Ed., P.O. Box 41, Bloomingdale, IL 60108.

Budding researchers. Two freshman students at Johnston County Community College in Overland Park, Kansas, have recorded some interesting observations of eating habits. Carrie Carmichael noted that five out of ten six-year-olds who brought lunch to a YMCA day camp threw their sandwiches into the trash after consuming dessert and a soft drink. Nicole Linck, who observed patrons at a frozen yogurt shop, judged that 37 out of 83 (45%) were overweight. The overweight individuals ordered more quickly and were far more likely to order toppings; but four changed their orders to larger sizes after reading a sign that said, "yogurt is 95% fat free."

Safeway accused of illegal boycott activity. The U.S. Commerce Department has charged Safeway, the nation's largest supermarket chain, with 449 violations of the U.S. law prohibiting cooperation with an unsanctioned foreign boycott (the Arab economic embargo of Israel). If found guilty, the company could face fines of up to \$10,000 per violation. Safeway called the charges "preposterous," but the head of the Commerce Department's Office of Anti-Boycott Compliance said that months of private negotiations had failed to reach an agreement. The case could take years to resolve, first through administrative procedures and later, perhaps, through the courts.

Anthology published. The Dushkin Publishing Group, Sluice Dock, Guilford, CT 06437, has published *Nutrition 87/88*, its first annual sourcebook of nutrition articles. Edited by Charlotte Cook-Fuller, Ph.D., of Towson State University, it contains 65 significant articles from newspapers, magazines, newsletters and scientific journals. Copies can be ordered by mail [\$9.50] or by calling 1-800-243-6532.

Fundraising ploy. Last year, Kentucky State Representative Tom Riner offered six Fiber Energy Bars to recipients who contributed \$25 to his campaign fund. The bars were made by United Sciences of America (USA), a multilevel company which went bankrupt this year following adverse publicity and legal difficulties [see NF 4:25-31]. Riner's letter claimed (inaccurately) that the bars were "the result of three years of work by Nobel prize-winning scientists." Despite the hype, Riner was re-elected. He and his wife, who preceded him in office, also sell Shaklee products.

Suit over stomach staples. A 23-year-old man whose stomach staples popped has filed suit. According to *Physicians Financial News*, the 305-pound man had 70 staples implanted as a weight-control measure. However, two days later he was allowed near a refrigerator and ate so much that the staples burst. Disclaiming liability, the hospital has replied that the patient's negligence was to blame, that he was aware of his prescribed diet and knew the consequences of not staying on it.

FDA lowers enforcement priority. The FDA's action plan issued in July 1985 listed health fraud as one of ten priorities [see NF 2:48, 3:2]. Under this program, the agency conducted an extensive public education program which included a national health fraud conference and 21 regional conferences. *A Plan for Action, Phase II*, issued in May 1987, no longer lists health fraud as a priority but covers it in a single paragraph among more than 40 pages of plans. During the past two years the agency has taken very few enforcement actions against quack products. The new document suggests this policy will continue by promising immediate action only against "direct health hazards" (which are rare) and public education against "economic frauds" (which are rampant). Strong educational efforts will continue, however, including another national health fraud conference during 1988. The plan's top goal is efficient review of proposed AIDS therapies, vaccines and related products.

Food safety for travelers. Whereas travel to Western Europe, Scandinavia, Australia and New Zealand poses no greater health hazard than travel in the United States and Canada, the risks of travel to other areas depend mainly on the traveler's local living conditions and length of stay. According to an article in the July 1987 *Drug Therapy*, those who briefly visit large cities, stay at good tourist hotels, and eat only in reputable restaurants run little risk of contracting a serious food-borne disease. Well-cooked meat and fish are generally safe unless contaminated after cooking; however, cysts of the organisms that cause toxoplasmosis, trichinosis and tapeworm remain infectious when meat is smoked, salted or dried. Raw vegetables, especially lettuce, should be avoided, since it is virtually impossible to clean them of the cysts or eggs of certain parasites. Peelable raw vegetables and fruits with unbroken skins are generally safe if the diner peels them and discards the skin. It is also prudent to forgo dairy foods, including cheeses, because improperly pasteurized dairy products can transmit serious infections. However, milk that has been boiled can be safely consumed. Untreated water is a vehicle for many disease-causing organisms. Boiled water is safe, and carbonated beverages are usually sterile. But using ice without being sure it is sterile is one of the most common errors travelers commit. Bottled water is not necessarily safe, and alcohol does not sterilize local water or ice. Beer and wine present few infection hazards. Following such rules does not necessarily prevent uncomplicated traveler's diarrhea, but it does reduce the risk of developing more serious food-borne bacterial and parasitic diseases.

QUESTION BOX

Q. Should parents be concerned and/or intervene if their child is under six and obese?

A. A "wait-and-see" approach is unwise in children who are developing obesity. Although clearly identifiable hazards are rarely present in the pediatric age group, the problem of obesity increases with its duration. Moreover, obesity during childhood can have adverse psychological and behavioral consequences. Severe caloric reduction is unwise since this may hinder growth. Parents should try to prevent undesirable weight gain by establishing a balanced diet, good eating habits, and increased activity patterns. However, excessive pressure to lose weight should be avoided because it could lead to unhealthy dieting practices or eating disorders such as anorexia or bulimia.

MISLEADING CLAIMS MADE FOR GRAPEFRUIT JUICE

Stephen Barrett, M.D.

According to an ad in the October 1986 *Health Magazine*: "Keeping healthy and fit takes work. And all that work takes its toll; like the loss of fluids and elements your body needs. Florida's got a refreshing way to give them back. 100% grapefruit juice. It's high in potassium, the one thing active people can't get enough of in their diets. Potassium balances sodium levels to regulate blood pressure and fight off fatigue." During the same month, a similar ad in *Prevention Magazine* included the message: "Florida grapefruit juice. It's sodium free and full of potassium, a combination that helps control blood pressure."

These statements, of course, are a mixture of fact, fantasy and outright falsehood. The idea that potassium is "the one thing active people can't get enough of in their diets" is ridiculous. The idea that the "work" of keeping fit "takes its toll" by causing "loss of fluids and elements your body needs" is misleading. People who exercise on a hot day will need to replace fluid loss. But "keeping fit" does not create any special nutritional needs that require special attention to one's diet. Nor do people who "keep fit" have a greater need for grapefruit than anyone else.

Lowering dietary sodium won't help everyone with high blood pressure, but only those "sensitive" to sodium. High-blood-pressure patients taking diuretics that increase potassium excretion need to have adequate intake of potassium and are sometimes advised to consume potassium-rich foods. But people at significant risk of potassium depletion from diuretics usually require a potassium supplement.

The statement that "potassium balances sodium levels to regulate blood pressure and fight off fatigue" suggests that eating grapefruit can help prevent high blood pressure—which is false. Nor can eating grapefruit "fight off fatigue." Perhaps the origin of this statement is the idea that potassium depletion caused by diuretics can cause muscle weakness. But again, the amount of potassium needed in such situations is more than grapefruit is like to supply.

After seeing these ads, I fired off a complaint to the National Advertising Division (NAD) of the Council of Better Business Bureaus in New York City. When NAD investigated, a Commission spokesperson said that the potassium deficiency claims were based on an opinion survey of athletes conducted by a nutrition consultant plus a study of the effects of intense conditioning in young men undergoing basic military training. In ad-

dition, a literature survey was provided as substantiation of the roles of sodium and potassium as nutritional factors in controlling blood pressure. NAD's investigator replied that the data obtained from the studies could not support broadly stated claims and expressed concern that the ad overstated the benefits of drinking normal quantities of grapefruit juice.

The spokesperson informed NAD that the claims had been discontinued and that a new campaign will promote grapefruit as a significant source of potassium when part of a healthy regimen, including proper diet and exercise. However, an ad from the "new" campaign states that grapefruit juice is "high in potassium with no sodium: a combination that, along with proper diet and exercise, can help control blood pressure." I believe this is still misleading because it has not been shown that drinking normal quantities of grapefruit juice will actually lower blood pressure.

These ads are part of a growing tendency of food producers to advertise biochemical facts about individual nutrients in their foods—a tendency that the FDA believes has great potential for fraud [see *NF* 3:89-91]. But the remarkable thing about the grapefruit ads is not their content but the fact that they were placed by the Florida Department of Citrus—a government agency! Funded by an excise tax on citrus fruits, its functions include supervision of the citrus industry, scientific research, and "a forceful advertising and promotional program." According to the Department's publicity director, their ads are written by an advertising agency and reviewed by the Department's scientific research department for accuracy.

Information about the Florida Department of Citrus was supplied by Debbie Carnegie, M.S., R.D., of Tallahassee, Florida.

CAN NUTRIPATHY TRANSFORM THE WORLD?

Jeff South

Why bother with medical school? For a lot less time and money, you can still be a "doctor" with a diploma on your wall from the American College of Nutripathy, a correspondence school in Scottsdale, Arizona. The school is headed by Gary Martin, who once ran a sales motivation institute. Its diplomas look as official as Harvard's. But critics say they are as bogus as the formulas Martin touts as effective against cancer, arthritis and other ailments.

Ads for the school appear regularly in *Let's Live*, *East West Journal*, *Medical Self-Care*, *Vegetarian Times* and *The Nutrition and Dietary Consultant*, all of which promote nutrition faddism. Many of the ads invite readers to "come help transform the world" by becoming a Doctor of Nutripathy.

A school brochure claims that "in mastering Nutripathy, you will be in possession of the true art of healing. You will know more about the Science of Health and Nutrition than the medical profession, chiropractic profession, osteopathic profession, homeopathic school and the so-called wholistic health school . . . You will have accomplished in a few months that the medically oriented school of nutrition has not achieved in all of its existence." The brochure also says, "We do not cater to the complicated and extensive body of trivia and irrelevance that today goes under the name of nutritional science."

Another brochure describes nutripathy as "the condensation of most all natural healing and counseling techniques available today . . . It is the basics 'boiled' from literally hundreds of different therapies and techniques." This brochure also states that nutripaths are different from naturopaths because "a Doctor of Naturopathy is trained to diagnose and treat disease . . . Doctors of Nutripathy have nothing to do with disease. Our concern is with health. We realize that the true cause of disease exists in the area of attitude, beliefs, lifestyle and environment . . . We begin on a very physical level and, as we learn about the client, gradually

elevate them physically, mentally and spiritually to become more of what God created them to be."

Martin claims that nutripathic tests can detect "imbalances which, if left to mature, must ultimately manifest as some form of disease process." He claims "to discover the root cause of the disease while it is still in the PREDIAGNOSABLE stage."

The college teaches financial health, as well as physical, and explains "how to set yourself up so that you can operate totally tax-free, legitimately." The school itself has tax-exempt status as a ministry of the Eternal Life Center, a nondenominational church which Martin established and serves as Pastor.

Martin says that the school was inspired by a vision of god. He has told state authorities that its degrees are "religious degrees, used solely for religious purposes within a religious organization." So far the school has survived attacks by state officials and others who have labeled it "an imminent danger" to the public. But it is facing its biggest threats since opening in 1976. A state board says the school must obtain a license, and the Arizona Attorney General's Office says it has reason to believe that graduates of the school are using their degrees to engage in the unlicensed practice of medicine.

A school brochure states: "The fact that we do offer business training should not be construed to imply that we are training you for a trade or vocation." But the brochure also encourages graduates to team up with a chiropractor, medical doctor or osteopath: "This way, you can work with insurance cases, which means you can reach many more people, and you have an instant practice. In addition, it shelters you from the 'establishment' until you feel comfortable enough to hang out your own shingle."

Martin's own shingle hangs at 6821 E. Thomas Road, which lies between a surgeon's office and an urgent care center. The building also houses the college, the Eternal Life Center, Nutripathic Formulas (a for-profit company that sells nutrition products and other

items by mail), and Natural Health Outreach, a clinic where Martin practices for "suggested donations" of up to \$700.

According to a clinic brochure, "Dr. Martin and Staff counsel and teach nutritional counseling, biochemical analysis, symptomatology, reflexology, iridology, sclerology, nutripathic therapy, mineral (hair) analysis, kinesiology, color therapy, radiesthesia techniques, stress counseling, colonic therapy, massage therapy and awareness techniques." In the Yellow Pages—under "Nutritionists"—the clinic advertises that its doctors can handle weight loss, fatigue, and other physical and mental matters. Martin also offers counseling by mail for a suggested donation of \$25.

A former patient, who requested anonymity, says he gave urine and saliva samples and got a computer printout that described his energy levels as dangerously low. The printout recommended frequent colonics (enemas), exercise on a small trampoline sold by Martin, and a diet that included many of Martin's products, such as Sprinkle, a powder made from raw vegetables, which costs \$6.45 for 4½ ounces. When the patient refused to pay the full "suggested donation," his balance due was turned over to a collection agency.

The urine/saliva test used by Martin was developed about 50 years ago by Cary Reams, a self-proclaimed biophysicist who was prosecuted during the 1970s for practicing medicine without a license. Reams, who also claimed to be guided by god, devised "a mathematical formula for perfect health, based on the biophysical frequencies of living matter." The formula, which Martin calls 'your Nutripathic Portrait,' looks like this:

1.5 6.4/6.4 7 1 3/3

According to Martin's book, *Nutripathy: The Final Solution to Your Health Dilemma*, the first three numbers represent sugars excreted in the urine and the acidity (pH) of the urine and saliva, and indicate how much "energy input" you have. The other numbers, said to represent your "mineral salts index, urine debris index and nitrate nitrogens over the ammoniacal nitrogens index," indicate how much energy your metabolism is using. "A low energy input and high energy drain," says the book, "means degeneration, rot, decay and death."

After evaluating an insurance agent, Martin once wrote: "The man may be in the early stages of slowly turning into a garbage dump, rotting from the inside, thereby experiencing nothing more at this time than an extreme energy loss."

Martin's book claims that "Nutripathy has nothing to do with disease" but is "based on the religious concept that God created man with certain nutritional needs and placed the source of those dietary needs in natural foods. Nutripaths believe that a properly combined diet of natural foods will allow a person to live in a

state of perfect health." Readers who can't find a nutripath in their community by looking under "Nutritionists" in the Yellow Pages are invited to locate one through the American College of Nutripathy, which charges \$20 for the "computer search" involved.

State officials are concerned primarily about the college, which has awarded hundreds of degrees to people throughout the United States and elsewhere.

The "degrees" offered are Bachelor of Nutripathic Science ("B.S."), Master of Nutripathic Science ("M.S."), Doctor of Nutripathy ("D.N."), Doctor of Nutritional Philosophy ("Ph.D."), Doctor of Nutripathic Philosophy ("Ph.D."), and Doctor of Nutripathic Theology ("Th.D."). On his letterhead, Martin is listed with three of these degrees plus "N.M.D.," although he denied any recollection of this when I interviewed him at his office in July. ("N.M.D." stands for "Doctor of Nutritional Medicine," a credential obtainable for \$250 from the American Nutritional Medical Association [see NF 3:52-53], whose 1986 directory listed him as "Gary A. Martin, NMD, DN, ThD, PhD.")

Martin's students work at their own pace and can get their degrees as quickly as they can pass the open-book tests, but those who don't finish in 1 or 2 years must pay extra. Those who wish to use nutripathy "on a professional basis" and desire "proper internship certification" are urged to take a \$100 two-day internship, which Martin describes as "the highlight of nutripathic education." Those who do so get a "certification plaque."

Martin insists that his courses require as much study as traditional programs. But even naturopathic officials in Arizona say his curriculum is a sham. "Naturopaths complete a college pre-med program and four additional years of study," says Milburn Shelton, who practices in Glendale. "Most then serve a two-year residency under an experienced colleague's supervision, and they must pass national and state exams." Martin is making "a deliberate attempt to mislead the public," says Shelton, who is on the Arizona Naturopathic Physicians Board of Examiners. "At a time when naturopaths are struggling for legitimacy from a skeptical medical establishment, Martin is making us all look like quacks."

Martin responded, "I don't think they like the

fact that nutripath sounds like naturopath. But Good-year didn't like Goodrich."

In 1985, the naturopathic board condemned the college as an "imminent danger to the health and well-being of the citizens of the state." The board also asked the Arizona Attorney General and the U.S. Postal Service to shut down the operation. Michael Cronin, a Phoenix naturopath, bought various school publications, including a book called *How to Practice Nutripathy and Prosper Beyond Your Wildest Dreams*, and turned them over to the authorities. "Gary Martin is creating a nationwide network of unqualified 'doctors' who know a lot more about lining their pockets than they do about healing," Cronin says.

In 1985, under a new state law, the Arizona Board for Private Postsecondary Education began regulating private degree-granting institutions. The panel told Martin he would need a license for his school. According to the board's minutes, Martin refused to apply or to heed a subpoena to appear before the panel. But Martin asserts that he did comply with the board's request for a meeting.

In December 1985, Martin's organization sued the board. The two sides wrangled for 1½ years. Then, as the case was set for trial in Maricopa County Superior Court, they agreed to drop the lawsuit and try to resolve their differences. The board since has ordered its executive director to inspect the school and report her findings.

Scottsdale police have also investigated and referred the matter to the Attorney General's office. Kristi Riggins, an assistant attorney general who handles fraud cases, won't comment on the case, but did say it can be difficult to prove a person claiming to be a minister is practicing medicine without a license because the law exempts religious healing.

Arizona law defines the practice of medicine as "the diagnosis, treatment or correction of, or the attempt or holding of oneself out as being able to diagnose, treat or correct any or all human disease, injuries, ailments, infirmities, or deformities, physical or mental, real or imaginary, by any means," but exempts "any person while engaged in the practice of religion, treatment by prayer, or the laying on of hands as a religious rite or ordinance." Martin, 42, who lives with his wife, Linda, in a north Scottsdale home befitting a medical doctor,

claims the law is on his side. He asserts that the college is an "educational ministry" of the Eternal Life Center, "a church for all religions." And he calls nutripathy "an ancient religious healing science which allows the body's God-given innate healing power to flow throughout the system."

Some of the school's literature cites the Bible and preaches "the Gospel of Christ-consciousness." But other publications appear secular: One brochure, touting the clinic as "a superior, wholistic health-care program unsurpassed in North America," never mentions theology. Neither do the college's ads.

Martin, who was reared a Methodist in Iowa, also denies that his graduates diagnose or treat illness. They merely "guide patients to the elimination of disease," he says. When counseling a patient, for example, Martin says he prefaces his advice with such remarks as, "If I were you . . ." In this way, he contends, he avoids breaking the law.

A school brochure states: "It is always possible that, if you exceed your boundaries as a doctor of nutripathy, you could be subject to the 'practicing medicine without a license' complaint. This is why it is imperative that you use the proper Nutripathic Disclaimer and Contract with every client, no matter how well you know the person or how you are related."

Noting that no state law requires nutripaths to be licensed, Martin urges new practitioners to "stay within the bounds of nutritional counseling. Don't diagnose and don't treat disease. This is what the establishment gets most uptight about. Just quietly do your thing. Help people get well the Nutripathic way and the word will spread . . . Years from now when we have 5,000 practicing Nutripaths, the patients who have been to these nutripaths are going to be our strongest allies when we have enough political clout to consider protective licensing." He warns, however: "If you do not mail a monthly newsletter to your patients you are not going to make it as a Doctor of Nutripathy. You must stay in touch with your people. People are fickle and programmable . . . Every patient who has ever been to a Nutripath needs to be logged, regularly mailed to, and asked, annually, whether or not they wish to remain on your mailing list. This is worth millions to you over a lifetime."

Nutripathic Formulas sells more than a hundred

EDITORIAL BOARD

EDITOR: Stephen Barrett, M.D. **SENIOR ASSOCIATE EDITOR:** Manfred Kroger, Ph.D. **ASSOCIATE EDITORS:** Denise Ferko-Adams, R.D., Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** Virginia Aronson, R.D., M.S.; John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Mark Fuerst; Kathy King Helm, R.D.; Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

products, including Toxoid Formula, which costs \$81.95 a gallon and carries a disclaimer: "We make no medicinal claims for this product." However, a 6-page brochure distributed by Martin contains 56 testimonials claiming that this formula has been effective against acne, cancer, colitis, diaper rash, poison oak, psoriasis, ulcers, varicose veins, warts, yeast infections, and dozens of other health problems. According to the brochure, an Illinois woman said the formula dissolved a lump on her right knee, and that her husband used it to heal a bruise he got sliding into home plate. "He even sprayed it on his B.V.D.s to keep them from sticking to the wound."

Federal laws require that drug products intended for the prevention or treatment of disease be labeled with adequate directions for their intended uses and cannot be sold across state lines without FDA approval. Toxoid Formula, for which claims are certainly being made, has neither adequate directions nor FDA approval.

At least one of Martin's graduates has been charged with practicing medicine without a license. Last October, Marcos Freddy Martinez of New York pleaded guilty and received a year's probation, according to Doris Crespo, an investigator for the Bronx District Attorney.

"Can the school really be held responsible for what the graduates do with their education?" Martin said when I described the case to him.

Martin's literature describes him as a rebel against the medical establishment. He discourages patients from seeking conventional treatment, which he calls "shamanism." He condemns vaccinations and states, "All drugs are evil." In another pamphlet, Martin said he had received a letter from a woman vacillating between his college and the University of Texas medical school's nutrition program. Martin replied: "You are torn between studying what you know to be the truth, versus an orthodox, impractical and basically worthless nutrition and dietetics curriculum." But Martin told me he has mellowed since making such attacks and recommends modern medicine for broken bones and life-or-death situations. He says his graduates focus on preventing illness by "educating people in the prediagnosis stage of life," before traditional methods can detect their diseases. And he says his school promotes "financial, social, physical, mental and spiritual prosperity."

Prospective students must purchase a \$13 packet containing an application, literature describing the school, a product order form, and a copy of *Nutripathy: The Final Solution*. Applicants must sign a statement acknowledging that "Nutripathy is a religious science of health" and that "Nutripathic methods are not for the purpose of diagnosing, alleviating, mitigating, curing, preventing or caring for 'disease' in any manner whatsoever." They must also agree not to use the knowledge they obtain for any such purpose and to "release the College, authors, publishers and/or any instructors

from any damages, claims or liability whatsoever, as a result of the information presented." The application fee is \$100, but the packet contains a \$100 credit certificate good for 30 days from the date stamped on the certificate.

Degrees from the school's Department of Nutrition cost \$1,995 each with advance payment or \$2,495 in installments. (In 1984, these fees were \$800 and \$1,000.) People who generate referrals by placing brochures in health food stores are promised a recruiting bonus of \$200 for each person who signs up for one of these courses. Participating stores are also promised \$200.

Students must get the bachelor's and master's degrees in nutripathy before pursuing a doctorate. For fees ranging from \$30 to \$400, the nutrition department also offers 25 "mini-courses," including "Nutripathic Arthritis Studies," "To Cleanse or to Surgery," "Nutripathic Emotional Recovery Studies," "Nutripathic Master Herbalist Course," and "Sin, Fear and Guilt Removal." Upon request, "a beautiful Certificate of Completion" is available for all mini-courses. The Mini-Course Curriculum Guide states that the courses "are not intended to replace physicians or appropriate medical treatment. They are offered as an aid in bringing increased knowledge to facilitate improvement."

The college's Department of Theology offers four diplomas for \$500 each. Students may study nutrition and theology simultaneously. Martin ordains the theology graduates and offers to help them establish their own Eternal Life Centers.

Students are urged to buy the products they'll be selling to patients, including "flower formulas" to overcome depression, a solution that supposedly kills the urge to smoke, oral drops to relieve arthritis and inhibit aging, aphrodisiac herbs, and a water filter. The school also sells a laboratory kit for \$750, a urine/saliva manual for \$1,000, a *How to Prosper as a Natural Health Practitioner* manual for \$100, and T-shirts for \$10.

No state agency recognizes the college, whose faculty—according to court records—consists of Martin and Charles Huge. The school is advertised as "accredited" and touts approval by the International Accrediting Commission for Schools, Colleges and Theological Seminaries. This operates from the home of George and Helen Reuter in Holden, Missouri. Mrs. Reuter says their agency accredits about 150 schools, most of them religious and correspondence programs. But she acknowledged that it is not recognized by the U.S. Department of Education or any other governmental body.

According to Martin's teachings:

- Vaccinations are harmful and unconstitutional. "Over half the people in the U.S. are now suffering from delayed reactions, resulting in chronic diseases, from the shots they previously received."
- "Of so-called four basic food groups, only one of them has any relevance to human well-being. Our natu-

ral diet is of fruits, with some vegetables and fewer nuts and seeds . . . Cooked foods are pathogenic. The eating of cooked foods and items in our diet other than raw fruitarian fare results in diseases and distorted development."

- "How about an eye wash that gets rid of cataracts? . . . If the cataract is caused by a calcium buildup, as most of them are, then the PGA B-15 EYE WASH will do the trick. Just drop in each eye at least twice daily and keep the eyes closed for at least four minutes."

- Appliances and fluorescent lighting emit "conflict energy" that causes cancer and other problems. To neutralize these rays, Martin sells "nutripathic diodes." "We have seen symptoms like regular headaches go away" when people wear the diodes in their pockets or as pendants, or attach them to fluorescent lights. Air travelers find that the devices eliminate jet lag.

Martin acknowledges that the American College of Nutripathy's curriculum is unorthodox. He states in a newsletter that "orthodox medicine is a tool of the anti-

christ consciousness. It is satanic. It is witchcraft . . . It is a religion that demands complete obedience or you will be excommunicated." He claims that as society realizes the limits of conventional medicine, it will turn toward nutripathy and other alternative forms of health care: "People who used to be labeled quacks are becoming people to be listened to." But James A. Lowell, Ph.D., vice president of the National Council Against Health Fraud, calls Martin's advice irresponsible and unsupported. "He wouldn't pass Biology 101," says Lowell, who is also a professor at Pima Community College in Tucson.

Despite his numerous disclaimers, Martin appears to be selling unapproved and misbranded drugs, practicing medicine without a license, and operating his school illegally. It remains to be seen, however, whether any law enforcement agency can curb his activities.

Mr. South is a reporter for *The Phoenix Gazette*.

BRIEFS

Carlton Fredericks dies. Carlton Fredericks, a prominent promoter of food faddism, died July 28 at the age of 76. A heavy smoker, he died of a heart attack. He was the host of "Design for Living," a one-hour six-day-a-week talk show on radio station WOR in New York City since 1957. Although he lacked nutrition credentials, he considered himself an expert and gave copious advice in books and in articles for health food publications. During the past few years he also did "nutrition consultations" for \$200 each at the offices of Robert Atkins, M.D. (author of *Dr. Atkins' Diet Revolution*).

Health publications rated. An expert panel assembled by *U.S. News & World Report* concluded that *Nutrition Forum* is "an outstanding, hard-hitting, antiquackery publication with no-nonsense style." The 4-person panel reviewed 13 health publications and assigned up to four points each for accuracy, readability and timeliness [Sept. 7, pp. 54-55]. For nutrition newsletters, the scores were: *Tufts University Diet and Nutrition Newsletter* 11.75, *Nutrition Forum* 11.00, and *Environmental Nutrition* 9.25. The magazine ratings were: *Hippocrates* 10.25, *American Health* 10.00, *Health* 8.25, and *Prevention* 7.375. The scores for health newsletters were: *University of California, Berkeley, Wellness Newsletter* 11.75, *Harvard Medical School Health Letter* 11.25, *Mayo Clinic Health Letter* 11.25, *Healthline* 10.25, *Executive Fitness Newsletter* 9.5, and *Executive Health Report* 9.5.

Diet and heart disease. The American Heart Association has published guidelines for "an optimal preventive diet for heart disease." Written for professionals, they can be obtained from AHA's national headquarters at 7320 Greenville Ave., Dallas, TX 75231. [Ask for booklet # 71-003-C.]

Dietary "variety" analyzed. The 1977-78 U.S. Department of Agriculture's Nationwide Food Consumption Survey has been used to evaluate the effects of dietary variety on dietary quality. Four researchers at The Pennsylvania State University have examined data from 3,701 individuals to see how the type and variety of foods affected their intake of 11 nutrients, percentages of calories from fat and sugar, and total intakes of calories, sodium and cholesterol. For vitamins and minerals, the researchers concluded that selecting foods from each of five major food groups (fruits; vegetables; grain products; milk and milk products; and meat and alternatives) was a simpler concept and was generally more important than choosing a variety of foods from within each of the five groups. They also concluded that altering the scope of food choices in line with the U.S. Dietary Guidelines (for example, using low-fat milk rather than whole milk) is more important than variety within each group [*Journal of the American Dietetic Association* 87:897-903, 1987].

Height/weight data. According to the 1986 *Statistical Abstracts of the United States*, the average woman in the United States is 5'4" tall and weighs 142 pounds—a little heavier than ten years ago. The average man is 5'9¼" and weighs 173 pounds, slightly less than a decade ago. Based on 1983 figures, the National Center for Health Statistics has reported that 16% of Americans are at least 30% over desirable weight, up from 14.5% in 1977.

Weight and longevity. Four scientists from Harvard University have evaluated 25 major studies of the association between body weight and longevity [*Journal of the American Medical Association* 257:353-358 1987]. Each study was flawed by failure to isolate and allow for the effects of cigarette smoking, high blood pressure, diabetes, and/or disease-induced weight loss. (The current Metropolitan Life Insurance Company's table of desirable weights, for example, are too high because the effects of smoking were not taken into account.) The scientists concluded that the impact of obesity on premature death has been underestimated and that the lowest death rates probably occur at weights at least 10% below the U.S. average.

Interstate raw milk shipments banned. After 15 years of stalling, the FDA has finally ordered that milk and milk products in final package form for human consumption in interstate commerce be pasteurized. In the August 10 *Federal Register* [52:29509-29514], the agency concluded that raw milk poses risks of serious infections with *Salmonella* and other organisms. The nation's largest source of certified raw milk is Steuve's Natural, Inc., a former division of Alta-Dena Dairies in City of Industry, California. Raw milk is also sold by the Mathis Dairy, of Decatur, Georgia. The new rule, which took effect September 9, was forced by a federal court order [see *NF* 4:12]. Raw milk sales have been banned in 27 states but are still permitted in the rest, including California. Raw milk can still be shipped across state lines to dairy processing plants for pasteurization.

FTC attacks Kraft. The Federal Trade Commission has charged Kraft, Inc., with misrepresenting the calcium content of Kraft Singles American Process Cheese Food. In an administrative complaint, the agency charged the company has falsely advertised that a slice of Kraft Singles contains the same amount of calcium as five ounces of milk and contains more calcium than do most imitation cheese. According to trade sources, Kraft's net sales for 1986 were \$8.7 billion, with dairy products accounting for \$651 million.

"Anti-aging" skin products attacked. The FDA has sent regulatory letters to Avon Products, Inc., Alfin Fragrances, Inc., and Estee Lauder, Inc., stating that the companies must seek FDA approval to continue claiming that their products have "anti-aging" effects. Because the companies portray the products as repairing cells beneath the skin surface, the FDA contends the products are drugs and require FDA approval. Alfin's Glycel skin care products have attracted considerable publicity because they were endorsed by cardiac surgeon Christian Barnard. Many other companies have been making anti-aging claims for their skin products.

Fluoridation scoreboard. Figures from the Centers for Disease Control indicate that from 1980 through 1986, governing bodies voted for fluoridation 162 out of 215 times while 83 out of 123 referendums were defeated.

Fluoridation materials. The American Dental Association has produced two items for promoting community water fluoridation. *Nature's Idea: Fluoridation*, is a free campaign package, including a 35-page manual, which can be ordered from Ms. Nancy Fehrenbacher, Staff Associate, ADA Council of Community Health, 211 E. Chicago Avenue, Chicago, IL 60611. *Fluoridation: The Facts and the Challenge* is a 15-minute videotape available for \$70 from the ADA Order Department at the same address. (Ask for #832 and specify ½" VHS, ½" Beta, or ¾" videotape.)

Mood-food link questioned. *Managing Your Mind and Mood Through Food*, a new book by Judith J. Wurtman, Ph.D., and Margaret Danbrot, has been criticized by the American Dietetic Association. "The food-mind-mood connection put forth is interesting and provocative," said an ADA news release. "But in the dawn of research investigating this potential, it may be presumptuous to extend to humans research findings derived from work done with purified chemicals and rats, and to use this as a basis for diet counseling or public education." Noting that readers are asked to rate their own responses to sample meals, the release points out that this methodology is open to subjectivity and the power of suggestion, and that it is simplistic to suggest that mood can be controlled by the manipulation of a single aspect of life such as diet. The book's general dietary advice and sample menus are nutritionally sound. But the authors make irresponsible claims like: "You can learn to make mood changes occur almost instantly" and "The range of big and little problems that can be alleviated simply by eating the right food at the right time is practically limitless!"

NEW RULES PROPOSED FOR HEALTH MESSAGES

The U.S. Food and Drug Administration (FDA) has proposed new regulations for health-related messages on food labels [*Federal Register*, August 4, 1987, pages 28843-28849]. In an accompanying news release, Health and Human Services Secretary Otis Bowen, M.D., said, "We want to permit, and in fact, encourage science-based statements regarding the benefits that classes of foods can provide. But we are trying to draw a line between scientifically based, general statements and those that are merely theories or are linked too closely to a particular commercial product."

Controversy in this area erupted in 1984 over ads suggesting that the high fiber content of Kellogg's All-Bran made it useful in preventing cancer [see NF 2:69, 3:19-20]. The ads had been designed with help from the National Cancer Institute (NCI) and were acceptable to the Federal Trade Commission. Sales of high-fiber, ready-to-eat cereals increased by 37% within less than a year. But FDA officials thought that linking a specific food product to NCI's general dietary guidelines might make All-Bran a "drug" subject to premarket proof of effectiveness. Kellogg and two industry groups then petitioned the agency to allow certain types of health claims in food advertising or labeling [see NF 3:89-91].

The FDA is proposing:

- Information must be truthful and not misleading to consumers. It must not overemphasize or distort the role of a food in enhancing health or preventing or alleviating disease. If a health-related claim is false or misleading, the agency may take action under the misbranding and/or new drug provisions of the Food, Drug, and Cosmetic Act.

- Claims must be supportable by scientific evidence from well-designed studies performed and evaluated by appropriate experts. A single study could not be used to support a claim if it conflicts with the majority of available pertinent evidence.

- Claims must be consistent with generally recognized medical and nutritional principles for a sound total dietary pattern—keeping in mind that nutrition is a function not of specific foods, but of total diet over time.

- Any product bearing health-related information must comply with existing nutrition labeling requirements [see NF 3:41-43].

- The same criteria may be applied to vitamins, minerals and other supplements, but the extent to which the criteria can be met may be limited. Although supplements are useful for individuals suffering from actual nutrient deficiencies, scientific data regarding good nutrition and health focus primarily on the role of foods, not supplements. It is generally more practical to

emphasize healthful dietary patterns than to identify and stress individual compounds. For these reasons, it may be more difficult for dietary supplements to meet the proposed criteria.

- Manufacturers may make health-related claims that conform to these guidelines without prior FDA approval, with the understanding that the manufacturer's activity may be subject to regulatory action.

The proposed regulations would apply to product labels but not to advertising, over which the Federal Trade Commission has primary jurisdiction. Nor would they apply to meat and poultry products, which are supervised by the U.S. Department of Agriculture.

The FDA's proposal also calls for the Assistant Secretary for Health to establish a standing committee to develop some suggested health messages. The committee would be chaired by the FDA Commissioner and include representatives of other Public Health Service agencies and the Food Safety and Inspection Service of the U.S. Department of Agriculture. The Federal Trade Commission would function as a liaison.

The committee's purpose would be to convey the advantages of dietary patterns that the committee believes would help to improve the public health. The messages would not refer to specific brands or products but would emphasize how a total dietary plan can be helpful. The committee would also consider whether messages are appropriate for dietary supplements. The messages may be subjected to consumer research such as field testing to help ensure that they are understood by consumers.

After messages are announced in the *Federal Register*, manufacturers could use them with assurance that they are legal. Manufacturers would still be free to develop their own messages or modify those of the committee. But enforcement action could still be taken if the messages go too far.

On August 10, *The New York Times* blasted the proposed regulations in an editorial titled "The Snake Oil Diet," which said:

"The new rules do not require food companies to list negative facts about foods, even if they far outweigh the benefits . . . Worse, the FDA has failed to insist that it prescreen claims. The agency lacks the resources to monitor the deluge of claims that will now appear, and will doubtless take years to rescind even the most outrageous. Just when knowledge has been gained of how proper diet can reduce heart disease and cancer, the Administration proposes to let industry unleash a babble of misleading claims that will allow bad foods to masquerade as good. If the FDA cannot write better rules, it had better continue the ban on health claims by

writing none."

Along similar lines, the Center for Science in the Public Interest has petitioned the FDA to prohibit health claims for nutrients not linked to major health problems and to require that health claims be accompanied by an explanation that one's total diet, not an individual food, can reduce the risk of disease. CSPI also requested that claims be prohibited until firm guidelines are in place. It believes that without firm regulation, many segments of the food industry will act irresponsibly.

CSPI has been very active in this issue and has driven many misleading claims from the marketplace by complaining to government and voluntary agencies. In one case, the FTC stopped claims that vegetable pills would protect against cancer. In another case, the New York Attorney General ruled that "beef gives strength" is misleading because beef alone won't give you strength. In another case, a food manufacturer was forced to stop saying that canned vegetables were as nutritious as fresh-cooked. In another case, a soup company had claimed that soup is "health insurance" even though its high sodium content could cause difficulty for people with high blood pressure. In yet another case, coffee had been promoted as something that "lets you calm yourself down" even though caffeine can make people nervous.

Victor Herbert, M.D., Professor of Medicine at Mt.

Sinai School of Medicine is also very wary of nutrition advertising. In comments to government officials and in the May/June 1987 issue of *Nutrition Today*, he has pointed out that food companies and supplement manufacturers often engage in deception by omission of adverse facts.

Public comments on the proposed regulations can be submitted through November 2, 1987. The FDA is particularly interested in the following issues:

- Is it in the interest of public health that health information, including information regarding specific diseases, appear on food labeling?
- Are the principles upon which the FDA has based its criteria reasonable?
- What types of scientific evidence should be considered adequate to support healthy information which might appear on food labeling?
- What role, if any, do dietary supplements have in promoting or enhancing nutrition and health? Are there sufficient scientific data to allow the use of health information on the labeling of dietary supplements?
- What priority should the FDA assign to enforcement actions against false or misleading health-related claims on package labels?

Comments should be identified with Docket No. 85N-0061 and submitted in duplicate to the Dockets Management Branch (HFA-305), FDA, Rm. 4-62, 5600 Fishers Lane, Rockville, MD 20857.

BOOK REVIEW

Title: *Design Your Own Vitamin and Mineral Program* (1987)

Author: Shari Lieberman, M.A., R.D.

Publisher: Doubleday & Company, Garden City, N.Y.

Price: \$8.95 softcover

Reviewed by: Stephen Barrett, M.D.

Ms. Lieberman claims to have researched the most up-to-date professional journals to provide "the most comprehensive, unified, and scientifically sound picture of what vitamins and minerals can—and cannot—do for you." I believe she has failed miserably.

For example, she claims that "you cannot get all the nutrients you need from today's food" and that "the RDAs are the nutritional equivalent of the minimum wage. They are probably enough to keep you alive, but how good is the quality of that life?" Instead, she postulates higher "Optimum Daily Allowances." And she suggests that "nutrition should be our first line of defense if an illness or condition is not life-threatening." These ideas are not scientifically supportable.

She also states that in her private practice she

counsels 50 people each week: "They come to me with every variety of problem and needs. Some are specific, such as acne, psoriasis, thinning hair, menstrual problems, blood sugar problems, intestinal disorders, high blood pressure, high cholesterol, an inability to sleep, fatigue, depression, or nervousness. These people turn to nutrition as an adjunct or an alternative to the treatment offered by their physician."

Although some of these conditions are diet-related, most are not, and few provide reasons to take supplements. But Ms. Lieberman claims to have found them valuable for dozens of problems, including aging, cataract prevention, kidney stones, depression, asthma, and shingles. The book suggests that everyone should take supplements.

Most junk nutrition books are written by people with neither credentials nor scientific training in nutrition. Ms. Lieberman has both, but seems to have gone astray. Last year—based on evidence presented at a hearing in December 1985—the American Dietetic Association censured her for failing to adhere to accepted practice standards. Perhaps they should do it again.

NUTRITION FORUM

VOL. 4 NUMBER 10 OCTOBER 1987

ISSN 0748-8165

THE MERCURIAL KURT DONSBACH

Stephen Barrett, M.D.

Kurt W. Donsbach, D.C., N.D., D.Sc., Ph.D., has played an important role in keeping the health food industry several steps ahead of the law. Since 1975 he has been chairman of the board of governors of the National Health Federation (NHF), the industry's militant lobbying arm. His other activities and enterprises have been so numerous and complex that no one—including Donsbach himself—seems able to document all of them with certainty.

Donsbach (pronounced Dons'—bah) graduated in 1957 from Western States Chiropractic College, in Portland, Oregon, and practiced as a chiropractor in Montana, "specializing in treatment of arthritic and rheumatoid disorders." From 1961 to 1965, he worked in "research development and marketing" for Standard Process Laboratories and the Lee Foundation for Nutritional Research. These companies, headquartered in Milwaukee, Wisconsin, were operated by Royal Lee, a nonpracticing dentist who helped found NHF. In 1963, Lee was described by a prominent FDA official as "probably the largest publisher of unreliable and false nutritional information in the world."

While Donsbach worked for Lee, he lived in California, did literature research, and gave nutrition seminars (primarily to chiropractors) on how to determine nutritional deficiencies. "I would catalogue the signs so an individual could see a nutritional deficiency syndrome by directing their attention towards specific areas," he stated during a 1985 deposition. He also testified that in 1962, he acquired a doctor of naturopathy (N.D.) degree from the now-defunct Hollywood College of Naturopathic Medicine and became licensed as a naturopath in Oregon.

After Lee became ill, Donsbach left his employ and opened Nature's Way Health Food Store, in Westminster, California, and Westpro Laboratories, in Garden Grove, California, which repackaged dietary supplements and a few drugs.

In 1970 undercover agents of the Fraud Division of the California Bureau of Food and Drug observed Donsbach representing to customers in his store that vitamins, minerals and/or herbal tea were effective against cancer, heart disease, emphysema (a chronic lung disease) and many other ailments. Charged with nine counts of illegal activity, Donsbach pleaded guilty in 1971 to one count of practicing medicine without a license and agreed to cease "nutritional consultation." Most of the products Donsbach "prescribed" were packaged by Westpro Labs. He was assessed \$2,750 and served two years' summary probation.

In 1973, Donsbach was charged with nine more counts of illegal activity, including misbranding of drugs; selling, holding for sale, or offering for sale, new drugs without having the proper applications on file; and manufacturing drugs without a license. After pleading "no contest" to one of the "new drug" charges, he was ordered to pay a small fine and was placed on two years' summary probation with the provision that he rid himself of all proprietary interest in Westpro Labs. In 1974, he was found guilty of violating his probation and was fined again.

Donsbach sold the company to RichLife, Inc., of Anaheim, California, a subsidiary of Moxie Industries, of Atlanta, Georgia, for \$250,000. He was also promised \$20,000 a year for occasionally conducting seminars and operating the company's booth at trade shows. The agreement also gave RichLife sole right to market Dr. Donsbach Pak Vitamins, which RichLife later described as "specialized formulas" to "help make your life less complicated, more healthy." Among the products were *Arth Pak*, *Athletic Pak*, *Dynamite Pak*, *Health and Beauty Pak* and *Stress Formula Pak*.

Donsbach then became president of Metabolic Products, a company specializing in "orthomolecular concepts," which he sold in 1975. According to literature from Metabolic Products, its garlic extract could

"prevent cellular deterioration," its alfalfa product had "anti-toxin properties" which could help to overcome "-itis diseases," and so on.

In 1975, Donsbach began producing *Dr. Donsbach tells you everything you always wanted to know about . . .* a large series of booklets on such topics as acne, arthritis, cataracts, ginseng, glandular extracts, heart disease, and metabolic cancer therapies. According to Donsbach, more than eight million have been sold. The booklets were published by the International Institute of Natural Health Sciences, which sold distribution rights to RichLife.

In 1984, Donsbach was sued by Jacob Stake, of Urbana, Iowa, who claims that he became ill and was hospitalized as a result of ingesting large amounts of vitamin A over a 2½-year period. The suit papers state that Stake began taking the vitamin at age 16 because it was recommended in Donsbach's booklet on acne. The case is still pending.

During the mid-1970s, Donsbach began affiliating with Union University, an unaccredited school in Los Angeles, where he says he acquired a master's degree in molecular biology and a Ph.D. in nutrition. He also says he was awarded an honorary doctor of science degree from Christian University, an unaccredited school which, he testified, had operated in Los Angeles. (However, two reporters have said he told them that his "D.Sc." was obtained from a midwest bible college.)

In 1977, Union University formed a Department of Nutrition—"with Kurt Donsbach, Ph.D., Sc.D., as Dean of the Department." RichLife, Inc. then offered scholarships to its retailers who wished to further their education. Later Donsbach launched and became president of his own school, Donsbach University, which in 1979 was "authorized" by California to grant degrees. (This status had nothing to do with accreditation or other academic recognition, but merely required the filing of an affidavit which describes the school's program and asserts that it has at least \$50,000 in assets.)

Donsbach University, which operated mainly by mail, initially offered courses leading to B.S., M.S. and Ph.D. "degrees" in nutrition at fees ranging from \$1,495 to \$3,795, with a 20% discount for advance payment. Most of the "textbooks" required for the "basic curriculum" were books written for the general public by promoters of questionable nutrition practices, including Donsbach, Carlton Fredericks, Lendon Smith, and Robert Atkins. The original "faculty" had seven members, including Donsbach, and Alan H. Nittler, M.D. (who, according to NHF, "lost his medical license in 1975 because he utilized nutritional therapies"). But ads for the school promised "the finest quality nutrition education available anywhere." Donsbach University has also offered courses in iridology, homeopathy, herbal therapy, and chiropractic business administration, as well as a \$495 "mini-course" in nutrition for retailers

who wanted a "Dietary Consultant" certificate.

In 1979, Donsbach began publishing the *Journal of the International Academy of Nutritional Consultants*, with Dr. Nittler as its editor. The first issue had a press run of about 25,000 copies, most of which were sent free-of-charge to chiropractors. The second issue explained that Academy members could be listed in a directory, and that the Academy "will in no way encourage or tolerate the practice of medicine under the guise of nutritional consultation" and would establish a legal fund to protect its members from "undue and unfair harassment by bureaucracies or agencies." Regular membership in the academy, open to anyone, cost \$10 per year (later raised to \$12/year) and included a subscription to its journal. "Professional membership," which cost \$50 per year, included a directory listing plus "beautiful certificate for your office." Sustaining membership, which cost \$150 a year, gave a 15% discount on advertising in the journal. Most of its 50 or so sustaining members had commercial interests in methods promoted by the journal. In 1981, the journal was renamed *Health Express*, Donsbach took over as editor-in-chief, and efforts were made to market it through health food stores and newsstands.

One of the journal's many ads was for nutritional cassette tapes, made by Donsbach, which could be obtained by writing to "Dr. Donsbach's Tapes" at the same address as his school's. A retailer who responded to the ad was sent two price lists, not from the school, but from Health Education Products, a company apparently located nearby. One list was for Donsbach's "Health Library" (of books and booklets) and cassette tapes (which include *Happier Sex Life* and *Herbal Medicine*). The other was for food supplement formulas such as *Optimum Nutrition*, *High Q*, *Anti-Oxidant Formula*, *Stress Nutrition*, *Renew-F* and *Renew-M*. According to a catalog of Nutri-Books, the largest distributor of books and related products to health food stores, *Dr. Donsbach's Nutritional Tape Cassettes* are "like having Dr. Donsbach as your personal physician right in your own home. Each . . . gives pertinent information and direction to aid in diagnosis and remedial action."

During 1983, the International Academy of Nutritional Consultants merged with a similar group to be-

come the American Association of Nutritional Consultants. For a few months, Donsbach was listed as chairman of the group's national board of counselors and later he was listed as a contributing editor to its journal (which also absorbed *Health Express*). In 1983 and 1984, Donsbach was listed as publisher of the *Journal of Ultramolecular Medicine*, a publication for homeopaths who use computerized galvanometers to diagnose disease [see NF 4:6-8]. He has also published a 4-page newsletter called *Herb-Letter*.

In 1982, Donsbach formed and became board chairman of Health Resources Group, Inc., which sold supplement products to health food stores through HRG Enterprises (formerly called D&B Enterprises) and a multilevel company called Nutrition Motivation. HRG also operated Preventive Medicine and Nutrition Care Centers in Huntington Beach and Monrovia, California, and a syndicated radio talk show called "Let's Talk Health," which Donsbach hosted. HRG's products were promoted frequently during the broadcasts, which were beamed by satellite to about 20 small stations. Listeners were invited to call in questions on a toll-free number.

In 1984, Donsbach announced that he had repurchased from RichLife the right to sell products with his name, and HRG began promoting such products as Orachel (claimed to be effective against heart disease), C-Thru (claimed to be effective against cataracts) and Prosta-Pak ("nutritional support for the prostate gland").

In June 1985, the FDA sent Donsbach and HRG a regulatory letter indicating that claims made for Orachel made it an unapproved new drug that was illegal to market. A few months later, New York Attorney General Robert Abrams had Orachel seized from several retail outlets in the New York City area and filed suit to block further sale and distribution of the product throughout the state. It turned out, however, that before either of these actions were taken, Donsbach had transferred ownership of HRG Enterprises to a business associate. Marketing of Orachel was stopped, but Ora-Flow, an identical Donsbach product, is still being marketed.

In July 1985, Abrams brought actions against Donsbach, his University, and the International Institute of Natural Health Sciences, charging that they lacked legal authorization to conduct business within New York State and that it was illegal to advertise unaccredited degrees to state residents. Abrams also charged that the Institute's Nutrient Deficiency Test was "a scheme to defraud consumers" by inducing them to buy dietary supplements to correct supposed deficiencies reported with the test.

This test is composed of 245 yes/no questions about symptoms. When the answers are fed into a computer, a report of supposed nutrient deficiencies and medical conditions is printed out. However, experts who have evaluated the questions do not believe they provide a basis for evaluating nutritional status. More-

over, a scientist with the FDA's Buffalo district office who analyzed the test's computer programs in connection with prosecution of a Donsbach University "graduate" has found that no matter how the questions were answered, the test reported several "nutrient deficiencies" and almost always recommended an identical list of vitamins, minerals and digestive enzymes. The questionnaire also contains a section with questions about the subject's food intake during the past week. However, the answers given did not affect the printout of supposed deficiencies!

In 1986, Donsbach and the Institute agreed to: 1) restrict the sale of its Nutrient Deficiency Test to health care professionals legally authorized to practice within New York State; 2) stop marketing in New York State all current versions of its nutrient deficiency questionnaire and associated computer analysis services; 3) place conspicuous disclaimers on future versions of the questionnaire to indicate that the test should not be used for the diagnosis or treatment of any disease by either consumers or professionals; and 4) pay \$1,000 in costs. Donsbach and the University agreed to disclose in any direct mailings to New York residents or in any nationally distributed publication that the school's degree programs are not registered with the New York Department of Education and are not accredited by any accrediting commission recognized by the U.S. Department of Education. The University also agreed to pay \$500 to New York State.

During 1986 and part of 1987, Donsbach was "therapy coordinator" of the Bio-Genesis Institute in Baja, Mexico, which offered "chronic and acute care for degenerative disorders." Included in its scope were "aging rejuvenation, allergies, arthritis, cancer, cardiovascular, cataracts, immune stimulation, and multiple sclerosis." The treatments offered included oral and intravenous chelation therapy, laetrile, live cell therapy, homeopathy, DMSO, and colonics. Hydrogen peroxide is also used intravenously, orally, and in ear drops, a nasal spray, a tooth gel, a pain gel, breath drops and enemas. The cost of treatment at Biogenesis Institute was \$795 for the 4 Day Executive Program, \$2,750 for the 11 Day Rejuvenation Program, and \$5,000 for the 24 Day Total Care Program. But the Institute's information packet included a 20% discount certificate and stated that "there will be no charge if your condition is unimproved by the time you leave."

In 1987, Donsbach University announced that Donsbach had resigned as president and board chairman and that the school is applying to be re-named International University for Nutrition Education. Donsbach also began operating the newly-built Hospital Santa Monica, in Baja, Mexico, whose 21 Day Total Care Program is similar to that advertised for the Biogenesis Institute. Brochures from Hospital Santa Monica describe it as a 60-bed multimillion dollar facility and state

that payment in advance is required. Patients without insurance must pay \$5,000 with cash or a cashier's check, while those with satisfactory insurance must deposit \$2,500.

Donsbach has claimed that thousands of people have enrolled in his university and that more than 1,000 have graduated. As his graduates began representing themselves to the public as nutrition professionals, the American Dietetic Association began a drive for passage of state laws to restrict use of the word "nutritionist" to qualified professionals with accredited training.

Donsbach's logo is "Health is Wealth." Despite his

apparently enormous gross income, he filed for bankruptcy in March 1987, listing no assets and over \$3 million in debts claimed by more than 100 creditors.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 21 books including *Vitamins and "Health" Foods: The Great American Hustle*. In 1984 he received the FDA Commissioner's Special Citation Award for Public Service in fighting nutrition quackery. He has been tracking Donsbach's activities since 1971.

STOCK BEING PEDDLED IN AIDS SCAM

Stephen Barrett, M.D.

According to promotional material, Immune America, Inc., is a Los Angeles-based firm "specializing in the research, development and marketing of high-quality nutritional products designed to assist in the treatment of immune system dysfunctions," and its president, Elizabeth Huntley-Robinson, Ph.D., is "one of the nation's leading immune nutrition research scientists."

These claims were made during August 1987 on Financial News Network's *Penny Stock of the Week*, which airs lengthy commercials for "selected low-priced stocks . . . that have the investment potential for high returns." Listeners are urged to contact a toll-free number for further information.

According to Dr. Robinson, "At Immune America we have developed a system of nutritional products and dietary regimen with which we've been able to rebuild the immune system even in the presence of crisis immune disorders such as AIDS, Epstein-Barr virus, and flu symptoms . . . We're talking about three products, three nutritional food supplement products which are sold over-the-counter, and a dietary system which works synergistically."

The company's taped commercial was aired in two five-minute segments. The first featured a live interview with a woman who said her symptoms of Epstein-

Barr virus (the virus responsible for infectious mononucleosis) had improved dramatically on Immune America's program. The other segment featured a testimonial from an AIDS patient who said he had dropped chemotherapy and had no intention of going back.

Literature supplied by brokers offering the stock states that Dr. Huntley has a Ph.D. in biological and medical sciences and an M.S. in biology from Brown University and a B.A. in physics from Swarthmore College. The other listed board members of Immune America are Wilbert C. Wade, Jr., a former national sales manager for Health Valley Natural Foods, and Judith K. Cutler, public relations director of Robinson Consultants. Marketing of the company's products is scheduled to begin in October in high-AIDS areas such as San Francisco and New York City.

According to the literature, Immune America's Nutrition System will cost \$100 to \$150 per month, compared to \$400 to \$800 per month for chemotherapy. The literature also claims that "Immune America does not believe that its products are subject to FDA approval," but warns that FDA regulation, if successful, "would have a material adverse effect on the company." It appears that about 2,000 potential investors have made inquiries as a result of the telecasts.

Under federal law, it is illegal to market any product for the mitigation or treatment of disease without FDA approval as safe and effective. The company's plans are also illegal in New York and California, whose attorney generals have been alerted to them.

Supplement products alleged to "strengthen the immune system" have been sold in health food stores for about two years [see NF 3:24]. But as far as I know, they have not been promoted with patient testimonials or the use of nationwide TV.

INFORMATION WANTED

If you find any newsworthy items, such as a published article or news report, or have a personal experience that might be of interest to our readers, please send it to Stephen Barrett, M.D., P.O. Box 1747, Allentown, PA 18105.

ADDITIONAL THOUGHTS ON THE RDA

Henry Kamin, Ph.D.

It is remarkable what mythology has risen about the Recommended Dietary Allowances (RDA). One misconception stems from the fact that they are expressed in units per day. This is amplified by the frequent error of translating the "D" of RDA into the word "Daily" instead of "Dietary." Somehow the impression has been created that an RDA of each vitamin must be taken every day. This is completely false! The "daily" portion of the intake unit is simply a convenient way to express average daily intake for vitamins and minerals. The time over which the average should be taken is highly variable—from a week or a few weeks for thiamin (which is used up relatively rapidly) to as much as several years for vitamin B₁₂. There is no need to consume an RDA of any vitamin every day. Intermittent eating of appropriate foods does perfectly well. I suspect that I get most of my vitamin A in summertime when I gorge on tomatoes and fresh cherries. My body's storage facilities can then keep me well supplied year-round.

There is also a misconception that RDA are "minimums," designed to prevent disease rather than to insure "vibrant health." I can relate "vibrant health" to physical fitness, but I have great difficulty in defining such a state in nutritional terms and distinguishing it from absence of disease. The RDA are purposely generous. We design them to represent amounts that—even allowing for variability within the total population—are high enough that no improvement in health should be expected from increasing intake above RDA levels. We genuinely try to cover any possible benefit that may be gotten from the nutrients obtainable in a mixed diet.

In addition, safety factors incorporated into the RDA are intended to insure that even the outriders of a variable normal population are covered. One of the first questions I asked members of the current RDA committee was whether they knew of any normal individual who, while taking the RDA of any nutrient, developed any indication of shortage of that nutrient. None of us could think of a single example. I am convinced that the RDA protect the entire normal population. Our intent is to protect everyone from getting too much as well as too little. All chemicals, at some levels, can have pharmacological effects—good, bad, or both. But the RDA don't deal with nutrients as drugs.

Perhaps the most important misconception is that people are at great risk of developing a nutrient deficiency by casual or "junk food" eating. This is simply not so [see NF 4:33-37]. Special conditions such as pregnancy, breastfeeding and a few other situations do affect

the RDA. But these are provided for in the RDA tables, and recommendations are made about supplementation in the few cases where it is appropriate.

Finally, there is confusion and controversy about the purposes of the RDA. A distinction should be made between a "nutrient" approach (which is used in formulating the RDA) and a "dietary pattern" approach to nutrition. It is a damaging error to confuse the two approaches when considering individual nutrients. Data on the relationships between the individual nutrients specified in the RDA and the incidence and severity of chronic disease are weak—far weaker than the relationships between total nutrition pattern and the development of chronic diseases.

The RDA exemplify the "nutrient" approach. We inventory the materials that must be eaten because the body cannot make them, and make provisions for sufficient total intake to meet caloric and protein needs. These nutrient needs can be quantified—though we must allow for individual variation and a margin of error for safety's sake.

The effect of total dietary pattern on health also has validity. This is a much broader field and cannot be quantified nearly as well as the RDA. This approach considers not only vitamins and minerals but all of the various materials that may affect health: fiber, plant phenolics, exotic compounds, toxins, cancer-causing agents, percentage of calories as fat, types of fat consumed, and so on. It also encompasses the effects of eating patterns on obesity, which has its own set of consequences.

Dietary patterns can also affect growth and development during childhood and adolescence and can influence the development of chronic disease and aging. But we are nowhere near being able to quantify this large group of nutritional variables and can only make broad recommendations such as "Don't put on too much weight" or "Eat broccoli; there are several reasons why it's good for you." Recommendations of this type have been summarized in the 1985 Dietary Guidelines for Americans and amplified in booklets published by the U.S. Department of Agriculture [see NF 3:30-31 and 3:87]. But considerable clinical research is needed to determine whether more specific advice is justifiable.

Dr. Kamin is professor of biochemistry at Duke University Medical Center and chairman of the 1980-1985 RDA committee of the National Academy of Sciences.

NEW REPORT ON NATURAL CARCINOGENS IN FOOD

Many naturally occurring substances have been found to be carcinogenic (cancer-causing) using the customary criteria for assessing the cancer-causing potential of man-made substances. Other carcinogens are produced by cooking and by the actions of microorganisms. These types of carcinogens are more numerous, more widespread, and in many cases more potent than man-made carcinogens in food. However, according to a report by the American Council on Science and Health (ACSH), this should not cause alarm but indicates that evaluation of natural and man-made carcinogens in food should be better balanced. The report, *Does Nature Know Best? Natural Carcinogens in American Food*, discusses more than 20 substances including nitrosamines, aflatoxins, and carcinogens produced by cooking.

"Every time you eat a piece of toast, a mushroom, or a charcoal-broiled steak, you're eating carcinogens," said ACSH executive director Elizabeth M. Whelan, Sc.D. "But there's no reason to believe that natural carcinogens in our food supply are a significant hazard to our health in the amounts ordinarily consumed. The variety in our diets prevents us from being exposed to

truly dangerous amounts of any one potentially harmful food component."

The ACSH report—now in its third edition—concludes:

- The best way to minimize the potential hazard posed by naturally occurring carcinogens is to eat a wide variety of foods

- The common assumption that "natural" is safe and "man-made" is suspect is contrary to current scientific knowledge

- Regulatory emphasis should be on the potency and level of exposure to carcinogens rather than on whether their origin is natural or artificial

- Our priorities are mixed up. Extensive testing of synthetic substances wastes scarce scientific resources if more potent natural materials are ignored or unrecognized as major contributors to disease. Our efforts should be focused on the few substances that pose a clear hazard to human health rather than a multitude of tiny or hypothetical ones.

BRIEFS

Chewing tobacco reduces ability to taste. According to a brief report in the April 30, 1987 *New England Journal of Medicine*, tests administered to eight users and nine nonusers at the Monell Chemical Senses Center in Philadelphia demonstrated that long-term use of smokeless tobacco can elevate recognition thresholds for sweet, salty and bitter solutions.

International athletes must eat carefully. Special precautions are needed to prevent gastrointestinal illnesses among athletes competing in foreign countries. According to Jacqueline Berning, R.D., a nutrition consultant for U.S. Swimming (the governing body for U.S. competitive amateur swimming), 90% of the U.S. swimming team and staff developed severe diarrhea within three days of arrival and 60% suffered from vomiting at the World Championships for Aquatic Sports, held last year in Madrid. Although the U.S. team still placed first overall, individual performances suffered. Unfamiliar food and water, less refrigeration, and use of foods from street vendors played a role in the illnesses.

Fluoride classic revised. The third (1986) edition of *Fluorides and Dental Health* has been published. Edited by Ernest Newbrun, D.M.D., Ph.D., the 289-page textbook covers fluoride metabolism and toxicology, community water fluoridation, fluoride supplements and dentifrices, topical fluorides, and the legal, economic and political aspects of fluoridation. Copies are \$35.75 from Charles C Thomas, Publisher, 2600S. First St., Springfield, IL 62794.

Notable quote. "If health claims are permitted on food product labels without regard to whether they are broadly important, the public will soon be deluged with health messages of all sorts. This will promote chaos and confusion in the marketplace rather than useful public education. Important health messages will be overwhelmed by noise from unimportant ones . . . Advertisers will try to make everything seem important for something." —Paul Sage, FDA Consumer Safety Officer, regarding FDA's proposed regulations for health claims on food labels [see NF 4:63-64].

Raw milk verdict overturned. The presiding judge has overturned the \$40,000 jury award to the family of Paul B. Telford. The jury concluded that Telford had died as a result of drinking contaminated raw milk sold by the Alta-Dena Dairy [see NF 4:57]. But the judge ruled that the evidence was insufficient to hold the dairy responsible. The family plans to appeal to a higher court.

FDA evaluating fish oil claims. According to an article in *Food Chemical News*, the FDA is evaluating claims made on the labels of fish oil capsules to see whether they are supported by existing scientific data. At a recent talk, an FDA official said that higher intake of fish oil should be obtained by eating more fish and that the safety aspects of fish oil supplement use "have not been addressed." He also noted that the National Institutes of Health have begun several studies involving fish oil capsules.

Pharmacy slashes supplement stock. To cut costs, reduce waste, and deliver appropriate dosage levels, Methodist Hospital in Houston, Texas, has established standards for vitamin and mineral supplements stocked by its pharmacy. The standards were developed by a joint committee of the pharmacy and dietary departments and ratified by the executive committee of the medical staff. The criteria for selection were based primarily on the Recommended Dietary Allowances and guidelines developed by the American Medical Association's Department of Foods and Nutrition. Twelve categories were established and bids were obtained to select one product for most categories. The pharmacy now stocks 13 multiple-ingredient products instead of 107. Products containing single ingredients were not included in this process, and a "full complement" is still stocked [*Journal of the American Dietetic Association* 87:777-778 1987].

BOOK REVIEW

Title: *Never Satisfied—A Cultural History of Diets, Fantasies and Fat* (1986)

Author: Hillel Schwartz

Publisher: The Free Press, Div. of Macmillan, Inc., 866 Third Ave., New York, NY 10022

Price: \$19.95

Reviewed by: Manfred Kroger, Ph.D.

Histories of diets, food habits, and health have been written before. James Trager's *Belly Book* and Ronald Deutsch's *Nuts Among the Berries* are two of the most notable. But none is more satisfying than this one. Hillel Schwartz is a scholar; yet his style is absorbing, not stodgy. The depth and breadth of his work are conveyed by more than a hundred pages of notes and thousands of citations at the end of the book. More than a hundred trademarked products are discussed.

Most of the book's eleven chapters deal with the follies that typify the human relationship with food. A prologue sets the stage for the history of dieting, body shape and the business that surrounds them. Sylvester Graham is pronounced the first American "weight watcher" in Chapter 2, which also examines "thinness" in the age of Andrew Jackson. Then comes the Victorian era characterized by the American Disease of dyspepsia. Chapter 4 takes us to the turn of the century when gluttony was clearly associated with fatness and the "disease" of obesity. Fasting, Fletcherism, calorie-counting, and the diet drugs developed during this period are described in detail. Chapter 6, "The Measured Body," describes America's new-found fascination with weigh-

ing. Schwartz did extensive research into the development of scales—all sorts of them, from penny public scales to bathroom and kitchen models.

During and after the Depression, fatness became linked with circulatory disease and heart attacks and valid scientific pronouncements became common. But there has been no let-up in the moneymaking activities of those who sensed profits in all of this. Chapter 8 ("Thin Bodies, Fat Profits") describes the beginnings of our current low-calorie way of life; how the faddism of Graham, Post and Kellogg has evolved into blue-chip companies selling "light" food; and how new sweeteners are giving good old sucrose a run for the money.

Chapter 9 ("Baby Fat") contrasts the "fine fat baby" of the late 1700s and today's anorexic teens. The last two chapters discuss the "weightless" body, the current preoccupation with dieting and working out, as well as the "political economy" surrounding eating and body perception, in which Jane Fonda is a major figure.

The guiding principles for healthful eating are gradually being shaped by expert consensus instead of grandmother's folk wisdom, but we have a long way to go. Despite scientific progress, most Americans are still governed by irrational myths of the past. But Schwartz never chides us for being naive. He is the superb historian, holding up the mirror of the past for us to examine ourselves clearly. Oh, boy, do we look silly!

Dr. Kroger is Professor of Food Science at The Pennsylvania State University.

SUMA: A QUESTIONABLE NEW HERB

Varro E. Tyler, Ph.D.

P. T. Barnum's old adage about a sucker being born every minute seems applicable to unproven herbal remedies as well. Indeed, the two may be closely related. One of the most recent herbs of this sort marketed in the United States is suma, the dried root of a tropical plant native to the Amazon rain forests. It is being sold in capsules and compressed tablets containing 200 to 750 mg of the dried root and costing about 12 to 25 cents.

According to literature supplied by its producers, suma—or *para todo* (for everything) as it is known to the native shamans—is derived from *Pfaffia paniculata* (Mart.) Kuntze. However, *Index Kewensis*, the supreme authority on botanical nomenclature, designates the plant *Hebanthe paniculata* Mart.

The advocacy literature refers to suma as "Brazilian ginseng" and promotes it as an immune-enhancer or adaptogen, which supposedly helps the body adapt to new stresses by restoring natural immune resistance. The literature also notes that cancer is one of the main illnesses treated with suma in Brazil and claims that it has been used in the Amazon for at least 300 years as a tonic, aphrodisiac (sexual stimulant), and remedy for diabetes, tumors, and skin problems including wounds. If that is so, the drug has been a well-kept secret, for it does not appear in any of the numerous and extensive compilations of medicinal plants of the world.

Chemical studies of suma root have been conducted by Japanese investigators. They have succeeded in isolating and characterizing a new nortriterpene called pfaffic acid and six new saponin derivatives of that acid named pfaffosides A, B, C, D, E, and F. Preliminary tests revealed that certain of the pfaffosides inhibit the growth of cultured tumor cell melanomas (B-16). Of the six, pfaffoside F was the most active, causing inhibition at a concentration of 30 micrograms per milliliter.

This initial indication of antitumor activity is in-

teresting, of course, but not at all unusual. Activity of this sort has been reported for many of the constituents of the more than 40,000 plants screened for possible anticancer effects in the ongoing program of the National Cancer Institute. Yet not a single agent for general use in the treatment of human cancer has resulted from this intensive effort.

Often when unproven recommendations are made for this or that herb, we can at least take some comfort in knowing that the plant has been widely used as a folk medicine for hundreds or even thousands of years without reports of adverse effects. For example, the root of valerian (*Valeriana officinalis* L.) was used by the ancient Greeks and Romans, appeared on Anglo-Saxon remedy lists in the 11th century, has held official status in various editions of both the *United States Pharmacopeia* and the *National Formulary*, and is now widely marketed as a drug in Western Europe. Thus it is possible to characterize valerian as an apparently safe and effective drug even though it has not been approved as such by the U.S. Food and Drug Administration. The safety of suma, however, is completely unknown. While we are told that it is an ancient remedy, at least in Brazil, no such information appears in the medicinal plant literature. In addition, toxicity testing, either in animals or in humans, has never been reported in the scientific or clinical literature.

Lacking evidence that suma is either safe or effective for any condition, I consider it inappropriate for public consumption.

Dr. Tyler, Vice President for Academic Affairs at Purdue University, is an expert in pharmacognosy (the science of medicines from natural sources) and is author of *The New Honest Herbal* (1987), published by the George F. Stickley Company, Philadelphia.

NOVEMBER 1987

ISSN 0748-8165

WHAT IS CLINICAL ECOLOGY?

Stephen Barrett, M.D.

"Clinical ecology" is based on speculation that multiple symptoms are triggered by hypersensitivity to common foods and chemicals. Advocates of this belief describe themselves as "ecologically oriented" and consider their patients to be suffering from "environmental illness," "cerebral allergy," "allergy to everything," or "twentieth century disease," which can mimic almost any other illness.

Clinical ecologists speculate that: 1) although one substance may not have an effect, low doses of different substances can add or multiply their effects; 2) hypersensitivity develops when the total load of physical and psychological stresses exceeds what a person can tolerate; 3) patients often crave and become addicted to foods that make them ill; 4) changes in the degree of exposure can affect that degree of sensitivity to offending substances; and 5) "hypersensitivity" that can be difficult to diagnose and treat. Some proponents have informed patients that they have "an AIDS-like illness."

According to proponents, potential stressors include practically everything that modern humans encounter, such as urban air, diesel exhaust, tobacco smoke, fresh paint or tar, organic solvents and pesticides, certain plastics, newsprint, perfumes and colognes, medications, gas used for cooking and heating, building materials, permanent press and synthetic fabrics, household cleaners, rubbing alcohol, felt-tip pens, cedar closets, tap water, and electromagnetic forces. Signs and symptoms are said to include depression, irritability, mood swings, inability to concentrate or think clearly, poor memory, fatigue, drowsiness, diarrhea, constipation, sneezing, running or stuffy nose, wheezing, itching eyes and nose, skin rashes, headache, muscle and joint pain, urinary frequency, pounding heart, swelling of various parts of the body, and even schizophrenia. Proponents state that virtually any part of the body can have "elusive symptoms for which no organic

cause can be found."

To diagnose "ecologically related" disease, practitioners take a history that emphasizes dietary habits and exposure to environmental chemicals they consider harmful. A physical examination and certain standard laboratory tests may be performed, mainly to rule out other causes of disease. Standard allergy tests are usually normal.

Various nonstandard tests are also used, the main one being provocation and neutralization. In this test, the patient reports symptoms that develop within ten minutes after various concentrations of suspected substances are administered under the tongue or injected into the skin. If any symptoms occur the test is considered positive and lower concentrations are given until a dose is found that "neutralizes" the symptoms. Elimination and rotation diets are used with the hope of identifying foods that cause problems.

In severe cases, patients may spend several weeks in environmental control units designed to remove them from exposure to airborne pollutants and synthetic substances that might cause adverse reactions. After fasting for several days, the patients are given "organically grown" foods and gradually exposed to environmental substances to see which ones cause symptoms to recur.

Treatment requires avoidance of suspected substances and involves lifestyle changes that can range from minor to extensive. Generally, patients are instructed to modify their diet and to avoid such substances as scented shampoos, aftershave products, deodorants, cigarette smoke, automobile exhaust fumes, and clothing, furniture and carpets that contain synthetic fibers. Extreme restrictions can involve staying at home for months or avoiding physical contact with family members. "Ecologically ill" patients may think of themselves as immunological cripples in a hostile world of dangerous foods and chemicals and an un-

caring medical community. In many cases, their life becomes centered around their illness.

During the past few years, clinical ecology has been investigated by three prominent scientific panels:

- The California Medical Association Scientific Board Task Force on Clinical Ecology conducted an extensive literature review and held a hearing at which proponents testified. Its report was published in February 1986 in the *Western Journal of Medicine*.

- The Ad Hoc Committee on Environmental Hypersensitivity Disorders established by the Minister of Health of Ontario, Canada, received submissions, heard testimony from a large number of professionals and laypersons, and observed practitioners at work. Their report, which was more than 500 pages long, was reviewed by an expert advisory panel which published its recommendations in September 1986.

- The American Academy of Allergy and Immunology (AAAI) published a position statement on clinical ecology in its August 1986 *Journal of Allergy and Clinical Immunology*. The statement was produced by AAAI's Practice Standards Committee and was based on an extensive literature review and comments by AAAI members.

All three groups concluded that clinical ecology is speculative and unproven. The CMA Task Force stated that "clinical ecology does not constitute a valid medical discipline" and should be considered "experimental" only when its practitioners begin to use scientifically sound experimental methods. The task force also expressed concern that unproven diagnostic tests can lead to misdiagnosis that results in patients becoming psychologically dependent, believing themselves to be seriously and chronically impaired. The Canadian experts pointed out that since diagnosis of "environmental hypersensitivity" is based on diagnostic tests of unproven reliability, it is impossible to make definitive statements about its prevalence. AAAI said that "although the idea that the environment is responsible for a multitude of human health problems is appealing, to present such ideas as facts, conclusions, or even likely mechanisms without adequate support is poor medical practice" and that "advocates of this dogma should provide adequate studies . . . which meet the usually accepted standards for scientific investigation."

Rejection by the scientific community has not dampened the enthusiasm of clinical ecologists, about 400 of whom belong to the American Academy of Environmental Medicine (formerly called the Society for Clinical Ecology). This group, which holds meetings and publishes a quarterly journal, is composed mainly of medical doctors and osteopaths. Last year the journal announced that the paper on which it is printed had been changed because several readers had complained

that the old paper had made them ill. In the same issue, the editor complained that he wasn't receiving enough acceptable manuscripts to maintain a four-times-a-year schedule.

The Human Ecology Action League (HEAL), formed in 1976, is composed mainly of laypersons and has chapters and support groups in about 100 cities. It distributes physician referral lists and publishes *The Human Ecologist*, a quarterly magazine of news and advice for patients and their families.

One area of great concern to proponents is whether insurance companies will pay for their treatment, which can be quite expensive. Advice on how to press for such payment is available from HEAL. In 18 cases reported to the Canadian committee, patients bore an average annual cost of \$4,463, with a range from \$400 to \$12,378, most of which was not covered by insurance companies or government programs.

In the United States, many suits have been filed by "ecologically ill" patients seeking reimbursement from insurance companies. In January 1987, the Association of Trial Lawyers of America voted to establish a clearinghouse on ecological illness and its legal aspects. The proposal's author was Earon S. Davis, J.D., M.P.H., a former executive director of HEAL, who publishes the bimonthly *Ecological Illness Law Report* and operates a referral service for 200 interested attorneys.

Many doctors who treat "environmental illness" believe that they themselves have it. In 1977 a federal tax court ruled that the extra cost of "organically grown" foods could be deducted as a medical expense by Theron Randolph, M.D., a leading proponent, and his wife, Janet. The Randolphs claimed that Janet experienced mental confusion, crossed eyes, and difficulty in walking when she inhaled or ingested contaminants, and that Theron had suffered from loginess, malaise, headaches, nausea and anorexia due to contaminated foods.

A few practitioners who consider themselves clinical ecologists use computerized galvanometers to diagnose "energy imbalances" and select homeopathic remedies or other products to correct these imbalances.

Although the FDA considers such devices "a significant risk" to the public and has been "investigating" them for more than a year, it has not yet attempted to stop their use.

Critics of clinical ecology have suggested that "environmental illness" is psychosomatic although its symptoms don't fit clearly into any disease category. Patients in this situation are often relieved to get a "physical" diagnosis which encourages them to play an active role in their care. However, two recent studies suggest that many of them give up much more than they get.

In the January 1986 *Archives of Internal Medicine*, Abba I. Terr, M.D., an allergist affiliated with Stanford University Medical Center, reported on 50 patients who had been treated by one or more of 16 clinical ecologists for an average of two years. He had evaluated most of these patients because they had made a Worker's Compensation claim for industrial illness. Although all had been diagnosed as "environmentally ill," Dr. Terr could find no unifying pattern of symptoms, physical findings or laboratory abnormalities. Eight of the patients had not gotten their symptoms until after they had consulted the clinical ecologist because they had been worried about exposure to a chemical. Eleven had had symptoms caused by preexisting problems unrelated to environmental factors, and 31 had multiple symptoms. Their various treatments included dietary alterations (74%), food or chemical extracts (62%), an antifungal drug (24%), and oxygen given with a portable apparatus (14%). Fourteen of the patients had been advised to move to a rural area, and a few were given vitamin and mineral supplements, gamma globulin, interferon, female hormones and/or oral urine. Despite treatment, 26 patients reported no lessening of symptoms, 22 were clearly worse, and only two improved.

Noting that the provocation-neutralization test played a major role in the misdiagnosis of most of the patients he examined, Dr. Terr pointed out that scientific studies have shown it is unreliable. He concluded that although exposure to chemicals can cause disease, it is unlikely that the diagnostic and treatment methods of clinical ecology are effective. He also concluded that

its methods and theories appear to cause unnecessary fears and lifestyle restrictions.

Carroll M. Brodsky, M.D., Ph.D., professor of psychiatry at the University of California (San Francisco) School of Medicine, made similar observations after studying eight people who had filed claims for injury primarily by airborne substances following diagnosis by clinical ecologists [*Psychosomatics* 24:731-742, 1983]. He concluded that they became "adherents of physicians who believed that symptoms attributed by orthodox physicians to psychiatric causes are in fact due to common substances in air, food, and water." He also stated that clinical ecologists "neither promise nor give hope of eliminating the offending condition, and the patients do not seem to expect it . . . [They] seem content with their condition and with the reassurance that their symptoms have a physical cause . . . Yet we must also recognize that these patients have had symptoms for many years, and whether seen as neurasthenic, hypochondriacal, or phobic, they are among the most resistant and difficult to treat . . . These patients search for healers who will provide them with an explanation of their experiences and symptoms that makes sense to them and fulfills a number of psychological needs."

Is clinical ecology ever effective despite its scientific shortcomings? Do its practitioners do more harm than good? These questions can be answered only through careful observation of large numbers of patients for several years, beginning with their first visit to a practitioner. As far as I can tell, proponents have neither the inclination nor the ability to carry out such studies, and nonbelievers don't feel there is sufficient benefit to invest the large amount of time and expense that would be required. Meanwhile, in my opinion, a high degree of skepticism is justified.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 21 books including *Vitamins and "Health" Foods: The Great American Hustle*. In 1984 he received the FDA Commissioner's Special Citation Award for Public Service in fighting nutrition quackery. His investigation of clinical ecology was subsidized by the American Council on Science and Health.

“CANDIDIASIS HYPERSENSITIVITY”

Stephen Barrett, M.D.

Have you ever taken antibiotics on a frequent basis? Have you ever been troubled by premenstrual tension, abdominal pain, or loss of sexual interest? Do you crave sugar, breads or alcoholic beverages? Do you have recurrent digestive problems? Does exposure to tobacco smoke provoke moderate to severe symptoms? Do you experience fatigue, depression, poor memory or nervous tension? Are you bothered by hives, psoriasis or other chronic skin rashes? Have you ever taken birth control pills? Are you bothered by headaches? Do you feel bad all over without any apparent cause?

According to an article in the April 1986 *Redbook* magazine: “If you have three or four ‘yes’ answers, yeast possibly plays a role in causing your symptoms. If you have five or six ‘yes’ answers, yeast probably plays a role in causing your symptoms. If you have seven or more ‘yes’ answers, your symptoms are almost certainly yeast-connected.” The article’s author was said to be “on her way to recovery” from a debilitating case of “the yeast syndrome.” In the same issue, an ad from Nature’s Way Products, of Springville, Utah, invited *Redbook*’s 12 million readers to “Take the Yeast Test,” by tabulating their answers to similar questions.

The yeast in question is *Candida albicans* (sometimes referred to as monilia), a fungus normally present in the mouth, intestinal tract and vagina. Under certain conditions, it can multiply and infect the surface of the skin or mucous membranes. Such infections are usually minor, but serious and deeper infections can occur in patients whose resistance has been weakened by other illnesses.

Promoters of “candidiasis hypersensitivity” claim that even when signs of infection are absent, the yeast can cause or trigger multiple symptoms such as fatigue, irritability, constipation, diarrhea, abdominal bloating, mood swings, depression, anxiety, dizziness, unexpected weight gain, difficulty in concentrating, muscle and joint pain, cravings for sugar or alcoholic beverages, psoriasis, hives, respiratory and ear problems, menstrual problems, infertility, impotence, bladder infections, and prostatitis. According to its promoters, 30% of Americans suffer from “candidiasis hypersensitivity.” Many clinical ecologists view it as an underlying cause of the “environmental hypersensitivity” or “immune system dysregulation” that they postulate. It is also being touted as an important factor in AIDS, rheumatoid arthritis, multiple sclerosis, and schizophrenia as well as “hypoglycemia,” “mercury amalgam toxicity” and other fad diagnoses.

Nature’s Way manufactures Cantrol, a “complete program to fight yeast infections.” The program includes: acidophilus (“to help keep yeast colonies under control”); vitamins, minerals, co-enzymes and polyunsaturated fatty acids (“to help strengthen the immune system”); Pau d’arco (“a popular South American herb”); and “dietary guidelines, which if followed, can help you ‘starve’ the rampant yeast colonies.” A 21-day supply retails for \$23.95.

Ads for Cantrol, which have been running in “health food” magazines for several years, invite people to take simple self-tests that ask whether they have common symptoms and have ever taken antibiotics. According to the ads, positive responses to at least 3 out of 6 questions (or 6 out of 14 in some ads) indicate “a high or very high probability” of yeast infection. Last year ads began stating (in very small print): “This self-test is provided for general information only and is not intended to be used for self-diagnosis without the advice and examination of a health professional.” But these ads also say, “If you suspect you have a *Candida albicans* infection, put Cantrol to the test.”

Before the *Redbook* article was published, Nature’s Way notified retailers that an ad in the same issue would “specifically instruct the consumer to go to their local health food store to purchase Cantrol.” The ad contained a toll-free number for ordering the product or obtaining further information. According to a company official, more than 100,000 people responded.

The main promoters of “candidiasis hypersensitivity” have been C. Orian Truss, M.D., of Birmingham, Alabama, author of *The Missing Diagnosis* and William G. Crook, M.D., of Jackson, Tennessee, who wrote and published *The Yeast Connection*. Dr. Crook says his book was produced after a 1983 television talk show appearance drew 7,300 requests for further information.

According to Crook, “If a careful check-up doesn’t reveal the cause for your symptoms, and your medical history [as described in his book] is typical, it’s possible or even probable that your health problems are yeast connected.” He also claims that tests such as cultures don’t help much in diagnosis because “*Candida* germs live in every person’s body . . . Therefore the diagnosis is suspected from the patient’s history and confirmed by his response to treatment.”

Crook claims that the problem arises because “antibiotics kill ‘friendly germs’ while they’re killing enemies. And when friendly germs are knocked out, yeast germs multiply. Diets rich in carbohydrates and

yeasts, birth control pills, cortisone and other drugs also stimulate yeast growth." He also claims that large numbers of yeasts weaken the immune system, which is also adversely affected by nutritional deficiencies, sugar consumption, and exposure to environmental molds and chemicals. To correct these alleged problems, he prescribes allergenic extracts, antifungal drugs, vitamin and mineral supplements, and diets that avoid refined carbohydrates, processed foods, and (initially) fruits and milk.

Due largely to Dr. Crook's promotion, public interest in "candidiasis hypersensitivity" has grown rapidly. Several other books have been published, and many manufacturers offer "yeast-free" supplements which presumably are "safer" than ordinary ones. More than a dozen manufacturers are marketing such products as Candi-Care, Candida-Guard, Candida Cleanse, Yeast Fighters, Yeast Guard, and Yeastop. In *Health Foods Business* one retailer reported serving about 150 "Candida customers" a week, with an average checkout ticket of \$80. Another said she had sold 350 copies of *The Yeast Connection* during the previous 18 months. Another retailer told *Natural Foods Merchandiser* that when she noticed how well the book was selling, she placed it on sale and set up a display in which copies were surrounded with yeast control products.

The American Academy of Allergy and Immunology (AAAI), the nation's largest professional organization of allergists, has issued position statements strongly criticizing the concept of "candidiasis hypersensitivity syndrome" and the diagnostic and treatment approaches used by its proponents [*Journal of Allergy and Clinical Immunology* 78:271-277 1986]. These AAAI position statements conclude: 1) the concept of candidiasis hypersensitivity is speculative and unproven; 2) its basic elements would apply to almost all sick patients at some time because its supposed symptoms are essentially universal; 3) overuse of oral antifungal agents could lead to the development of resistant germs that could menace others; 4) adverse effects of oral antifungal agents are rare, but some inevitably will occur; and 5) neither patients nor doctors can determine effectiveness (as opposed to coincidence) without controlled trials. Because allergic symptoms can be influenced by many factors, including emotions, experiments must be designed to separate the effects of the procedure being tested from the effects of other factors. Two years ago Dr. Crook told me he had no intention of conducting a controlled test because he was "a clinician, not a researcher."

The antifungal drug most often prescribed by proponents of "candidiasis hypersensitivity" is nystatin (Mycostatin, Nilstat), which seldom has significant side effects. However, they also prescribe ketoconazole (Nizoral), which has an incidence of liver toxicity (hepatitis) between 1 in 10,000 and 1 in 15,000 and has been

responsible for several deaths [*Journal of Infectious Diseases* 152:233, 1985]. For this reason it should be prescribed only for serious infections. Both of these drugs are expensive.

Last year two doctors from Loyola University Stritch School of Medicine reported seeing four young women whose nonspecific complaints included chronic fatigue, anxiety and depression [*Journal of the American Medical Association* 255:3250, 1986]. All four mistakenly believed they had disseminated candidiasis and were taking nystatin or ketoconazole, which had been prescribed by their family physicians. All had read *The Yeast Connection* and had carried the book into the office during their visits. One patient on ketoconazole had hepatitis, which resolved when the drug was stopped.

Worse yet, a case has been reported of a child with a severe case of disseminated candidiasis who had been seen by a "candida doctor" and given inadequate treatment [*New England Journal of Medicine* 314:854-855, 1986]. The report concluded that "the advice of yeast connection advocates may be inappropriate even for illnesses in which candida is implicated."

More than two years ago I asked the FDA to stop Nature's Way from claiming that Cantrol can prevent or treat yeast infections. (Such claims make the product an unapproved new drug that is illegal to market in interstate commerce.) An FDA official who forwarded my request to the Health Fraud Branch pointed out an additional problem: "The product's fanciful name also suggests its use in the control of cancer. Those in the know would find this suggestion reinforced by the representation that the product's ingredients include Pau D'arco, the notorious Brazilian herbal cancer cure. This and the claim that the drug strengthens the immune system subtly assert that the product is also a cancer remedy."

Despite the seriousness of this situation, I have seen no evidence that the FDA is doing anything to correct it. Nor have I seen any evidence that the state licensing boards are interested in protecting the public from the medical abuses described in this article.

AAAI's position statements on clinical ecology, candidiasis hypersensitivity syndrome, and unproven procedures for diagnosis and treatment can be obtained by sending a stamped, self-addressed 4" x 1/2" envelope to the American Academy of Allergy and Immunology, 611 E. Wells St., Milwaukee, WI 53202.

**COMING SOON
HOXSEY TREATMENT
STILL AVAILABLE**

BRIEFS

National Health Fraud Conference. The FDA and St. Mary's Hospital of Kansas City, Missouri, are co-sponsoring a conference for individuals, groups, and government agencies interested in fighting quackery. The meeting is scheduled for March 13-15 in Kansas City. The entrance fee is \$200, but some scholarships are available. To register or obtain more information, contact Linda Strub, St. Mary's Hospital, 2800 Main, Kansas City, MO 64108 (816-756-1222).

New quackery booklet. The FDA and Council of Better Bureaus have published a 9-page booklet, *Quackery and the Elderly*, which explains why the elderly are vulnerable and briefly discusses cancer, arthritis and "anti-aging" frauds. Free copies can be obtained from the Food and Drug Administration, HFE-40, 5600 Fishers Lane, Rockville, MD 20857.

B₆ and PMS. A double-blind study of 55 women who reported moderate to severe premenstrual mood changes found that vitamin B₆ improved autonomic symptoms (dizziness and nausea) but did not relieve depression or anxiety, which the researchers thought were more disabling [*Obstetrics & Gynecology* 70:145-149, 1987]. Participants in the study were given either a 50 mg vitamin B₆ tablet or a placebo three times a day with meals for three months. The researchers concluded, "In light of the potentially toxic effects of low doses of B₆ and the fact that our data do not clearly indicate supplementations to be of clinical significance . . . professionals should more closely reexamine the propriety of recommending this supplement to women with premenstrual syndrome."

Author withdraws from ADA. Shari Lieberman, R.D., author of *Design Your Own Vitamin and Mineral Program* [see NF Sept. 1987], has withdrawn from the American Dietetic Association (ADA). Ms. Lieberman, who advertises that she practices "preventive medicine, holistic health and progressive nutrition," was censured in 1985 for failing to adhere to the group's Standards of Professional Responsibility. In August 1987, Dr. Stephen Barrett asked the ADA to determine whether she was still violating its standards. When notified of this, she resigned.

New food products. According to *DFS-Dorland New Product News*, food manufacturers introduced 6,107 new products to U.S. markets during 1986, up 9% over 1985. The most active categories in 1986 were brownies, wine coolers, flavored seltzers, imported beers, soft drinks, isotonic beverages, premium cookies, chocolate bars, and blended juice drinks. Calcium-fortified foods, ethnic foods, and microwaveable foods also enjoyed success. During the first quarter of 1987, 1,725 products were introduced, a 23% increase over the same period in 1986.

United Sciences is defunct. The founder and five other former officials of United Sciences of America (USA) have settled the suits brought against them and the company by the Attorneys General of New York, Texas and California. Without admitting fault, they have agreed to pay \$35,000 to each of these states and to refrain from making any of a long list of unproven, misleading and/or illegal statements about USA's food supplement products. The company itself, which had declared bankruptcy in January 1987 [see NF 4:25-32], had its assets liquidated by auction on May 12th and no longer exists. However, its products, including a Youth Formula that had not been marketed, are now being sold by USA Star Products of Richardson, Texas, which notified former distributors that it had obtained the rights to market them.

Marketing trends. According to an article in *Delta Airlines' September 1987 Sky Magazine*, high-tech research companies can track the behavior of individual households from TV sets to checkout counters. One company, for example, can test the effect of commercials by recording what channels are being watched and comparing this with purchases made by household members as tabulated by computers at supermarket checkouts. Sky also reports a trend toward "megamarkets," supermarkets that contain upwards of 100,000 square feet of floor space, stock 70,000 items (four times as many as the "typical" supermarket), and generate revenues of \$2 million a week. They may also sell clothing and electronic equipment and provide a wide range of basic customer services such as dry cleaning and shoe repair. According to the magazine, "futurists envision patrons riding motorized minicarts up and down the aisles, tossing groceries into the front."

FDA seizes primrose oil. During the past few years, several companies have been selling capsules of evening primrose oil (gamma linolenic acid) with various claims that it is effective against high blood pressure, premenstrual syndrome, benign breast disease, obesity, brain damage due to alcohol, and hyperactivity in children. In 1985, the FDA notified its field officers to inform these marketers that evening primrose oil could not be sold legally in the United States. In February 1987, after several warnings, the agency seized capsules with a retail value of \$120,000 from Swanson Health Products of Fargo, North Dakota. When the company made no move to claim them, the capsules were destroyed under a court order.

"Life Extension" products seized. On February 26, 1987, FDA officials and U.S. marshals seized large quantities of Life Extension Products marketed by the Life Extension Foundation of Hollywood, Florida. The products included BHT (promoted for herpes and AIDS), DMSO (for arthritis and bursitis), Coenzyme Q₁₀ (for cardiovascular disorders and increased longevity), and Cognitex (to enhance mental function). Subsequently, the Foundation announced that it had sold the marketing rights for its nutrient products to Life Extension International, of Tempe, Arizona. If they remain independent of each other, the Foundation can promote the ingredients in the products, while Life Extension International can sell them without claims. Foundation president Saul Kent plans to promote legislation to weaken the FDA.

Aspartame passes another test. Researchers from Duke University have conducted a double-blind test on 40 people who reported experiencing headaches repeatedly after consuming products containing aspartame [*New England Journal of Medicine* 317:1181-1185, 1987]. Most of the subjects were well educated and overweight and had a family or personal history of allergic reactions. The incidence of headaches after aspartame (35%) was not significantly different from that after placebo (45%). No serious reactions were observed and the incidence of symptoms other than headache following aspartame was also equivalent to that after placebo. The researchers concluded, "This finding emphasizes the importance of double-blind studies to assess adverse reactions to a food or food ingredients." The study was supported by a grant from the NutraSweet Company. Reprints can be obtained from Susan S. Schiffman, Ph.D., Department of Psychiatry, Duke University Medical Center, Durham, NC 277110.

Comatose patient dies. Six weeks after the New Jersey Supreme Court authorized removal of her feeding tube, Nancy Ellen Jobes died. The court decreed that the patient's right to self-determination could supersede the treatment policies of a medical institution. Ms. Jobes had been comatose since 1980 as a result of an anesthesia accident [NF 3:7].

Drinking water hotline The U.S. Environmental Protection Agency has established a toll-free hotline for general and technical information about the quality of drinking water. The number is 1-800-426-4791 (382-5533 in the Washington, D.C. area). The line is open Mondays through Fridays from 8:30 a.m. to 4:30 p.m. Eastern Time.

"Diet doctor" sued. According to *Physicians Financial News*, Blue Cross and Blue Shield of Northern Ohio is suing under the federal Racketeer Influence and Corrupt Organizations (RICO) Act to recover money paid for fraudulent claims submitted by a doctor who was operating a diet clinic. Following a tip on the company's anti-fraud hotline, a claims analysis revealed that the doctor was the highest paid family practitioner in the plan's service area. Undercover investigators then posed as patients and found that treatment routinely consisted of a very brief discussion with the doctor, a weigh-in, and purchase of diet supplements. But following every visit, the doctor submitted a claim for one hour of individual psychotherapy at \$80.

QUESTION BOX

Q. What is modified food starch? Why is it added to foods?

A. Modified food starch results from the chemical treatment of raw starch. This treatment involves bleaching, oxidizing, or cross-linking (combining) starches with other substances to make them more useful and versatile in food formulations. Modified starches are found in such foods as soups, pie fillings, sauces, gravies, and infant foods, where they serve to control texture, viscosity, acid stability, and gel structure. Moderate additions of modified food starch to infant foods and other processed foods are not thought to pose any dietary hazard.

AVOIDING SALMONELLA INFECTIONS

Morris G. Mast, Ph.D.

"Salmonella" has almost become a household word during the past two years. Reports in the media imply that salmonella infections are something new and that human foodborne illness is increasing as a result. Although salmonellosis is actually not new and may not actually be increasing, it does deserve attention from everyone involved in food handling and preparation.

Salmonellae comprise a large group of bacteria that cause a variety of infections in humans and animals. The first species of salmonella was isolated in 1885 by D.E. Salmon, for whom the organism is named. Although the bacteria can be found practically everywhere, they are mainly associated with animals, especially in the gastrointestinal tract. Insects, rodents and pets—especially dogs, cats, turtles and birds—can also carry these bacteria. Humans become infected by eating contaminated food or through contact with a contaminated animal or human carrier. The most common disorder in humans—and the focus of this article—is a gastroenteritis which is usually mild and self-limiting. In addition to cramps and diarrhea, its symptoms can include vomiting, headache and fever.

Because salmonellosis is frequently mistaken for the flu, it is virtually impossible to determine the number of cases that occur each year. The Centers for Disease Control has estimated that in 1986 there were 37,000 cases of salmonellosis in the United States—a 50% increase over the number 10 years ago. However, at a national salmonellosis seminar in 1978, a USDA official said the incidence at that time could be anywhere from 20,000 to 2 million cases annually. So, although case reports have increased, it is unclear whether the problem is greater or doctors are simply more aware of it and therefore reporting it more often.

To reduce the incidence of salmonellosis, a two-pronged approach is required: 1) the food production and processing industries must make efforts to produce and process salmonella-free products; and 2) consumers and food service personnel must handle food properly.

Theoretically, it is possible to produce and process salmonella-free products. But such procedures are expensive and may be impractical. The poultry industry, for example, has pursued research efforts to control salmonella bacteria for many years. Studies have identified three factors that serve as vehicles for salmonellae to enter poultry populations: feed contamination, environmental contamination, and egg transmission. All three of these areas must be controlled simultaneously to eradicate the bacteria.

Would consumers be willing to pay the additional cost of producing and processing salmonella-free foods? Probably not, especially when they understand that simple precautions will prevent salmonellosis even when an uncooked product harbors the organism. The key principles are heat and cleanliness. Salmonella bacteria are readily destroyed when foods are heated to an internal temperature of 155°F, which is well below the 175-185°F range in which poultry is commonly cooked.

Problems in food handling result from recontamination, which can be reduced by adhering to the following guidelines:

- Don't use the same platters and utensils before and after cooking.
- Always wash your hands, kitchen countertops, utensils, dishes and cutting boards thoroughly with soap and hot water after contact with raw meat, poultry and other raw foods. You might even use separate cutting boards for raw and cooked meat. Never use the board for any food that will not be cooked unless you first wash the board thoroughly in detergent and water.
- When thawing frozen meat in the refrigerator, don't allow it to touch or drip onto other food.
- After cooking, don't allow meat, poultry and other foods to stand at room temperature for longer than two hours. Bacteria grow well under these conditions and thrive at temperatures between 45°F and 115°F. Keep foods below 40°F. Remember that foods contaminated with salmonellae may not smell or taste abnormal.
- Be on guard for pets with symptoms of salmonella infection. Pet feeding dishes, toys or bedding should not be allowed in the kitchen or near items in contact with family's food. Wash your hands thoroughly after handling pets and before preparing food. Teach your children to wash their hands before they enter the kitchen.

Everyone who handles foods should be educated about these basic practices. An ideal place to begin is in the elementary schools.

There's no need to panic about salmonellosis. Protection can be achieved by following the above guidelines.

Dr. Mast is a professor of food science at The Pennsylvania State University.

HOXSEY TREATMENT STILL AVAILABLE

James A. Lowell, Ph.D.

Not long ago, at 7:00 a.m. on a sunny Saturday morning, a colleague and I boarded a bus with twenty others at the Ambassador Hotel in Los Angeles and headed south toward San Ysidro, California, and the Mexican border. Along the way, we stopped several times to pick up passengers, swelling our ranks to nearly forty. At the border we left our American bus and squeezed into a smaller Mexican bus which shuttled us to the cancer clinics in Tijuana.

The trip was sponsored by the Cancer Control Society, a Los Angeles-based group which promotes "alternative" therapies and preaches that cancer, heart disease, diabetes, arthritis and multiple sclerosis are "degenerative" conditions caused mainly by poor diet. Although medical science recognizes that diet and cancer are related, it does not believe that any of these diseases are caused by dietary deficiency or cured by dietary change. The Cancer Control Society, however, advocates dietary regimens and disproven drugs such as laetrile, which it claims is a vitamin deficient in persons with cancer. In fact, it supports virtually anything claimed to be a "nontoxic alternative" to the "cutting, burning and poisoning" used by scientific practitioners. It sponsors meetings, publishes a journal, sells publications, distributes a directory of practitioners who offer "nontoxic therapies," and provides lists of patients willing to give testimonials for such methods. Its Mexican tour operates several times a year and costs \$75.

Tijuana contains many modern buildings, and shopping centers are springing up everywhere. But filth and squalor are still very much in evidence. One clinic operator told us that after taking one quick look at the town, many potential patients return to the United States without even making the 15-minute trip to his clinic.

Our first stop was the Bio-Medical Center operated by Mildred Nelson, R.N. Carved into a hillside along the treacherously steep General Ferreira Avenue, this facility is located high above the city in a mansion

that was formerly a private residence. The clinic, surrounded by a high wall, is identified only by a small yellow sign with white letters.

After walking through a guardhouse door, we entered a spacious central courtyard containing manicured lawns, a pool, and a walk-in aviary. The house is a large two-story structure which contrasts with the unpretentious single-story stucco homes that surround it. Although modern in design, it incorporates a hodgepodge of architectural features, including a shake roof, yellow and white plastic awnings, and 20-foot Dorian columns, two of which flank oversized carved wooden doors. From its windows or the adjoining balcony, one can see for miles across Tijuana and into the United States. One end of the building has a dressing room and the other end houses several treatment rooms and Mildred Nelson's office. We were told that the second story is not used because it is unfinished.

The Bio-Medical Center treats cancer patients on an outpatient basis. While many treatments last only one day, certain laboratory tests or special cases may require that the patient spend one or more nights in a motel. When this is necessary, most elect to return to the cleanliness and comfort of the motels in San Ysidro.

Nelson's treatments are based on the secret formulas of the late Harry Hoxsey, who originally said they were passed down to him by his father. Later, however, he claimed that his great-grandfather had developed them in 1840 after one of his horses with a cancerous growth on its leg cured itself by grazing among herbs in a corner of a pasture. Hoxsey's father died of cancer in 1919, and his mother died of cancer two years later.

Hoxsey began promoting his method in the early 1920s. During the late 1920s, in Illinois, he was convicted three times of practicing medicine without a license. In 1930, he was permanently enjoined from violating the Iowa State Medical Practice Act. In 1936, after unsuccessful attempts to practice in other states, he moved to Dallas, Texas and continued to see patients at the

Hoxsey Cancer Research Foundation until vigorous action by the FDA between 1950 and 1960 forced him to stop. In various trials against Hoxsey, the government demonstrated that the patients he claimed to have cured fell into three categories: 1) those who never had cancer; 2) those who had been cured of cancer before they went to his office; and 3) cancer patients who still had their disease or had died despite Hoxsey treatment.

Hoxsey's operations were taken over by Mildred Nelson, who had worked for years as Hoxsey's chief nurse. Nelson told us she joined him in 1946 after he had treated her mother for skin cancer. Mildred said that she originally thought Hoxsey was a quack but accepted a job at his clinic and became so impressed after one year that she decided to stay. After the Texas clinic was shut down, she tried opening new facilities in several other locations in the United States. Finally, under Hoxsey's tutelage she moved to Tijuana and opened the Biochemical Research Institute a few doors away from the current clinic building. The structure now houses the clinic "pharmacy," where patients are sent to pick up their medications. Hoxsey, who had been suffering from a heart condition he blamed on persecution by the medical establishment, died in 1973, years after the Mexican operation was in full swing.

Nelson is a small woman with short-cropped grey hair and steel blue eyes who appears to be in her late 60s. While explaining the workings of her clinic, she was never without a cigarette smoldering in her tobacco-stained fingers.

During our visit, we spent over an hour interviewing her privately after we indicated that my colleague (Lynn) might be interested in treatment. Several years ago, Lynn had parts of both ovaries removed after a biopsy had revealed precancerous cells. Although there is no current evidence of malignancy, she is being monitored carefully by a cancer specialist.

Nelson began the interview by showing us around the clinic and explaining that her move to Tijuana was the result of persecution and vilification by the "establishment authorities" and the AMA. In Mexico, she said, she was free to help people without government interference. Then she told Lynn that "cancer always comes back" and that she would be in "extreme danger" without Hoxsey treatment. The treatment, Nelson claimed, was especially effective against ovarian cancers and would probably prevent recurrence. Even though Lynn is a teacher with a strong science background and several years of experience in investigating quackery, she was in tears by the time Nelson finished her promotional pitch. As we left, Nelson handed us a booklet entitled *Do You Have Cancer?*, which described the clinic and contained 12 pages of testimonials from patients who believed the Hoxsey regimen had helped them.

Nelson's outpatient treatment costs \$3,500, up from \$1,800 three years ago. The fee is for lifelong care, which includes the initial one-day treatment plus any return visits. Patients are encouraged to wait six months but may return sooner if necessary as long as they follow the recommended regimen. Laboratory fees of \$150-\$450 are extra and must be paid when tests are run. Special medications, which also cost extra, may be prescribed. Normally, at least 30% of the total cost must be paid on the first visit, with the balance due in monthly installments. Patients can obtain an itemized list of services rendered, but the clinic personnel will neither provide insurance forms nor help fill them out. This is because few insurance companies in the United States will knowingly reimburse patients for unproven treatments at Mexican clinics. Nelson says she will never turn people away for lack of money if they explain to her beforehand they can't afford to pay.

Patients checking in at the clinic are asked to complete a registration form which asks for diagnosis as well as identifying information. They are told that this is the best time to leave copies of medical records if any are available. Urine and blood samples are collected for standard tests and a medical history is taken by a physician. After undergoing physical examination, the patient is x-rayed, and in some cases computerized tomography scans (CT-scans) are obtained at a cost of \$350-\$500. After analyzing the test results and discussing them with other doctors at the clinic, the examining doctor gives the patient a diagnosis and recommendations for treatment.

Nelson's remedies are of two basic types, external and internal. External cancers are treated with a "red external paste," which contains antimony trisulfide, zinc chloride and bloodroot, and a "yellow external powder," that will literally burn off skin tissue. Until the advent of good surgical techniques, escharotics such as these were used to destroy external cancers. Unlike surgeons, however, such compounds are unable to distinguish between normal and abnormal tissues, so they can destroy large amounts of healthy tissue along with the cancer. In fact, during our visit we encountered one patient whose ear was being treated by Nelson. Most of the ear was missing.

The "internal formula," used for internal cancers, is a liquid containing licorice, red clover, burdock root, *Stillingia* root, barberry, *Cascara*, prickly ash bark, buckthorn bark and potassium iodide. According to Nelson, this combination is supposed to restore the acid/base balance and "deal with the DNA," the genetic material of the body. This explanation is interesting because *nothing* was known about DNA when the original treatments were developed by Hoxsey's father and little was understood about acid/base balance during Hoxsey's lifetime. Other medications—which cost extra—include superoxide dismutase (SOD), vitamin B₁₂, Gerovital, DMSO, and some we have not encountered elsewhere: probolin liver, TST-100, rosette "cactus," and Shulte's medications.

Like the other Mexican clinics, Nelson's clinic also places its patients on a special diet. Hers excludes tomatoes, vinegar, alcohol, pork, bleached flour or white sugar, carbonated beverages, and spicy foods. Food supplements include yeast and iron tablets, vitamin C, and calcium capsules. Patients are advised to drink at least two quarts of fluid daily, including large quantities of grape juice diluted by half with water.

Nelson claims that her success rate in curing cancers is 80% if the lymphatic system is not involved. Melanomas and ovarian tumors respond best, she adds. While she says she has records to support such statistics, she is quick to point out that they might not be adequate for orthodox investigation. Much of her data come from patients who are treated and later call or write back saying they have been cured. Although she claims to have accurate records on every one of the thousands of patients she has treated, she also said she has no idea how many patients she treats each year.

Nelson also claims that the efficacy of her treatment has never been scientifically evaluated. That is untrue, however. In *The Medical Messiahs*, historian James Harvey Young describes how the National Cancer

Institute evaluated 137 case reports submitted by Hoxsey and concluded that they showed no evidence that his treatment had helped any of them.

In 1955 Senator John Haluska of Pennsylvania introduced Hoxsey to the State senate while holding Kathy Allison, a young girl from Indiana in his arms. In a lengthy oration, Haluska declared that Hoxsey had cured her cancer. However, eight months later she was dead.

In 1985, David Zinman, a medical writer for *Newsday*, interviewed patients undergoing the Hoxsey treatment. One was Betty Diede of Portland, Oregon. At first, her tumors seemed to shrink, but within six months they had obviously enlarged and she was back for further treatment. Another patient was Nellie Davis from Adelaide, Australia, whose colon cancer had spread to her liver. She told Zinman she felt much better as a result of the Hoxsey treatment, yet her tumors had enlarged so greatly that she had to wear a maternity dress to cover her swollen abdomen.

Another recent case was that of Karen Ziegler, a 12-year-old California girl who was diagnosed with stage II Hodgkin's disease in November 1983. Her parents refused orthodox therapy and instead took her to various unorthodox practitioners. According to *The Choice*, a publication that promotes unorthodox methods, Karen was treated at least twice with the Hoxsey preparations at the Bio-Medical Center. Nevertheless, she died on Christmas Day 1985 at the age of 14 from a disease whose cure rate is close to 90% with standard medical treatment.

Dr. Lowell, who has graduate degrees in botany and genetics, is Professor of Life Sciences at Pima Community College in Tucson, Arizona, and is vice president of the National Council Against Health Fraud. His recently revised book, *Health Hoaxes and Hazards*, is available for \$13.50 from the Nutrition Information Center, 255 N. Granada, #2058, Tucson, AZ 85701.

QUESTION BOX

Q. Is rheumatoid arthritis related to diet?

A. Not usually. Most investigations of this issue have not been rigorously designed. One well designed study has concluded that some patients with this condition may be helped [*Lancet* 1:236-238, 1986]. There have also been reports that short periods of fasting may help. However, it is likely that fewer than 5% of individuals with rheumatoid arthritis will improve after elimination from their diet of a specific food [*Annals of Internal Medicine* 106:619-621, 1987]. According to Frederic C. McDuffie, M.D., the Arthritis Foundation's Senior

Vice President for Medical Affairs, "In most individuals with rheumatoid arthritis who believe that their disease is worsened by a specific food, any improvement following elimination is probably a placebo effect."

The Arthritis Foundation recommends that rheumatoid arthritis patients who believe their disease is worsened by a food consult with their physician and undergo a trial elimination of the food under medical supervision to see whether any improvement results.

ADVICE IN HEALTH FOOD STORES

Clare Aigner, R.D., M.S.

Do health food store personnel give reliable advice? And do they operate within the law? To explore these issues I posed five questions by phone or in person to salespeople from ten "health food stores" in Allentown, Pennsylvania and nearby communities:

Question #1: "My mother has been complaining that her eyes are sore, her vision is blurred, and she sees colored halos around bright lights. Do you have any suggestions?" These symptoms are typical of glaucoma, an eye disease which, if untreated, can cause blindness. So the correct answer is "See a doctor." Only seven of the ten retailers made a recommendation of this type.

Question #2: "I'm training for a wrestling tournament and need to lose ten pounds but keep my energy levels up. Do you have any advice?" Although the correct answer is to lose weight slowly with a balanced diet, six of the stores suggested amino acids or other supplements.

Question #3: "I lost 15 pounds in the last month. I don't know why and I'm concerned. Do you have any advice?" Since unexplained weight loss could be a symptom of hyperthyroidism, diabetes, cancer and many other potentially serious diseases, the correct answer is "See a doctor." Only three of the ten retailers advised this.

Question #4: "I'm pregnant, and my doctor told me to take calcium supplements. I heard that dolomite is a good source. Is it?" Although dolomite contains absorbable calcium, the FDA has recommended that pregnant women avoid dolomite because some samples have contained undesirably high levels of lead. Six stores said that dolomite is not the best source of calcium, but only three of the six mentioned the lead problem.

Question #5: I heard that bee pollen is good to take. Is it? Bee pollen costs about \$45/pound and contains no nutrients not readily obtainable from a balanced diet. It is falsely reputed to aid endurance and be a special source of energy. The only energy it can

provide comes from its caloric value, which is small. Bee pollen can also cause allergic reactions. Only four stores warned of its allergic potential, while the rest said it was a good energy source. One even claimed it was possible to live on bee pollen and water alone.

The table on pages 2 and 3 describes my results. In cases where correct advice was given, even though the reason behind it was wrong, I gave credit for a "correct" answer. Even so, the stores in my community gave correct answers less than half the time. Similar results were reported by researchers from the American Council on Science and Health in a survey of stores in New York, New Jersey and Connecticut published in the Council's May/June 1983 newsletter.

Only one store answered all five questions correctly. "We don't prescribe because it's against the law," a co-owner later told me. "We are not vitamin pushers. Most health food stores start out as vitamin stores and add a little food. We began eight years ago as a food store and added some vitamins. If you eat properly, you don't need them."

The American Dietetic Association (ADA) is collecting case reports of people harmed by inappropriate nutrition advice from bogus "nutritionists," health food store operators, and others. Since opening its registry in October 1986, the ADA has documented more than 100 cases.

Under federal laws, it is illegal to market products with oral claims that they can mitigate or cure disease unless these claims have FDA approval. Under state laws, only physicians and a few other types of licensed practitioners can diagnose and treat diseases. Health food store operators who recommend products for specific symptoms or conditions could be prosecuted for violating drug laws as well as for practicing medicine without a license. But government agencies have shown little or no interest in this problem.

	% correct	Blurred vision and halos around lights	How can a wrestler lose ten pounds and keep up energy?
Store #1	80%	✓See a doctor	✓Mentioned protein supplements but said it could be done with food
Store #2	20%	"Might be cataracts." Could try vitamin A (25,000 IU), zinc, and Eye-Bright herbal tea	Mentioned megavitamins, octacosanol and amino acids. Said "You can't get enough vitamins in food because soil is depleted."
Store #3	20%	✓See a doctor	Suggested All-in-1. Advised against carbohydrate powders
Store #4	60%	✓See a doctor	✓Said it could be done with three balanced meals. Advised taking a multivitamin supplement
Store #5	100%	✓See an optometrist	✓Said there are different viewpoints and presented alternatives. Said it could be done with regular food
Store #6	20%	It might be a nutrient deficiency or even a digestive problem. Suggested beta-carotene.	Suggested grapefruit diet, carbohydrate powders, Amino-Fuel, ornithine, arginine, phenylalanine and "vitamin B ₁₅ "
Store #7	60%	✓See a doctor or nutritionist	Suggested carbohydrate powder
Store #8	0%	Suggested Eye-Bright herbal tea	Suggested arginine, ornithine and amino acid complexes
Store #9	80%	✓See an optometrist	✓Go to "a place where they can determine your nutritional needs"
Store #10	20%	✓See an ophthalmologist. Also said it could be cataracts or "vitamins—you get to that age and your body doesn't make B-vitamins"	Suggested arginine, ornithine and glutamine
% correct	46%	70%	40%

During the past few years, dietitians have gained passage of licensing laws in seventeen states, nine of which also define and regulate the practice of nutrition. These laws allow health food retailers to give limited advice about diet and use of their products, but do not permit nutritional assessment or counseling. In 1987, Florida passed a law forbidding the advertising, labeling or commercial distribution of any product lacking FDA approval and represented to have an effect on blood

disorders, bone or joint diseases, kidney disorders, cancer, diabetes, gallbladder disorders, heart disease, high blood pressure, disorders of the ear, mental disease, mental retardation, paralysis, prostate gland enlargement, impotence, baldness, venereal diseases, breast enlargement, immune system disorders, life expectancy, stress and tension, the body's defense mechanisms, and several other conditions and body processes.

These laws make it riskier for health food stores

Unexplained 15-pound weight loss	Is dolomite a good source of calcium for pregnant women?	Is bee pollen good to take?
✓See a doctor	✓No, because it has lead in it	Yes—a good source of vitamins, minerals and energy; and good for allergies
"We have things for that. Come in."	✓No, because of lead. Suggested calcium carbonate	Yes—a good energy source. "You could live on water and bee pollen alone."
Suggested protein powder	Yes	Good for energy
Advised to find out why, but did not mention doctor. Mentioned protein and carbohydrate powders.	✓No, because it is difficult to absorb	Yes—good because it contains an enzyme that releases oxygen to the body
✓Get medical help	✓No, because of lead	✓Bee pollen provides only small amounts of energy
Said there are things, but couldn't guarantee them	✓No, because it is difficult to absorb	A good source of energy
Suggested protein powder	✓No, because of lead	✓Bad because some people are allergic to it
Suggested protein powder and B vitamins	Dolomite is good calcium source	A good energy source
✓See a doctor	Dolomite is all right but not the best. Recommended 1,000 mg	✓Bad because some people are allergic to it
Suggested amino acids and protein powders	Dolomite is an excellent source and is also good for the nerves	Good for allergies and energy
30%	60%	30%

to give" therapeutic" advice; but it remains to be seen whether these laws will be enforced.

Ms. Aigner is a dietitian employed by the Wood Company, a food service management company in Allentown, Pennsylvania.

CANADIAN "HEALTH FOOD" SURVEY RELEASED

During the summer of 1986 the Canadian Health Protection Branch (the equivalent of the U.S. Food and Drug Administration) surveyed public perception of health foods, natural foods and the medicinal use of herbs. The survey, conducted by university students, asked twenty specific questions in face-to-face interviews with 4,557 urban and rural residents in five major population centers.

Two conceptions emerged from the survey's attempt to determine whether there is a generally held definition of "health foods." One is that health foods are basic foods such as vegetables, fruits, nuts, grains and dairy products that are free of chemicals or additives. The other is that health foods are fad foods that have little to do with good health and much with the promotion of products for profit. Almost two-thirds of those interviewed said there is a difference between health foods ("unprocessed, organic, California-type foods") and foods recommended for a healthy diet (Basic Four Food Groups, Canada Food Guide).

The survey also found:

Usage: When specifically asked, fewer than half of the respondents claimed to be regular users of "health foods." (Interpretation of this figure was complicated by the fact that many respondents perceived grains, nuts, fruits, vegetables and dairy products as health foods.) About one-third said they used "organic" foods and 18% used herbs for medicinal purposes. Forty-two percent of respondents said they took a daily vitamin and/or mineral supplement. Of these, 25% took a multivitamin, 14% took vitamin C, and 10% took calcium. Only 64% of respondents said they were aware that it is possible to damage their health by taking too much of vitamin or mineral supplements.

Sources: Most respondents who said they were users of health foods cited supermarkets as the shopping outlet they patronized most. Specialty stores scored second, although most respondents thought that prices were higher. Other significant sources were open air markets and farms, but not door-to-door sales, house parties and health professionals.

Medical value: About 24% of the respondents had treated themselves with either a food, a drink, or a diet supplement which they thought could cure a medical problem. When asked whether they had heard of any cures for arthritis, cancer or depression, Vancouver residents cited vitamin B-complex (47%) for depression; fiber (43%) for cancer; cod liver oil (24%) and garlic (11%) for arthritis, and vitamin C (19%) for cancer. Two other products associated with medical benefits were vitamin E (various skin conditions) and ginseng (virility and fertility). Spirulina and taheebo tea were not well known to the respondents.

Motivation: The enthusiasm of a friend was by far the most dominant influence on the consumer to buy a new and unfamiliar food or diet supplement. This was highest (44%) among youth but dropped off to 23% for the oldest age group. Store personnel reportedly influenced 30% of respondents.

Diet patterns: When asked whether there was anything they were trying to cut down on, 58% of women and 40% of men said sugar, 41% of women and 36% of men said fats, and 35% of women and 28% of men said salt. Coffee and red meat were mentioned also.

Pesticide use: About 27% of the respondents said they were opposed to the use of pesticides in the production of food crops, and 52% wanted controls on the use of pesticides.

False claims: When asked what action they would take if victimized by a false claim about a food, beverage or cosmetic, one-third said they would avoid buying the product again, and many preferred taking legal action. Only 18% would contact the place of purchase. Almost 80% of the people said that promoters of health foods should be required to show proof of the claims they make about their products. Only 12% said, "Let the consumer decide."

Nutrition knowledge: Three-fourths of respondents had never taken a nutrition course, this percentage being as high as 91% for the oldest age group. The three major sources of nutrition information were stated to be magazines, newspapers, and radio and television, in that order. The majority wanted more nutrition information supplied by the government and more nutrition education at various levels of schooling.

Copies of the report (Cat. No. H39-110/1987) can be obtained from the Health Protection Branch, Food Directorate, HPB Building, Tunney's Pasture, Ottawa, Ontario K1A 0L2.

QUESTION BOX

Q. Does the stomach shrink when food intake is very small—for example, when someone is on a diet?

A. Contrary to popular belief, the stomach does not shrink after periods of limited food intake. The empty stomach is a flabby bag of predetermined size. When food is eaten, the stomach expands to accommodate it. As the food leaves the stomach, the smooth muscles contract and allow the stomach to resume its original shape. When food intake is low for long periods of time, the stomach does not shrink but merely remains its original size.

BRIEFS

Fiber labeling petition. The Center for Science in the Public Interest (CSPI) wants the FDA to order disclosure of dietary fiber content (grams per serving) on all nutrition labels. In 1979, the agency said it would not do this until there is: 1) a clearer consensus on a definition of dietary fiber; 2) methods of analysis are developed; and 3) the significance of fiber in the diet is better understood. According to CSPI's petition, all of these criteria have been met. CSPI also wants the FDA to take regulatory action against misleading claims, many of which are quoted in the petition.

Comatose patient dies. Six weeks after the New Jersey Supreme Court authorized removal of her feeding tube, Nancy Ellen Jobes died. The court decreed that the patient's right to self-determination could supersede the treatment policies of a medical institution. Ms. Jobes had been comatose since 1980 as a result of an anesthesia accident [NF 3:7].

Reagan and bee pollen. According to *Parade Magazine*, President Reagan has been eating bee pollen since 1961 and says it is an energy restorative. The company which supplies it—as 153-calorie snack bars—claims that bee pollen has rejuvenating properties and helps Reagan maintain his natural hair color.

Laetrile case ends. As instructed by the U.S. Court of Appeals, Federal Judge Luther Bohanon has ended injunctions he issued in 1977 that prohibited government agencies from interfering with the importing of "personal supplies" of laetrile by "terminal" cancer patients. Bohanon also dismissed the lawsuit that prompted the injunction. The plaintiff was Glenn Rutherford, who believed that laetrile had cured his cancer (contained in a rectal polyp) even though it had been treated by cauterization in its early stages. Since laetrile lacks FDA approval, marketing it in interstate commerce remains illegal.

New help for quackery victims. The National Council Against Health Fraud has established a Task Force on Victim Redress to help victims of quackery obtain competent legal assistance. The task force will also help government agencies prosecute cases involving quackery and health fraud.

Adolescent vitamin use. A study of 163 students in rural Iowa high schools found that 64% thought natural vitamins were better than manufactured ones, 56% thought that most teenagers need vitamin and mineral supplements, 50% thought people who felt tired and run-down probably need more vitamins and minerals, and 47% thought extra vitamin C prevents colds [*Journal of the American Dietetic Association* 87:1063-1065, 1987]. Supplement use was reported as almost daily by 16%, several times per week by 7%, several times per month by 13%, and less often during the past year by 21%. The higher the level of false beliefs, the more likely students would state that vitamins gave them energy, cured their colds, made them feel nutritionally safer, helped them perform better in sports, and/or made them healthy.

Food stamps for vitamins? U.S. Representative Mickey Leland (D-TX) has asked the U.S. Department of Agriculture to allow recipients of food stamps to use them to purchase nutritional supplements. Leland, who chairs the House Select Committee on Hunger, announced this in September at the annual conference of the Council for Responsible Nutrition (CRN), a trade association for supplement manufacturers and major distributors [see NF 4:38-39]. He also asked CRN members to set up pilot programs to help inner-city school children or the elderly to "give your fellow citizens and the government proof of the value of supplements that cannot be denied." *Editor's note:* Although some people might benefit from such a program, a poor diet plus supplements can still be a poor diet. Rather than encourage supplement use, it would be better to promote dietary improvement.

Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

Study finds no sugar-hyperactivity link. Researchers at the National Institute of Mental Health have found no link between sugar, aspartame, saccharin and hyperactivity in a double-blind test of 30 preschool boys [*American Journal of Psychiatry* 144:1487-1490, 1987]. Reprints can be obtained from Markus J.P. Kruesi, M.D., Child Psychiatry Branch, National Institute of Mental Health, 9000 Rockville Pike, Bldg. 10, Rm. 6N240, Bethesda, MD 20892.

Beech-Nut pleads guilty. Beech-Nut Nutrition Inc. has pleaded guilty to 215 felony counts of adulteration under the Food, Drug, and Cosmetic Act for selling flavored sugar water labeled as apple juice for babies [see NF 3:91]. In a plea bargain, the company admitted shipping the bogus juice between December 1981 and March 1983 and agreed to pay a \$2 million fine plus \$140,000 for investigative costs.

Roche ads improve. For many years, Hoffmann-La Roche has engaged in misleading advertising campaigns to promote supplements to pharmacists as well as the general public. Since 1979, various campaigns have suggested that busy people need supplements for "insurance," that biotin should be included in supplements (even though dietary deficiency is virtually nonexistent in the United States), and that supplements of "Protector Vitamin E" protect against inadequate dietary intake (despite the fact that vitamin E deficiency has never been reported on a dietary basis in an American adult). However, Roche's latest campaign does not mention supplementation. It merely describes "six of the ways to help reduce your risk of cancer": 1) stop smoking; 2) include fiber in your diet; 3) cut down on fats; 4) eat foods high in vitamins C and E; 5) have regular medical check-ups; and 6) eat foods rich in beta-carotene. Hoffmann-La Roche produces most of the bulk nutrients repackaged by other manufacturers.

NEW THOMPSON COMPANY CAMPAIGN IS MISLEADING

Stephen Barrett, M.D.

The William T. Thompson Company of Carson, California, which is probably the health food industry's most prominent supplement manufacturer, has developed an "informational packaging" system it predicts "will change the vitamin business forever." Twelve of its products are now being sold with "progress reports" that explain the supposed rationale for each product and relate it to published research. The company has also opened a research center" to provide information to retailers and consumers.

The new packaging is quite striking. Each of the products is encased in clear plastic so that the bottle and the first and last pages of the report are visible. The reports are about 5" x 6" and are titled "Advances in Nutritional Research." The left side of the front page is bright orange, and the right side is white with black type which includes a prominent headline. The reports, which range from 2 to 20 pages, describe how nutrients are vital to body functioning and how the accompanying Thompson product can provide what your body needs.

According to Thompson's technical director John Foster, "the reports were reviewed by two sets of lawyers and submitted to the California Department of Food and Drug. There was no formal response, but in phone conversations an official told us that nothing in there alarmed them." Ray Wilson, a pharmacology specialist

with the Bureau, confirmed that he had met with Thompson representatives and looked over some of their proposed messages: "They came with the concept. We said that the information would be the labeling and that this would be all right if it were accurate and not misleading. But we did not do an in-depth review of what they wanted to say."

Here is my "in-depth review" of the products and the messages in their published brochures:

- *Muscle Revitalizers* is said to be "a unique combination of vitamins, minerals, amino acids and botanicals formulated to aid your own muscle recovery process by providing your body with the nutrients to help repair muscle tissue and replenish the nutrients that strenuous activity depletes. Thompson Muscle Revitalizer is the repair kit you swallow." While it is true that ingredients in the product perform useful functions in the body, they are readily obtainable from food.

- *Energy Maximizers*, which contains bee pollen, is said to "help your body maximize its natural energy generating potential." The report states that bee pollen, "has been used extensively as a dietary supplement by athletes," but fails to indicate that scientific studies do not support its use.

- *Omega-3*, a fish oil supplement, is said to be able—together with proper diet and exercise—to help lower blood cholesterol levels. Although exercise and

dietary measures are proven, fish oils have not been studied enough to determine whether supplementation is safe and effective.

- *Ultimate C* contains 500 mg of vitamin C and 5 mg of zinc. One sentence of the report notes that "research does not seem to support the theory" that vitamin C will prevent colds. But the rest of the report relates vitamin C to immunity and claims (falsely) that our bodies don't store it well.

- *Immune System Fortifiers* are promoted with the claim that "today's stressful lifestyles, and environmental toxins, can overwork the immune system leaving it vulnerable to attack and susceptible invasion by virus, bacteria, and various microorganisms." I don't believe that "environmental toxins" cause infections or that supplementation boosts immunity (except in seriously malnourished individuals).

- *Calcium Magnesium Formula* is pitched by telling why adequate calcium intake is important. The report is accurate but provides no help in judging when supplementation might be appropriate.

- *Fizzycal*, which contains calcium, magnesium and vitamin D, is offered as an alternative to milk.

- *Diet Support* is a reasonably formulated multivitamin/mineral product that contains 100% of the U.S. RDA for most of its ingredients. Noting that many popular diets are unbalanced, the report suggests that a sup-

plement be taken to help ensure that good health is not compromised. This is misleading because most dieters don't need supplements.

- *Multivitamin Mineral Formula for Women* is promoted with suggestions that it is difficult for women to get the nutrients they need from food, even if they eat a balanced diet. This is untrue.

RDA+ contains 100% of the U.S. RDAs for vitamins and minerals plus extra amounts of "The Protector Vitamins: beta carotene, E and C." The booklet suggests (falsely) that the American diet contains so many "heavily processed foods" that getting the nutrients we need is difficult. The "Protector Vitamin" concept is also misleading because there is no evidence that above-RDA amounts protect against anything.

- *Essential 32* is pitched with the idea that it is more complete than other multivitamin supplements because it contains all of the essential amino acids. This is absurd because the American diet is not deficient in amino acids.

- *PMS Basic* contains vitamin B₆, vitamin E, and magnesium. The retailer from whom I obtained the product said that the "progress report" was out of stock and supplied a package insert instead. The insert describes a long list of symptoms which the ingredients in the product supposedly can help. Claims of this type for a product are illegal without FDA approval.

MORE B₆ TOXICITY REPORTED!

Neurological symptoms have been reported in more than 100 women who took vitamin B₆ for more than six months [*Acta Neurologica Scandinavica* 76:8-11, 1987]. To obtain these data, all patients taking B₆ who were attending a private practice in London specializing in premenstrual syndrome were asked whether they were experiencing altered sensations in their arms, legs or skin, or had noticed unexplained pains or muscle weakness. They were also asked to have their serum B₆ levels checked. Those who reported symptoms underwent neurological evaluation.

The normal range for serum B₆ is 3.16 to 18 nanograms per milliliter. (A nanogram is one billionth of a gram.) Levels greater than 18 ng/ml were found in 172 women, of whom 103 complained of neurological symptoms. Of these, 20% had taken less than 50 milligrams (mg) of B₆ per day, 38% had taken at least 50 mg but less than 100 mg, 31% had taken at least 100 mg but less than 200 mg, and 11 had taken at least 200 mg but less than 500 mg. (The Recommended Dietary Allowance is 2 mg/day.)

The symptomatic women had taken B₆ for an average of 2.9 years, with a range from six months to

over five years. Their symptoms included twitching, bone pains, abnormal skin sensations (pins and needles, numbness, burning, crawling, and itching), muscle weakness (including difficulty in walking, running, and holding things) and the feeling of electric shocks down the spine. Many of the women feared that they had multiple sclerosis, and a few had undergone cardiac evaluation because of shooting chest pains. Three months after stopping B₆, 55% of the women reported partial or complete recovery, and at six months, all had recovered completely. However, other researchers have reported a few cases of women who took 500 mg or more and did not recover completely. Research in dogs and rats has shown that moderate dosages of B₆ can cause reversible symptoms but high dosages cause permanent neurological damage.

This study indicates that women who take B₆ supplements for long periods of time can develop neurological symptoms even with dosages previously thought safe. The minimum dosage that can cause trouble is unknown but is less than the amount commonly prescribed for premenstrual tension.

MILK: WHAT'S IN A NAME?

Manfred Kroger, Ph.D.,

Only mammals can produce milk, which is actually the fluid of the mammary gland. All milks contain the same basic ingredients but in different amounts. Other fluids known by the name "milk" are merely plant exudates or other white liquids.

The milk of several hundred mammals has been studied. Except for milk from the major domesticated dairy animals, the usual way of naming a milk, and the least complicated, would be to state the conventional animal or species name and add the word milk to it. That would give us whale milk, reindeer milk, rabbit milk, cat milk and so on. However, tradition and convention have dictated the naming of milks and have caused some inconsistencies. Sometimes we use the breed or species name of the particular mammal, and other times we use the name of the female. And often we do so interchangeably. Horses' milk is usually called mares' milk. Ovine milk is either called sheep milk or ewes' milk. And caprine milk (goat milk) is sometimes goats' milk, but never she-goat milk. Asses' milk and donkey milk can be found in the historic literature, but never jenny ass milk. Similarly, dog milk, the kind a puppy would drink, sounds acceptable; not so bitch's milk. And "sows' milk" is preferred over hog milk, pig milk or swine milk.

The food consumed first by many humans is human milk, which is usually described and cataloged as such. Other correct terms are mother's milk (from one woman) or mothers' milk (the pooled milk of many donors, as in a human milk bank), and breastmilk (also breast milk), probably the current popular term used by lactating women (nursing mothers or breastfeeding mothers) and such organizations as La Leche League International and Natural Childbirth associations.

Breastmilk production can vary greatly from mother to mother. Some produce little or none, especially when malnutrition is present. Others can produce large amounts. The amount produced (or drunk by babies) every year is unknown. If 100,000,000 babies are born and nursed every year and receive about 1 pint (1 pound or ½ kilogram) of breastmilk daily for six months, the annual human milk production would be 9,100 million kilograms (4,136 million pounds or 481 million gallons).

World cow milk production is about 1 trillion pounds (450 million metric tons or 116 billion gallons), which is about 200 lbs/year for each of the 5 billion persons now inhabiting the Earth.

The terms cow's milk and cows' milk are often interchangeably and erroneously used. According to the rules of grammar, the former denotes the milk from a single cow, whereas the latter is mixed milk or herd milk, or milk in general. The term "cow milk" is hardly ever used. Cows' milk can also be called bovine milk — a term often used by scientists who publish their research results. For the same reason, the adjectives caprine, ovine, porcine and equine are used to describe work with milk of goats, sheep, sows and mares, respectively. There are even scientific papers dealing with murine milk, the lacteal secretion of the genus *Mus* to which the mouse and the common house rat belong.

Cows' milk comes from the mature female of the genus *Bos*. A female moose is also a cow, but her milk is not cow's milk but moose milk. There is a large market in the world for the milk of the water buffalo, the domesticated Asiatic buffalo of the genus *Bubalus*. That milk is usually called buffalo milk or buffaloes' milk. The American buffalo, by the way, belongs to the genus *Bison*, so its milk, about which scientists know very little, would have to be called bisons' milk.

Since there are several notable breeds of dairy cattle, we also have the specific and meaningful terms Guernsey milk and Jersey milk, for no other reason than to distinguish them from Holstein or Holstein-Friesian milk. Guernsey and Jersey milk have a higher fat content (about 6% instead of 4%) and look somewhat yellowish rather than white. (That's why you may see Golden Guernsey milk touted in an advertisement.) Brown Swiss, Ayrshire and Milking Shorthorn cows also provide milk, of course, but their milk (or is it milks?) is not labeled with a special name.

There are also differences among milks from the dairy industry's commercial standpoint. Standard market milk contains 3.25% fat, while low-fat milk contains 2% and skim milk (also called skimmed milk but never spelled skimmilk) contains less. Skim milk, in theory, contains no fat, but since absolutes are impossible to achieve, any milk with up to 0.5% fat can be called skim milk. Milk with more than 10% fat is called cream. Whipping cream has about 38% fat. And then there is dry milk, also called milk powder or milk solids. But that's another story.

Dr. Kroger is a professor of food science at The Pennsylvania State University.

WIC REFORM MEANS MORE MOTHERS AND CHILDREN SERVED

Senator Tom Harkin

In the closing days of the 100th Congress, legislation passed that will dramatically improve the health and well-being of thousands of women and children in the United States. On January 8, 1988, the President signed the Commodity Distribution Reform Act into law.

The Special Supplemental Food Program for Women, Infants and Children — usually referred to as "WIC" — has been in place since 1972. But thanks to this new law, program directors will gain new leeway in allocating funds and be able to help as many as 630,000 additional participants.

Since its inception as an experimental program 16 years ago, the WIC program has provided food to help pregnant and lactating women, infants, and children age five and under improve their diets and reduce their chances of health problems caused by poor nutrition. Highly nutritious foods such as milk, cheese, eggs, cereal, peanut butter, beans and infant formula are provided to more than 3.4 million people each month.

To qualify for participation, women, infants or children at or near the poverty level must be found by a medical professional to be at nutritional risk. The medical evaluation includes checking for anemia as well as growth and developmental retardation.

The WIC program also provides nutrition counseling and coordination with ongoing preventive health care. Direct services include a health assessment, nutritional counseling, food vouchers, and monitoring of participating grocery stores. The combination of nourishing food, nutrition education, and preventive health care makes WIC unique and different from other federal food or health programs.

According to an extensive evaluation undertaken by the U.S. Department of Agriculture, WIC is one of the most efficient programs run by the federal government.

The average administrative cost per person is only \$8 per month, and the average food cost is a mere \$32 per person. Yet consider the proven benefits:

- WIC has contributed to a reduction of 20-33% in the late fetal death rate.

- The head size of infants whose mothers receive WIC during pregnancy increased measurably.

- Women who participate in WIC have had longer pregnancies leading to fewer premature births. This not only benefits the infants, but it saves millions of dollars in Medicaid bills that would otherwise have been required for intensive neonatal care. In 1985, newborn intensive care cost \$2.4 to \$3.3 billion, which is about \$15,000 per baby. The average cost of WIC benefits for a pregnant woman is under \$250.

- Each dollar spent in the prenatal component of WIC saved 49 cents in Medicaid costs during just the first 45 days of infant life, according to one study done in Missouri. Another Missouri study found that the federal government saved 83¢ in Medicaid costs for every dollar spent on WIC. The new law requires the Agriculture Department to conduct further studies to measure how much state programs can save during the first 60 days after birth as a result of WIC participation by pregnant women.

- A Yale University School of Medicine study found a remarkable decrease in the prevalence of anemia among low-income children in New Haven since the early 1970s. The researchers concluded: "The marked improvement can most probably be attributed to the nutritional supplementation with iron-fortified foods provided by the WIC program."

- WIC also appears to lead to better mental performance. Four and five-year-olds whose mothers participated in WIC during pregnancy had better vocabulary scores, and children who participated in WIC after their first birthday had better digit memory.

Despite the many benefits, however, problems arose with certain rigidities of program design. As originally designed, the WIC program was required to spend 80% of its budget on food, while the administrative costs were limited to 20% of a state's overall budget. This was mandated to ensure that the federal funds allocated for WIC would achieve their primary purpose: to provide nutritious food directly to at-risk women and children.

According to the USDA, infant formula purchases comprise approximately 30% of all WIC food costs and could amount to more than \$400 million in sales per year. Close to one-third of all infant formula purchased in the United States is purchased through the WIC program. Over the years, as the price of formula increased, a greater proportion of WIC dollars has been spent on infant formula. As a result, WIC directors sought ways to economize in this portion of their food budgets.

With approval from USDA's Food and Nutrition Service (FNS), which oversees the program, several states experimented with competitive bidding for their purchases of formula and achieved the result they had hoped for. While the average retail price of a 13-ounce can of concentrated iron-fortified formula is about \$1.40, Oregon obtained a net price of 60¢ per can, 60¢ a can, Mississippi 61¢ per can, and FNS itself 73¢ per can. Vermont and Ohio realized similar savings. Implemented nationwide, this would save \$242 million a year. According to a report by the U.S. General Accounting Office, if every WIC program in the United States saved comparable amounts in fiscal year 1988, between 221,000 and 630,000 additional eligible participants could be served at no additional cost. (Federal fiscal years run from October 1 through September 30.)

WIC directors, excited by the potential savings, wanted to use the "extra" food money to provide food to additional participants. Unfortunately, the 80/20 ratio mandated under the old law put a crimp in their plans. If a state managed to save a substantial amount of its food dollars by purchasing infant formula at a 40% discount, it would have additional food funds, but no additional administrative funds to cover the costs of certifying and delivering benefits to the additional recipients. And under the old law, participants could not receive food without also undergoing health screenings, receiving nutritional counseling and so on. As a result, the "extra" food money could not be spent. The regulation designed to ensure the efficient operation of WIC backfired against the very people it was designed to protect!

WIC directors from all over the country appealed to Congress for a legislative remedy. The Reagan Administration opposed changing the 80/20 formula, however. In hearings before the Senate Agriculture Subcommittee on Nutrition, which I chair, Assistant Secretary for Food and Consumer Services, John W. Bode testified against allowing any of the extra food funds to

be spent on administrative costs.

Nevertheless, the testimony of numerous state WIC directors and simple logic convinced my colleagues to approve an amendment which I introduced to enable WIC programs to realize additional savings through competitive bidding. As approved, the bill allows states to use 10-20% of the savings from rebates or competitive bidding for the costs of providing additional services. This is done by estimating the number of new participants a state will be able to serve under its revised infant formula pricing structure. Additional administrative funds are then allocated at the state's current rate of individual participant administrative cost.

Even after the new law takes effect, millions of needy and eligible women, infants and children will not be able to participate in the WIC program because of budget restrictions. WIC is not an entitlement program and therefore can serve only as many people as its annual appropriation permits. Although Congress has provided for some growth in the program through the years, it still reaches only 40% of those eligible. The 1987 WIC appropriation was \$1.66 billion, but the Congressional Budget Office estimated that it would require \$1.73 billion in 1988 just to maintain the current service level in fiscal year 1988. Congress finally approved the 1988 WIC appropriation at \$1,802,363,000, permitting a modest increase of services.

The need, however, continues to grow. According to the Children's Defense Fund, a respected public-policy advocacy group, the number of impoverished Americans has increased from 26 million during the 1970s to 32 million today, and one out of every five children under age six is poor.

Many of these children live in families with working parents. A family of three that has a full-time minimum-wage paycheck lives 28% below the poverty line. About 40% of poor children belong to a family whose incomes is less than \$4,000 per year.

Participation in WIC has increased by 73% since 1980, including 11% during the past two years. But the budget hasn't kept pace with demand. According to the Center on Budget and Policy Priorities, many states restrict entry into WIC and do not certify entire categories of eligible participants because there are no funds to

serve them. At least 75 counties in the United States have no WIC program at all. Some states certify no children beyond their first birthday, regardless of whether they are anemic or have other medical problems. The Iowa WIC program, for instance, has to decide between serving toddlers in families making \$15,000 or infants in families making \$17,000. Other states deny service to children who are medically determined to be at risk but have not yet developed a medical problem. Administrative cost requirements discourage WIC administrators from encouraging breastfeeding.

Such practices undermine the preventive value that Congress intended for the WIC program. I am hopeful that our society will recognize how important it is to

ensure the health and well-being of future generations and that national and Congressional priorities will change. Meanwhile, we can only work to ensure that successful programs such as WIC are maintained and improved.

Senator Harkin (D-Iowa) is Chairman of the Senate Subcommittee on Nutrition. *Editor's note:* The Center on Budget and Policy Priorities, 236 Massachusetts Avenue, N.E., Suite 305, Washington, DC 20002, offers detailed reports on WIC legislative and administrative news as well as related maternal and child health developments. Its newsletter, published nine times a year, costs \$45.00/year for individuals and agencies and \$22.50 for students and nonprofit organizations.

BOOK REVIEW

Title: *The Right Dose — How To Take Vitamins and Minerals Safely* (1987)

Editor: Patricia Hausman, M.S.

Publisher: Rodale Press, Emmaus, Pennsylvania

Price: \$24.95

Reviewed by: Charles W. Marshall, Ph.D.

At last a book from Rodale Press which stresses the hazards of overdosing with nutrient supplements. The 528-page book even contains case histories of people treated for vitamin or mineral poisoning. I believe, however, that the book contains serious errors and has little practical value.

Ms. Hausman, a former staff member of the Center for Science in the Public Interest, holds a masters degree in nutrition from the University of Maryland. According to the book's jacket, she "spent two years delving through more than 4 million pieces of scientific research to find out what can and cannot go wrong when taking the oral supplements popular today." (With no days off, this would come to 5,479 "delves" per day.)

The book's first chapter pitches "nutrition insurance" with a chart on vitamin loss through cooking and lists 14 situations where "supplements may give your body a boost." Chapter 2 discusses her concept of safety and her belief that people generally have more to gain

than to lose by taking supplements. Seventeen chapters cover individual vitamins or minerals, and the final chapter covers three additional minerals. Most have a "Diet Detective" chart to help estimate your daily intake from food, and all offer recipes for foods rich in the nutrient under consideration. Each chapter also contains a table indicating the amount of the nutrient in common supplements.

The book's main pitch seems to be: To avoid missing out on many possible special health benefits, you can take supplements as long as you stay within a "safe" range. This sort of faith might make sense if dosages above the Recommended Dietary Allowances (RDA) offered proven health benefits to the average reader. I don't believe they do. In a few places she provides so much information and so many disclaimers that it is difficult to determine what she is actually recommending. But some of the dosages she considers safe appear too high.

Dr. Marshall, a retired biochemist, is author of *Vitamins and Minerals: Help or Harm?*, which won the American Medical Writers Association award for best book of 1983 for the general public and also became a special publication of Consumer Reports Books. Copies of the revised (1985) edition are available for \$12 from the George F. Stickley Co., 210 W. Washington Square, Philadelphia, PA 19106.

BRIEFS

B₆ toxicity addendum. Dr. Katharina Dalton, who reported 103 cases of nervous system toxicity in women taking vitamin B₆ for premenstrual syndrome [see *NF* 5:7], has indicated that the lowest dosage among them was 20 mg/day for two years, while the shortest time was two months on 100mg/day.

Health Fraud Conference. The program has been announced for the National Health Fraud Conference to be held March 13-15 in Kansas City, Missouri. The meeting is intended to: 1) exchange information on current health fraud activities; 2) help government agencies, voluntary groups, and industry organizations to strengthen their health fraud programs; 3) increase networking links; and 4) provide guidance for disseminating educational materials to consumers. Speeches, workshops and exhibits will include: current trends; conducting investigations; filing complaints; organizing an antiquackery group; working with health insurers, legislators and the media; protecting the elderly; quack devices; and frauds related to arthritis, cancer, AIDS, allergy, nutrition, athletics, and mental health. Registration costs \$225, but multiple registrants from the same organization are \$200 each. Discount airfares are available through Eastern and Continental Airlines. Further information can be obtained from Linda K. Strub, National Health Fraud Conference Coordinator, 2800 Main—7th Floor, Kansas City, MO 64108 (telephone 816-753-5700, Ext. 2545).

New animal drug standards. The FDA has announced stricter safety standards for new veterinary drugs proposed for use in food animals. Manufacturers of any proposed animal drug that is potentially carcinogenic must now provide the government with a method to test food products from the treated animal for residues. The test must be sufficiently sensitive to reveal a level of residue that would ensure a maximum lifetime risk of 1 in a million. The previous limit of two parts per billion did not take potency of the carcinogen into account. Manufacturers have been required for several decades to provide the FDA with a residue assay of almost all drugs intended for use in food animals. However, the new standards define the test that must be submitted if a drug has caused cancer when fed to test animals. They also recommend a method for evaluating data obtained from lifetime studies of mice and rats fed high levels of the drug. About 80% of U.S. livestock and poultry receive some animal drug during their lifespan. Drug therapy has helped turn the chicken from a difficult-to-raise, disease-prone creature into a mass-produced food.

Anti-Quackery Litigation Fund. Victor Herbert, M.D., J.D., has filed suit against the American Quack Association, the National Health Federation (NHF), Kurt Donsbach [see *NF* Oct. 1987], Peter Joseph Lisa and 22 other individuals, groups and publications. The suit charges that after Lisa wrote a book falsely accusing Dr. Herbert of killing patients, the others conspired to disseminate this information and did other things intended to damage his reputation in order to discredit him as an effective critic of health frauds. At its annual convention in January 1988, NHF announced that a "First Amendment Free Speech Legal Defense Fund" had been set up and that nearly \$30,000 had been collected. Meanwhile, a fund has been set up to help Dr. Herbert finance his suit. Contributions can be sent to the Herbert Anti-Quackery Litigation Fund, c/o Michael K. Botts, Esq., P.O. Box 33008-N, Kansas City, MO 64114.

Alcohol warning considered. Legislation has been introduced into Canada's House of Commons to require marketers of alcoholic beverages to spend 15% of their advertising budget to warn about alcohol's possible dangers.

Vitamin C and colds. A controlled study has found that men who were given 500 mg of vitamin C four times a day were less likely than control subjects to acquire colds during a week of exposure to men infected with one particular cold virus. (During this week all were housed in special living quarters.) The vitamin C was taken for 3½ weeks before exposure and for two weeks afterward. During the period of exposure, 7 of the 8 men receiving the placebo but only 4 of the 8 receiving vitamin C contracted colds. However, 2 in the vitamin C group started shedding virus after they returned home. The placebo group had more severe symptoms. Although the number of subjects was small, the study involved only one cold virus, used subjects that had no antibodies to that virus, and checked vitamin C blood levels as before and during the study. The results were presented at a virology symposium last November by Elliot C. Dick, Ph.D., Professor of Preventive Medicine at the University of Wisconsin, who directed the study. However, he has indicated that no paper will be published until the experiment is repeated during 1988. Since many large experiments have found no preventive effect from vitamin C supplementation, further "positive" results will require careful interpretation and additional studies to determine if and when supplementation is practical. Dr. Dick's study was funded by Hoffmann-La Roche.

Table salt may facilitate low-sodium diet. A study has found that students on a low-sodium diet compensated only slightly for the reduced dietary sodium by adding table salt to their food [JAMA 258:3275-3278, 1987]. The 13-week study involved 11 students at the University of Pennsylvania who were enrolled in a study of diet and taste. During the first three weeks and the last week of the study, the students ate a normal hospital diet that was not restricted in sodium. For the remaining ten weeks, the sodium in their food was reduced but they had unlimited access to a saltshaker. Although the sodium content of their food was about 50% lower, ten of the students added table salt to compensate for less than 20% of the reduction. Previous studies have shown that people who sharply reduce the sodium level of their diet usually come to prefer food with less salt. In this study, however, the students did not change their preference and reported that the food they had salted tasted similar to the normal hospital food. The researchers suggest that since the saltshaker places salt on rather than in the food, subjects retained enough sensory experience with salty tastes to prevent preference changes. If this is true, changes in taste perception after dietary sodium is lowered may be due to less experience with salty tastes and not the amount of sodium ingested. The authors suggest that it is possible to lower sodium consumption and retain a palatable diet by consuming low-sodium foods but using a saltshaker. But studies using large numbers of individuals with different salting habits over longer periods of time are needed to indicate the best way(s) to reduce sodium intake.

Sodium and high blood pressure. A double-blind study has tested whether five men with "salt-sensitive" high blood pressure would react differently to sodium chloride (table salt) and sodium citrate [New England Journal of Medicine 317:1043-1048, 1084-1085]. After being placed on a low-sodium diet, each was rotated through one cycle in which a placebo was followed by sodium chloride and sodium citrate and another cycle in which the placebo was followed by the sodium products in reverse order. Only sodium chloride raised the subjects' blood pressure. The researchers emphasized that because the study was small, it provides no basis for making dietary recommendations for people with high blood pressure. Although most people ingest sodium mainly as sodium chloride, many ingest significant amounts of other sodium salts (ascorbate, bicarbonate and gluconate). Studies are needed to clarify how different sodium salts affect blood pressure in both normal and hypertensive individuals.

Iron in soybean hulls. Most iron found in high-fiber plants combines with the fiber and is difficult for humans to absorb. But the U.S. Department of Agriculture has identified an easily digested form of iron in fiber-rich soybean hulls. This discovery might lead to using soybean hulls to fortify breads and other baked goods with more iron and fiber. Further information on this subject can be obtained from Joseph Laslow, Physical Chemistry, Northern Research Center, USDA Agricultural Research Service, Peoria, IL 61604.

NATUROPATHIC ACCREDITATION

In September 1987 the U.S. Department of Education recognized the Council on Naturopathic Medical Education (CNME) as an accrediting agency for naturopathic schools. Currently there are two such schools, John Bastyr College in Seattle, Washington, which has been accredited by CNME, and National College of Naturopathic Medicine in Portland, Oregon. Accreditation by a federally recognized agency allows access to federal research grants and student loan programs. Naturopaths practice in most states, but are licensed only in Alaska, Arizona, Connecticut, Florida, Hawaii, Oregon, Utah and Washington. In these states they have the right to diagnose disease and to prescribe "natural" therapeutics. Some practitioners of naturopathy obtained their training many years ago at chiropractic schools and are licensed as chiropractors.

Naturopaths view diseases as the body's effort to purify itself, and claim to help the body heal itself by ridding it of toxins. Their methods include fasting, "natural" food diets, vitamins, herbs, tissue minerals, cell salts, homeopathic remedies, manipulation, acupuncture, massage, minor surgery, exercise and colonic enemas. Naturopathic education now consists of two years of basic sciences and two years of clinical naturopathy.

Like chiropractors, who have had a recognized accrediting agency since 1974, naturopaths use a wide variety of unscientific practices. But the accreditation system judges how programs are organized rather than the validity of what they teach. With accreditation behind them, naturopaths are working on licensure in more states.

STUDY FINDS SWIMMING INEFFECTIVE FOR WEIGHT CONTROL

David Steinman

Grant Gwinup, M.D., who is professor of medicine and chief of the division of endocrinology at the University of California's Irvine Medical Center, is frequently asked by patients to help them design exercise programs to lose weight. Commonly he prescribed swimming regimens for patients with orthopedic problems or injuries that prevented them from engaging in high-impact aerobic exercise.

For many years, Dr. Gwinup observed that most patients who swam for exercise enjoyed it but didn't seem to lose weight. He decided to test this observation with a controlled experiment.

Gwinup's landmark study — published in the *American Journal of Sports Medicine* [15:275-279, 1987] — involved 45 women, aged 20 to 40, whose weights averaged about 150 pounds. All were considered "minimally to moderately obese," with estimated body fat content of 30-40%. The women were divided into three equal groups: 1) walkers, who walked at increasing speeds until they were "pleasantly exhausted"; 2) cyclists, who rode stationary bicycles; and 3) swimmers, who used the Australian crawl or backstroke in a heated lap pool whose temperature ranged from 74°F to 78°F.

All participants were advised to eat as they pleased "whenever and whatever they desired. In fact, they were instructed to not keep track of what they ate," says Gwinup. But all were intent upon weight loss. Only a single variable — exercise mode — was controlled. The study used women because more of them had the time to participate. But Gwinup believes the results would be identical with men.

All participants were asked to exercise briskly once a day, to systematically increase the amount at weekly intervals, and to record what they did. The majority exercised for at least nine out of every ten days. The compliance rate among swimmers who completed the study was the best of the three groups, but swimmers also had the highest dropout rate. For various reasons, only 11 walkers, 10 cyclists and 8 swimmers reached the goal of 60 minutes per day.

To ensure that the fitness level was similar among the groups, Gwinup measured their resting heart rate every two weeks throughout the six-month study period. Testing confirmed that each exercise produced comparable cardiovascular fitness and that everyone who completed the study achieved a "training effect."

During the study, the average resting pulse for the group dropped from 75 to 63. But their weights provided stark contrast. Walkers averaged a 10% weight loss (15 pounds), cyclists lost 12% (18 pounds), but swimmers gained about 3% (nearly 5 pounds).

What kind of weight was lost or gained? Gwinup based his conclusion on measurements of the triceps fat deposit (midway between the elbow and shoulder in back of the arm). He assumed that all other fat deposits would change in the same direction. "Walkers and cyclists had reduced fat volume. But the swimmers remained the same. So, they didn't lose fat. They probably built up muscle," Gwinup says. He speculates that water, even if the same temperature as the air, removes energy in the form of heat from the body 30 times as effectively as air.

Gwinup's speculation is supported by Dr. Kin-itsu Hirata, a member of the Department of Physical Education of Chukyo University in Toyota-Nagoya, Japan. His book, *Selection of Olympic Champions* (1980), asserts that "Long-distance swimmers — channel swimmers — are much stouter . . . They must have fatty, stout figures because the fatty, stout figure is buoyant, can tolerate cold and store much energy for swimming a very long time." Many other experts agree that long-distance swimmers tend to retain more fat.

Marathon swimmer Lynne Cox has reached the same conclusion from personal observation. Cox, who has crossed the English Channel twice in world record time, has probably done more cold-water swimming than anyone else alive. In 1976 she swam the Magellan Strait at the tip of South America in 42° water. More recently she swam nearly three hours in a 40° lake in Iceland and frolicked for half an hour in 37° water amidst icebergs in Glacier Bay. Last fall, wearing only a bathing suit, cap and goggles, she swam almost three miles through the Bering Sea, where water temperatures range from 34° to 39°F. Her swim was part of a U.S.-Soviet study of cold-water physiology. Yet for all her cold water and marathon swimming, Cox says she does not lose weight. She's 5'6" and 180 pounds.

"I can do all these extreme distances, but the weight's still there. When I swam the English Channel, I lost only two or three pounds — most of it water."

Her body fat recently was measured at about 37% by Hal Goforth, Ph.D., a research physiologist at the

Navy's Health Research Center, San Diego, who specializes in cold water physiology. "Most athletes would feel obese if their body fat were beyond 22%," Goforth says.

"I always have had extra body fat. And I always have been swimming," Cox says. So, it is difficult to separate cause from effect. Which came first, excess body fat or cold water swimming? On the other hand, look at marathon runners. They are so lean and muscular. They have a very low percentage of body fat, because their bodies are dealing with hyperthermia — too much heat — and fat would make them retain heat."

Top male and female distance runners carry as little as 5-10% body fat, Goforth says. "Their bodies don't want extra weight because that would mean more work," Cox says. "But swimmers — particularly long-distance and cold-water swimmers — are dealing with two different factors: hypothermia and their need for buoyancy, which means their bodies want to retain fat."

Sportsmedicine expert Gabe Mirkin, M.D., notes that, "During exercise on land, air provides insulation and body temperature rises slightly and remains elevated for several hours afterward. But exercise in water — which is a very poor insulator — does not raise body temperature."

How do these findings relate to the body of the typical lap swimmer? Many lap swimmers find the typical "heated" pool feels cool. Even so-called warm lap pools may be too cold for the body to effectively lose weight, says Gwinup: "I think most people consider the fat stores of the body as a fuel tank. But fat has insulating properties, too. In water that is colder than the body, a message is conveyed somehow to the hunger center that to prevent heat loss more caloric intake is needed and that more fat may be needed for insulation. Presumably, this stimulates the appetite mechanism to increase caloric consumption, so that when you swim you have complete compensation; for every thousand calories you burn you eat a thousand more." Gwinup thinks the swimmers in his study must have eaten more food each day to compensate for their body heat loss.

But that doesn't mean you should avoid an exercise regime that includes swimming. Pro triathlete Scott Molina professed little surprise at the study's result but suggested a way around it. "I experienced weight gain when I trained in cold water in Southern California when I swam in the ocean near La Jolla and even in pools that were as warm as 78°, he said. "The body is real sensitive. You can work out hard swimming, but if the water is too cold you may very well gain weight. That's why I wear a wetsuit and work out in water between 82° and 84°. That's about the right temperature to swim regularly and avoid weight gain."

Colleen Cannon another triathlon star, swam the 100 and 200 meter butterfly from 1978 to 1982 while at

Auburn University. "I was a little bit heavier when I swam," she says. But since she added training for running and bicycling, she has lost weight.

Kate Delhagen, another world-class triathlete, has concluded that some swimmers gain weight from added muscle. "Swimmers tend to develop their upper body, particularly their shoulders and chest," she told me. And once in the water, it is harder for many of them to raise their heart rate. So a runner who exercises for an hour may exert far more effort than a swimmer during the same amount of time.

Dr. Goforth believes that total work involved makes the difference. He cited a recent experiment at Ball State University in which swimmers increased their daily distance from 4,000 meters to 8,000 meters and lost weight.

"Exercise is not simple," Gwinup says. "You should have definite objectives. Ask yourself whether you want to lose weight, build muscle, or develop cardiovascular fitness. Exercise should be prescribed the same way a doctor gives a prescription for medicine. Swimming is a great exercise, but the ideal person for a swimming regimen should have no weight problem and need to exercise mainly for cardiovascular fitness. For cardiovascular fitness, nothing is better than swimming. But most people in this country exercise for weight loss. If that is your objective, you shouldn't swim."

Mr. Steinman is the running and triathlon columnist for *City Sports Magazine* and an associate adjunct professor of liberal arts at National University.

QUESTION BOX

Q. If you drink on an empty stomach, does eating afterward affect how much alcohol is absorbed?
A. Yes. Alcohol needs no digestion. It diffuses through the stomach wall soon after arrival in the stomach and reaches the brain within minutes. However, alcohol consumed with or close to a meal is absorbed more slowly. Food mixes with the alcohol so that it reaches the stomach wall more slowly. Food also slows the rate at which alcohol enters the small intestine, where it is absorbed most quickly. Retardation of alcohol absorption is greatest during or following a heavy meal, mild following a light meal and slight when the meal is consumed one hour after drinking. Absorption is quickest when the stomach is empty. Thus, to slow absorption, meals should be eaten just before, with, or immediately following alcohol consumption.

NEW REPORT ON DIETARY FIBER

The Life Sciences Research Office of the Federation of American Societies for Experimental Biology (FASEB) has conducted a scientific assessment of the role of dietary fiber in health. The report, composed of 171 pages of text supported by 66 pages of references, was prepared at the request of the FDA and published in June 1987. The panel evaluated the effects of various fiber sources on specific diseases and concluded:

- **Colon cancer:** Epidemiological data show a fairly consistent inverse relationship between intake of fiber-containing foods and cancer of the large intestine. However, studies comparing the diets of patients with and without colon cancer have been contradictory. Some have shown a relationship between the incidence of colon cancer and the presence of certain cancer-causing substances whose concentration in the feces may be reduced by dietary fiber — particularly whole-grain cereals and bread. But further research is needed to clarify the mechanisms involved and the influence of various dietary fibers.

- **Constipation:** Many studies have shown that dietary fiber, particularly wheat fiber and other insoluble sources, is useful in the prevention and treatment of constipation.

- **Diabetes:** Clinical trials have shown that supplements of soluble fiber sources such as guar gum, pectin and oat bran can be useful in decreasing insulin requirements, improving blood sugar control, and lowering blood cholesterol levels in diabetic subjects. High-carbohydrate diets which contain large amounts of complex carbohydrates also have similar effects. These effects cannot be attributed solely to the fiber content of such diets.

- **Diverticular disease:** Epidemiological data suggest a relationship between low-fiber intake and diverticular disease. Clinical evidence suggests that diets high in fiber (especially wheat bran) may relieve the symptoms of uncomplicated disease. (Diverticulosis is a condition in which the walls of the large intestine develop pouches. If they trap fecal material and become inflamed, the condition is called diverticulitis.)

- **Gallstones:** The influence of dietary fiber on gallstone formation and regression is unresolved. Although some experiments show an association between dietary fiber content and stone formation, it is not known whether specific dietary factors or overall diet are responsible for this finding.

- **Heart disease:** Epidemiologic data on the relationship of dietary fiber to atherosclerotic heart disease are inconclusive. Clinical studies show that soluble fibers such as pectin, guar gum, locust bean gum, oat gum, or psyllium mucilloid significantly reduce total blood cholesterol and LDL cholesterol with little effect

on HDL cholesterol levels. Insoluble fibers such as bran or cellulose have no significant effect. Clinical studies show a lowering of blood pressure in response to increased amounts of fiber from various sources. But these trials are difficult to interpret because the other dietary components varied.

- **Irritable bowel syndrome:** The patients most likely to benefit from increased fiber intake (wheat bran) are those whose chief complaint is constipation. But neither bran nor a high-fiber diet is a panacea; treatment of accompanying anxiety or depression should be undertaken.

- **Obesity:** Limited data from clinical trials suggesting that dietary fiber supplements or high-fiber diets are useful for weight reduction are contradictory. Dietary fiber may have a role as an adjunct in the treatment of obesity, but controlled, long-term trials are needed before such a role can be established.

- **Peptic ulcer:** Epidemiological studies are inconclusive. Clinical evidence suggests little benefit from high-fiber diets.

- **Possible adverse effects:** The evidence that dietary fiber can decrease the bioavailability of iron, zinc and other minerals is conflicting. Although some experiments have shown that high-fiber diets can decrease mineral absorption, other have not. Some fibers appear to increase mineral excretion, while others do not. Isolated cases of adverse effects have been reported with consumption of large amounts of purified fiber sources. The panel concluded that a moderate level of fiber intake does not appear to pose a problem with respect to mineral balance.

After reviewing estimates of current fiber intake, the panel recommended that healthy adults consume a wide variety of whole-grain products, fruits and vegetables, leading to a dietary fiber intake range of 20-35 grams per day. The panel emphasized that this range of intake may not be appropriate for children, the elderly, or persons consuming special diets.

Copies of the report can be obtained for \$20 from the FASEB Publications Office, 9650 Rockville Pike, Bethesda, MD 20814.

CAN SUPER BLUE GREEN HELP SAVE THE WORLD?

Michael Paros

Blue-green algae form a thick mat of scum across lakes. They clog filters in reservoirs. They make drinking water taste foul and recreational swimming unpleasant. They like brackish ponds and produce a putrid smell. But to Daryl J. Kollman, president of Cell Tech Inc., "They are a miraculous gift from Mother Nature."

Cell Tech harvests this scum from Upper Klamath Lake in southern Oregon and markets it as Super Blue Green Algae, "a totally natural, well balanced food, containing over 35 different vitamins, minerals and amino acids beneficial to physical and mental health." According to a company promotional tape, "By detoxifying your systems and balancing your nutritional levels, Super Blue Green provides your body and spirit with ingredients that result in experiences of increased energy, mental clarity, dietary control and feelings of overall well being. This can enable people to deal with the many stresses of this modern world."

My first exposure to Super Blue Green was through a classified ad in a San Diego newsletter called *Wholistic Living*:

ENERGY FOR LIFE. Super Blue Green Algae promises increased vigor and mental alertness in three weeks or your money back—\$45. Information/orders 546-1577, Emily.

When I called, Emily said her migraine headaches had stopped, her hair was healthier, and she had less craving for sweets, "all from taking Super Blue Green Algae." She promised to send literature and urged me to try some products.

Two days later, a three-inch-thick packet arrived in the mail. From this material, I learned that Cell Tech harvests *Aphanizomenon flos-aquae* (Super Blue Green Algae) and freeze-dries it to preserve its nutrients. Two Cell Tech products, Omega Sun and Alpha Sun, contain algae in capsule form. Sixty 250-mg capsules retail for \$22.92 and \$15.84 respectively. The difference in price is

said to be due to 5-7% greater concentration of brain/nerve nutrients in Omega Sun—achieved by removing the cell wall from the algae. A third product, Liquid Brain Food, is described as a concentrated solution of Omega Sun. A 30-ml bottle costs \$20.00.

According to one brochure, "Alpha Sun acts more on the body than the mind, while Omega Sun is used for added mental energy. The Liquid Brain Food is for emergency situations when there is a need for instant mental strength." Omega Sun is said to "dramatically increase your mental powers, stamina and overall health," while Alpha Sun "helps give you the energy, mental clarity and alertness you need in today's world."

Intrigued by these claims, my roommate Tuyen Nguyen and I decided to experiment with Super Blue Green Algae and drove to Escondido to obtain some from Emily the next evening.

At Emily's house, we quickly purchased one bottle each of Omega Sun, Alpha Sun and Liquid Brain Food. After filling out a money-back guarantee, Emily expressed concern about one of us falling asleep on the way home and urged us to try some Liquid Brain Food. "Please take some now. I always take some before I go on long nighttime drives," she insisted. She handed me a half-dropperful of Liquid Brain Food and told me to place it under my tongue for thirty seconds. To my relief, it had only a strong cinnamon flavor. Tuyen took some also, but fell asleep on the way home anyway.

A Cell Tech newsletter contains a testimonial which says: "Each time I try Liquid Brain Food I'm more impressed and amazed. The way it makes me feel did not used to be legal. I take it in the afternoon, start smiling within 15 minutes, and feel happy, relaxed and ready for anything—ALL EVENING LONG! It supports my sense of humor and allows me to be a bit outrageous—a quality I personally cherish." Amused as I read this, I tried to picture Super Blue Green as the "recreational drug" of the future.

According to a Cell Tech brochure, "The algae is rich in valuable minerals, vitamin B₁₂, chlorophyll, as well as having an almost perfectly matched amino acid profile with humans." Kollman contends that the algae "contains eight times more Vitamin A than carrots" and "enough nutritional energy to help metabolize food intake." Another brochure declares: "Blue green algae is also rich in neuropeptides, which are protein derivatives that contain two or more amino acids and have the ability to nourish the brain directly." To Kollman, "the value of Super Blue Green's nutrients are biologically obvious."

Not so obvious to Dr. Paul Saltman, Professor of Biology at the University of California at San Diego. "This is absolute nonsense. There is no scientific evidence that chlorophyll is a valuable source for humans. I've never heard of whole neuropeptides passing through the blood-brain barrier. As for protein, vitamin A and B₁₂, our normal diets provide us with enough. The amounts of nutrients in these algae capsules are insignificant."

The labels on Cell Tech products support Saltman's assertion that the amount of nutrients in each capsule is minimal. Six capsules of Alpha Sun (the recommended daily dose) fail to provide even 1% of the U.S. Recommended Daily Allowance for any of the trace minerals listed on the label. In fact, the only significant nutrient in Super Blue Green algae is B₁₂, of which the label states that 180% of the U.S. RDA is provided. There is evidence, however, that the B₁₂ in blue-green algae is mainly useless analogs of the cobalamin B₁₂ needed in small amounts by the human body. In addition, some B₁₂ analogs found in algae can actually interfere with human cobalamin metabolism.

The algae's 60% protein content is very high for a plant. But the recommended daily dose of six capsules yields approximately 0.9 grams of protein—less than the 2.4 grams in a slice of whole wheat bread, 4 grams in a tablespoon of peanut butter or 1.3 grams in a medium-size banana.

"It is not the quantity of protein that is important, but the quality," counters Kollman. Cell Tech claims that its algae's amino acid profile is almost identical to ratios used by the human body. However, Cell Tech fails to mention that more than half of these amino acids are not essential because our bodies automatically synthesize adequate amounts. Broccoli and Super Blue Green algae appear to have similar essential amino acid profiles. But one cup of broccoli yields twice as much amino acid as Super Blue Green algae at a fraction of the cost. Furthermore, 3½ ounces of broccoli contain more vitamins (including Vitamin A) and minerals than six capsules of Alpha Sun.

Not that these facts have totally escaped Kollman, who, with a master's degree in education, considers

himself an expert on nutrition and agriculture. Kollman accuses the competition (i.e., almost all foods found in the supermarket) of falsely reporting nutritional content. "When you buy the food in the store, you really get nothing. It looks like broccoli but it isn't," asserts Kollman. "If you don't believe me, just buy a tomato and eat it. It tastes like cardboard. Why is that? Minerals taste! If you don't understand that, take a penny out of your pocket and taste the copper."

Inspired by such arguments, Tuyen and I began our Super Blue Green regimen. The first day we took one Alpha and one Omega capsule, as recommended by Emily. Although we had heard of miraculous first-day transformations, we experienced no change in physical or mental health. That night we took a dropperful of Liquid Brain Food, ignoring Kollman's warning in the Cell Tech letter: "Beware, Liquid Brain Food can keep you up 'till all hours!" Within three hours of taking this "crowd pleaser of the Cell Tech products" we were both fast asleep.

During the next five days, we increased our dosage, following Kollman's advice "to listen to your body" (which remained silent). By the sixth day, we were taking nine capsules at a time and going on occasional Liquid Brain Food binges. Yet our energy levels remained the same as before, and we experienced no change in appetite, sleep or emotions. Worse yet, my wart had failed to disappear—despite claims in a pamphlet that it might. In desperation, we raised our dosage to 14 capsules, reminding ourselves of the "guy from Boulder who took 100 capsules and was fine except for being awake for three days."

Finally, on the eighth day, both of us were able to report a dramatic physical change . . . GAS!

Apparently we were going through a "cleansing crisis." According to one Cell Tech brochure, "Super Blue Green acts as a catalyst and resource builder so that the body can release toxic buildup from the past. The toxic elimination can and does show up in as many creative ways as there are people. Some of these are: Intense sweating, headaches, stinky feet, fatigue and tiredness, hives, boils, crankiness, tumors, sore throat, hair loss, itchy skin, memories from the past, acidic stomach, gas, and many others."

Actually, if toxicity occurs, it seems more likely from the algae. In 1961, a toxic alga was reported in Klamath Lake in the same species used in Super Blue Green products. Although later tests failed to show further toxic strains, it is interesting to note the similarities between Cell Tech's version of "detoxification" and the effects of alga toxins on humans. Gas, diarrhea, nausea, tiredness, throat irritation and itchy skin have been reported in the scientific literature, and large doses of toxic algae have caused tumors when injected into small animals.

Aphanizomenon flos-aquae has been identified as one of the seven most poisonous blue-green algae [Bioscience 27:797-802, 1977]. Its toxicity is due to saxitoxin, a paralytic shellfish poison first isolated from toxic mussels and clams about 30 years ago. Even low doses of crude extract injected into white mice will cause death in less than five minutes.

In 1984, a U.S. marshal seized 84 bottles of algae capsules containing a toxic strain of the species *Aphanizomenon flos-aquae* from Bio-Nutritional Products in Mamaroneck, N.Y. The source of the capsules was based in Klamath Falls, Oregon, and had collected the algae from Klamath Lake [FDA Consumer, March 1985].

The company, K.C. Laboratories, had had \$120,000 worth of capsules seized in 1983 after the FDA charged that the algae was "an unsafe food additive." This company had produced an array of products under the trade name Blue-Green Manna, which it claimed could treat Alzheimer's disease, allergies, arthritis, and leukemia and many other illnesses [see NF 2:22-23]. The owner of K.C. Laboratories was Victor Kollman, brother of Daryl Kollman. In 1987, a U.S. District Court issued a permanent injunction barring Victor from the algae business.

Cell Tech maintains that it has been separate from K.C. Laboratories from the beginning, even though both companies were founded during the same year. According to Daryl Kollman's wife Marta, the two brothers parted ways in 1979.

"We just couldn't deal with his ethics. He wouldn't even eat his own algae," Marta Kollman told me in a telephone conversation. "It was this kind of dishonesty that got Victor in trouble. He made two key critical mistakes. First he claimed he was a doctor, which he's not. Secondly, he made claims that the products could cure illnesses. Once you've done that, the FDA considers it a drug," said Marta.

Sure enough, all of Cell Tech's literature contain disclaimers that the products do not provide "cures" for diseases and are not intended as a substitute for medical care. Throughout Daryl Kollman's lectures, he refers to the algae as a "whole food" and denies that it is a drug or even a food supplement.

Despite this disclaimer, it is clear that "drug" claims are being spread by Cell Tech distributors. Ads in

Vegetarian Times and *Total Health* state that daily users of Super Blue Green Algae commonly report "increased physical stamina, memory and mental clarity; alleviation of stress, anxiety and depression; relief from hypoglycemia, fatigue, mood swings and allergies; better control of appetite and weight; improved digestion and assimilation of food; faster recovery from side effects of certain medical treatments; and heightened anti-cancer and anti-pollutant immune functions."

In addition, testimonials from people identified by their initials in a 12-page packet from a local distributor claim that Super Blue Green has "stabilized" a woman with Alzheimer's disease, "given leverage during weight-lifting," helped clients withdraw from cocaine, caused a calcium deposit to disappear, reduced jet-lag, cured a 40-year case of constipation, and restored the health of a pet dog.

Ironically, the first successful court trial under the Pure Food and Drug Act of 1906 (predecessor of our current Food, Drug, and Cosmetic Act) involved a product called Cuforhedake Brane-Fude. "Yet in 1987 a company can get away with selling Liquid Brain Food because of our government's ineffectiveness," says James Lowell, Ph.D., an expert on algae who has followed the activities of K.C. Laboratories and Cell Tech closely.

Cell Tech appears to be growing rapidly. Anyone can become a distributor by completing an application and buying a sales kit for \$20.00. Marta Kollman said Cell Tech has over 6,500 distributors nationwide and ships out roughly 1,500 bottles daily. At this moment, the company is moving to a larger building. "We are expanding our harvesting plant. Soon we'll have the whole lake, because the other guy, Victor, is out of business," says Marta.

Meanwhile, Daryl Kollman has announced his candidacy for the 1988 Presidential election. His promises—no less modest than those for Super Blue Green—include "comprehensive recovery" of our environment, our economy and our health. Super Blue Green Algae, he claims, is "the cornerstone, the foundation, for a new way of living."

Mr. Paros is in his junior year and is majoring in molecular biology at the University of California/San Diego.

Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Mark Fuerst; Kathy King Helm, R.D.; Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

BRIEFS

Quackery conference successful. Close to 300 federal and state enforcement officials, insurance executives, antiquackery activists, and others met in Kansas City, Missouri, for the first National Health Fraud Conference held since 1963. After "declaring war" on health fraud, Deputy FDA Commissioner John J. Norris said his agency expected to cosponsor another national meeting in 1990 and 30 regional conferences during the next two years.

Snack food composition. A study of ten "natural" snack foods and their supermarket counterparts has found that the amounts of calories, protein, vitamins, calcium and iron were similar in comparable products, but most of the "natural" products cost more [*Environmental Nutrition* January 1988]. All products contained 2% or less of the U.S. RDA for most nutrients. Three of the natural snacks were lower in sodium and three were higher. Fat was slightly lower in two of the natural products, but essentially the same in most — and the natural products were as likely as the others to have saturated fats (palm or coconut oil). The study was directed by Melanie L. Polk, M.Sc., R.D., a dietitian in West Hartford, Connecticut.

Racketeering suit. Aetna Life Insurance Company has charged Stanislaw R. Burzynski, M.D., and the Burzynski Research Institute of Houston, Texas, with violating the Racketeer Influenced and Corrupt Organizations (RICO) Act. Aetna's claim, filed December 31, 1987, states that Burzynski planned and participated in a scheme to defraud various insurers, involving an alleged cancer treatment he calls Antineoplastons (ANPA). The scheme involved insurance claims which identified ANPA as "chemotherapy" administered on the Institute's premises. Usually, however, after a brief training period, it is self-administered by the patient or patient's family. Aetna believes that many millions of dollars have been paid mistakenly by insurers who thought that Burzynski was offering a proven chemotherapy program. ANPA, which Burzynski says is a naturally occurring peptide, lacks FDA approval and may not be legally marketed across state lines. Since the RICO Act allows recovery of triple damages, a successful suit could deter others who use unproven methods from falsely reporting to insurance companies what they are doing.

Artificial feeding. A review article has been published on the legal status and ethics of withholding intravenous or tube feeding from individuals believed to be in irreversible coma [*New England Journal of Medicine* 318:286-290, 1988]. Since courts place considerable weight on what patients would have wanted, the authors suggest that doctors encourage their competent patients — particularly elderly ones — to discuss and document their wishes. Reprints of the article are available from Bernard Lo, M.D., Box 0320, Room A-405, University of California, 400 Parnassus Ave., San Francisco, CA 94143.

Fruit and vegetable research. The U.S. Department of Agriculture has earmarked about \$2 million to look for alternatives to sulfites in preserving quality in salad bar fruits and vegetables. Fruits and vegetables begin to soften and brown shortly after they are cut, cored or sliced. Scientists are exploring the inside makeup of these foods to determine why they spoil and develop techniques to slow down the spoilage. Sulfites, which had been used to prevent the spoilage, were banned by the FDA last year because of their tendency to trigger allergic reactions in asthmatics.

Antifluoridation petition denied. The U.S. Environmental Protection Agency (EPA) has denied a petition to add inorganic fluorides to its list of toxic chemicals subject to reporting under the Superfund emergency planning and community right-to-know programs. Inorganic fluorides are commonly added to drinking water supplies to reduce the incidence of tooth decay. In denying the petition, EPA said it had found no case where total fluoride exposure from industrial sources and drinking water adversely affected health [*Federal Register*, May 29, 1987].

Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

AIDS and food companies. According to the January 13 *Wall Street Journal*, many food processing companies and food service firms are concerned about AIDS, but want to act quietly to avoid causing panic among workers and customers. The AIDS virus does not survive outside the body and is transmitted only through the intimate sharing of body fluids (such as semen) or introduction into another person's blood stream. But if a worker is found to have AIDS, a company might still lose co-workers and customers. On the other hand, firing an AIDS victim could trigger a job discrimination lawsuit. In response to this dilemma, companies and trade associations have begun low-keyed educational campaigns to indicate that AIDS cannot be transmitted by "casual" means such as handling food. Companies are also developing policies for dealing with workers who become AIDS victims.

Reported weight loss inaccurate. A follow-up study of former participants in a weight-control program has found that weights they reported averaged 5.9 pounds (2.9%) less than weights determined by actual weighing at the clinic [*Journal of the American Dietetic Association* 87:1198-1201, 1987]. The study involved 39 women and 107 men aged 28 to 63 years who were four or five years post-treatment. The participants were surveyed by telephone shortly before a check-up but were not told the results would be validated against their scale weight at the clinic. The researchers concluded that "use of self-reported weight is not adequate for the assessment of long-term weight-loss maintenance unless the magnitude of discrepancy is adjusted in some way." Similar findings have been reported by other researchers.

Suction lipectomy. Use of suction through a narrow tube to remove undesirable local deposits of body fat is now one of the most common plastic surgery procedures in this country. It involves a small incision through the skin and insertion of a tube connected to a high-vacuum suction machine. Common operative sites have been the thighs, hips, knees, abdomen, buttocks, upper arm, breasts and under the chin. Although some doctors claim that fat does not return to the treated areas, systematic follow-up data are lacking—and fat has returned in some animal studies. After reviewing published reports, *The Medical Letter* [December 18, 1987] has concluded that the procedure "has produced satisfactory results in some patients, but the long-term effects of the procedure are not known." Though the procedure is usually safe, infection, persistent pain, persistent swelling, skin discoloration, and distortions of contour have been reported. A few fatalities have occurred.

Sulfites and potatoes. The FDA has proposed to stop restaurants from using sulfite preservatives on fresh (unpacked and unlabeled) potatoes. FDA Commissioner Frank E. Young, M.D., Ph.D., said the agency's safety review showed that sulfites pose no health hazard to the general public but can cause reactions in up to one million people, many of whom are asthmatics. Reactions range from hives, itching, dizziness, nausea and diarrhea to shortness of breath, and, in rare instances, fatal shock. Since 1982, the FDA has received 1,400 consumer complaints about sulfites, and four deaths have been attributed to ingestion of sulfite-treated hash-brown and cottage-fried potatoes served in restaurants.

Sulfite labeling of meat products. The U.S. Department of Agriculture now requires meat and poultry processors to list sulfiting agents on product labels whenever the products contain confirmable levels of sulfur dioxide, sodium sulfite, sodium bisulfite, potassium bisulfite, sodium metabisulfite, or potassium metabisulfite. These substances are used to preserve foods, such as potatoes and other ingredients, that may be added to processed meat and poultry products. The USDA policy, like that of the FDA, requires sulfite labeling when products contain 10 parts per million or more of any sulfite. (The FDA has jurisdiction over foods other than meat and poultry.) Sulfites are prohibited in fresh meat and poultry products, but can still be used in stews and other processed meat or poultry products.

New foods for patients who can't chew. Food technologists at the U.S. Army's Natick Research and Development Center in Natick, Mass., have developed "dental liquids" for patients whose jaws are wired shut, throat cancer patients, and toothless patients awaiting dentures. According to a Center staff member, these patients often refuse to eat when they tire of bland or oversweet foods. The new products, which are being tested in 12 military hospitals, include French toast, chicken in wine sauce, beef or turkey and gravy, spaghetti, sloppy joes, pork with stuffing, barbecued chicken, chile con carne, noodles Parmesan, vegetables, strawberry shortcake and apple pie. The foods are finely ground, dried, and sealed in pouches that can be stored for three years at room temperatures. To prepare them for consumption, the dried foods are mixed with hot water in a blender. According to *American Dental News*, the researchers have developed a 2-day prototype menu of 20 items and are working on a 5-day regimen that will provide patients with about 2,200 calories per day.

Diet pill fraud attacked. The Federal Trade Commission has charged that advertising claims that Dream Away amino acid pills will cause users to lose weight while they sleep (without dieting or exercise) are false and deceptive. The agency has asked the U.S. District Court in Phoenix, Arizona, to issue an injunction and order payment of consumer redress.

United Sciences of America. Information about United Sciences of America suitable for teaching purposes is available for \$40 from the Lehigh Valley Committee Against Health Fraud, Inc., P.O. Box 1747, Allentown, PA 18105. Included are a 12,000-word report published by the American Council on Science and Health, the April 1987 *Nutrition Forum* article, a brief update, and the company's introductory videotape.

Poultry more popular. Americans ate more poultry than beef last year, and the U.S. Department of Agriculture predicts poultry will pull even further ahead this year. According to *Changing Times* magazine, increased production caused poultry prices to fall last year while short supplies of beef and pork led to increased prices. Poultry's popularity is also a result of health concerns, to which beef producers are responding with meat that is leaner and better trimmed.

Questionable product survey. A telephone survey of 1,514 American adults conducted by Louis Harris and Associates for the U.S. Department of Health and Human Services has estimated the extent of public use of selected unproven treatments. Some of its findings were: 1) 26.4% of those surveyed reported having used one or more "questionable" treatments; 2) word-of-mouth was the most common stimulus for use; 3) use of questionable products did not vary much with age or educational level; 4) those with the greatest trust in doctors were least likely to use questionable treatments; and 5) 36% of arthritis sufferers had used questionable treatments. Those surveyed reported getting health advice from the following "alternative" practitioners: chiropractors (21%), nutritionists (15%), religious counselors (5%), health product salespeople (5%), spiritual healers (3%), herbalists (3%), and acupuncturists (3%).

Chinese cookbooks. A 336-page compendium of 700 books on Chinese cooking published in English during the past century is available for \$47 from Garland Publishing, 136 Madison Ave., New York, NY 10016. Each entry outlines the features of each book and contains a brief evaluation. The compendium was written by Jacqueline M. Newman, Ph.D., R.D., Associate Professor of Home Economics at Queens College in Flushing, New York.

GREAT EARTH PROHIBITED FROM MAKING FALSE CLAIMS

The Federal Trade Commission has charged in a complaint that Great Earth International, Inc., has falsely claimed that three of its food supplements would enable users to lose weight, build muscle, burn fat, promote healing, protect against mental and physical fatigue, and/or strengthen the immune system. A proposed consent agreement, released simultaneously, would settle the charges and prohibit Great Earth from making unproven claims for other products as well.

Under the agreement, Great Earth must have substantiation for claims that any product will: 1) cure or prevent any disease or other undesirable physical or mental condition; 2) assist a user in losing or controlling weight or fat; 3) improve or strengthen any body organ or function; or 4) eliminate or reduce any harmful substance or organism that may be found in the body or environment. Great Earth will also be prohibited from

claiming that GHR Formula-P.M. (now called Tri-Amino Plus P.M.), L-Ornithine, or L-Arginine can stimulate production of human growth hormone, help users achieve rapid or substantial muscular development, promote weight loss during sleep, or promote burning of fat or building or toning of muscles. Nor may the company use the name "Growth Hormone Releaser" or any similar name unless it can substantiate that the product actually stimulates growth hormone release.

After a period of public comment, the Federal Trade Commission will issue a final consent order which, if violated, can result in a penalty of up to \$10,000/day for each violation.

Great Earth International is the nation's second largest health food store chain with about 150 retail outlets, most of which are owned by franchisees and licensees.

“BODYBUILDING” HERBS

Varro E. Tyler, Ph.D.

Nutrition Forum readers are probably well aware of the unwise and illegal use of anabolic steroids by some athletes. When used without medical supervision, these drugs have been linked to such serious side effects as jaundice, testicular atrophy, decreased bone growth in adolescents, and increased masculinity in women.

It is also probable that few persons knowledgeable in sound nutrition peruse the pages of *Ironman* or similar magazines devoted to bodybuilding. In recent years, these publications have been promoting concoctions of herbs, vitamins, minerals, amino acids, “glandular” products, and the like as legal substitutes for steroid drugs.

What herbs are involved in such promotions? Advertisements emphasize a curious mixture of purported “adaptogens” and “aphrodisiacs.” For example, the Conan Corporation of Jefferson, Ohio, promotes ginseng root, unicorn root, palmetto berries, and yucca as “Roid Replacers” that exert a “tonic effect on glandular secretions.” Hathaway’s Health Foods of Shawnee, Kansas, offers an Herbal Combination Cap in two versions. The one for males contains fo ti teng, damiana, licorice root, and sarsaparilla. For females, dong quai is substituted for fo ti teng. According to the advertisement, “These special herbs contain and enhance hormonal activity.”

Perhaps the most curious of the hyperbolic claims is contained in the advertisements by Amino Discounters of Tucson, Arizona. That company offers yohimbe bark extract in tablet form, not for its yohimbine content, but “because it contains significant quantities of methyltestosterone.” The tablets are said to contain an average of 25 milligrams of methyltestosterone derived from yohimbe bark.

A similar claim is made by Pacifico Enterprises of Dayton, Ohio, for its Smilax, a liquid preparation of sarsaparilla leaf. According to a recent ad, “Smilax *Officinalis* is the only true source of testosterone . . . Smilax is not a drug. Smilax is an herb.” And an ad by Vita-Life Products, Inc., Staten Island, New York, claims that, “Testosterone builds mass and strength and it occurs naturally in the herb Mexican Sarsaparilla.”

To this list of alleged bodybuilding herbs must be added schizandra and astragalus. Nature’s Way of Springville, Utah, recommends them, along with Korean white ginseng and Siberian ginseng (eleuthro) to “increase endurance, fight fatigue and speed recovery the way Soviet athletes do.”

In considering the validity of the claims made for these various products, it should first be stated em-

phatically that none of them has any proven anabolic steroid activity. Nor can any of them produce the fast muscular gains or increases in strength sought by bodybuilders and other athletes. It should also be said that some of the claims made for these products are ludicrous to the informed reader. For example, yohimbe bark certainly does not contain methyltestosterone. In fact, this substance is man-made and has never been isolated from any natural source.

Sarsaparilla, obtained from various *Smilax* species, does contain a number of steroids, including sarsapogenin, smilagenin, sitosterol, etc. But none of these compounds has the necessary molecular configuration to function in an anabolic manner. Further, none of them is converted to an anabolic steroid in the body following ingestion. Testosterone is present in minute amounts in certain animal tissues but has never been detected in plant material of any kind. To say that *Smilax* is not a drug but an herb belies the fact that the root of various species of this genus was listed as a drug in the official compendia for nearly 150 years.

It is hard to understand why organizations selling products intended for human consumption are being permitted to advertise them with claims totally unsubstantiated by clinical or scientific evidence. About the best that can be said of herbal “bodybuilding” products is that they are less harmful than the anabolic steroids they are intended to replace.

Dr. Tyler, Vice President for Academic Affairs at Purdue University, is an expert in pharmacognosy (the science of medicines from natural sources) and is author of *The New Honest Herbal* (1987), published by the George F. Stickley Company, Philadelphia.

QUESTION BOX

Q. What happens if too much protein is consumed?
A. The requirement for protein is limited. Protein from food must supply the body with amounts of the essential amino acids at levels sufficient to meet the protein-synthesizing needs of the body. Extra protein is metabolized for energy or converted to fat and stored. The daily recommended intake of protein for adult Americans is 0.8 grams per kilogram of body weight. Most Americans exceed this amount routinely.

HOW TO EVALUATE COMMERCIAL WEIGHT LOSS PROMOTIONS

William T. Jarvis, Ph.D.

The National Council Against Health Fraud disparages commercial weight control programs that:

1. Promise or imply dramatic, rapid weight loss (substantially more than one percent of total body weight per week).

2. Promote diets that are extremely low in calories (below 800 calories per day; 1200-calorie diets are preferred) unless under the supervision of competent medical experts.

3. Attempt to make clients dependent upon special products rather than teaching how to make good choices from the conventional food supply. (This does not condemn the marketing of low-calorie convenience foods which may be chosen by consumers.)

4. Do not encourage permanent, realistic lifestyle changes including regular exercise and the behavioral aspects of eating wherein food may be used as a coping device. (Programs should focus upon changing the causes of overweight rather than simply the effects, which is the overweight itself.)

5. Misrepresent salespeople as "counselors" supposedly qualified to give guidance in nutrition and/or general health. Even if adequately trained, such "counselors" would still be objectionable because of the obvious conflict-of-interest that exists when providers profit directly from products they recommend and sell.

6. Require large sums of money at the start or require that clients sign contracts for expensive, long-term programs. Such practices too often have been abused as salespeople focus attention upon signing up new people rather than delivering continuing, satisfac-

tory service to consumers. Programs should be on a pay-as-you-go basis.

7. Fail to inform clients about the risks associated with weight loss in general, or the specific program being promoted.

8. Promote unproven or spurious weight loss aids such as human chorionic gonadotropin hormone (HCG), starch blockers, diuretics, sauna belts, body wraps, passive exercise, ear stapling, acupuncture, electric muscle stimulating (EMS) devices, spirulina, amino acid supplements (e.g., arginine, ornithine), glucomannan, and so forth.

9. Claim that "cellulite" exists in the body.

10. Claim that use of an appetite suppressant or methylcellulose (a "bulking agent") enables a person to lose body fat without restricting accustomed caloric intake.

11. Claim that a weight control product contains a unique ingredient or component unless it is unavailable in other weight control products.

I find it helpful to keep this list handy. When talk show representatives inquire about questionable weight-loss programs or books, I go over the list with them. That usually sets them straight.

Dr. Jarvis is professor of health education at Loma Linda University and president of the National Council Against Health Fraud. Information about the Council can be obtained by sending a self-addressed envelope to P.O. Box 1276, Loma Linda, CA 92354.

NEW HELP FOR QUACKERY VICTIMS

Victims of health and nutrition frauds can encounter great difficulty obtaining redress through the courts. Many are afraid of lawyers. Some are embarrassed at having been fooled. Often victims do nothing, simply dismissing the fraud as one of life's lessons. Lawyers unfamiliar with cases of this type can have a difficult time handling them.

In response to these problems the National Council Against Health Fraud has created a Task Force on Victim Redress, chaired by NCAHF board member Stephen Barrett, M.D. The task force will offer: 1) a law-

yer referral service for the public; 2) information on unproven, fraudulent and potentially dangerous treatments; 3) a registry of expert witnesses; 4) information on defense witnesses; 5) reports on cases adjudicated, settled, and in progress; and 6) class action suits by defrauded victims. Help will also be available to insurance companies and law enforcement agencies.

Victim referrals should be made to Michael Botts, Esq., 421 W. 87th St., Kansas City, MO 64114 (telephone: 816-444-8615).

NUTRITION FORUM

ISSN 0748-8165

“NUTRITION” AGAINST DISEASE: A CLOSE LOOK AT A CHIROPRACTIC SEMINAR

High blood pressure, arteriosclerosis, ulcerative colitis, diabetes, infectious hepatitis, epilepsy, goiter, pancreatitis, kidney failure and receding gums are not the kinds of ailments chiropractors should treat. Recently, however, two dozen chiropractors gathered in Fort Lee, New Jersey, to hear how to treat these and many other diseases nutritionally. And they were taught how to bilk insurance companies in the process.

The chiropractors each paid \$125 to attend a six-hour seminar hosted by Berman Chiropractic Supply (BCS), of Warwick, New York, which sells chiropractic instruments and supplies. BCS is the exclusive north-eastern distributor for Nutri-West, a supplement manufacturer based in Douglas, Wyoming. Not surprisingly, the supplements recommended were made by Nutri-West.

The real star of the seminar was Nutri-West's 1987 "therapeutic food manual," a \$60 item given to everyone who pre-registered for the meeting. Entitled *Silver Bullets*—"A Clinician's Guide to Therapeutic Nutrition", this 164-page book lists 142 conditions ranging from acidosis to whooping cough and lists Nutri-West products for each one.

The seminar's featured speaker was Robert Cass, a naturopath with close ties to Nutri-West. Cass works with Paul White, D.C., the company's owner, in developing new supplement formulas and helped write some product literature that Nutri-West distributes. The seminar flyer also describes Cass as "executive director of the Los Angeles-based Nutritional Blood Analysis Program, a national clinical and therapeutic diagnostic program" and currently involved in setting up a chiropractic college in India. Although Cass wrote *Silver Bullets*, he is not identified in the book as its author. Instead, the title page states that "permission to reproduce and market this manual has been assigned to Clinical Results, 24000 Bessemer St., Woodland Hills, CA 91367"—which is Cass's business address.

Silver Bullets begins with disclaimers that presumably represent attempts to protect Cass from liability. The front cover states: "RESTRICTED TO DOCTORS LICENSED IN THE PROFESSIONAL HEALING ARTS." This message is repeated on the title page, which also states: "It is left to the discretion of the licensed healing arts professional to determine if the considerations and commentaries included in this manual are appropriate for their patient. Neither Clinical Results nor the publishers of this manual can be held responsible for errors, inaccuracies, omissions or any inconsistency herein."

The book's introduction gives an additional caution: "The information contained in this manual should not be construed as rendering diagnosis or treatment of any disease or preclude clinical testing or to substitute for necessary medical care. Therefore the statements contained herein should be viewed as being merely empiric [sic] based on reported clinical investigation and research of symptomatology, blood and urine chemistries, physical examination, observation, etc. The treating physician is solely responsible for his patient's treatment program and should understand that the commentary in this manual does not relieve him of his liabilities and responsibilities for his patient's diagnosis and treatment programs. Nutritional suggestions presented are certainly not designed to constitute a cure, specific or otherwise of any condition noted but are in fact designed to offer supplemental suggestions for the overall general nutrition of his patient's diet and are designed as an adjunctive support to medical, chiropractic, osteopathic, acupuncture, naturopathic, dental etc. procedures and treatments deemed necessary by the practicing physician. It is left to the sole discretion of the user of this manual to determine if the commentary and considerations in this manual are appropriate for their patient."

The book's foreword was written by George Goodheart, D.C., who states: "Concise and to the point [this manual] carries the authority that only clinical experience can bring. Healing arts professionals all over the world will find themselves referring to it throughout their busy practice schedules." Goodheart is the originator of "applied kinesiology," a system of diagnosis and treatment based on the theory that every organ dysfunction is accompanied by muscle weakness that may be correctable by "nutritional" methods. Its practitioners also claim that nutritional deficiencies, allergies, and other adverse reactions to food substances can be detected by placing substances in the mouth so that the patient salivates. "Good" substances will make specific muscles stronger, whereas "bad" substances will cause specific muscle weaknesses. Dr. White learned about applied kinesiology from Dr. Goodheart and has promoted it vigorously ever since.

Despite the many disclaimers, *Silver Bullets* offers a system of treating illnesses that is as simple as following a cookbook. Each ailment is followed by a list of Nutri-West products, the recommended dosage (the accuracy of which is said to be "greatly enhanced" with applied kinesiology testing), and phrases describing the supposed purpose of each product. A "commentary" section provides additional explanation and advice. For most conditions the number of products recommended is between two and eight.

Take epilepsy for example. The book prescribes 40 tablets daily: 2 tablets 4 times a day of Pit-Lymph-Whole ("regulates endocrine balance"); 2 tablets 4 times a day of RNA-DNA-Plus ("specific cell activators"); 3 tablets 3 times a day of Liva-Lymph-Plus ("liver metabolism factors"); 2 tablets 4 times a day of Chlorophyll-Plus ("liver detoxification and source of organic magnesium"); and 1 tablet 4 times a day of niacin ("nourishes nerve supply").

For arteriosclerosis, *Silver Bullets* recommends: Super EPA ("anti-plaquing factors"); GB-Plus ("thins bile viscosity, liver/gall bladder decongestant"); Lipotrophic Plus ("to reduce cholesterol/blood fats"); Aspartic-K ("source of potassium/cardiac support"); Lyso-Lymph Forte ("anti-fibrotic factors/proteolytic enzymes"); and Cardio Lymph Chelate ("supports vasculature to increase circulation").

At the seminar Cass said Cardio-Lymph Chelate is an oral chelation product that is "absolutely wonderful." He said it "takes plaque off the wall" of arteries and "scrapes them down." According to the commentary in *Silver Bullets*, after improvement occurs, the "maintenance program is 1 three times a day for life."

Cass asked the many people who had brought tape recorders not to use them. His reason: "We'll get into some sensitive material later on." And with no tape recorders, "I'll deny everything that I say."

Cass said a lot about two services he offers—Nutritional Blood Analysis and The Bio-West Report—that are designed for the chiropractors who use *Silver Bullets*. For years, he said, chiropractors have complained that they want to use nutrition but can't get paid for it. According to Cass, his services diagnose patient diseases and prescribe the supplements to help solve that problem. "I want to help you make money selling nutrition," Cass said.

For Nutritional Blood Analysis, the chiropractor sends Cass a specimen of the patient's blood and a "subjective but useful" questionnaire that the patient has filled out. After the blood is tested, Cass feeds the results plus data from the questionnaire into his computer. The doctor then receives a printout—the patient's "personalized therapeutic report."

The profit, however, is in the blood, which Cass has analyzed by one of several cooperating laboratories. These labs carry out a complete blood count, a SMAC-24 (which measures the blood levels of 24 chemicals), and several other tests. If the patient is insured, the labs accept insurance assignment as payment in full.

"Private insurance and Medicare—that's hot, huh?" said Cass, emphasizing that the analysis "doesn't cost anybody anything." The blood work and analysis is worth \$110, Cass said. But the labs bill the insurance companies \$290 to compensate for reimbursements that may amount to only 60-80% of the total. The lab pays Cass a fee and keeps \$130 to \$140 for itself.

The chiropractor profits from nutritional blood analysis in two ways: by selling patients the Nutri-West supplements prescribed in the Nutritional Blood Analysis Report, and by "creative billing" of insurance companies, Cass said. He explained that chiropractors can't bill insurance companies for the therapeutic report itself. To get around that problem, Cass advised them to bill the report—worth between \$35 and \$50—as an office visit. "Generally speaking," Cass said with a smile, "creative insurance billing is the way to go these days."

A chiropractor using nutritional blood analysis can bill for other things as well, said Cass, including the charge for drawing the blood (code 9900 on the insurance form, he noted helpfully) and the office visit (code 90060) at which the blood was drawn. The total take for one patient's blood analysis "could come to \$200 when all is said and done—very easily," Cass said.

Copyright © 1987 by the GEORGE F. STICKLEY COMPANY
Nutrition Forum ISSN 0748 8165 is published monthly by the George F. Stickley Company, 210 W. Washington Square, Philadelphia, PA 19106. Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES: \$30/yr., \$57/2 yrs., \$81/3 yrs., prepaid; VISA and Mastercard acceptable; foreign postage by airmail add \$18.00.

Cass provides the chiropractor with two reports: one "for professional use only" and one for the patient. What's in a typical Nutritional Blood Analysis Report? Each chiropractor was given a sample on a patient identified as Barbara, a 51-year-old woman.

The analysis, which bears a 1986 Cass copyright, contains this disclaimer: "The information in this outline should not be construed as rendering diagnosis or treatment of any disease or preclude additional clinical testing or to substitute for necessary medical care. Therefore the statements contained herein should be viewed as being merely empiric [sic] based upon clinical research and investigation. The treating physician is solely [sic] responsible for his patient's diagnosis and treatment programs and by requesting this discussion acknowledges full and complete liability for his patient's diagnosis and treatment programs. Nutritional suggestions presented are not designed to constitute a specific cure for the treatment of any condition but are designed to offer supplemental feedings in the overall nutritional enhancement of the patient's diet. Although Nutri-West products are suggested in this report, the considerations expressed are not necessarily those of Nutri-West."

The sample report contains fifteen pages of tables and text. Seven pertain to "Barbara" and the rest give general information and advice that includes warnings against white flour and refined sugar. One page is a list of "vitamin and mineral robbers" said to be adapted from a magazine article by Earl Mindell on "Why We Should Take Vitamins." Barbara's analysis begins with a table that compares the results of Barbara's blood tests with "lab ranges" and "nutritional balance" ranges and interprets the results outside the "nutritional range" as "high" or "low." [Editor's note: For most values, the "nutritional balance" range is narrower than the range considered normal by the scientific community. Thus many people will have "high" or "low" values inappropriately reported.]

Barbara's report lists many problems: functional digestive disturbances and malabsorption syndrome; liver, adrenal, biliary, thyroid, pituitary and autonomic imbalances; reactive hypoglycemia; calcium mobilization problems; lowered resistance; possible parasite involvement; presence of bacterial/viral infection; dehydration pattern; high sodium; protein malabsorp-

tion; overstimulated osteoblastic activity indicating osteoarthritis/osteitis and other bone problems; creatine phosphokinase (CPK) pattern disturbances; menopausal "hot flashes"; and circulatory insufficiencies.

The recommended solution includes dietary changes and copious amounts of Nutri-West supplements. Barbara was prescribed Nutri-West's Adreno-Lymph-Plus (for "adrenal support, reactive hypoglycemia, hypotension, and allergies"), Hypo-Di-Gest (for "blood sugar handling problems and digestive support"), Core Level Thymus (for "support of immune functions"), Lipotrophic-Plus ("fat metabolizer and bile thinner/mobilizer"), GB-Plus ("gallbladder/liver decongestant"), and Pare-X and #8 VMF (for "digestive function, parasites, and inflammation").

The report instructed Barbara on the proper times to take the supplements and the number of tablets to take. And it offered this advice: "FOLLOW the Schedule of Nutritional Adjuncts and the dietary outlines contained in your report JUDICIOUSLY. The road back to health can be a fascinating and rewarding ADVENTURE!" Chiropractors get a 50% discount on Nutri-West products and presumably charge list price to patients. Barbara's program would cost more than \$5.00/day.

For chiropractors who don't want to do blood work, Cass offered another way to make money: his Bio-West Report. The chiropractor sends Cass a questionnaire that the patient has filled out, along with other information about the patient's blood pressure, medications taken, health habits, and underarm temperatures (which supposedly indicate thyroid function). The questionnaire—also used for the Nutritional Blood Analysis—contains more than 150 signs and symptoms for the patient to circle. Cass enters the information in his computer and produces the patient's Bio-West Report—a prescribed list of nutritional supplements for the patient's "clinical nutritional program."

The Bio-West Report contains a disclaimer almost identical to that of the Nutritional Blood Analysis. However, according to the sample Cass distributed, if the patient circles "tendency to asthma," the printout responds: "Indicative of a need for HCl and adrenal support. Also indicative of possible food reaction sensitivities." The recommended supplements are Lyso-Lymph-Forte, #6 LNG, Calc-Acid, C-1000TR, Pneumo-Lymph, Adreno Lymph-Plus, Histo-0-Cal, Duo-Lymph, Pare-

Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Mark Fuerst; Kathy King Helm, R.D.; Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

X, and #8-VMF. The Chiropractor is referred to *Silver Bullets* to learn how many times a day the patient should take each supplement.

What if the patient needs coffee to get going? "Indicative of a reactive hypoglycemia pattern with biliary adrenal insufficiencies," the printout reports. The suggested supplements: Core Level Bile, GB-Plus, Hypo-Digest, Multi-Gland Chelate, Amino-All, Adreno-Lymph-Plus, and B-Complex.

Heart palpitations indicate "a need for vitamin B and alkaline minerals"—which means the supplements Trypto-CLM, B-Complex, and Cardio-Lymph-Chelate.

The Bio-West Report costs the patient \$30, Cass said, adding that insurance companies probably can't be billed for it. But insurance code 99050—retrieval of data—was "a possibility" that chiropractors could try using to obtain insurance reimbursement.

Chiropractic is based on the false belief that spinal misalignments are the major cause of diseases, and that many if not most ailments can be helped by manipulation ("adjustment") of the spine. Chiropractors are licensed to do spinal adjustment in all 50 states, but they are not allowed to prescribe drugs, and in many states they are not permitted to diagnose or treat disease.

Cass suggested that nutrition supplements may be necessary for chiropractors' spinal adjustments to work. "As the chiropractic profession knows, our responsibility is to get the spine into alignment. That's the bottom line," he said. Nutritional supplements "assist the body to come into balance," he said. And once that happens, "the body can come back into alignment."

Chiropractic journals carry ads from many companies that sell supplement products, and several of these companies conduct seminars on the use of their products to treat disease. The number of chiropractors

using these approaches is unknown, but is probably several thousand.

Under federal law, substances intended for use in "the diagnosis, cure, mitigation, treatment or prevention of a disease" are considered drugs. Products not generally recognized by experts as safe and effective for their intended use are "new drugs," which cannot legally be marketed in interstate commerce. This also applies to vitamins and related products purported to treat or prevent disease even if they are marketed as "foods" or "nutritional supplements." Federal law also requires that drugs be labeled with adequate directions for use. Some states have similar laws.

Nutri-West markets more than 200 products which it classifies as glandulars, minerals, amino acids, digestives, enzymes, herbals, unsaturated fatty acids, specialty items, gels and topical applications. The "glandular" products and some of the mineral and specialty products contain bits of "raw tissue concentrates" from various animal glands. Although Nutri-West labels merely list ingredients, the intended use of the products for treating and preventing disease is clear from this seminar as well as materials given out by Nutri-West and its distributors.

According to an article in the *Cheyenne Star-Tribune*, Nutri-West was investigated by the FDA in 1985 and stopped selling an alleged gallbladder remedy to which the FDA objected. Federal regulatory agencies tend to shy away from the activities of state-licensed practitioners, leaving them to the supervision of state boards. This seminar indicates that Nutri-West and Cass deserve a closer look.

The author is a prominent investigative reporter who lives in New York City.

BRIEFS

Chiropractor "prescribing" stopped. The Supreme Court of Georgia has upheld a ruling by the Georgia State Board of Chiropractic Examiners that nutritional treatment is not within the scope of chiropractic under Georgia law. The case began when the Board took action against a chiropractor who had used a blood analysis report as the basis for treating a heart patient with six products that contained vitamins, minerals, enzymes and/or amino acids. According to the November 1987 *ACA Journal of Chiropractic*, the chiropractor claimed he was treating dietary deficiencies. But the Court held that "an article that happens to be a food but is intended for use in the treatment of a disease fits squarely within the drug definition" of state and federal laws. Chiropractors are not allowed to prescribe drugs.

Notable quote: "The health food industry is founded upon food terrorism. It justifies its very existence on the false notion that supermarket foods are unhealthful . . . Some consumer groups also engage in food terrorism by launching ill-founded attacks on the safety of the American food supply. They apparently feel that in order to justify their existence they must create the illusion that they are protecting the public from a poisoned food supply. They exploit the media by appealing to public cynicism. Consumers are always pictured as victims in a "we" vs. "they" scenario. Health behaviorists generally recognize that individual tastes and choices determine the healthfulness of people's diets. Food terrorists teach that some political solution is necessary."—William T. Jarvis, Ph.D., *NCAHF Newsletter*, Jan./Feb. 1988.

Author organizing referral list. Jack Z. Yetiv, M.D., Ph.D., author of *Popular Nutritional Practices*, has invited physicians, dietitians and other nutrition professionals who agree with his book's views to register with him for possible patient referrals. He has also invited victims of quackery to share their experiences with him. The book is now available in paperback for \$5.00 per book plus \$1.00 postage from LVCAHF, Inc., P.O. Box 1747, Allentown, PA 18105. (Orders unaccompanied by payment will be returned.)

Drinking water hotline. The U.S. Environmental Protection Agency provides a toll-free hotline for general and technical information about the quality of drinking water. The number is 1-800-426-4791 (382-5533 in the District of Columbia).

Anti-irradiation bill vetoed. A bill to prohibit the sale or distribution of irradiated food in New Jersey was pocket-vetoed by the state's governor. Although the bill had passed the State Senate by a vote of 30-3 and the State Assembly by 62-3, the veto could not be overridden because the legislative session had ended. Food irradiation opponents plan to have the bill reintroduced.

Vitamin sales lagging? *Health Foods Business's* annual mail survey concluded that sales at about 7,000 health food stores totalled \$1.8 billion (down 10.2% from 1986), including \$441 million for vitamins and supplements (- 42.3%), \$119.6 million for bulk herbs (+ 58%), \$54.2 million for herb teas (+ 32%), \$22.4 million for macrobiotic foods (- 22%), \$10.8 million for grains and cereals (- 24%), and \$72.9 million for books (+ 8%). Despite the extraordinary drop in vitamin sales, the magazine's editorial director said that most people with whom he had talked felt that business had been good, that the number of responses to the survey had been fewer than usual, and that many of them had come from small stores. Thus, he cautioned readers "not to take the results too literally." In an interview in *Whole Foods*, Jerry Horn, president of General Nutrition Corporation said that GNC's 1,200 stores had grossed about \$350 million during 1987. Horn cited a Gallup Poll report that 14 million people stopped using supplements between August 1986 and August 1987, "primarily because these consumers felt they are eating better." But he suggested that this "drop" might have been due to overstatement of supplement sales in the past. Criticizing industry estimates of between \$2.6 and \$3.5 billion, he said, "No one can tell me how they gather the sales figures . . . I don't think it was ever over \$1.5 billion. As a matter of fact, it may not be a whole lot bigger than \$1 billion."

General Nutrition may be penalized. Under a proposed consent agreement with the Federal Trade Commission, General Nutrition Corporation will donate \$600,000 for nutrition research to settle charges that it engaged in unfair and illegal marketing practices. The proposed agreement would settle complaints filed during 1984 in which the FTC objected to GNC's promotion of Healthy Greens (a dried vegetable/vitamin/mineral product alleged to help prevent cancer—see *NF* 3:38) and six amino acid products alleged to help muscular development, extend life, or cause weight loss during sleep. GNC would be prohibited from making these claims or any other claim for any product that cannot be substantiated by scientific evidence. The research funds will be paid to the American Diabetes Association, American Cancer Society and American Heart Association to support research or fellowships in nutrition, obesity or physical fitness. Public comments will be accepted until May 23, 1988, after which the Commission will decide whether to accept or modify the proposed order. Once final, violations of FTC consent agreements can trigger penalties of up to \$10,000 per day. The address for comments is: FTC/Office of the Secretary, Room 136, 6th St. and Pennsylvania Avenue, Washington, DC 20580.

Victor Herbert on tape. Audiotaped discussions by Victor Herbert, M.D., Professor of Medicine, Mount Sinai School of Medicine, are available from Soundwords, 56-11 217 St., Bayside, NY 11364. The topics are *Understanding Nutrition* (2 tapes/\$25.90), *Nutrition Quackery & Fraud* (2/\$25.90), *Vitamins & Minerals* (\$12.95), *Vegetarian Diets* (\$12.95), and *Why Fad Diets Fail* (\$12.95). Shipping is 75¢ per order.

Fat substitute announced. The NutraSweet Company, a subsidiary of Monsanto Company, has announced plans to market a low-calorie, low-cholesterol fat substitute made of natural protein from egg white or milk. Called Simplese, the product is produced by a new cooking process that changes the protein into a substance that can be used to make products with the taste and texture of ice cream, butter, cheese spreads, creamy salad dressings and mayonnaise. In press releases, the company said foods made with Simplese would provide "all the pleasure and none of the penalty" of eating fat-laden foods and would lower the cost of some foods. Predicting that Simplese would be marketed within 12 to 18 months, the company claimed that since it is merely a change in the physical form of commonly used foods, it is like a recipe and does not need regulatory approval. However, the FDA responded that approval is needed, and the company has agreed to seek it. In 1986, the company sold \$700 million worth of aspartame (NutraSweet, Equal), but its exclusive patent expires in 1992.

"Health freedom" blasted. *The Unhealthy Alliance: Crusaders for "health freedom"* is available for \$3.00 from the American Council on Science and Health, 1995 Broadway, 18th Floor, New York, NY 10023. Written by Nutrition Forum editor Stephen Barrett, M.D., the 12,000-word report describes the purposes and activities of the National Health Federation (NHF), Health Alternatives Legal Foundation (HALF), American Quack Association (AQA) and Coalition for Alternatives in Nutrition and Healthcare (CANAH). The report also provides detailed background information on their leaders plus descriptions of many of the questionable methods they promote. Dr. Barrett concludes: "NHF, HALF, AQA and CANAH are antagonistic to accepted scientific methods as well as current consumer protection laws. Instead of supporting the rules of science and law, they want to destroy them. They want the right to market methods without the responsibility of ensuring that they are effective. In my opinion, the 'freedom' they espouse would be nothing more than a hunting license for quacks."

Nutritionist licensing update. In March Washington became the 18th state to regulate nutrition professionals with passage of a law certifying dietitians and nutritionists. The votes for passage were 96-0 in the state's House of Representatives and 97-1 in its Senate.

Information about sugar. A new videotape and other excellent educational materials designed to counter misinformation about sugar can be obtained by contacting Sarah Setton, Director of Public Affairs, The Sugar Association, 1101 15th Street, N.W., #600, Washington, DC 20005.

"Anti-aging" cosmetic claims should stop. The FDA has ordered 22 cosmetic firms to stop making claims that their skin cream products could influence cellular effects on the aging process. The Food, Drug, and Cosmetic Act defines cosmetics—which can be sold without FDA premarket approval—as products intended to cleanse or to superficially beautify. But any claim that a product changes the structure or function of the body or cures or treats a condition requires that the product's safety and effectiveness be demonstrated to the FDA before it is marketed. Last year the agency warned several major cosmetic companies to stop making claims that their products could counteract, retard or control the aging process, or to rejuvenate, repair or renew the skin. Some firms modified their labels, but claims unacceptable to the FDA continued for many products. The current order is intended to apply to all cosmetic firms, not just those to whom it was sent. Manufacturers were given 30 days to comply or face regulatory action.

Total food costs. According to the Food Institute, American consumers spent \$454.5 billion for food in 1987, up from \$438.8 billion in 1986. At-home food expenditure totalled \$305.8 billion, only \$7.5 billion more than in 1986. Food spending took 14.7% of after-tax income, continuing a slight downward trend.

Roger Williams dies. Biochemist Roger J. Williams, Ph.D., famed for his discovery of pantothenic acid, died February 20th at the age of 94. As a professor at the University of Texas and director of the Clayton Foundation Biochemical Institute, he was involved in additional scientific research. However, during his later years, he proposed a concept of "biochemical individuality" which encouraged above-RDA supplementation for everyone. He supported claims that megavitamins were effective against mental retardation and various illnesses, and he helped the health food industry gain passage of a law that weakened FDA jurisdiction over the dosage of vitamin products.

Kellogg modifies misleading ads. The National Advertising Division (NAD) of the Council of Better Business Bureaus has reported that ads for Kellogg Company's Special K cereal have been modified [NAD Case Report, 3/21/88]. Television ads had stated "Protein helps you keep the muscle while you lose the fat. That's what's special about Special K. It has the highest level of dietary protein of any cereal," while package labeling said, "Did you know the last time you starved yourself to lose fat, you might have lost muscle too?" Newspaper inserts made similar claims. When challenged, the company claimed that its messages were intended for people under severe calorie restrictions who could benefit by increasing protein intake. NAD agreed that Special K was a significant source of protein compared to other brands of ready-to-eat cereal and that a portion served with milk would be a useful component of a nutritionally balanced weight-loss diet. However, NAD also pointed out that people on severely restricted diets would benefit from supplementary protein of higher biological value and in more concentrated form than can be obtained from a cereal-based product. In continuing discussion, the company said that its advertising had been modified and now focuses on the contribution of a Special K breakfast to a nutritionally balanced diet and exercise program. *Editor's note:* This report illustrates two things: 1) financial penalties are needed to DETER companies from using misleading doubletalk in advertising; and 2) complaints to NAD can be effective against national advertisers. Its address is 845 Third Ave., New York, NY 10017.

SUNRIDER WARNINGS ISSUED

Stephen Barrett, M.D.

The FDA has warned consumers that Nutrien and Vitalite powdered drink mixes produced by Sunrider International of Torrence, California, should be avoided because testing has disclosed the presence of salmonella bacteria in a soybean extract used in the products. According to an FDA news release, the company has agreed to begin a nationwide recall but has refused to provide the FDA with specific distribution information. The release states that at least five reported cases were associated with an initial product recall earlier this year. Since then, three more complaints have been investigated with tests in two individuals indicating the presence of salmonella.

The California Department of Health Services has also issued a warning against public consumption of the products and has embargoed several lots of the extract from which they were made, while the Utah Department of Agriculture has barred further shipment of finished products made from the soybean powder extract.

Sunrider markets its products nationally through a multilevel network with more than 40,000 distributors and reported gross sales of about \$7 million per month. Anyone can become a distributor by completing an application and paying \$24 for a sales kit. Distributors can profit from retail sales and receive a percentage of the sales of other distributors that they sponsor. The company began operations in December 1982 in Orem, Utah, and moved its headquarters to California in July 1987. Its board chairman and current president is Tei Fu Chen, who was also the company's co-founder.

According to "The Sunrider Story," which appears in many company publications, ancient Chinese temple priests who were leading developers of the martial arts discovered special plant and herb combinations for increased endurance, energy and mental alertness and also discovered a balm to expedite healing of torn or bruised muscles. Chen's great-grandfather was able to obtain manuscripts containing the secrets of 5,000 years of research and became a prominent herbal physician. He and Chen's father began teaching them to Chen during his eighth year. Chen subsequently became a Taiwanese National Kung Fu champion, a medical doctor (in Taiwan), a licensed pharmacist (in the U.S.), a biochemist, and a "world renowned nutritionist."

"At the age of twenty," the story continues, "he became a Senior Research Scientist. He then spent 15 years in continued research, testing the principles taught in the manuscripts according to modern science and technology . . . As a young man, Dr. Chen was physically weak. He was small, underweight and over-

powered by physical allergies and illness. His own story of transformation was adequate proof of the legitimacy of the secrets on the pages of the manuscripts . . . The Sunrider Corporation is so named because of Dr. Tei Fu Chen's belief that we can 'Ride The Sun' to health and prosperity." ("If you can ride the sun, the day will never end.")

Sunrider literature claims that, "every disease is caused, retained, encouraged, or aggravated by a lack of nutrition." The company markets three product lines: Kandesn, Vitalite, and Sunergy.

Kandesn is a group of skin-care products said to "combine the finest herbal ingredients with the "Essence of Pearl" using ancient formulas to create products that enhance the health and beauty of the skin" and to "nourish the body . . . from within and without."

The Vitalite program promises "high energy level, manageable appetite, mental alertness, sustained well-being, effective metabolic pace, emotional stability, balance in body systems, and efficient cleansing processes." It includes supplement capsules, meal-substitute drinks that contain powdered protein and herbs, an herbal beverage, a vegetable soup mix, high-fiber cookies, and other low-calorie snacks. Kits containing a complete 2-week supply of Vitalite products wholesale for \$149.95.

The Sunergy line is composed of whole food concentrates, herbs, and supplements. The concentrates are listed in the table below. The herbs (goldenseal root, dandelion root, Korean white ginseng, white willow bark, Siberian ginseng root bark, and dong quai) are promoted with various claims that they help nourish, cleanse, purify and/or balance the body, increase hormone production, or enhance the power of the body. The supplements are Energy Plus (to provide energy and alertness), a stress formula ("to help the body resist the stresses of daily living"), and Metabalance 44 (said to include 15 vitamins despite the fact that only 13 exist for humans and the product contains only 12).

According to a notice in the company's bi-monthly magazine *Sunwriter*, "The Sunrider philosophy does not focus on disease, treatment, or cure . . . We are concerned with providing the body with the nutrition it needs to perform its miraculous functions. If the body needs to be healed, it has all the necessary equipment and procedures to accomplish the task, if it is given the essential nutrition. The Sunrider Corporation does not attempt to respond to specific illnesses . . . Prescribing treatment for disease is contrary to Sunrider philosophy to treat the body as a whole and give it the strength to heal itself. Instead of trying a specific treatment for a

specific ailment, Dr. Chen recommends the use of eight products in the Sunpack which address specific nutritional needs of the body."

Despite this disclaimer, Sunwriter invites distributors to submit letters and articles about how they were helped with health problems and offers a free \$145 Sunpack for those that are published. Most issues contain testimonials about weight-loss—including one claiming a loss of 67½ pounds in 59 days—and many contain success stories involving serious disease. Readers have reported that arthritis, ulcers, high blood pressure, lupus erythematosus, shingles, emphysema and pancreatitis have been helped, and one article even suggests that the products enabled a man to be removed from a kidney machine!

Although some Sunrider publications state that "a good nutritional program does not eliminate the need for health professionals," others imply that Sunergy products are superior to prescribed medications: "When you introduce a chemical substitute for an ailing organ or body system, that organ or system atrophies. The substitute may make a person feel better, but that feeling is nothing more than an 'illusion of health.' The organ or body system is still sick." But Sunrider products can "restore the body's capacity to regulate itself." The company claims that "nearly the entire medical philoso-

phy is based on substitution," whereas Sunrider works by "regeneration." According to a Sunrider cassette tape, there are plant combinations that will "support the genetic control of the body in all of the different body areas," and Sunrider products are "system-specific concentrated regenerative whole foods." *Product Bulletin #200*, distributed in 1984, advises readers that each Sunrider formula "favors a particular body system."

In 1983, the FDA sent Sunrider a notice of adverse findings which contains several criticisms of Nutrien Concentrate and Calli Tea. The company was ordered to stop claiming that Nutrien was adequate and effective to "produce energy, long life, and lasting health" and that Calli was "designed for health and beauty" and helps the user to be "slender, energetic, and full of life."

During 1984, the FDA obtained an injunction prohibiting Sunrider from marketing an unapproved sweetener extracted from the herb *Stevia rebaudiana* and sent the company a regulatory letter telling it to stop making more than 50 explicit claims that Assimilaid, Lifestream, Prime Again, and Concold (now marketed as Conco) could benefit specific organs or were adequate and effective against various disease conditions. Although these claims were stopped, I believe Sunrider is still violating the Food, Drug, and Cosmetic Act.

CLAIMS MADE FOR SUNENERGY PRODUCTS INCLUDED IN THE SUNPACK

Product	Number of Herbs	Stated Purposes*
Alpha 20 C (capsule)	5	Supplies nutrition used by the body to restore balance to the immune system; when the body has established genuine stability in the system, growths and distortions of cells are greatly prohibited
Assimilaid (capsule)	10	Gives the body the nutrition it needs to stimulate, lubricate, and equalize its digestive processes
Calli (tea)	5	Enhances the powers of the mind and heightens the ability to concentrate; helps body cleansing systems operate efficiently to reduce toxic waste and eliminate cholesterol and dangerous fatty substances
Conco (capsule)	6	Nourishes the body's ability to avoid and overcome illnesses
Lifestream (capsule)	8	Enhances the vital performance of circulatory and cardiovascular systems
Nutrien (drink mix)		Nourishes the body to improve cell-energy processes; supports the body in dealing with its challenges and addictions; helps create a sense of emotional wellbeing; provides nutrition the body needs to maintain stamina, strength, and beauty
Prime Again (capsule)	14	Nourishes glands that enhance the reproductive processes of both men and women; balances the nervous system, adrenal and hormone responses
Sunbreeze Balm (ointment)		Soothes tension, sore muscles, and abrasions; improves circulation, relieving pain as it accelerates healing; gives great relief in cases of arthritis, sore throat, toothache, ache, etc.; relieves congestion, motion sickness, sluggishness and tension, and increases mental alertness

MAY/JUNE 1988

ISSN 0748-8165

THE RISE AND FALL OF LAETRILE

Benjamin Wilson, M.D.

Laetrile is the trade name for *laevo*-mandelonitrile-beta-glucuronoside, a substance allegedly synthesized by Ernst T. Krebs, Jr., and registered with the U.S. Patent Office for the treatment of "disorders of intestinal fermentation." This compound is chemically related to amygdalin, a substance found naturally in the pits of apricots and various other fruits. Most proponents of Laetrile for the treatment of cancer use the terms "Laetrile" and amygdalin interchangeably.

Amygdalin was originally isolated in 1830 by two French chemists. In the presence of certain enzymes, amygdalin breaks down into glucose, benzaldehyde, and hydrogen cyanide (which is poisonous). It was tried as an anticancer agent in Germany in 1892, but was discarded as ineffective and too toxic for that purpose. During the early 1950s, Ernst T. Krebs, Sr., M.D., and his son Ernst, Jr., began using a "purified" form of amygdalin to treat cancer patients. Since that time scientists have tested substances called "Laetrile" in more than 20 animal tumor models as well as in humans and found no benefit either alone or together with other substances. Along the way its proponents have varied their claims about Laetrile's origin, chemical structure, mechanism of action, and therapeutic effects. Its place in history is assured, however, as a focus of political activities intended to abolish the laws protecting Americans from quackery.

Krebs, Sr. — Laetrile's "grandfather" — worked as a pharmacist before attending the San Francisco College of Physicians and Surgeons, from which he received his medical degree in 1903. During the influenza pandemic of 1918, he apparently became convinced that an old Indian remedy made from parsley was effective against the flu. He set up the Balsamea Company in San Francisco to market the remedy as Syrup Leptinol, which he claimed was effective against asthma, whooping cough, tuberculosis and pneumonia as well. During the early 1920s, supplies of Syrup Leptinol were seized by the FDA on charges that these claims were false and fraudulent. During the 1940s, Krebs, Sr., promoted Mutagen, an

enzyme mixture containing chymotrypsin, which he claimed was effective against cancer. He and his son also patented and promoted "pangamic acid" (later called "vitamin B₁₅"), which they claimed was effective against heart disease, cancer, and several other serious ailments. Krebs, Sr., died in 1970 at the age of 94.

Ernst T. Krebs, Jr. — Laetrile's "father" — has often been referred to as "Dr. Krebs" although he has no accredited doctoral degree. He attended Hahnemann Medical College in Philadelphia from 1938 to 1941, but was expelled after repeating his freshman year and failing his sophomore year. After taking courses in five different colleges and achieving low or failing grades in some of his science courses, he finally received a bachelor of arts degree from the University of Illinois in 1942. In 1973, after giving a 1-hour lecture on Laetrile, he obtained a "Doctor of Science" degree from American Christian College, a small, now-defunct Bible college in Tulsa, Oklahoma. The school, founded by evangelist Billy James Hargis, had no science department and lacked authority from Oklahoma to grant any doctoral degrees.

Laetrile's origin

Several versions of Laetrile's development have been published. In a 1962 book, Krebs, Sr., said that he had theorized that "cancer proteins" could be broken down by an enzyme he had prepared when he was a pharmacy student. When the substance proved too toxic in animal experiments, he boiled it and obtained better results. However, according to Michael Culbert, another prominent Laetrile promoter, Krebs ran a lucrative business analyzing smuggled whiskey for wood alcohol and developed Laetrile while working on a bourbon flavoring extract. During experiments with a mold growing on the barrels in which the whiskey was aged, he isolated an enzyme that he thought might have anti-tumor activity. When his supply of barrel mold was exhausted, he switched to apricot pits and used extracts (which he called Sarcarcinase) for various tests on animals and hu-

mans during the next two decades. In 1949, Krebs, Jr., modified his father's extraction process and named the result Laetrile.

Historian James Harvey Young has noted that Krebs, Sr., presented yet another version to FDA officials during an interview in 1962. Then he dated Laetrile's birth to 1951 and said he had tested it on patients but kept no records [Markle, G.E., and Petersen, J.C.: *Politics, Science and Cancer: the Laetrile Phenomenon* (1980), Westview Press, Boulder, Colorado]. Noting that this version was made public much earlier than the others, Dr. Young suspects that Laetrile's origin was backdated to try to evade new drug provisions of 1938 and 1962 FDA laws. In 1977, after thorough investigation, FDA Commissioner Donald Kennedy concluded, "While it appears that Dr. Krebs, Sr., was utilizing some substance, which apparently had the trademark Sarcasinase, before 1938, there is no evidence that the substance is identical . . . to the present-day Laetrile" [Laetrile: *The Commissioner's Decision*, H.E.W. Publication No. 77-3056].

Proponents' rationales

In 1902, a Scottish embryologist named John Beard theorized that cancer cells and cells produced during pregnancy called trophoblasts are one and the same. According to Beard, trophoblasts invade the uterine wall to form the placenta and umbilical cord. The pancreas then produces chymotrypsin, which destroys the trophoblasts. Beard postulated that if the pancreas fails to produce enough chymotrypsin, trophoblasts circulate through the body of both mother and infant, making them vulnerable throughout life to cancer.

In 1945, Krebs, Jr., founded the John Beard Memorial Foundation to "develop and apply" Beard's theories. In 1950, the Krebs published a version of Beard's thesis and stated that amygdalin kills trophoblast cells where trypsin has failed. They claimed that cancer tissues are rich in an enzyme that causes amygdalin to release cyanide which destroys the cancer cells. According to this theory, noncancerous tissues are protected from this fate by another enzyme which renders the cyanide harmless. After enforcement agencies began trying to ban Laetrile as a drug, the Krebs claimed that amygdalin is a vitamin ("B₁₇") and that cancer is caused by a deficiency of this vitamin. None of these theories is valid.

Claims for Laetrile effectiveness have also shifted. At first it was claimed to cure cancer. Later it was claimed to "control" cancer. When the "vitamin" theory was developed, it was touted as a cancer preventive. It has also been claimed to be effective in relieving pain associated with cancer and in facilitating treatment with chemotherapy.

Scientific review

One of the first practitioners to use Laetrile was Arthur T. Harris, M.D., who had trained in Scotland and

reportedly studied embryology under John Beard. Harris, who had been doing family practice in Southern California, renamed his office the Harris Cancer Clinic. Within a year he submitted a report to *Coronet Magazine* which claimed that he was "working on something out here that is going to be the answer to cancer if there will ever be one," but the magazine did not report what he was doing.

By that time, the California Medical Association was receiving inquiries about Laetrile. When members of its Cancer Commission approached Krebs, Sr., he claimed that "limited" trials of toxicity in animals had been performed with satisfactory results, but that the records had been destroyed. No human trials involving Laetrile had been undertaken, but the Commission was offered case reports of patients in which spectacular results had supposedly been observed. However, the details claimed by the Krebs team could not be confirmed by other sources. The Commission was able to obtain a small supply of Laetrile for animal tests at three medical centers — all of which produced negative results.

At one point, the Krebs' agreed to supply Laetrile for a controlled clinical investigation at Los Angeles County Hospital. But later they said they would do so only if a Laetrile advocate were put in charge — which was not acceptable to hospital authorities. The Commission then evaluated the records of 44 patients treated according to the Krebs' recommendations. Two years had elapsed since the first of these patients had been treated with Laetrile. Nineteen had already died and there was no evidence that Laetrile had helped any of the others.

Marketing increased

In 1956 Ernst T. Krebs, Jr., was introduced to Andrew R.L. McNaughton, who has been dubbed Laetrile's "godfather" by its supporters. McNaughton is the son of the late General A.G.L. McNaughton, commander of the Canadian Armed Forces during World War II. General McNaughton also served as president of the United Nations Security Council and the National Research Council of Canada.

Andrew McNaughton was educated at a Jesuit College and subsequently received training in electrical engineering, geology, mining, and business administra-

tion. During the war he was the chief test pilot for the Royal Canadian Air Force. Subsequently, he made a fortune by converting cheaply obtained war surplus items into useful products for other nations. He provided arms for the emerging nation of Israel and was also a double agent for Fidel Castro, ostensibly working for the Batista government in Cuba but often arranging for purchases to be hijacked by Castro supporters. For his efforts, Castro made him an "honorary citizen of Cuba."

McNaughton met Krebs shortly after he had incorporated the McNaughton Foundation, which was seeking projects "on the outer limits of scientific knowledge." Intrigued by Krebs' account of the "Laetrile Wars," McNaughton began promoting and distributing Laetrile. In 1961, to facilitate distribution in Canada, he founded International Biozymes Ltd. (later renamed Bioenzymes International Ltd), located in the same building as the McNaughton Foundation. Eventually, he built factories in seven countries.

It has been alleged that a major Biozymes stockholder (under someone else's name) was a New Jersey mobster who was convicted of conspiring to bribe public officials in connection with gambling. In 1977, McNaughton told *American Medical News* that he had treated the man's sister with Laetrile and that the man was a "wonderful guy" who had given \$130,000 to the McNaughton Foundation.

During the 1970s, McNaughton experienced considerable difficulty in his financial dealings. In 1972 he was permanently enjoined from selling Biozymes stock in the United States as a result of a suit brought by the Securities and Exchange Commission. In 1973 he was charged by Italian police with having taken part in a \$17 million swindle involving purchasers of Biozymes stock who were under the impression that they were investing in an Italian Laetrile factory. In 1974, in a Canadian courtroom, McNaughton was found guilty of stock fraud involving a company named Pan American Mines. It appears that \$5 million had mysteriously disappeared. McNaughton was fined \$10,000 and sentenced to serve one day in jail. A warrant for his arrest was issued after he refused to pay the fine and left Canada without serving his sentence.

Publicity mounts

Besides overseeing production, McNaughton also sought publicity for Laetrile. He was able to convince a

Jersey City surgeon, John A. Morrone, to attend a presentation that Krebs, Jr., gave in Montreal. After having lunch with Krebs, Jr., Morrone reportedly went back to New Jersey a "convinced laetrilist," and began using Laetrile on his patients.

At McNaughton's request, Morrone wrote a report on ten patients he had treated with Laetrile, which was published in 1962 in *Experimental Medicine and Surgery*, a journal no longer being published. McNaughton also arranged for a freelance writer named Glenn Kittler to write two magazine articles and a book on Laetrile. Kittler, who had studied to become a priest before becoming a journalist, had been an associate editor of *Coronet* magazine in 1952. The articles were published in March 1963 in *American Weekly*, a Sunday supplement to the Hearst newspapers. Immediately afterward, Kittler's book, *Laetrile: Control for Cancer*, was rushed into print with an initial press run of 500,000 copies. The book carried a foreword by McNaughton — with his Foundation's Montreal address. According to Kittler, the book's publisher was so confident that publicity from the articles would boost sales that he didn't send prepublication advertising to book distributors. When sales lagged, Kittler claimed that pressures from the AMA and FDA were partially responsible.

Support groups

The efforts of McNaughton and Kittler were not fruitless, however. Cecile Hoffman was a San Diego schoolteacher who had undergone a radical mastectomy in 1959. After reading Kittler's book, she visited the McNaughton Foundation in Montreal and received Laetrile. Although she was unable to find an American physician who would administer her intravenous Laetrile injections, she did find Ernesto Contreras, M.D., just across the Mexican border in Tijuana. This was perhaps the most fortunate thing that ever happened to Dr. Contreras.

Contreras was a former Mexican Army pathologist who was in private practice in Tijuana. After he administered the Laetrile, Mrs. Hoffman became convinced that it controlled her cancer and saved her life. She remained a fervent Laetrile supporter until she died of metastatic breast cancer in 1969.

Hoffman's convictions led her to form the International Association of Cancer Victims and Friends (IACVF) in 1963. (The word Victims was later changed to

Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yativ, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

Victors.) IACVF's purpose was "to educate the general public to the options available to cancer patients, especially terminal cancer patients." Joining forces with health food industry promoters, the association began holding annual conventions in Los Angeles that drew thousands of people. These meetings provided a forum for virtually anyone who either promised or sold a cancer remedy that was not recognized as effective by the scientific community. The Krebs spoke often at these conferences. IACVF also founded the Cancer Book House, which sold literature promoting unorthodox cancer treatments. In addition, it arranged for room, board and transportation to Contreras' clinic from a California motel near the border.

Contreras, meanwhile, expanded his clinic and added translators to his staff to accommodate the influx of American patients. Business was so brisk that in 1970 he constructed a new clinic — the Del Mar Medical Center and Hospital — which he promoted as "an oasis of hope."

In 1973, several leaders left IACVF to found the Cancer Control Society, whose activities are similar to those of IACVF. Another group promoting dubious cancer therapies is the National Health Federation (NHF), which supports a broad spectrum of questionable health methods. This group was founded in 1955 by Fred J. Hart, president of the Electronic Medical Foundation, a company that marketed quack devices. NHF sponsors meetings, generates massive letter-writing campaigns, and helps defend questionable methods in court cases. Four people who have served on its board of governors and the husband of its current president have been convicted of laetrile-related crimes.

Legal problems

The first seizure of Laetrile in the United States occurred in 1960 at the former Hoxsey Cancer Clinic, which was then being operated by osteopathic physician Harry Taylor, a former Hoxsey employee. Two months before the seizure, a federal court judge had ordered Taylor to stop distributing the various Hoxsey concoctions. The seizure was not contested by Taylor.

In 1961 Krebs, Jr., and the John Beard Memorial Foundation were indicted for interstate shipment of an unapproved drug — not Laetrile but pangamic acid. After pleading guilty, Krebs was fined \$3,750 and sentenced to prison. However, the sentence was suspended when Krebs and the Foundation agreed to terms of a 3-year probation in which neither would manufacture or distribute Laetrile unless the FDA approved its use for testing as a new drug.

In 1959 the California legislature had passed a law similar to the Federal Food, Drug, and Cosmetic Act, banning commerce of hazardous foods, drugs and cosmetics within California. The California Department of Public Health then formed a Cancer Advisory Council

which studied Laetrile and other dubious cancer treatments. The ten physicians and five research scientists carried out their investigation from 1960 to 1962 and issued their report in May 1963.

During 1962 and 1963, the Cancer Advisory Council examined more than 100 case histories submitted by various proponents and concluded that none provided any evidence that Laetrile was effective against cancer. The Council also reviewed the California Medical Association's 1953 report on Laetrile, as well as a "new synthetic" Laetrile purportedly developed by Krebs, Jr. In addition, medical records of 144 patients treated with Laetrile were reviewed from physicians in both the United States and Canada.

After the Council determined that the drug was "of no value in the diagnosis, treatment, alleviation or cure of cancer," it recommended that regulations be issued to ban the use of Laetrile and "substantially similar" agents for the treatment of cancer. Despite considerable opposition from Laetrile promoters, the regulation was issued under provisions of California's Cancer Law and became effective November 1, 1963.

The Krebs family returned to court several more times. In 1965, Krebs, Sr., was charged with disobeying a regulatory order forbidding interstate shipment of Laetrile and pleaded "no contest." The following year he pleaded guilty to a contempt charge for shipping Laetrile in violation of injunctions and failing to register as a drug manufacturer. He received a suspended 1-year sentence. In 1974 Ernst, Jr., and his brother Byron pleaded guilty to violating the California state health and safety laws. Each was fined \$500, given a suspended sentence of six months, and placed on probation. Byron had his osteopathic license revoked the same year for "mental incompetence", and died shortly thereafter. In 1977, Ernst, Jr., was found guilty of violating his probation by continuing to advocate Laetrile and was sentenced to 6 months in the county jail. He was jailed during 1983 after the appeals process ended.

Meanwhile, Howard H. Beard (not a relative of John Beard), who had worked with Krebs and Dr. Harris, suffered an unfavorable ruling from the California Cancer Advisory Council. For many years he had promoted various urine tests purported to measure the level of human chorionic gonadotropin (HCG). Both Krebs and Beard had claimed that all cases of cancer could be diagnosed on the basis of an elevated HCG test. In 1963 Krebs, Jr., stated that the "scientific implementation" of Laetrile relied upon Beard's test.

Beard had further claimed that an elevated HCG level was sufficient indication for treatment with Laetrile, even in the absence of clinical findings or a positive biopsy for cancer. A true believer in his test, he reportedly began taking Laetrile himself after noting that his urine test was not quite normal. Beard maintained a laboratory offering mail-order service, including measurement of the urinary HCG levels.

Beard developed at least three alleged cancer tests, the most notable of which was his Anthrone Color Test. He claimed nearly 100% accuracy if patients who were pregnant, had liver disease or diabetes, or were taking sex hormones were excluded. He also claimed that the test was so sensitive that it was able to detect the development of cancer within 2-3 weeks after malignant transformation took place.

During the early 1960s the California Cancer Advisory Council had provided Beard with 24-hour urine specimens from 198 patients, as well as two "urine" specimens which consisted of lactose dissolved in water. Simultaneous tests were performed at the California State Public Health Laboratories. Beard was unable to identify which urine came from patients with cancer and which came from patients with other conditions. The investigation also demonstrated that Beard's test results had nothing to do with cancer but depended mainly on the amount of lactose in the urine. Consequently, the test was banned in California as of August 1965. In 1967 Beard was indicted by a federal grand jury in Texas on nine counts of mail fraud related to the marketing of his test. After pleading no contest, he was given a 6-month suspended jail sentence and 1-year probation.

Further efforts toward respectability

The McNaughton Foundation persisted in trying to make Laetrile respectable. They commissioned the SCIND Laboratories in San Francisco to conduct animal studies involving a transplanted tumor system in rats. Although the Foundation had reported that weekly doses of 1 or 2 grams of Laetrile had produced "a brilliant response" in cancer patients and the rats received human equivalents of 30-40 grams, the results were negative.

Undaunted by the negative report, the McNaughton Foundation filed an Investigational New Drug application with the FDA. The FDA responded with a routine form letter giving permission — subject to further review — for investigational clinical trials involving Laetrile. However, eight days later, when the review was completed, the agency requested additional information from the McNaughton Foundation to correct "serious deficiencies" in the application. When this was not produced, the authorization for clinical trials was withdrawn.

While the McNaughton Foundation was attempting to have Laetrile recognized as a drug, Krebs, Jr., began claiming that it was a vitamin, which he called B₁₇. (It only took him about 20 years to come to this conclusion.) Krebs apparently hoped that as a "vitamin" Laetrile would not be subject to the "safety and efficacy" requirements for new drugs. He may have also hoped to capitalize on the popularity of vitamins.

By 1974 Dr. Contreras stated that he was seeing 100-120 new patients per month, with many more pa-

tients returning to obtain additional Laetrile. Patients typically were charged \$150 for a month's supply. Contreras acknowledged that few of his cancer patients were "controlled" with Laetrile. While admitting that 40% of the patients displayed no response, he claimed that 30% showed "most definite responses" to the drug. However, these statistics may not be reliable. In 1979 he claimed to have treated 26,000 cancer cases in 16 years. Yet when asked by the FDA to provide his most dramatic examples of success, Contreras submitted only 12 case histories. Six of the patients had died of cancer, one had used conventional cancer therapy, one had died of another disease after the cancer had been removed surgically, one still had cancer, and the other three could not be located.

The first "metabolic" doctor

John Richardson was a general practitioner who began practice in the San Francisco Bay area in 1954. In 1971, after discussions with Krebs, Jr., he decided to become a cancer specialist. He had not encountered overwhelming success as a general practitioner. His 1972 income tax return revealed that he had grossed \$88,000 in his medical practice, leaving a net of only \$10,400 taxable income.

Richardson's practice boomed as a result of his newly found status as a cancer "expert." He states that "Our office soon was filled with faces we had never seen before — hopeful faces of men and women who had been abandoned by orthodox medicine as hopeless or "terminal" cases." In 1974 he reported that his medical practice had grossed \$783,000, with a net income of \$172,981. By charging patients \$2,000 for a course of Laetrile, Richardson managed to increase his net income 17-fold in just two years. According to his income tax returns, Richardson grossed \$2.8 million dollars from his Laetrile practice between January 1973 and March 1976. The actual amount of money he received may have even been higher. In *Laetrile Case Histories*, he claimed to have treated 4,000 patients, with an average charge of \$2,500 per patient. Culbert states that by 1976 Richardson had treated 6,000 patients. If these figures are correct, Richardson would have grossed between \$10 and \$15 million dollars during this time.

Richardson's practice changed significantly after he began treating cancer patients with Laetrile. He also began treating what he termed "pre-clinical syndrome" patients with Laetrile. These were patients with no identifiable tumor or lesion who complained of feelings of "impending doom, malaise, unexplained or vague pains, headaches, bowel changes, loss of appetite, loss of energy, and depression." According to Richardson, cancer patients reported a reduction in pain, an improved appetite, return of strength, and an improved mental outlook. In addition, high blood pressure returned to normal.

In spite of these "dramatic improvements," Richardson admitted that most of his cancer patients died. In an attempt to overcome this, he increased the Laetrile dosage to nine grams, six days a week, and placed patients on a vegetarian diet and "massive" doses of regular vitamins. Richardson coined the phrase "metabolic therapy" to refer to this combination of diet manipulation, vitamins and Laetrile.

In June 1972, Richardson's office was raided and he was arrested for violating California's Cancer Law. He was convicted of this charge, but the conviction was overturned on a technicality and a new trial ordered. Two more trials followed which resulted in hung juries. Hearings before the California Board of Medical Quality Assurance in 1976 resulted in the revocation of his California medical license. He then worked at a Mexican cancer clinic. During the 1980s he practiced under a homeopathic license in Nevada until he had open heart surgery and entered an irreversible coma.

Political explosion

Dr. Richardson's arrest triggered the formation of the Committee for Freedom of Choice in Cancer Therapy (now called the Committee for Freedom of Choice in Medicine). The group's founder and President was Robert Bradford, a former laboratory technician at Stanford University. Michael Culbert, who at the time of Richardson's arrest was an editor at the Berkeley Daily Gazette, became a major spokesman for the Committee, editing their newsletter, *The Choice*, and writing two books promoting Laetrile: *Vitamin B-17: Forbidden Weapon Against Cancer* (1974) and *Freedom From Cancer* (1976).

Culbert was assisted in editing *The Choice* by Maureen Salaman, wife of Committee vice-chairman Frank Salaman. The Committee's legislative advisor was Georgia Congressman Larry McDonald, a urologist who used Laetrile. CFCCT's activities were closely allied with the John Birch Society, to which Richardson, Bradford, Culbert, the Salamans and McDonald all belonged. Soon after its formation, CFCCT established local chapters throughout the United States and used bookshops associated with the John Birch Society to hold meetings and distribute literature.

In May 1976 Richardson was indicted, along with his office manager, Ralph Bowman, and fellow CFCCT members Robert Bradford and Frank Salaman, for conspiring to smuggle Laetrile. A year later all were convicted of the charges. Bradford was fined \$40,000, Richardson \$20,000, and Salaman and Bowman \$10,000 each. During the trial it was disclosed that Bradford had paid \$1.2 million dollars for 700 shipments of Laetrile and that Richardson had banked more than \$2.5 million during a 27-month period.

The NCI scientist

Although facing problems on some fronts, the

Laetrile movement gained adherents. Dr. Dean Burk was a biochemist with a Ph.D. from Cornell Medical College who had joined the National Cancer Institute (NCI) in 1939 as a research fellow. After ten years he was appointed as Head of the Cytochemistry Section of the National Cancer Institute, which had a staff of four persons at the time of his retirement 25 years later.

At McNaughton's request, Burk did an experiment in which Laetrile was used to kill a tissue culture of cancer cells. He reported to McNaughton that he could "see the cancer cells dying off like flies." Eventually Burk concluded that Laetrile was the most effective treatment available for cancer, that it relieved the pain of terminal cancer victims, and that it might be useful in preventing cancer. He also claimed in Congressional testimony that Laetrile was less toxic than sugar. Burk became fast friends with Krebs, Jr., and was given a permanent room in Krebs' San Francisco mansion. He was soon on the "Laetrile circuit" and was given the Cancer Control Society's "Humanitarian Award" in 1973.

Burk also became active in opposing fluoridation and spoke against it in many cities throughout the United States and Europe. An inveterate tobacco user, he claimed in Congressional testimony that he had developed a safer cigarette.

The professor

In 1977, Harold W. Manner, Ph.D., chairman of the biology department at Loyola University in Chicago, achieved considerable notoriety by claiming to have cured mammary cancers in mice with injections of Laetrile and proteolytic enzymes and massive oral doses of vitamin A. What he actually did was digest the tumors by injecting digestive enzymes in amounts equivalent to injecting a woman with a pint of salt water containing about 1½ ounces of meat tenderizer every other day for six weeks. Not surprisingly, the mice developed abscesses where the enzymes were injected, the tumors were liquefied, and the injected tissue fell off. Since no microscopic examinations were conducted and the animals were observed for only a few weeks following treatment, no legitimate assessment of this type of therapy could have been made. But Manner announced at a press conference sponsored by the National Health Federation that a combination of Laetrile, vitamins and enzymes was effective against cancer. He reported his experiments in a chiropractic journal and wrote a book called *The Death of Cancer*.

Manner also founded the Metabolic Research Foundation whose stated purpose was research into "metabolic diseases," which — according to him — included arthritis, multiple sclerosis, and cancer. Sponsored by the Nutri-Dyn company, he held seminars throughout the country for chiropractors and unorthodox physicians. Nutri-Dyn manufactured processed animal glands ("glandulars"), which Manner said would

help the corresponding body parts of cancer patients. In 1982, a reporter from WBBM-TV Chicago became Metabolic Physician #219 by attending a seminar in Los Angeles and donating \$200 to the Metabolic Research Foundation. To indicate his "professional" background, the reporter used the initials "D.N.," which, he later explained, stood for "Doctor of Nothing." Manner promised to refer ten patients a year to him.

According to Manner, the Loyola University administration became upset with his activities and asked him to either give them up or resign from his position at the school — so he resigned. Today he performs public relations for the Clinica Manner in Tijuana, Mexico, and continues to solicit health practitioners to become "Metabolic Research Physicians."

The Rutherford case

Glen Rutherford was a 55-year-old Kansas seed salesman who was found to have a grape-sized polyp of the colon in 1971. When a biopsy revealed that it was cancerous, he was advised to have it removed. Fearful of surgery, he consulted Dr. Contreras, who treated him with Laetrile, vitamins and enzymes, and cauterized (burned off) the polyp. Although cauterization usually cures this type of cancer when it is localized in a polyp, Rutherford emerged from this experience claiming that Laetrile had cured him and was necessary to keep him alive. *People Magazine* reported that he also began taking 111 pills (mostly vitamins) costing \$14 per day. In 1975 he became lead plaintiff in a class action suit to force the FDA to allow "terminal" cancer patients to obtain Laetrile for their own use.

The case was heard before Judge Luther Bohanon in the Western Oklahoma United States District Court. Bohanon was extremely sympathetic to Rutherford's wishes. In 1977 Bohanon issued a court order permitting individuals to import Laetrile for personal use if they obtained a doctor's affidavit stating they were "terminally ill." Two years later, the U.S. Supreme Court rejected the argument that drugs offered to "terminal" patients should be exempted from FDA regulation. However, further efforts by Rutherford and his supporters plus defiant rulings by Bohanon enabled the affidavit system to remain in effect until 1987, when it was finally dissolved.

Legislative action

During the mid-1970s, Laetrile promoters portrayed themselves as "little guys" struggling against "big government" and began trying to legalize the sale of Laetrile. Eventually, 27 states passed laws permitting the sale and use of Laetrile within their borders. Federal law still forbade interstate shipment of Laetrile, and since it was impractical to manufacture it for use in just one state, these state laws had little or no practical effect. Proponents hoped, however, that if enough states legalized its use within the states, Congress would change

the federal law as well. Although bills were introduced to exempt Laetrile from FDA jurisdiction, they were unsuccessful and petered out with the death of Congressman McDonald in 1983.

In 1977, a U.S. Senate subcommittee chaired by Senator Edward Kennedy (D-MA) held hearings on Laetrile that developed interesting testimony. Dr. Richardson claimed that the FDA, AMA, National Cancer Institute, American Cancer Society, Rockefeller family and major oil and drug companies had all conspired against Laetrile. Robert Bradford said that he would welcome a test of Laetrile but that "orthodox medicine was not qualified" to do one. However, he, Krebs, Jr., and Richardson were unable to agree on the formula for Laetrile. Senator Kennedy concluded that the Laetrile leaders were "slick salesmen who would offer a false sense of hope" to cancer patients. *The New York Times* commented that the Laetrile promoters were regarded by the Senators "with a blend of amusement and contempt."

Victims in the news

As Laetrile became newsworthy, several cancer victims treated with it drew widespread media scrutiny. One was Chad Green, who developed acute lymphocytic leukemia at age 2½. Although he was rapidly brought into remission with chemotherapy, his parents started him on "metabolic therapy" administered by a Manner Metabolic Physician. When Chad developed signs of cyanide toxicity, Massachusetts authorities had him declared a ward of the court for treatment purposes only. His parents then brought suit to reinstitute "metabolic therapy." When the court ruled against them, they fled with Chad to Mexico, where he was treated by Dr. Contreras. Several months later Chad died in a manner suggestive of cyanide poisoning. Dr. Contreras stated that the boy had died of leukemia, but was a good example of the effectiveness of Laetrile because he had died a pleasant death! Chad's parents stated that he had become very depressed because he missed his grandparents, his friends and his dog.

Joseph Hofbauer was a nine-year-old with Hodgkin's disease. Unlike Chad Green's parents, Joseph's parents never allowed him to receive appropriate treatment but insisted that he receive Laetrile and "metabolic therapy." When New York State authorities attempted to place him in protective custody, his parents filed suit and convinced family court judge Loren Brown to rule against recognized treatment of Hodgkin's disease. Brown stated that "This court also finds that metabolic therapy has a place in our society, and hopefully, its proponents are on the first rung of a ladder that will rid us of all forms of cancer." Joseph died of his disease two years later. Acute lymphocytic leukemia and Hodgkin's disease both have a 95% 5-year survival rate with appropriate chemotherapy.

During 1980, movie star Steve McQueen attracted considerable attention when he was treated with Laetrile at another Mexican clinic under the supervision of William D. Kelley, a dentist who had been delicensed by the State of Texas after several brushes with state and federal law enforcement authorities. Although McQueen gave a glowing report when he began his treatment, he died shortly afterward.

NCI studies

In response to political pressure, the National Cancer Institute undertook two studies involving Laetrile. The first was a retrospective analysis of patients treated with Laetrile. Letters were written to 385,000 physicians in the United States as well as 70,000 other health professionals requesting case reports of cancer patients who were thought to have benefited from using Laetrile. In addition, the various pro-Laetrile groups were asked to provide information concerning any such patients.

Although it had been estimated that at least 70,000 Americans had used Laetrile — only 93 cases were submitted for evaluation. Twenty-six of these reports lacked adequate documentation to permit evaluation. The remaining 68 cases were “blinded” and submitted to an expert panel for review, along with data from 68 similar patients who had received chemotherapy. That way the panel did not know what treatment patients had received. The panel felt that two of the Laetrile-treated cases demonstrated complete remission of disease, four displayed partial remission, and the remaining 62 cases had exhibited no measurable response. No attempt was made to verify that any of the patients who might have benefited from Laetrile actually existed. The reviewers concluded that “the results allow no definite conclusions supporting the anti-cancer activity of Laetrile.”

Although the NCI mailing had not been designed to uncover negative case reports, 220 physicians submitted data on more than 1,000 patients who had received Laetrile without any beneficial response.

In July 1980 the National Cancer Institute undertook clinical trials of 178 cancer patients who received Laetrile, vitamins and enzymes at the Mayo Clinic and three other prominent cancer centers. The study included patients for whom no other treatment had been effective or for whom no proven treatment was known. All patients had tumor masses that could easily be measured, but most of the patients were in good physical condition. Since Laetrile proponents were unable to agree on the formula or testing protocol for Laetrile, NCI decided to use a preparation that corresponded to the substance distributed by the major Mexican supplier, American Biologics. The preparation was supplied by the NCI Pharmaceutical Resources Branch and verified by a variety of tests. The dosage of Laetrile was based on the published recommendations of Krebs, Jr., and the

Bradford Foundation.

The results of the trial were clear-cut. Not one patient was cured or even stabilized. The median survival rate was 4.8 months from the start of therapy, and in those still alive after seven months, tumor size had increased. This was the expected result for patients receiving no treatment at all. In addition, several patients experienced symptoms of cyanide toxicity or had blood levels of cyanide approaching the lethal range [*New England Journal of Medicine* 306:201-206, 1982]. An accompanying editorial concluded: “Laetrile has had its day in court. The evidence, beyond reasonable doubt, is that it doesn't benefit patients with advanced cancer, and there is no reason to believe that it would be any more effective in the earlier stages of the disease . . . The time has come to close the books.”

Bradford and American Biologics responded to the study with three different lawsuits against the National Cancer Institute, alleging that as a result of the study, they had sustained serious financial damage from a drastic drop in demand for Laetrile. All three suits were thrown out of court.

Epilogue

As long as there remain crippling and fatal diseases, there will undoubtedly be individuals eager to offer “alternatives” to scientific treatment and large numbers of desperate individuals willing to purchase them. The Laetrile phenomenon started with a pharmacist-physician who developed one concoction after another for the treatment of serious diseases, especially cancer. It continued with his son, a self-imagined scientist, who spent many years in college but failed to earn any graduate degree. A man who earned his fortune from gun-running and a catholic newspaper columnist promoted it as a persecuted drug that cured cancer. A cadre of John Birch Society members saw the repression of Laetrile as a sinister plot against their basic freedoms. After it was dubbed “vitamin B-17,” an army of health food devotees promoted Laetrile, along with vitamins and diet, as nature's answer to cancer.

After peaking in the late 1970s, the “Laetrile Movement” ran out of steam in the wake of the Supreme Court decision, the NCI study, the death of Steve McQueen, and other unfavorable publicity. But as the Laetrile fantasy faded, its prime movers added many other “miracle cures” to their arsenal and added AIDS, arthritis, cardiovascular disease and multiple sclerosis to the list of diseases they claim to treat. Although they appear to speak with sincerity, they still fail to sponsor the type of research which could persuade the scientific world that anything they offer is effective.

Dr. Wilson, who practices surgery in Dallas, Oregon, is a board member of the National Council Against Health Fraud.

BRIEFS

Diet patches banned. Meditrend International of San Diego is a multilevel company that has been marketing adhesive patches it claims can control appetite. Users have been instructed to place 1 or 2 drops of a "homeopathic appetite control solution" on a patch and wear it all day affixed to an "acupuncture point" on the wrist — so it can "bioelectrically" depress the appetite center of the brain. A 1,000-calorie low-fat diet is advised. Although company literature notes that "effectiveness is directly related to the degree in which you reduce your usual daily food intake," it has claimed that one user lost 63 pounds in 37 days. In February 1988, the company asked its distributors to destroy any product literature in their possession and said new literature was being developed "that is being approved by the legal department of the FDA." In May, the FDA issued a Talk Paper stating that (contrary to suggestions that diet patches meet FDA standards) no nonprescription skin patch has been approved by the agency for any use and that the FDA is reviewing the status of these products. A few days later, the Pennsylvania Department of Health said there is no evidence that diet patches work and banned the sale, within Pennsylvania, of patches marketed by Meditrend International and the Dermaline Corporation of Las Vegas.

Fit for Life update. Harvey and Marilyn Diamond, authors of *Fit for Life* and *Healthy Living*, are now publishing a bimonthly 4-page newsletter called *Keeping In Touch With FIT FOR LIFE*. The first six issues have attacked nutritionist licensing, food irradiation and immunization of children, and have advised women with suspected breast cancer to seek nutritional treatment rather than surgery. (The Diamonds regard most breast cancers as lymph glands filled with "toxic waste" that can be "cleansed" by eating fruits and vegetables.) The April/May 1988 issue states: "We have always had the dream that Fit for Life could be much, much more than just a book. We have shared visions of food emporiums where people would be able to sit down and enjoy wonderful Fit for Life meals or sip Date Shakes while they shopped. We have visualized Fit for Life resorts and healing centers and our own line of products in the supermarkets. We have dreamed about nationwide seminar tours which would allow us to meet our friends face-to-face, and our own radio show, allowing you to call in and talk to us. Over the last six months all of this has been formulated into the Fit for Life Enterprises business plan and we are now a health lifestyle corporation!" The address for subscriptions (\$15) is 2210 Wilshire Blvd., Suite 118, Santa Monica, CA 90403.

"Allergy" hoax. Concerned about unfair attacks on food additives, Caroline Richmond, a medical historian at London University, wrote a spoof manifesto for the Dye Research Allergies Bureau (DRAB), a spin-off of a larger group called the Food Additives Research Team (FART). According to the manifesto, the public was being put at risk by unscrupulous manufacturers who made clothes stuffed with unnecessary dyes solely to boost their profits. After sending a copy to the leading organization campaigning against additives on behalf of supposed allergy sufferers, Ms. Richmond was surprised that the group's newsletter reported on DRAB and people wrote to her that dye fabrics had caused them all sorts of problems. After the hoax was revealed, the allergy group maintained that dyes did cause allergies and that Ms. Richmond had unwittingly performed a public service by highlighting this problem.

Concern about urethane. According to FDA officials, urethane (ethyl carbamate) is carcinogenic for several species of animals and must therefore be considered a possible carcinogen for humans [FDA Consumer 22(3):16-17, 1988]. Since January 1986, the FDA and Bureau of Alcohol, Tobacco, and Firearms have sampled about 1,200 alcoholic products for urethane levels. They found some bourbons contained up to several hundred parts per billion (ppb), table wines generally varied from zero to 25 ppb, vodka contained little or none, and plum and cherry brandies varied from 200 to 12,000 ppb. Urethane forms during the fermentation of alcoholic beverages, especially when products are heated, and is not completely avoidable. In 1985, Canada set regulatory limits for table wines (30 ppb), ports and sherries (100 ppb), distilled spirits (150 ppb), and fruit brandies, cordials and liqueurs (400 ppb). During the past few months, the FDA has accepted voluntary plans to reduce urethane levels in American-made wines and whiskeys. But according to Richard Ronk, acting director of the FDA Center for Food Safety and Applied Nutrition, "the extent of the risk to the consumer is not clear. Until we have more information on the toxicity of the chemical and how much of it can be avoided in the manufacture of alcoholic beverages, it would be inappropriate to establish regulatory limits or to recall alcoholic products." At the FDA's request, the National Toxicological Program, funded by several federal agencies, has agreed to give urethane its highest priority for study in 1988. This research, to be completed in the next few years, is expected to yield the toxicological information needed to assess the risk posed by urethane in alcoholic beverages.

Chik-Chek flunks. Chik-Chek, manufactured by Diversified Diagnostics of Moraga, California, entered the mail-order marketplace in the spring of 1987 in the wake of national publicity about salmonella. It was claimed to be able to detect salmonella and other dangerous bacteria in raw meat, poultry, milk and eggs within 15 minutes. However, the U.S. Agriculture Department's Food Safety and Inspection Service tested 60 kits and concluded that Chik-Chek was neither reliable nor useful. The test results included both false negatives and false positives and even indicated that bacteria were present in sterile lab solutions. The test kit directed users to dip a cotton swab in raw chicken juices and then in two solutions provided with the kit. If results were positive, users were to thoroughly wash their hands and any utensils that had been in contact with the poultry or juice. But these precautions should be routine after handling any raw meat or poultry. Marketing of the test kits appears to have stopped [*Food News for Consumers* 5(1):13-14, 1988].

Eating habits deteriorating? A study by Pillsbury Corporation has concluded that 26% of Americans are now "Chase and Grabbits" who are most likely to subsist on fast food, frozen dinners, and carry-out pizza.

Alcohol warning labels? S. 2047 and H.R. 4441 have been introduced in the U.S. Congress to require alcoholic beverage labels to carry warnings similar to those on tobacco products. The bills are supported by a coalition of more than 50 national consumer, health and alcoholism organizations. The warnings would state: 1) The Surgeon General has determined that the consumption of this product, which contains alcohol, during pregnancy, can cause mental retardation and other birth defects; 2) Drinking this product, which contains alcohol, impairs your ability to drive a car or operate machinery; 3) This product contains alcohol and is particularly hazardous in combination with some drugs; 4) The consumption of this product, which contains alcohol, can increase the risk of developing hypertension, liver disease and cancer; and 5) Alcohol is a drug and may be addictive. Meanwhile, two suits have accused beverage manufacturers of negligence. In one case, a plaintiff has accused four beverage manufacturers of negligently failing to warn on their labels that alcohol intake during pregnancy can damage the fetus. In the other case, a man with cirrhosis of the liver contends that two manufacturers were negligent because they failed to: 1) warn that their beverages can damage health; 2) indicate how much alcohol could be safely consumed over long periods of time; and 3) test their products to determine what amounts could constitute a long-range hazard.

Food safety hotline. During June, July and August, residents of Florida, Illinois and Massachusetts will be able to dial 1-800-426-3758 to ask questions on any aspects of food safety. This is a pilot project of U.S. Departments of Agriculture and Health and Human Services, which hope to reduce the incidence of food-borne illnesses. The project's results will be used to determine whether a nationwide hotline will be set up.

"Organic" carrot scandal. The *San Francisco Chronicle* has reported that carrots packaged by Pacific Organics were removed from the shelves of area natural food stores amid reports they were ordinary carrots repackaged to look "organic." According to the article, the switch was documented by an employee of a competing firm who posed as a writer for an organics newsletter and was given a tour of Pacific's plant. She returned with a photograph of a dumpster full of emptied carrot bags from another supplier who normally handles non-organic produce and other photos showing workers stuffing carrots into clear cellophane. (Suspicion had arisen because Pacific Organics was able to provide large quantities of supposedly organic carrots after the harvest season had ended and other supplies had dried up.) California is one of a few states that legally defines "organic" as grown without pesticides or artificial fertilizers. Although violators of the law can be criminally prosecuted, the chief of the California health department's food and drug branch does not remember the state investigating or prosecuting any such case.

Dietary fat/breast cancer study scrapped. The Women's Health Trial, designed to see whether reducing dietary fat will prevent breast cancer, has been stopped. According to a report in *Medical World News*, the National Cancer Institute's board of counselors concluded there is little evidence supporting the hypothesis that dietary fat is a cause of breast cancer and judged the trial design inadequate to test the theory.

Defamation suit settled. West Publishing Company has agreed to settle a lawsuit under undisclosed terms and has issued a retraction and apology to Elie A. Shneour, Ph.D., Director of Biosystems Research Institute, San Diego, California. The retraction states that Dr. Shneour's book *The Malnourished Mind* had been inadvertently placed in a list of "not recommended" books in the third (1984) edition of *Understanding Nutrition*, by Eleanor Whitney, Ph.D., R.D. According to Dr. Shneour, the suit was filed because West had refused to correct the error when he pointed it out to them. The current (1987) edition of the *Understanding Nutrition* does not contain a nonrecommended book list.

Psychic health foods? Uri Geller has announced plans to market "health cosmetics" under the name Uri with a big ad in the *National Enquirer*. In the April *Whole Life Times*, he said that no claims would be made for these products, but they would have something "quite secret." Geller also plans to market health products, health foods, and perfumes with crystals to "energize" them. During the interview, Geller claimed he has turned lead into gold (a "very, very small" amount), destroyed cancer cells in laboratory flasks, and exerted "a tiny molecular influence" at the 1987 Geneva Peace talks. Geller became famous by claiming to use psychic powers to bend spoons, start watches, and read the contents of sealed envelopes. His claims to have psychic ability were thoroughly discredited by James Randi who duplicated Geller's feats and explained how they were done in *The Truth About Uri Geller* (Prometheus Books, 1982).

Kentucky blasts unaccredited degrees. It is now a misdemeanor in Kentucky for any "unlicensed health care practitioner" to use an academic title or represent in any other manner that he or she possesses an academic degree unless the practitioner actually has a degree accredited by an agency recognized by the U.S. Department of Education or the Council on Postsecondary Accreditation. The new law defines "unlicensed health care practitioner" as "any person who, for compensation or with expectation of compensation, offers or undertakes to provide advice, counseling, diagnosis, treatment, therapy, correction, or rehabilitation relating to: 1) physical or mental health in general; 2) particular ailments, diseases, injuries, infirmities, disorders or disabilities, or their prevention; 3) nutrition diet, weight control, fitness or smoking; or 4) aging, baldness, or sexual performance."

DR. ROBERT MENDELSON DIES

Robert S. Mendelsohn, M.D., a leading critic of scientific health and nutrition care, died April 5, 1988, at the age of 61. Although he had taught at several medical schools and had been chairman of the Illinois state licensing board, Mendelsohn considered himself a "medical heretic." His criticisms were invariably harsh and destructive. He opposed licensing of nutritionists as well as water fluoridation, immunization, and screening examinations to detect breast cancer. His opposition to whooping cough vaccination, widely publicized through Phil Donahue's TV program, probably persuaded thousands of parents not to vaccinate their children against this disease.

Mendelsohn's book *Confessions of A Medical Heretic* charged that "Modern Medicine's treatments for disease are seldom effective, and they're often more dangerous than the diseases they're designed to treat"; that "around 90% of surgery is a waste of time, energy, money and life"; and that most hospitals are so loosely run that "murder is even a clear and present danger. His other books were *Male Practice: How Doctors Manipulate Women* and *How to Raise A Healthy Child in Spite of Your Doctor*.

From 1981 to 1982, Mendelsohn was president of the National Health Federation, the militant lobbying arm of the health food industry. He spoke frequently at NHF conventions and produced a newsletter and a syndicated newspaper column, both called *The People's Doctor*.

Mendelsohn was also president of the New Medical Foundation, a tax-exempt organization formed in the late 1970s to support "innovative forms of medical

education of the public and the medical profession." At a meeting sponsored by this group in 1984, he said, "Doctors complain that quacks keep patients away from orthodox medicine. I cheer! Since all the treatments, both orthodox and alternative, for cancer, coronary heart disease, hypertension, stroke, and arthritis, are equally unproven, why would a sane person choose treatment that can kill the patient?"

During the past two years, Mendelsohn appeared in ads by Naturally Vitamin Supplements of Scottsdale, Arizona, advocating daily use of Bio-Strath, a product described as an herb and yeast mixture containing "10 B-vitamins, 19 minerals, 18 amino acids and important active enzymes." [There are only eight B-vitamins.] According to Mendelsohn, Biostrath "can help people who experience daily tiredness, fatigue and difficult concentration . . . may stimulate the immune system. And may actually help us to assimilate more natural fuel from the foods we eat." Such claims are illegal in advertising and labeling.

In 1986, the National Nutritional Foods Association (an association of health food manufacturers, distributors and retailers) gave Mendelsohn its annual Rachel Carson Memorial Award for his "concerns for the protection of the American consumer and health freedoms." During the past year, he was honorary chairman of NNFA's membership drive.

Vera Chatz, who helped Mendelsohn produce his newspaper columns, has announced that the *The People's Doctor* newsletter will continue publication as *The Doctor's People*.

BIOTECH TO BRING FOOD WONDERS?

Manfred Kroger, Ph.D.

Plump, tasty tomatoes all year long, increased supplies of scarce natural flavors and colors, breads that remain fresh indefinitely, and cheeses that "age" in days instead of months . . . All of these and much more lie within the vision—and possibly eventual reach—of food biotechnologists. But while the new knowledge can improve the quality and quantity of foods and save food dollars, the changes aren't likely to be obvious soon, according to the Institute of Food Technologists (IFT), the 23,000-member professional society of food scientists.

"With few exceptions, most short-term results of modern biotechnology applied to food production will be invisible to the consumer's eye," the IFT Expert Panel on Food Safety and Nutrition has pointed out. "However, indirect effects on existing products, such as cost savings and product improvement, will be far-reaching," the IFT panel says in its new 14-page scientific status summary on food biotechnology. The report's principal authors were Bruce P. Wasserman, Ph.D., and Thomas J. Montville, Ph.D., of Rutgers University and Edward L. Korwek, Ph.D., J.D., of Hogan and Hartson, Washington, D.C.

The term "biotechnology" embraces a number of techniques. Biotechnologists know how to transfer genes from one organism to another. For some applications, they can "program" microbes and plant cells to produce large amounts of now-scarce natural products such as food colors and flavors. These scientists can "custom-make" an antibody and target it to a tiny portion of a protein to change its properties.

The properties of all living things, plant or animal, are determined by their genes. In foods, these properties include form, texture, color, taste, nutrient value and resistance to environmental stresses that can ruin or spoil them.

Changing the genes of plants to resist stress can substantially increase the world food supply, a large fraction of which is lost to pests or spoilage, especially in less developed nations.

Genes are made up of strings of relatively simple compounds (nucleotides) linked in intertwined helical chains hundreds or thousands of units long, called DNA (deoxyribonucleic acid). The sequence of nucleotides in DNA provides a blueprint for arranging amino acids to reproduce proteins. During the last 20 years, biotechnologists have discovered how to chemically snip out specific nucleotides and replace them with others in the DNA chain, thus changing the associated protein and its function.

The IFT scientists believe new biotech techniques will be adapted to processes in the dairy, baking, brewing and enzyme industries. In cheesemaking, for example, the enzyme rennin is used to convert milk into cheese. Rennin used to be obtained from calves' stomachs. Calf rennin makes superior cheese but is scarce. Now food biotechnologists can produce rennin from yeast by cloning the gene for calf stomach rennin and transferring it to yeast.

Enzymes also play an important role in food processing and in the way foods spoil. The IFT scientists point out that "protein engineering" has recently come into use as a technology for improving the way enzymes work. For example, allowing them to operate at higher temperatures would greatly increase the efficiency of many enzyme-catalyzed reactions. Understanding how to regulate enzymes at the genetic level could lead to the development of fruits and vegetables that ripen more slowly and thus have a longer shelf life.

Another important area where biotechnology will be used is detection of food poisoning. Monoclonal antibodies are already being used to speed up detection of salmonella bacteria from four days to one or two.

Biotechnology is a fast-evolving field. As IFT points out: "In some instances, the needed breakthroughs will come rapidly. In others, they may never come. One turn of events is predictable, however. As more new products are developed, the emphasis will shift from the technical to the legal arena. Clear and rational policies are needed on the regulatory status of bioengineered products."

Dr. Kroger is professor of food science at The Pennsylvania State University. Single copies of the IFT scientific status summary on food biotechnology can be obtained for \$1.00 from the Institute of Food Technologists, 221 N. LaSalle St., Chicago, IL 60601.

CORRECTION

"Advice in Health Food Stores" in our January 1988 issue was followed with a note that the Allentown Morning Call had purchased an article from the author but not published it for legal reasons. We have subsequently learned that this is incorrect. We regret the error.—Stephen Barrett, M.D.

SPORTS NUTRITION BASICS

Kathy King Helm, R.D.

Brian liked sports but didn't go out for a team because he couldn't keep up. Although he was tall and big for a 14-year-old, his looks were deceiving. His body was 26% fat, and he didn't have the strength or stamina to compete. He needed a nutrition-and-exercise program to lower his body fat level and improve his fitness.

Jennifer loved ballet—which required her to remain slender—but she also loved to eat. She lived in continuous conflict about her diet. When her weight rose after several days of thoughtless eating and heavy snacking, she would lower it by skipping breakfast, lunching on Coke and potato chips, and eating small portions at dinner. Bingeing and half-starving abused both her body and her mind. She needed education in sports nutrition.

Years ago a basketball coach changed his team's pre-game meal from steak to complex carbohydrate foods. He explained why, but the players really grumbled when it was served. Fearing they might blame the meal in case of a loss, the coach thought quickly. Right before the game, he said, "I know some of you are unhappy about the pre-game meal. So if anyone feels too weak to play, just let me know and you can sit this one out." No one complained again and fortunately, they won.

Although the basic guidelines for sports nutrition are clear to experts, fitting them to each athlete's or potential athlete's physical needs as well as to training and competitive schedules can be a challenge. Practice sessions often take place during family mealtimes, so an athlete's meals may be delayed, cold or caught-on-the-run. Most athletes have heard that complex carbohydrates are important, but many don't know how to use this information in a practical way. For example, they may realize that spaghetti, ice cream and orange juice contain carbohydrates, but may not be aware that fruits, vegetables and whole grain breads contain them too.

Many young athletes watch what the winners eat. Often they are influenced by others' food and bev-

erage choices or what the coach suggests—for better or worse. A coach or trainer who has a good grasp of sports nutrition may improve an athlete's eating habits when the parents can't.

General guidelines

Optimal endurance sports performance is strongly influenced by the availability of both carbohydrates and fats. Nutrition plays a central role in the storage and utilization of these fuels.

The ideal diet for an athlete should be high in carbohydrates (55% of calories), low in fat (30%), and moderate in protein (15%). This ratio is achieved not only by eating fruits, vegetables, grains and starches, but also by not eating large amounts of fattier meats, fried foods, and foods with added fat.

Glucose is the major fuel used during early minutes of exercise until fats can be metabolized for fuel. Glucose is stored in the liver and muscles in the form of glycogen, which consists of branched chains of glucose molecules.

The figures below show why carbohydrates are important in an athlete's diet. In this classic study, an athlete was fed a different diet each day for three days and then asked to ride a bicycle ergometer until totally exhausted. The times to exhaustion were:

High-carbohydrate diet	167 minutes
Normal mixed diet	114 minutes
Fat and protein diet	57 minutes

When a high-carbohydrate diet was compared to a normal diet and a high-fat diet, the carbohydrate diet produced a larger amount of stored glycogen in the exercising muscle and thus resulted in far more physical endurance [*Acta Physiologica Scandinavia* 71:140, 1967].

Sprint runners, swimmers and others who must exert near maximal muscle force for less than two min-

utes obtain nearly all of their energy from muscle glycogen. Fats must have oxygen available to be broken down for energy. In these events the flow of oxygen to the working muscles doesn't meet the demands for oxygen-dependent metabolism; therefore calories must be derived from the anaerobic breakdown of glycogen, which doesn't require oxygen.

Endurance training can increase the oxygen supply to working muscles and enhance the tissue's capacity to conduct oxygen-dependent metabolism. Consequently, the endurance-trained muscle is better able to burn fats for calories and thereby spare the use of glycogen. Fats provide most of calories for low- to moderate-intensity exercise (as well as "stop-and-start" sports) when oxygen is available.

Fat is stored in the body's fat cells and muscles as triglycerides, molecules that consist of glycerol and three fatty acids. Before fatty acids can be burned for calories, they must be carried to the exercising muscles and enzymes must release them from the triglyceride molecule. Since this process is slow to get started, the athlete may exercise for 30-40 minutes before the rate of mobilization of free fatty acids (FFA) equals or exceeds the rate of utilization in the exercising muscle fibers. However, small amounts of FFA contribute calories from the onset of exercise.

Proteins supply amino acids, the building blocks for muscle and other tissue growth and repair. During exercise, proteins usually provide 10% of the energy to fuel muscles, but this percentage can rise considerably when carbohydrate stores are depleted—as happens during marathon events, fasting, or severe dieting. When excessive protein is burned for calories, urea, a by-product, builds up in the body. As the body tries to excrete the urea in the urine, dehydration and loss of electrolytes and calcium may result. When more protein is consumed than the body needs, the excess is converted to fat and stored like all other excess calories.

The average athlete's diet usually contains more than adequate amounts of protein. For athletes, 1 to 1.5 grams of protein per kg of body weight is suggested. For adults, 0.8 grams of protein per kg body weight is adequate.

Young athletes may need 3,000 to 6,000 calories per day to cover their needs for sports, growth, and normal daily living. However, caloric needs of athletes can vary considerably from individual to individual. It is not

unusual to find a woman athlete who will gain weight on 2,000 calories per day. Or to find one athlete who eats 500 to 1,000 more each day than another even though both are similar in size, age, height and play the same sport. Recent reports suggest that what you eat may be more important than how much you eat and that a low-fat diet without total caloric restriction results in a loss of body fat.

Water/fluid replacement

Dehydration can debilitate an athlete quickly. A loss of only 3% of an athlete's weight due to dehydration (4.5 pounds in a 150-pound person) will affect motor movement. A loss of 10% in a short period of time could necessitate hospitalization.

Endurance athletes and others who exercise in hot climates or at high altitudes should realize that thirst isn't a reliable indicator of dehydration because it usually does not occur until after 2-4 pints of body water are lost. Athletes should drink a cup or more of water a minute or so before starting to exercise and another ½ to 1 cup every 15 minutes during exercise. (Keep in mind, however, that large amounts of water consumed 15-20 minutes before exercising can lead to a full bladder.)

To help avoid dehydration, some endurance athletes use a technique called hyperhydration or overhydration, which involves drinking 1-3 quarts of water before and/or during exercise. This added water helps maintain blood volume and body temperature. Although there may be some stomach discomfort, this possibility must be weighed against the negative effects and risks of dehydration.

Water is the best fluid to drink for events lasting less than an hour. However, athletes do use very dilute replacement beverages without apparent side effects. Cold drinks (40-50°F) leave the stomach faster than icy or warm liquids and haven't been shown to cause abdominal cramping.

Most drinks—including juices and soft drinks—contain 10% sugar because that concentration of sugar tastes best. At the recent meeting of the American College of Sports Medicine, Dave Costill, Ph.D., an exercise physiologist at Ball State University and a leading researcher on sports drinks, astounded the audience by stating that undiluted drinks can be absorbed rapidly

EDITORIAL BOARD

Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Mark Fuerst; Kathy King Helm, R.D.; Victor Herbert, M.D., J.D.; Joyce Julien, M.S., R.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

during exercise. Twenty years ago he had concluded that undiluted drinks were absorbed very slowly, but these studies were done while the athletes were resting. However, his recent research, done in heavily exercising athletes, showed that undiluted drinks leave rapidly from the stomach of athletes during heavy exercise and are absorbed rapidly when they reach the intestines. Evidently, exercise jostles the stomach and facilitates its emptying.

It is seldom necessary to add electrolytes like sodium and potassium. A 2-pound water loss results in an average sodium loss of 1 gram, which can easily be replaced by salting food. (A half-teaspoon of salt contains 1 gram of sodium.) Even less potassium is lost, and it is readily available in common foods.

Alcoholic and high-caffeine beverages act as diuretics and therefore tend to deplete an athlete's body of fluids, especially if only these beverages are consumed.

Pre-game meal

Athletes usually determine what to eat before the game by trial and error. The key points are timing (so food isn't left in the stomach), comfort, and blood sugar control. Some athletes use only beverages like water, dilute fruit juice, or a blenderized drink. Others feel a good meal at least 2-4 hours before competition will give them an edge. Either approach can be successful for a given individual.

The pre-game meal can greatly influence an athlete's blood sugar level which in turn can make an athlete feel in or out of control. Complex carbohydrates are ideal for maintaining the correct blood sugar level because they are absorbed more slowly than sugar but more quickly than proteins and fats.

The guidelines most athletes agree on for pre-game meals are:

- Eat complex carbohydrates (fruits, juices, breads, cereals, pancakes, pasta, rice, potatoes, other vegetables)
- Drink plenty of fluids, but avoid sugar and carbonation
- Avoid fats and high-fat foods because they delay digestion
- Avoid large amounts of roughage (tossed salad)

and gas-forming foods (some vegetables and dried beans), which may cause discomfort

- Eat only small portions of protein foods because they delay digestion

- Don't eat less than two hours before competition begins

Two sample meals of about 500-600 calories:

8 ounces orange juice	1 cup spaghetti
1 cup cold cereal	1/2 cup spaghetti sauce
2 slices whole wheat toast	1 slice French or Italian bread
2 T. apple butter	1 peach
8 ounces 2% milk	8 ounces 2% milk

Modified carbohydrate loading

That feeling when the body can't physically continue exercising—often called "hitting the wall" by athletes—occurs when muscle glycogen is depleted. Fat may still be in ready supply, but without glycogen the athlete's body can't utilize the fat efficiently. Endurance training itself stimulates the body to store 1½ to 3 times more glycogen than that stored in an untrained person's body. This increase in muscle glycogen is a biological adaptation to cover the daily exercise. Carbohydrate-loading supersaturates an athlete's muscles with more carbohydrate fuel (in the form of glycogen) than the muscles normally store. This extra supply can benefit an endurance athlete because it provides added glucose fuel.

Dr. Costill, who is also an expert on carbohydrate loading, has found athletes can ensure very large muscle glycogen storage simply by eating a carbohydrate-rich diet (at least 50% of the calories) during the 48-72 hours before an endurance event, provided they rest during that period. Glycogen loading has little influence on events lasting less than 90 minutes but is crucial to athletes in longer events, such as marathon runs.

"Bulking up"

For some sports—notably football—athletes are asked to gain weight and strength. The added muscle power and weight can be an advantage on the playing field. To increase muscle size, and thus strength, an athlete must stimulate muscle growth by exercising against increased resistance.

Protein is the building block for the muscle tissue. However, it's estimated that in the early stage of training only 5-8 grams of additional protein are needed. One cup of milk or an ounce of meat contains that much protein. As the athlete becomes stronger and is able to do more exercise, 10 grams of extra protein should be sufficient. However, most athletes already consume more than enough protein each day to cover this added requirement.

The recommended gain in muscle mass is about two pounds a week. For most people, this can be accomplished by eating an additional 1,000 calories per day, especially in the form of carbohydrates, which provide fuel for the added exercise and spare the protein needed for muscle growth.

Adequate rest (allow a day between exercise bouts of a muscle group) and sleep are also necessary for bulking up. They allow an athlete's body to recover from the exercise and resultant tissue breakdown, and to synthesize the added muscle tissue.

It's important to note that as young men mature, they first grow taller and then—about 12-18 months later—increase the size and strength of their muscles. Weight training with heavy weights shouldn't be started prematurely, especially in very young or very tall boys.

Staying strong while losing weight

Sports such as wrestling, rowing, boxing and karate require weigh-ins. Others such as gymnastics, figure skating and ballet encourage athletes to have slim bodies and yet be strong.

If an athlete's body is heavier than desired, it is important that the weight be lost correctly:

- Allow adequate time to lose weight. A good rate is 8-10 pounds per month. When weight is lost too

quickly, lean muscle and fat are burned for calories and strength and endurance may be lost.

- Use a percent body fat measurement, not just scale weight to determine an athlete's ideal body weight. Although experts don't agree on the exact numbers, it is usually suggested that male athletes measure 5-13% body fat and female athletes 12-22% body fat. Of course there are exceptions to all standards, but eating too little and exercising too much to become excessively lean will not improve performance.

- To lose fat but maintain muscle, an athlete should eat smaller portions of nutrient-dense food (300 or so calories fewer each day) and add 30-60 minutes of aerobic exercise to the daily routine.

Starvation diets can cause muscle loss, slower metabolic rate, tiredness, mood swings, and loss of strength and endurance. Weight loss through dehydration is even more debilitating and potentially dangerous. Athletes who eat properly while losing weight will feel like exercising and have the nourishment to do so.

Ms. Helm is a registered dietitian in private practice in Lake Dallas, Texas, and is a former board member of the American Dietetic Association.

BRIEFS

Weight loss in adolescent wrestlers. A study of 27 adolescent wrestlers found that the resting metabolic rate and resting energy expenditure of those who repeatedly lost and regained weight were lowered [JAMA 260:47-50, 1988]. The authors think that repeatedly "cutting weight" for competitive reasons can cause difficulty in weight control and other adverse effects. However, they state that further research is needed to confirm this.

Reliable information source. The Council for Agricultural Science and Technology (CAST), 137 Lynn Avenue, Ames, IA 50010, is a nonprofit educational organization representing food and agricultural science and technology. It publishes information on the scientific aspects of important issues in agriculture, food processing, nutrition, and health. It has about 5,000 members and an annual operating budget of about \$600,000. Membership costs \$20/year, which includes copies of special reports on diet and health, pesticides, food irradiation and many other subjects. Its quarterly magazine, *Science of Food and Agriculture*, costs \$5/year additional.

Videotape on carcinogens. A videotaped lecture entitled "Carcinogens, Anticarcinogens, and Risk Assessment" can be borrowed without charge from the Council on Agricultural Science and Technology. In the lecture, Bruce Ames, Ph.D., Chairman of the biochemistry department at the University of California, Berkeley, discusses: 1) how scientists learn about what causes cancer; 2) that the world is full of cancer-causing agents; 3) why life expectancy will continue to get longer; and 4) that cancer prevention will improve. The tape can be borrowed by sending your name, address and phone number to Mary K. Adams, CAST, 137 Lynn Ave., Ames, IA 50010. Copies can be purchased for \$15 from the Council for Chemical Research, One Bethlehem Plaza, Suite 911, Bethlehem, PA 18018.

Diet patches seized. After the FDA warned that "diet patches" were being illegally marketed [see NF 5:41], several companies began voluntary recalls. But San Diego-based Meditrend International did not. Consequently, in June, U.S. marshals seized patches and related materials with a retail value of more than \$22 million from the company and two of its suppliers.

Help wanted with special cancer study. A major evaluation of questionable cancer therapies is being done by a prominent medicolegal team led by attorney Grace P. Monaco. The initial subjects for study include herbs, teas, botanicals, DMSO, laetrile, Manner metabolic therapy, Hoxsey therapy, Gerson therapy, the Greek Cancer Cure, and the methods of Virginia Livingston Wheeler, Stanislaw Burzynski, and Lawrence Burton. The research team is particularly interested in seeing medical records, insurance claims and personal observations of any patient who has been treated with any of these methods. (Patients do not have to be identified; it is sufficient to provide medical records of any standard treatment and questionable methods, if available.) Court cases and newly introduced legislation involving questionable method are also of interest. The information should be sent to Mrs. Monaco at 1901 Pennsylvania Ave., Suite 1001, Washington, DC 20006 (202-835-0367).

Recommended publication. *Current Diet Review*, written by registered dietitians, is now in its third year of publication. Each issue provides detailed evaluations of three or four diet books or other sources of nutrition information. The book reviews usually include the results of a computer analysis of the diet as well as comments on accuracy, health considerations, comprehensiveness, readability, and the author's credentials. The editor and publisher is Lisa Teresi Harris, R.D., a school nutrition specialist. Subscriptions are \$18/year from *Current Diet Review*, P.O. Box 1914, Rialto, CA 92376.

New artificial sweetener approved. On July 27 the FDA approved the marketing of acesulfame K (the K stands for potassium) in the United States in such products as powdered drinks, puddings, chewing gum and tabletop sweeteners. The substance is about 200 times sweeter than table sugar and is chemically unrelated to aspartame and saccharin. It was discovered in 1967 by researchers of the West German company, Hoechst, which is represented here by Hoechst Celanese Corporation, Somerville, New Jersey. It is already sold in 20 countries for the dry uses just approved by the FDA. In some countries it is also used in soft drinks and baked goods. Acesulfame K passes through the body unchanged. Unlike saccharin, it leaves no aftertaste. Unlike aspartame, it is not broken down by heat, and there is no population group that needs to abstain from it (as phenylketonuric patients must do with aspartame). Acesulfame K will be test-marketed under the trade name Sunette, but general marketing is not expected until next year. Hoechst plans to seek FDA approval to use it in soft drinks and baked goods.

Alcohol labeling. The Bureau of Alcohol, Tobacco and Firearms has proposed to shorten the labeling requirement for whiskey and brandy treated with wood. Currently, a label on the front of the bottle must state that these products are "colored and flavored with wood chips [or wood slabs, etc.]" The proposed message would simply read "treated with wood" and could be placed anywhere on the front or back label. The purpose of the labeling is to inform consumers that the character of the product is not entirely derived from aging in a barrel.

Alcohol and breast cancer. Researchers who conducted a thorough analysis of the scientific literature of the past two decades have concluded that women who consume 1 ounce of alcohol daily are "slightly" more likely to develop breast cancer than those who do not [JAMA 260:652-656, 1988] and that greater alcohol intakes increase the risk further. However, the researchers caution that the data do not prove that a cause-and-effect relationship exists. They also point out that any increased risk should not be considered separately from a possible protective effect of alcohol against cardiovascular disease that has been suggested by other studies. Reprints of the report are available from Thomas C. Chalmers, M.D., Harvard School of Public Health, Technology Assessment Group L-7a, 677 Huntington Ave., Boston, MA 02115.

New "food freshener". The Monsanto Company has announced an alternative to sulfites, the "freshener" of fruits and vegetables now barred by the FDA for use on most foods. The new product—Snow Fresh—is said to be ideal for use in salad bars and other applications such as peeled potatoes, sliced apples, chopped broccoli and cauliflower, sliced green peppers, and shredded lettuce, cabbage and carrots. Untreated, these products quickly turn brown and become unappetizing. With treatment, the fresh color keeps for several days. The preservation effect results from delaying the onset of oxidation and enzymatic browning. Snow Fresh is simply a blend of four widely used food additives which are GRAS (generally recognized as safe): citric acid, ascorbic acid (vitamin C), sodium acid pyrophosphate, and calcium chloride. The product, a white powder, is dissolved in tap water, 1½ to 4 ounces per gallon, to make a solution used for dipping. A salad manufacturer in St. Louis has tested the new sulfite substitute and found it very satisfactory. Monsanto has not indicated when Snow Fresh will be marketed or whether FDA would first have to give a go-ahead for the blend, which seems unnecessary since all of its components appear safe.

FTC stops diet scam. The marketers of Dream Away and Advanced Dream Away have agreed to settle FTC charges of false advertising. The pills, which contain small amounts of amino acids and cost \$19.95 for a 21-day supply, were claimed to produce weight loss during sleep and without exercising or dieting. Under a court-approved settlement, Nutri Marketing, of Scottsdale, Arizona, has agreed to put \$1.1 million into an escrow account, which the FTC can use to repay buyers of the products. The settlement agreement also names Kingsbridge Media & Marketing Inc. and Frank E. Robinson, of Van Nuys, California, and Highcliff Inc., Vista Advertising, Mel Korey and Steve Corey, of Scottsdale, any of whom can be liable if Nutri Marketing defaults on its promise to pay. Consumers who think they are eligible for refunds should write to Nancy Warder, FTC, Washington, DC 20580.

Vitamin ad blitz planned. *PR Week* has reported that the Council for Responsible Nutrition (a group representing major supplement manufacturers and distributors) plans to spend \$4 million on a "consumer PR program centered around a "why-buy-vitamin" theme. A spokesperson for one of the ad agencies involved says the focus of the campaign will be to convince "healthy people" that they can benefit from vitamins and that supplements are not strictly for people with specialized nutritional needs. According to CRN president J.B. Cordero, the first goal will be "to get users (who have stopped taking vitamins) back into the fold."

Muscle stimulators used improperly. The *FDA Enforcement Report* of March 9, 1988, has warned that prescription-only electrical muscle stimulators are being improperly used by health spas and figure salons. These devices cause muscles to contract by passing electric current through electrodes (contact pads) applied to the skin. They are properly used under medical supervision to relax muscle spasms and to re-educate muscles after a stroke. However, claims that the devices can produce weight loss, "cellulite" removal, spot reducing, bust enlargement, wrinkle removal or nonsurgical facelifts are invalid.

Magazine sabotaged. *Whole Life*, a magazine catering to "New Age" and "health food" devotees, was forced to stop publication last winter for financial reasons. According to editor/publisher Marc Medoff, trouble developed when the magazine blasted leaders of the "Airplane Game," including some of his own advertisers, for preying on New York City's "New Age" community. (The game is an illegal pyramid scheme in which people are induced to buy \$1,500 tickets on an imaginary airplane with the hope that sales to other "passengers" will advance them into "pilots" who collect \$12,000 within a few days.) Medoff says that as soon as the issue containing his exposé was distributed, organizers of the scheme stole stacks of copies from health food stores by posing as representatives of the magazine. He hopes to resume publication later this year.

BOGUS CLAIMS FOR H₂O₂ STOPPED

A U.S. Postal Service Judicial Officer has ordered Kurt W. Donsbach, founder of DRK Supplements, and his nephew, Richard Donsbach, the apparent owner since 1985, to stop representing in mail order sales that a 35% solution of hydrogen peroxide is effective against cancer and arthritis. (The hydrogen peroxide commonly used to clean wounds is a 3% solution.) The California-based company had been selling peroxide products while Kurt Donsbach promoted their use for health purposes in publications and in lectures at health fairs throughout the U.S. According to a Postal Service news release, DRK operated booths at some of these fairs and referred prospects for treatment at a Mexican hospital administered by Kurt Donsbach.

The cease and desist order, issued July 20, 1988, forbids DRK and the Donsbachs from falsely representing that: 1) hydrogen peroxide used orally or intra-

venously is effective in preventing the onset or spread of cancer or ridding the body of cancer; 2) hydrogen peroxide used topically, orally or intravenously is effective against the pain and inflammation of arthritis; and 3) food-grade (35%) hydrogen peroxide is fit for human consumption. They are also prohibited from making unsubstantiated representations that hydrogen peroxide is effective against any other condition or that any other unproven remedy is effective against cancer or arthritis.

Earlier in the case, a federal court judge had issued a temporary restraining order permitting the Postal Service to stop mail to DRK containing remittances for hydrogen peroxide sales. Without acknowledging fault, the Donsbachs then agreed to the issuance of the cease and desist order rather than contest the charges further. [For information about Kurt Donsbach's many other activities, see the October 1987 *Nutrition Forum*.]

CRACKDOWN ON FISH OILS ANNOUNCED

The FDA has notified its field organization that "there is no general recognition of the therapeutic role of omega-3 fatty acids in human nutrition and health at the present time." The notice [*Health Fraud Bulletin* #7, revised 3/25/88] also indicated that although the role of various fish oils is a subject of research, "advertising and labeling claims for omega-3 products are based on interpretation of preliminary data by commercial interests." According to an article in *The New York Times*, more than 90 companies marketed fish oil capsules during 1987.

Interest in omega-3 products began soaring in mid-1985 after *The New England Journal of Medicine* published several articles suggesting that fish oils could have a role in preventing heart disease. However, most experts believe that even if such a role exists, nobody knows what dosage is appropriate and whether supplements are safe for long-term use. Instead, experts suggest eating fish several times a week (preferably broiled, baked or poached), not only to provide omega-3 fatty acids but also to replace meats that are high in saturated fats.

In April 1987, all FDA districts were asked to identify marine lipid products and submit labels and advertising for medical and regulatory review. Claims were found for the prevention or treatment of arthritis, atherosclerosis, cancer, diabetes, eczema and psoriasis, heart disease, high blood pressure and migraine headaches, as well as for effects on the immune system, platelet aggregation, prostaglandins, blood cholesterol or triglyceride levels. After medical review, FDA officials concluded that products marketed for any of these purposes are considered "prescription drugs," since the conditions involved are unsuitable for self-diagnosis and self-treatment by laypersons.

The FDA notice was distributed with a "model regulatory letter" that had been sent on April 11, 1988, from the Dallas District Office to Shaklee Corporation president David M. Chamberlain. According to the letter, Shaklee promotional material was suggesting that Shaklee EPA Natural Marine Lipid Concentrate is useful in the prevention or treatment of atherosclerosis and the lowering of cholesterol and triglycerides. The letter asked for a reply within ten days stating that Shaklee will discontinue the marketing of this product.

The Health Fraud Bulletin said that FDA district officials should continue to collect evidence of labeling violations and to send regulatory letters to violators whose actions have been reviewed and judged illegal by the FDA's Health Fraud Staff. The agency has also asked the Federal Trade Commission to review the advertising of fish oil products.

The National Nutritional Foods Association, which represents health food industry retailers, distributors and producers, has expressed "grave concern" about the FDA's actions.

Jack Z. Yetiv, M.D., Ph.D., has reviewed the status of fish oils in the August 5, 1988 *Journal of the American Medical Association* [260:665-670]. He believes that taking fish oils under medical supervision may benefit cardiovascular health and that preliminary observations suggest a possible future role in the treatment of autoimmune diseases such as psoriasis and rheumatoid arthritis. However, he warns that therapeutic amounts of fish oil (15-30 capsules) contain enough calories to cause significant weight gain and that side effects must be considered too. He also cautions that current data are insufficient to recommend fish oil supplements to the general public and that the dosage suggested on product labels (3-6 capsules) is low and has not been tested in long-term studies.

QUESTION BOX

Q. Does the color of egg yolks or egg shells have any nutritional significance?

A. No. Egg shell color is directly related to a bird's species, breed or strain. Edible eggs may be white, brown or blue. Some individuals are willing to pay more for eggs of one shell color or another in the mistaken belief that the color indicates higher quality or better nutritional value.

Yolk color is determined by such pigments as xanthophyll, lutein and zeaxanthin. These pigments are derived from what a hen eats. Knowing this, breeders can deepen egg yolk color by feeding fresh vegetable matter (such as yellow corn) or using feeds that are rich in pigments. Free-roaming hens eat more grass and therefore produce yellower yolks than do hens raised indoors. The major pigment of egg yolk is xanthophyll, which has a deep yellow color. Extracts of marigold petals—which are rich in xanthophyll—are commonly added to chicken feed.

It is erroneous to assume that more deeply colored yolks contain more carotene, vitamin A or riboflavin. Any color these nutrients contribute is totally masked by the plant pigments. Reference tables give the riboflavin content per average hen egg as 0.144 milligram, and the vitamin A content as 250 international units. Egg color, inside or outside, is also unrelated to cholesterol content.

BOOK REVIEW

Title: *Health from God's Garden* (1986)
 Author: Maria Treben
 Publisher: Thorsons Publishers, Inc., Rochester,
 Vermont
 Price: \$10.95
 Reviewed by: Varro E. Tyler, Ph.D.

Maria Treben, the world's best-selling herbal author, has compiled 128 more pages of fairy tales for her vast audience of natural-medicine enthusiasts who value fantasy and hope more highly than facts. Her 1980 book *Gesundheit aus der Apotheke Gottes*, translated into English as *Health through God's Pharmacy*, has sold over 4 million copies in editions published in 7 languages. Her current volume appeared in English last year under the title *Health from God's Garden* and is well on the way to becoming another best seller.

Does the new book contain any significant information not present in the former? Does it discuss new scientific or clinical studies to render it a more valuable reference? Does it cover many plants not previously discussed? Are valuable new remedies suggested for the promotion of "Glowing Health and Well-Being," as the book is subtitled? Unfortunately, the answer to all these questions is "No!" The 1986 book is little more than a rearrangement of its predecessor.

Following the pattern of most herbals, Treben's first book was primarily an alphabetical consideration of the various herbs. There was, to be sure, a minor section on advice for both minor and serious illnesses, but the bulk of the book was composed of monographs about individual herbs. To see what remedies were recommended for health problems, it was necessary to refer to the index for a list. Under sleeplessness, for example, you would find chamomile, cowslip, lady's mantle, ramsoms, St. John's wort, yellow dead nettle, and Swedish Bitters.

The new volume has a much more convenient format for those who wish to self-medicate. Most of it is devoted to a listing of disease states or conditions to which the reader can quickly turn and find the remedies conveniently grouped under the appropriate heading. The monograph on insomnia now lists most of the above-cited herbs plus some additional ones, such as hawthorn and meadowsweet.

Treben does divide her suggested remedies into two sections, one for minor health problems, and the other for serious illnesses that "can only be diagnosed by a doctor." This arrangement was probably chosen for legal reasons. The same may be said for the "Publisher's Note" which admonishes the reader not to regard the information provided as a substitute for professional medical treatment. Apparently, neither the author nor

the publisher wants to be held responsible if readers are harmed by taking the book too seriously.

Unfortunately, this late-20th century rendition of a 19th century home-health book contains a great deal of really bad information. Although I recognize that some herbs have useful therapeutic properties, I also know that many are potentially harmful. Maria Treben seems totally unaware of this latter potential. Apparently oblivious to modern scientific and clinical findings, she recommends such proven carcinogens as calamus (for underweight), comfrey root (for indigestion), and coltsfoot leaf juice (for asthma). And Swedish Bitters—which she characterizes as useful against almost everything including angina pectoris to gout—is a potent laxative composed of aloe, senna and rhubarb.

Treating arthritis with horsetail or nettle tea may not cause direct harm, but substituting them for prompt, effective treatment can lead to trouble. In the same vein, applying calendula ointment to a breast lump (despite the admonition to seek professional advice) could be disastrous. Since it isn't useful, why recommend it? Willow-herb tea is still listed as a cure for diseases of the prostate even though no scientific or chemical evidence and no folkloric history (except that created by Treben herself) support any efficacy in such conditions.

Many herbal enthusiasts now recognize that the only way their field of interest can gain appropriate recognition is to place it on a scientific, factual basis and to separate it completely from magic, superstition and wishful thinking. This book does nothing to advance that cause; indeed, because the author is well known, its impending popularity will prove to be a giant step backward for herbs and herbalism. If the book stimulates any questions, don't seek answers from the author. For, as she states in the introduction, "All you need to do is to read the book—it contains everything I know!" Regarding rational use of plant drugs, that is little indeed!

Dr. Tyler, Vice President for Academic Affairs at Purdue University, is an expert in pharmacognosy (the science of medicines from natural sources) and is author of *The New Honest Herbal* (1987), published by the George F. Stickley Company, Philadelphia.

ORGANIC GERMANIUM: ANOTHER HEALTH FOOD STORE JUNK FOOD

James A. Lowell, Ph.D.

Fans of "Li'l Abner" may recall when one of his teeth started receiving radio signals after he got a dental filling. Well, watch out health food fans. If you start swallowing germanium, the latest cure-all nutrient, there's no telling what might happen!

Germanium is a rare greyish-white metallic element of the carbon family (Atomic No. 32). At one time (inorganic) germanium crystals were widely used to make transistors. Their popularity in electronics gradually waned as better semiconductors and integrated circuitry became available. However, germanium still plays a role in both the electronics and space industries.

During the past few years various organic (carbon-containing) germanium compounds have been promoted as "miracle drugs." Health food manufacturers, writers and publishers have jumped on the bandwagon, along with some "research" institutes, ostensibly formed to study germanium's healing effects. Germanium compounds are actually being tested in scientific laboratories as immune system stimulants and anticancer agents. But the medical claims made by germanium promoters go far beyond what researchers are likely to find.

The patriarch

The current promotion of germanium products began after publication in 1980 of the book *Miracle Cure—Organic Germanium* by Kazuhiko Asai, Ph.D. Asai, born in Japan in 1908, was trained in mining and metallurgy in Berlin during World War II. In 1945 he returned to Japan and established the Coal Research Institute. According to the biographical sketch in his book, he discovered germanium in coal and developed a process to extract it from coal gas waste liquid. In the preface, Asai attributes his connection with germanium to "a working of some supernormal inevitability," states that his germanium compound was "divinely con-

ferred," and says his continued research into the properties of germanium seemed to be commanded from some outside source that transcended his own will. Later he describes germanium as a "health-giving substance—i.e., a substance which restores a condition of health to those afflicted with disease, and which sustains a condition of health in those who are healthy."

Asai says he began studying biologic sources of germanium after realizing that the woody sections of coal contain the highest amounts. He soon concluded that plants containing high amounts—including shelf fungus, boxthorn seed, wisteria, garlic, aloe vera, ginseng, chlorella algae, and comfrey—were "without exception those valued as Chinese medicinal herbs." (Some of these, most notably chlorella and comfrey, can cause serious illness in regular users.) Asai also attributed the alleged healing power of the water at Lourdes, France, to its germanium content.

By the mid-1960s, Asai's income from the coal industry had declined and his personal funds were nearly exhausted. However, he continued to operate his coal product lab until his first germanium product was synthesized in 1967. This was bis-carboxyethyl germanium sesquioxide, $(\text{GeCH}_2\text{CH}_2\text{COOH})_2\text{O}_3$, the water-soluble "organic germanium" most commonly sold in health food stores today. Asai dubbed it "Ge-132."

Asai says he tested it on himself by curing his "severe polyrheumatism complicated by arthritis, for which doctors had given little hope of improvement." After taking "large doses" for a few weeks, he was satisfied that it was not harmful. Then he did animal experiments from which he concluded that his wonder drug could cure virtually all animals of all conditions. Furthermore, he reasoned, the product was not a medicine because no amount he gave the animals was lethal. After additional toxicity tests in animals were conducted at "an authoritative research institute," he

opened the Organic Germanium Clinic near Tokyo, where no drugs were used except germanium. In 1969 he founded the Asai Germanium Research Institute. Asai died in 1984 at the age of 76. Friends attribute his death to a bleeding ulcer which he treated with germanium rather than undergoing standard medical treatment.

Oxygen Deficiency

Asai ascribed all diseases to "deficiency of oxygen." He stated that "cancer, heart disease and mental disease each undeniably strike when oxygen deficiency within the body occurs." He theorized that organic germanium worked by providing the "missing" oxygen to the body. He said that three things are required for successful treatment: 1) the individual must have a firm belief that recovery will occur; 2) a balanced diet must be maintained to prevent "blood acidity caused by excessive intake of hydrogen ions"; and 3) excessive mental stress must be avoided. Germanium will only work, Asai wrote, if lifestyle is adjusted to balance diet and eliminate stress. The germanium will then enrich the oxygen in the body and "expel pernicious pollutants from the body or at least decompose them into harmless substances."

Asai claimed that his germanium regimen was effective against all sorts of diseases, including cancers of the lung, bladder, larynx and breast, neurosis, asthma, diabetes, hypertension, cardiac insufficiency, inflammation of the maxillary sinus, neuralgia, leukemia, softening of the brain, fibroids of the uterus, cirrhosis of the liver, and some forms of blindness. Asai also claimed his germanium could regulate cholesterol and prevent birth defects, and that in children it can cure various brain diseases and relieve earaches, toothaches, nephritis, emphysema and dozens of other conditions. Oral doses along with topical applications can even cause extensive burns to heal with "hardly any scar." Although it doesn't cure muscular atrophy and mongolism (Down's syndrome) in children, germanium inhibits their progress. Moreover, Asai says, it confers immunity against influenza and German measles.

Other promoters have claimed that germanium can stop the damage of radioactivity, produce superoxides inside the body to help prevent aging, cure AIDS, prevent children's violence and autism, decrease the sensation of pain, eradicate allergies, destroy warts and corns, remove deeply imbedded splinters, improve circulatory disorders, restore sexual function and help people with hepatitis, osteoporosis, and cataracts.

Scientific studies

Germanium dioxide was tested as a cure for anemias and as a "blood purifier" as long ago as the early 1920s but was found to be ineffective. Later it was im-

plicated in kidney failure in patients who took doses over prolonged periods of time.

Today, legitimate researchers studying germanium-containing compounds are focusing on their efficacy as antitumor agents. The most thoroughly tested germanium compound is spirogermanium. Phase I trials in 1980 showed a partial response in a patient with a lymphocytic lymphoma. Phase II trials for antitumor activity were carried out against a wide spectrum of solid tumors and malignant lymphomas. Little noteworthy antitumor activity was reported. Although some research groups are still studying the efficacy of spirogermanium, it does not appear that it will play a significant role as a chemotherapeutic agent.

Two other germanium compounds similar to the health food store variety have been studied for antitumor activity. In mice neither compound was useful against most types of tumors on which they were tested, so they are not being widely studied as potential chemotherapeutic agents for humans.

Asai's "Ge-132" has been tested against several conditions. In 1980 it was found that injections of about 100 mg/kg of body weight had antitumor effects on mice and seemed to induce interferon activity. Subsequent studies indicated that oral doses (100 mg/kg) also had antitumor effects. Last year a Japanese research group suggested that Ge-132 works by causing T cells, which are part of the immune system, to produce gamma interferon which activates macrophages to destroy tumor cells. Promoters of germanium claim it works by causing the body to produce interferon, an anti-viral and anti-tumor agent. (They even claim this makes it effective against AIDS.) However, the only type of interferon currently being tested as an anti-tumor agent in clinical trials is alpha interferon, not the gamma interferon induced by Ge-132 in mice. It remains to be seen whether germanium sesquioxide will be effective in human trials.

Much of the data pertaining to the effectiveness of germanium as a therapeutic agent contained in a 65-page report entitled *GE-132 Outline*, published by the Asai Germanium Research Institute. In addition to claiming that germanium is effective against tumors, the report summarizes studies on germanium for treating

collagen disease, deafness, osteoporosis and a few other conditions. Since most of these studies were done in animals, their results should be considered preliminary. Additional work would be necessary to determine whether germanium has any practical use in treating these conditions.

Current manufacturers

Ge-132 is the trademarked name for germanium made under approval of the Asai Germanium Research Institute of Tokyo, Japan. Their Japanese patents have expired, but they hold current U.S. patents on the manufacturing process. After Asai's death, a group of businessmen took over the Institute. They now reserve Asai supplies for medical testing and use and have retained an attorney who specializes in government relations to apply to the U.S. Food and Drug Administration to test Asai germanium as an investigational new drug.

The other major Japanese manufacturer is Tokai Sangyo Co, Ltd., of Tokyo. According to Karl Loren, author of *The Report on Germanium, Has the Cure for Cancer and AIDS Finally Arrived?*, Sangyo manufactured about 95% of the Japanese Ge-132 formulated in 1987 and is the only current foreign supplier of "real" germanium to U.S. companies. Ads from the company state that its "100% pure" germanium is authorized by the Japanese government and that export of non-authorized organic germanium is illegal. However, some U.S. distributors claim to be obtaining it from other Japanese sources.

The major brand of germanium being marketed in the U.S. is GeOxy-132™ distributed by Global Marketing Associates, Inc., of San Francisco. According to company vice president Richard A. Merriam, GeOxy-132™ is the best possible product. Although it was originally imported, Merriam says, it is currently being manufactured domestically for Global by a New York subcontractor whose name is not public information. A Global brochure distributed to retailers calls GeOxy-132™ "the Electro-Nutrient" and states that it "optimizes life force" and that "life force wires your nerves to your brain and flows from one organ to the next in currents that are independent of the nerve paths." Global supplies GeOxy-132™ to 20 supplement companies which repackage and supply it to health food

stores. Some sell it as a single-ingredient product while others combine it with other ingredients popularized by the health food industry.

Another germanium manufacturer is Monarch Nutritional Laboratories of Ogden, Utah. According to Barry Johnson, an owner of the company and the chemist who formulates their germanium sesquioxide, their product is the highest grade, approaching 100%. He told me the company makes no other claim for the product and relies on word of mouth as a promotional tool.

A relative newcomer to the germanium manufacturing scene is Grow Company, Inc. of Hackensack, New Jersey. According to company representative Bob Koetzner, they grow a yeast (*Saccharomyces cerevisiae*) on a medium to which germanium dioxide has been added. After the yeast is harvested the cell walls are broken open and the product is freeze-dried. As a result, he says, their germanium is at least 97% bonded to yeast proteins—which, he states, makes it more of a food and more "natural" than other germanium products. He claims Grow Company's studies show that none of the common forms of germanium is toxic, but that Grow Co.'s product is better absorbed, primarily by the liver, and is retained for a longer period of time. Grow Co. sells its yeast to various distributors but prohibits blending, mixing or dilution of their products.

It also appears that at least one German manufacturer is producing germanium products for both the European and American markets.

How germanium is promoted

Misinformation about organic germanium is being spread through several sources, not the least of which is the Germanium Institute of North America (GINA). GINA's founder and executive director is Paris Kidd, Ph.D. Dr. Kidd, whose Ph.D. in zoology is from the University of California at Berkeley, described GINA as a "for-profit clearinghouse for information on germanium" whose goal is to promote safe, scientific, responsible and effective use of germanium-containing compounds.

GINA provides literature and advice to consumers and to health food retailers, manufacturers and distributors. It also assays products. Kidd told me he believes that the promotional "hype" on germanium has

Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Mark Fuerst; Kathy King Helm, R.D.; Victor Herbert, M.D., J.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Zev Remba (Washington Correspondent); Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

gotten out of hand. He acknowledged that germanium has not been proven to cure any human disease and said that his organization will not distribute lay articles that tout unsubstantiated claims for germanium. Nevertheless, much of the information provided by Kidd, including some in his newsletter, *Gina Speaks*, is not the sort encountered in the scientific literature. Instead, articles are written for the lay public and contain anecdotes and testimonials suggesting that germanium can help everything from AIDS to zits. Much of the information included in germanium advertisements comes from a 1986 monograph by Kidd entitled *Ge-132: Research Breakthrough from the Orient*.

Articles in health food industry publications touting germanium as a cure-all also cite the writings of Kidd and members of his Institute. For example, the August 1987 issue of *Whole Foods* extolled the miracle properties of germanium in its "Consumer Bulletin." This is a monthly page that contains a box for the retailer's business card and is intended for photocopying and distribution to customers.

Kidd himself touts germanium for chronic Epstein-Barr disease and candidiasis. These are controversial conditions that many fringe practitioners diagnose excessively in patients who suffer from general malaise or symptoms common among healthy individuals.

GINA's advisory board has included several practitioners who are not representative of mainstream science or medicine. One is Alexander Schauss, "Ph.D.," author of *Diet, Crime and Delinquency*. The book claims that normal people can be turned into criminals if they eat such foods as chocolate, eggs, corn, peas, citrus fruits, tomatoes, wheat and other small grains, cinnamon, dairy products, or artificial food colors. During lectures Schauss sometimes says, "As a physician I might tell you . . ." but he is not a medical doctor. In fact, a recent expose in the *Vancouver Sun* revealed that Schauss has been a "Ph.D. candidate" since 1981 at unaccredited California Coast University but had not completed the work needed for the degree.

GINA's lay research advisor is Betsy Russell-Manning, an advocate of dubious cancer therapies who has also written a book vilifying mercury amalgam fillings. One of the four members of the GINA's board of directors is Michael Rosenbaum, M.D., president of the Orthomolecular Medical Society, a group of physicians who believe that numerous diseases and conditions can be treated with megadoses of vitamins, minerals, and other "food supplements."

Kidd told me he recently disassociated himself from Schauss and certain other board members who he feels are not advancing the scientific study of germanium. Notable among these is Steven A. Levine, Ph.D., an Institute founder who is another prolific promoter of health food store variety germanium. Levine, who obtained his degree in genetics at the University of

California, Berkeley in 1976, is the Director of Research of Nutri-Cology, Inc., which does business as Allergy Research Group. Nutri-Cology, which is located in San Leandro, California, designs and sells "hypoallergenic" minerals, vitamin and glandular supplement products. Levine's major articles on germanium have been published in the *Journal of Orthomolecular Medicine* and the *Journal of Orthomolecular Psychology*, neither of which generally reflects the opinions of practitioners of scientific medicine. He has also presented papers on germanium to symposia sponsored by the Orthomolecular Medical Society and similar groups.

Another major germanium promoter is Karl Loren, who is associated with the Life Extension Educational Service of Glendale, California, and lectures regularly at conferences where questionable health products are promoted. Loren (whose real name is Loren Troescher) graduated from Harvard Business School in 1959. He is a minister in the Church of Scientology and, until recently, hosted a talk show on KIEV cable radio. He was fired from the show for promoting the dubious cancer therapy administered in Tijuana, Mexico, by James Keller—who is wanted by the FBI in connection with similar activities in Texas [see NF 2:36].

The competition for germanium sales among the various manufacturers is, to put it mildly, fierce. All claim their own products are extremely pure and that competitors' products may be adulterated or contaminated with toxic substances. Levine and Global have even filed suit against Loren because they objected to his implication that their products may be contaminated and of questionable origin.

Another book promoting germanium is *Germanium, A New Approach to Immunity*, by Betty Kamen, Ph.D. The book's back cover includes a testimonial from Michael Rosenbaum, M.D., president of the Orthomolecular Medical Society and board member of GINA. Kamen, whose Ph.D. in nutrition education was obtained at Columbia University, speaks at health food industry conventions and writes for several health food magazines. Her book on germanium calls oxygen "Vitamin O: the oxygen nutrient," and says it fits the definition of a vitamin because it is a substance found in food that is necessary for life but not usually manufactured by your body. This, of course, is not the proper definition of a vitamin. Kamen says that complex carbohydrates are the foods highest in oxygen, and that since we eat too few of these, we are often deficient in cellular oxygen. She also says that since water contains 85% oxygen, older people should drink more of it if they want to live longer.

Kamen calls germanium an "adaptogen," which she defines as a nontoxic, nonspecific compound that doesn't directly cure disease but enhances the body's ability to cope with any stress as needed. An adaptogen

can supposedly make low blood pressure higher, high blood pressure lower, normalize glucose levels, adjust cholesterol levels and correct acid/alkaline values.

Kamen also claims that external applications of germanium can be helpful. According to her book: ointment prepared with organic germanium "works wonders on skin rashes"; tablets placed on band-aids and applied to acupuncture points can relieve eyestrain, headaches and muscle soreness; women can relieve PMS by lining their underpants with the tablets; and supporters containing germanium may be the "prescription for tomorrow" for the relief of muscle pain and stress.

Kurt Donsbach, D.C., a health food industry leader, includes germanium in his unorthodox treatment of cancer patients at his Mexican clinic. He has also written a booklet about germanium that reiterates the claims of others.

Freedom of the press gives authors the right to make virtually any claim for any product. However, without FDA approval it is illegal for sellers to claim that germanium is effective against any disease. The claims by germanium manufacturers vary considerably. Whereas some make explicit therapeutic claims, others focus on purity and depend upon outside sources to make the therapeutic claims.

Natrol, a California firm that markets Germax germanium tablets, advertises that "Between six and ten million Japanese citizens use Organic Germanium. THEY CAN'T ALL BE WRONG. Twenty-seven Japanese hospitals, clinics and universities are currently researching Organic Germanium. Studies already conducted show an amazing versatility: 1) reduces chronic arthritis; 2) restores sexual function; 3) heals burns without scarring; 4) improves circulatory disorders; 5) oxygenates cells; 6) stimulates energy level."

Futurebiotics, of Brattleboro, Vermont, has advertised that germanium strengthens immune protection, restores and improves energy, promotes interferon production, fights "blues" and "blahs," and enhances total well-being. Its most notable such ad appeared in the July 21, 1987 issue of the tabloid newspaper *Globe*, which also contained an article headlined "Miracle health pill banishes pain and combats all ills." The ad contained a coupon offering a \$1 per bottle discount on Futurebiotics germanium products at any health food store. A few weeks before the ad appeared, the company contacted retailers by mail and telephone to suggest that they stock up.

Recently I purchased a bottle of Ultra Plan Germanium Immune Complex tablets, "certified natural" by Hi Health, the Scottsdale, Arizona health food chain for which they were "exclusively formulated." These contain GeOxy-132™. The label recommends "one tablet a day as a food supplement." Although the label makes no claims, the product's name suggests that it helps the

immune system, and literature I picked up at a Hi Health store reiterated many of Asai's claims. The pills also contain vitamins A, E and C, and selenium in a base of garlic, watercress and ginseng. Garlic and ginseng are herbs identified by Asai as high in natural organic germanium.

The Vitamin Shoppe, a New Jersey-based mail-order discount house that carries Nutri-Cology products, states in its current catalogue that, "Reports from the medical community indicate that germanium . . . has broad clinical applications . . . and appears to promote immune function by the dose-dependent stimulation of gamma interferon. It is non-toxic, and, individuals are encouraged to experiment with dosages in order to determine their own optimal protocol."

The most subtle promotion I have seen is in GNC's mail-order catalogue, which merely suggests that you may not be getting enough in your diet: "You've read about it . . . now germanium is available to you from General Nutrition . . . It is found very sparingly in the foods we eat. Order your germanium today!"

Profit potential

Currently, large quantities (e.g., 100 kg) wholesale for as little as \$2/gram, down about half since a year ago. Smaller quantities run about \$4/gram. The retail prices of tablets, which contain 5, 10, 25, 100 or 150mg, vary considerably from company to company. Most sell in the range of \$15 to \$66 per gram, but Nutri-Cology sells "sublingual tabs" containing 25 mg of pure germanium for \$10.25 each, which is \$410/gram.

One sublingual tablet per month would not be particularly expensive, but suggested dosages vary. The lowest recommended dose I have found is 10 mg a day for Ultra Plan Germanium. But, as Loren points out, small doses are not in keeping with Asai's (or other major promoters') recommendations. In fact, Asai regularly recommended 100 to 500 mg/day for many conditions. Moreover, clinical trials of efficacy for some conditions require doses of 30 mg/kg body weight per day. A 70-kg (154-pound) adult undergoing such a treatment would require 2.1 grams of germanium a day. Even using Nutri-Cology's 1-gram powders at \$5.75 each, treatment would cost over \$12 a day for an indefinite period of time for a regimen previously tested only in mice.

I doubt whether most health food faddists would spend this kind of money on "food supplements" recommended at a health food store or by an ad. However, some who consult "orthomolecular" doctors might be more willing to follow their advice to take large quantities of germanium.

FDA action

On June 28, 1988, the FDA determined the germanium products from Japan were entering the United

States illegally and issued an Import Alert stating that they were unapproved food additives and "new drugs" for which no new drug application had been filed. Specific products mentioned were Germanium Sesquioxide, Organic Germanium, Ge-132 and GeOxy-132. The notice pointed out that these products were being "repacked as health foods or as over-the-counter drugs with claims for use in severe medical conditions such as AIDS and cancer." The notice also referred to literature that "promotes germanium products for use in treating or preventing serious disease conditions under the following names: Germanium, Organic germanium sesquioxide, Pro-Oxygen, Immune Multiple, GeOxy-132, Vitamin O, Nutrigel 132, and Germax."

According to the FDA Alert, germanium products will no longer be allowed into the United States

unless they are genuinely intended for use in the semiconductor industry. It remains to be seen whether the FDA will stop the illegal marketing of organic germanium products produced within the United States.

Curiously, if scientific tests ever prove germanium useful for treating a human disease, germanium products would probably become prescription drugs that the health food industry could not legally sell to the public.

Dr. Lowell, who has graduate degrees in botany and genetics, is Professor of Life Sciences at Pima Community College in Tucson, Arizona, and is vice-president of the National Council Against Health Fraud. His recently revised book, *Health Hoaxes and Hazards*, is available for \$13.50 from the Nutrition Information Center, 255 N. Granada, #2058, Tucson, AZ 85701.

BRIEFS

Victor Herbert honored. The American Dietetic Association has awarded honorary membership to Victor Herbert, M.D., J.D., for "outstanding contributions to nutrition research" and "tireless and selfless dedication to stopping the proliferation of nutrition fraud."

Bogus nutritionist fined. Gary Pace has agreed to pay \$12,000 in penalties and costs and \$20,000 in restitution to settle charges brought by New York State Attorney General Robert Abrams that he had induced hundreds of clients to pay for "improper physical examinations, worthless laboratory tests, bogus nutrition advice, and unnecessary vitamin, mineral and herbal supplements." Pace had represented himself as a doctor, based on a "Ph.D. degree" in nutrition from Donsbach University, an unaccredited correspondence school [see NF 2:70-71, 4:24]. In December 1985, a state court permanently enjoined Pace from doing further "nutritional counseling" unless he obtained proper credentials or posted a \$150,000 bond.

Public concern about food safety. The Food Marketing Institute's sixth annual survey of consumer attitudes involved interviews with 1,019 shoppers. When asked what factors were "very important" when shopping for foods, they listed taste (88%), safety (83%), nutrition (72%), price (65%), storability (51%), and ease of preparation (39%). However, many of the safety concerns were unjustified: 75% of those interviewed considered pesticides and antibiotics to be "serious hazards," 61% felt that way about antibiotics and hormones in poultry and livestock, and 43% felt that way about irradiated foods.

Notable quote. When syndicated columnist Ann Landers was asked whether a new "diet pill" could cause people to lose fat while they sleep, she replied, "If it worked, you would be reading about it in the headlines of every newspaper in the country."

Coolers blasted. An article in the Center for Science in the Public Interest's August 1988 *Nutrition Action Healthletter* has charged that coolers are a threat to children and adolescents and will add to the nationwide problem of alcohol abuse. Although coolers average 6% alcohol by volume (beer averages 4% and most table wines range from 10% to 14%), their alcohol content is deemphasized in marketing. The marketing of coolers conveys a "healthful" image with added sex appeal. They are packaged to resemble sodas or juices, may not have an alcohol taste, are inexpensive, and in many states are sold in groceries and general merchandise stores where youngsters can obtain them easily. The article suggests: 1) coolers should be sold only with other alcoholic beverages; 2) the federal government should help schools mount educational campaigns to warn young people that coolers contain more alcohol than beer and most table wines; 3) cooler labels should clearly indicate that they are alcoholic beverages and should not be sold to anyone under age 21; 4) alcohol content in coolers should be limited to 2-3%; 5) warnings about alcohol abuse and information about calorie, ingredient and alcohol content should be required on all the labels of *all* alcoholic beverages, not just coolers; 6) excise taxes on alcoholic beverages should be raised; and 7) the media should be required to give equal time and space for health messages to balance alcohol ads.

Beech-Nut officers sentenced. Niels J. Hoyvald, former president and chief executive, and John F. Lavery, vice president of manufacturing of Beech-Nut Nutrition Corp., have each been sentenced to a year and a day in jail and fined \$100,000 for their roles marketing a beverage falsely labeled "apple juice." So far the company has been assessed nearly \$10 million in federal and state fines for making the imitation mixture, labeling it as pure apple juice, and selling it in 19 states and several foreign countries between 1978 and 1983 [see NF 3:91]. The \$2 million federal fine is by far the largest ever paid under the Food, Drug, and Cosmetic Act. Additional charges against the company are pending.

Licensing update. Since 1982, laws to regulate nutritionists have been passed in 21 states, Puerto Rico and the District of Columbia. Some make it illegal for unqualified persons to call themselves dietitians and/or nutritionists, while others define nutrition practice and who is eligible to do it.

Chiropractors and supplements. Seventy-four percent of chiropractors who responded to a survey by *Dynamic Chiropractic* (a newspaper sent free to all chiropractors) reported using nutritional supplements in their practice. The survey was conducted by inviting readers to complete a questionnaire printed in the newspaper. The editor reported that "6% of the 41,000+ DCs in the USA" had responded.

Egg caution. Scientists from the U.S. Centers for Disease Control have reported outbreaks of Salmonella food poisoning traced to the use of Grade A eggs or foods containing them. After sampling eggs from four egg-producing areas of the country, they found contamination in eggs produced in the Northeast. The U.S. Department of Agriculture is now investigating whether the eggs are contaminated before or after laying. In the April 8, 1988 *Journal of the American Medical Association*, the CDC scientists caution consumers to avoid raw or lightly cooked eggs and products made from them, such as Caesar salad, hollandaise sauce, and homemade ice cream. To be on the safe side, eggs should be boiled for seven minutes, poached for five, or fried for three on each side, until the yolk is not runny and the white is firm. Symptoms of Salmonella poisoning include abdominal cramps, diarrhea, fever, and sometimes nausea and vomiting. The symptoms which usually begin 5-72 hours after eating contaminated food and last from 24 hours to several days. There is greater risk of serious or even death in infants, the elderly, and the chronically ill.

Revici placed on probation. New York State authorities have revoked the medical license of 92-year-old Emanuel Revici, M.D., a physician who has claimed to be able to treat cancer and AIDS with "nutritional" methods. However, the revocation was stayed and Revici was placed on five years' probation on condition that he shall not treat patients for cancer unless: 1) the diagnosis was made by a physician unaffiliated with Revici; 2) before signing a consent form, the patients are urged to consult a board-certified cancer specialist and a psychiatrist or psychologist; 3) patients are informed that Revici's treatment approach is not sanctioned by the medical mainstream; and 4) patient records are available for inspection by employees of the New York State Department of Health's Office of Professional Medical Conduct. Revici is also forbidden to dissuade any patient from seeking other treatment elsewhere or using any treatment that is illegal.

Recipes modified. The Iowa Affiliate of the American Heart Association has published *The Healthy Holiday Cookbook*, a 127-page "collection of traditional holiday recipes modified to reduce the sodium, fat and sugar in our festive diets." The book briefly discusses dietary guidelines and contains 70 recipes with information on their carbohydrate, fat, protein, sodium and caloric content, and diabetic exchanges. Copies are available for \$7 from the American Heart Association, Iowa Affiliate, 1111 Office Park Road, West Des Moines, IA 50265.

Garlic/black seed product seized. On June 29, 1988, the FDA filed a seizure action charging that Conigar capsules, sold by Wellness Products, Inc., of Lewisville, Texas, were misbranded by claims of effectiveness against cancer and AIDS. Ads for Conigar had depicted newspaper articles with such headlines as "Eating Garlic May Save Your Life," "Scientist Finds Basis for Folklore's Claim that Garlic Can Prevent Cancer," "Garlic Can Fight Cancer," and "Use of black seed in fight against cancer, AIDS probed." The ads also contained an endorsement by A. Elkadi, M.D., medical director of the Akbar Clinic, Panama City, Florida, and pictured a Conigar bottle labeled "Clinically Approved by the Akbar Clinic." The advertised price was \$28.50 for 200 capsules—a month's supply. [According to *Third Opinion*, a recently published directory of "alternative therapy centers," the Akbar Clinic offers "a unique, comprehensive nontoxic metabolic therapy program designed to enhance or restore the body's immune system." The program is said to include "nutritional adjustment; nutritional supplementation with certain vitamins, minerals and enzymes; several natural immune enhancers; acupuncture; hyperpyrexia (fever therapy); bio-feedback; counselling; exercise; and focus on chronic infections."]

DEMAND GROWS FOR ANASAZI BEANS

Stephen M. Voynick

The Anasazi bean, a "heritage" variety of the common bean *Phaseolus vulgaris*, is carving a modest but growing niche in the dried bean market traditionally dominated by pinto, kidney, black and white beans. The reasons Anasazi beans are becoming increasingly popular are that they taste sweeter, take much less time to cook, and may not cause flatulence, the common problem associated with other dried beans.

Anasazi beans are as versatile in the kitchen as are the more familiar types and are only slightly more expensive. They are the size and shape of pinto beans, but have a distinctive, mottled purple-white coloration. The mottling of the skin is due to an anthocyanin pigment.

Beans are actually the seeds of certain legumes. Because of ease of cultivation and storage, low cost, acceptable taste, high nutritional value and cooking versatility, dried beans have been dietary staples since antiquity. Dried beans are high in protein and complex carbohydrates and contain little sodium or saturated fat. They are good sources of iron, thiamin, riboflavin, niacin, potassium, phosphorus and fiber.

AmerIndian cultures of Mexico have grown common bean varieties for at least 5,000 years. The Anasazi Indians of the American Southwest began cultivating the variety now named for them about 130 A.D. Cultivation continued until the Anasazis mysteriously vanished about 1200 A.D. Anthropologists believe the bean contributed to the longevity of the Anasazi culture.

The bean survived in the wild in the Four Corners region and was finally "rediscovered" near Indian ruins by white homesteaders in about 1900. In 1956, botanists excavated and identified the bean in numerous ruins of Mesa Verde National Park near Durango, Colorado. Believing the beans might have commercial potential, entrepreneurs Ernie Waller and Bruce Riddell founded the Adobe Milling Company, Inc., in Dove Creek, Colorado, in 1983. After collecting seed beans from Indian ruins and the gardens of long-time local residents, they planted the first commercial crop.

First-year sales totaled only 846 pounds, mostly to local or regional customers; lesser amounts were purchased by tourists as novelty or gift items. In 1985, as annual sales jumped to 37,000 pounds, mail from consumers revealed what may become a major selling point: Anasazis seem to produce relatively little "gas" when eaten.

Anasazi beans share the general nutritional composition of pinto and other dried beans, which, when

raw and dried, contain approximately 22% protein, 64% carbohydrate, 1% fat, and 11% moisture, with the remaining 2% composed of ash, fiber and minerals. However, significant differences have been found in their carbohydrate makeup. Anasazis contain about 30% more sucrose, fructose and glucose than do pintos, which accounts for their sweeter taste.

More important, the amounts of raffinose, stachyose and verbascose in Anasazi beans are only about 20% of those found in pinto beans. Joseph A. Maga, Ph.D., Director of the Food Research and Development Center at Colorado State University's Department of Food Science and Human Nutrition, notes that these sugars are the main causes of flatulence from dried beans. He emphasizes that their presence in Anasazi beans would still cause distress in some individuals and that the minimum level required to cause distress in the general population is not known. Nevertheless, he believes that Anasazis should generally cause less "gas" than pintos.

In 1987, Waller and Riddell trademarked the name "Anasazi beans" and sales reached 350,000 pounds. Thanks mainly to word-of-mouth promotion by satisfied consumers, 1988 sales are projected to exceed 1 million pounds. While the sharp increase is impressive, the current level hardly compares with that of the better-known dried beans. Americans annually consume about 500 million pounds of pinto beans alone.

The Adobe Milling Company, the only commercial source of Anasazi beans, now has 500 acres under cultivation near Dove Creek, Colorado. The high elevation (7,000 feet) and semi-arid climate (12-inch annual rainfall) allow the beans to be produced without chemical protection—which means they can be grown "organically." Yet few Anasazi beans are sold through "health" or "natural" food outlets. Most are sold through a limited retailer network in the Southwest or by mail order with United Parcel Service delivery to 44 states. (A 10-pound bag of Anasazis costs \$6.00 plus \$3.00 to \$6.50 for shipping and handling.) Recently, several western supermarket chains have begun stocking the beans.

Additional information can be obtained from Adobe Milling Company, P.O. Box 596, Dove Creek, Colorado 81324.

Mr. Voynick, a freelance writer who resides in Leadville, Colorado, majored in food technology at Rutgers University.

THE MANNER SEMINAR

Jeff South

Several months ago, Harold W. Manner, Ph.D., a former biology professor who directed a laetrile clinic in Tijuana, Mexico, was still recruiting patients desperate for cure and "alternative" health practitioners hungry for profits. On June 25-26, Manner spoke in Irving, Texas, hoping to expand his network of "qualified metabolic physicians," which he said included nearly 600 practitioners in the U.S. and several foreign countries. At a hotel near the Dallas-Fort Worth International Airport, the 63-year-old Manner touted his "break-throughs" both in treating diseases and in billing insurers. About 30 people attended the seminar, most of them chiropractors and naturopaths, from as far away as North Carolina and Oregon.

The seminar resembled a medicine show, with a bit of a pop-psychology thrown in. At one point the Manner Clinic psychologist dimmed the lights, played "When You Wish Upon A Star," and said that positive thinking is crucial to curing cancer. But a recurring theme was money. The clinic was making lots of it, and those attending the seminar were invited to share in this windfall. The silver-haired Manner, who resembled actor Jason Robards, promised them a \$200 "consulting fee" for each patient they referred to his clinic. That's just the beginning, he said, of an arrangement that "can substantially increase your annual income."

From the start, Manner admitted his treatment program was unconventional. He called it "metabolic therapy," which he defined as the use of natural food products and vitamins to prevent and treat disease by building a strong immune system.

Manner's background

Manner was born in 1925 in New York and grew up in rural New Jersey. He received his bachelor's degree in science from John Carroll University in 1949, a master of science degree from Northwestern in 1950, and a doctorate in biology from Northwestern in 1952. He taught biology at Utica College of Syracuse University, serving as chairman of the division of science and

mathematics from 1963 to 1969, and then chaired the biology department at St. Louis University until 1972. From 1972 to 1978, Manner was chairman of the biology department at Loyola University in Chicago. He continued to teach biology there until 1982, when he resigned under pressure from the school for his unconventional theories.

Manner established the Metabolic Research Foundation in Glenview, Illinois, in 1979, with himself as president, but later moved it to San Ysidro, California, across the border from Tijuana. He used to conduct four seminars a year, but now holds only two. Before teaming up with the Tijuana clinic, he operated another facility, the Emerald Isle Clinic, in Montserrat, West Indies.

"It is not a copper bracelet," Manner said of his treatment program. "It is good, solid science . . . I am an orthodox scientist. I use the scientific method." But on "God Still Loves Me," one of his instructional tapes, Manner says his theories are the product of divine inspiration. He said he would lie in bed at night pondering the problems of cancer and other diseases. "That beautiful Father in heaven would give me the answer. We'd try it, and it would work. Every part of our therapy comes from God's teachings." Even the use of laetrile is suggested in the Bible, Manner said.

On the tape, he calls himself a born-again Christian. Newspapers have quoted him saying he found religion in 1968 after years as an agnostic. He says his parents were Sunday school teachers and that evangelist Jimmy Swaggart converted him. He also says that fellow professors ridiculed him for carrying a Bible, preaching the gospel and other religious practices: "My fellow faculty members used to laugh at me because before examinations, I would pray with my students."

Manner's enterprises

The clinic and the Metabolic Research Foundation have been as enterprising in their financial affairs as in their pseudomedical procedures. The clinic rakes

in about \$1.5 million a year from insurance claims and an undisclosed amount in direct payments from patients, according to Manner's consultants. Additional income comes from book and vitamin sales and seminar and membership fees.

The Texas workshop cost \$200 in advance or \$250 at the door. Concessionaires offered cookbooks (Manner preaches the importance of diet); books on various cancer therapies, including *The Death of Cancer* and several others written by Manner; and tables of vitamins, mineral orotates, enzymes and other concoctions retailed by Manner Metabolic Products Inc. for as much as \$192.50 per bottle.

A flyer for the seminar promised instruction on how to recoup the cost of the seminar tenfold by becoming a "paid consultant" to the Manner Clinic. The participants received three tapes on Manner's treatment methods and religious beliefs. They also received several newsletters, brochures, and even a certificate that they had "successfully completed the Advanced Course in Metabolic Therapy," which Manner said might be useful in claiming educational credits. During the workshop and in subsequent mailings, participants were urged to order additional items, including audiotapes of the sessions (\$50) and a videocassette of the Foundation's 1987 meeting in Pennsylvania (\$23).

The bulk of the Manner organization's income comes from the Tijuana clinic, which can house up to 44 patients at a time. Manner's Metabolic Research Foundation became affiliated with the facility in 1982, when it was called the Cydel Clinic, according to its owner, Sergio del Rio. By offering Manner's therapies, "we began to see improvements in our patients which in many cases bordered on the miraculous," del Rio said. But he became worried after Manner "expressed concern that once he left us through retirement or death, everything he had worked for would be lost and forgotten." Vowing that "this would never happen," Cydel officials provided a laboratory for Manner; and on June 1, 1984, the Cydel Clinic was renamed in his honor. "In this way, patients far into the future will know that there is a Manner Clinic where the Manner therapies are practiced," del Rio said in a statement circulated at the seminar.

The clinic brochure calls the Manner Clinic the "World leader in disease prevention" and promises treatment based on "the latest scientific and medical information." Clinic employees meet patients at the San Diego airport and take them in a white van across the border into Mexico. Patients do not need passports, but are asked to bring their medical records.

The cancer, arthritis and multiple sclerosis programs each last 21 days. The cancer program costs \$7,500; the arthritis program, \$5,500; and the multiple sclerosis program, \$7,250. In addition, the clinic offers a 7-day "prevention program" for \$1,600 and a 7-day "cellular therapy" program in which the cells from unborn

or very young sheep are injected into patients to "reverse the aging process." The cellular therapy program costs \$3,500 if used alone, \$1,300 if taken simultaneously with another program, or \$2,750 to former clinic patients who return for it.

"While the U.S. health care delivery costs have been rising rapidly, our charges at the Manner Clinic have never risen over \$7,500 for the complete 21-day program including room and board," Manner said. He said the clinic has served about 4,000 patients and operates at capacity, with about a 2-week waiting list.

The clinic asks that payment be made in dollars or by credit card. "Due to international clearance problems, personal checks are not accepted," the brochure says. However, it urges prospective patients to "obtain insurance forms from your agent. We will assist in their completion. Most insurance companies will honor your claims." But he warns patients not to ask their company whether they are covered for his treatment. "All they have to do is call up and say, 'I'm thinking of going down to the Manner Clinic for laetrile . . . A flag is going to come up and that person will never get it.'" Instead, Manner refers them to the company that does his clinic's billings.

Creative billing

The clinic has retained a Houston-based firm, North American Health Insurance Coordinators Inc., to file the insurance claims. "It has been a godsend for us," Manner said, noting that without insurance coverage, many patients would be unable to stay at the clinic. "We get complete coverage for our patients from most insurance companies," he said. Some insurance firms pay even for the patients' airfare to and from San Diego and for the costs of their accompanying spouses, he said.

North American Health Insurance Coordinators Inc. "specializes in filing insurance claims for alternative health care," said Ronnie King, the company's claims supervisor. The firm files for several Mexican clinics, including Ernesto Contreras' Del Mar Medical Center in Tijuana, as well as some clinics in the United States, Germany and Greece. When claims are denied, King said, he routinely appeals "over and over, whatever's necessary to get the claim paid . . . everything short of litigation." The result: The company recovers at

Application to mail at second class postage rates is pending at Philadelphia, PA. SUBSCRIPTION RATES: \$25/yr., \$45/2 yrs., \$67.50/3 yrs., prepaid; VISA and Mastercard acceptable; foreign postage by airmail add \$10.00. Manuscripts, books for review, and other editorial correspondence should be sent to Dr. Stephen Barrett, P.O. Box 1747, Allentown, PA 18105. Correspondence concerning subscription, fulfillment and change of address should be sent to the GEORGE F. STICKLEY COMPANY.

least 90% of the clinics' charges and nearly all the claims it files on its behalf, King said.

"We recover \$100,000 to \$160,000 a month for the Manner Clinic," he told the seminar. "It's not so much what is on the claim as how it is presented." For example, on claim forms he refers to the facility as the Cydel Hospital; and for live cell therapy, "we list it as therapeutic injections," he said. The key is using the proper form from the American Medical Association and the right codes, King said. His company has succeeded in getting payments not only from insurers, including Blue Cross of Southern California, but also from some government programs, he said. Manner said his clinic has "a Blue Cross provider number, which gives us clearance right straight across the United States" and that the Canadian Medicare program has paid for Canadians treated at the clinic. Although U.S. Medicare refuses to pay for treatment outside the United States, many people have secondary health insurance that may have to pay when Medicare doesn't, King said. His company also seeks reimbursement for the supplements prescribed by the clinic, King stated. Manner said that patients are sent back to the United States with laetrile, vitamins and other medication, and the clinic prepares the forms required to export the products.

King said he frequently can persuade insurers to cover unconventional treatments by explaining that the patients have exhausted the standard therapies. He also stresses that the Tijuana clinics' fees are much lower than standard hospital bills. King said his service "opens new avenues to patients who never thought they could receive alternative treatment because they didn't think they could afford it."

In a solicitation to patients, King's company says: "We will prepare a standardized claim from the information provided by your doctor's office, using the numerical coding and terminology specific to your treatment. We will mail the claim to your insurance company and follow up on it with telephone calls to ensure it has been received and is being processed. Most claims are paid within 3-4 weeks . . . Out-of-pocket expenses such as travel, hotel, etc., may also be covered by your insurance policy. If so, we will file a claim for these after payment has been made for your medical treatment."

The company charges 16% of the amount it recovers. "If your insurance carrier denies payment after we have done everything possible to collect for you, you will owe us nothing," the solicitation says. But the Manner Clinic does not let the company's fees cut into its revenues. When billing insurers, Manner said, "We take that 16% and add it as administrative costs."

Manner's network

The clinic maintains a steady stream of referrals from its associates throughout the United States and other countries, Manner said. Chiropractors and other

health care providers can become associates by joining the Metabolic Research Foundation for \$100 (or \$25 after attending a Manner seminar). Manner said he realizes that associates lose money when they refer patients. "It's going to cost you money . . . It's not fair to you." So for every referral, "we'll automatically send you a check for \$200." And when the clinic discharges patients, it sends them back to its associates for follow-up. "What you charge, how many times you want to see the patient, that's your decision," Manner said.

He asks that the associates continue prescribing the supplements given at the clinic. This is another source of income for the associates, who can buy products from Manner Metabolic Products Inc. and resell them to patients at a 100% profit.

The associates have a symbiotic relationship with the clinic, Manner said. He said the clinic provides free advice to participating physicians. Manner himself offered to do blood tests for associates' patients at no charge: Associates could send the blood vials to him at his home in Hollywood, Florida. "I do 30-40 pieces of blood work a night," Manner said. He said he had a toll-free telephone number and carried a beeper. "You always want to feel free to call the doctors at the clinic or me," he told the seminar participants. Associates have been invited to visit the clinic at least once a year, especially when the Metabolic Research Foundation holds its annual meeting.

Manner said the clinic and its insurance consultants were trying to get insurance companies to cover follow-up treatment by the associates. "This would also include the reimbursement for all supplements and medications," Manner said. "Although the details of this new program have not yet been worked out, you can imagine the enthusiasm this generated in the minds of our physicians and nutritional consultants."

Besides making initial referrals, the associates can send patients back to the clinic for what Manner described as a "booster shot" of his intravenous cocktail. So if their patients' health appears to decline during the follow-up care, "you might suggest they spend another week at the clinic," Manner told the seminar participants. Patients get a discount on their return visits.

At last February's annual meeting of the Metabolic Foundation, members were welcomed by Francisco Diaz Martinez, chief of medical services for Tijuana. He stated "how proud the Mexican government was to have our clinic located in Tijuana," Manner recalled in a subsequent newsletter. "He also promised the continued support of the government and the health department. I wondered, as he was speaking, if we ever will be afforded the same hospitality by our own government and the health departments in the United States."

Manner was painfully aware of how the U.S. medical establishment views him. On March 12, he wrote a letter to U.S. Rep. Morris Udall, who chairs

Congress' Technology Assessment Board. "One of my concerns is that the U.S. medical and scientific community has not had the opportunity to read about or explore the work that I and the physician members of the Foundation have accomplished in the area of nutritional metabolic therapy," the letter states. "This metabolic therapy is not patented and could be administered by every primary care physician in even the smallest communities in the United States. I am asking your help in getting the Office of Technology Assessment to develop a clinical protocol that is identical to what we use in Tijuana, Mexico. It is imperative that a clinical protocol be released by OTA, so that our health professionals can begin immediately to implement human clinical trials."

Manner contends that the "American Cancer Industry" has tried to suppress his accomplishments. "I was and still am a respected scientist," he said in his letter. But after advocating metabolic therapy, "I was immediately branded as a 'quack' by the United States cancer establishment."

Manner's theories

At the Texas seminar, Manner frequently cited the work of John Beard, who published a book on the enzyme treatment of cancer in London in 1911, and of Ernst T. Krebs Sr. and his son, Ernst Jr., who embraced Beard's ideas and advocated laetrile therapy. Manner said that when he began using laetrile in his research, he was skeptical, but in 1977 he announced he had cured cancer in mice with injections of laetrile, vitamin A, and enzymes. A chiropractic journal published this research and Manner touted his results through press conferences and public lectures. In a 1978 interview in *Mother Earth News*, Manner claimed he had been harassed by the FDA and that he had stored copies of 17 patient records "in a locked bank vault in Canada . . . known only to me and a few friends. When I have 100 of these files, I'm hoping to put them in a package, to take them to Washington, D.C., and I think the whole laetrile controversy will be over." However, the alleged files and Manner's intent to send them to Washington were not mentioned again in any of the dozens of subsequently published materials distributed at the Texas seminar.

Manner has given contradictory opinions of conventional treatment for cancer and other diseases. One of his brochures says, "The cancer patient should not exclude from consideration other forms of cancer therapy such as radiation, chemotherapy and surgery. Fortunately, the nature of metabolic therapy permits its use in conjunction with conventional therapy." But at the seminar, he bitterly attacked standard therapies as ineffective and dangerous. Manner's claimed success rates for cancer were also contradictory. On a tape recording, he said 74% of the clinic's patients "will never have to worry about that cancer again." But a brochure refers to "a success factor of 68%," with success defined

as elimination of either the cancer or its threat to life.

Manner claimed that in recent years a significant reassessment of the nature and causes of cancer has taken place: "Cancer was formerly believed to be a localized disease, characterized by a lesion, usually in the form of a growth, which appeared at some specific part of the body. This localized lesion was thought to be the result of activity produced by an invading virus, carcinogenic agent, or some form of trauma such as a blow. Today, there is a growing conviction among researchers and physicians that cancer is a complex disease that is the end result of a disturbed metabolism (body chemistry) . . . The frequent recurrence of a malignancy after treatment with the conventional methods of surgery, radiation and/or chemotherapy results because the basic underlying metabolic cause of the cancer is rarely considered and consequently remains uncorrected."

The human body is under constant bombardment by carcinogenic chemicals in our food, water and air, Manner said. "Each day, in every human being, large numbers of normal embryonic cells become cancerous." Fortunately, he added, most people have an immune system strong enough to neutralize or destroy the cancerous cells. "If the immune system, however, is weakened from poor nutrition, excessive environmental pollutants or a continuing debilitating stress, the cancer cells are uninhibited and will multiply rapidly, forming the symptomatic 'growth' of cancer," Manner contended. "One of the primary objectives of all metabolic therapy is to revitalize the body's immune system, to restore it to a fully functional condition . . . We can remain healthy if we supply the individual cells of the body with the proper amounts of oxygen, nutrients, enzymes, minerals, amino acids and other essential nutrients from both our diet and nutritional supplements. Of equal importance is the ability of the body to eliminate the waste products of cellular metabolism through proper bowel movements, efficient breathing, normal excretion, etc. Treatments must be provided which will help the body detoxify itself by eliminating harmful pollutants."

Conventional treatments, such as radiation and chemotherapy, cause a "complete depression of the immune system" and can "turn a normal person into a zombie," Manner said. "You don't depress the system you need to fight a disease, and that's exactly what they're doing."

Cancer treatment at the Manner Clinic

Manner said his patients undergo a series of tests, including a blood count, a SMAC-24 and a hair analysis, which he contended "will tell us whether metals are present in deficient or excessive amounts" in the body. The SMAC-24 is a standard test, but Manner rejected the laboratory norms of the medical establishment. These represent an average for the population, and "if the population becomes sicker, the ranges become

greater," Manner said. Therefore, he recommended that his associates use narrower "optimum" ranges he had devised. On the basis of these tests, Manner would recommend supplements to correct supposed mineral excesses and deficiencies.

Upon entering the clinic, patients are put on a two-day juice fast. Manner also believed they must achieve two bowel movements a day; if the fast does not stimulate the bowels, patients receive an herbal laxative and a soapsuds enema. The goal is to achieve "a bowel transit time of 12 hours," The protocol for Manner's cancer therapy states: "Anything longer than this is dangerous, for it allows chemical reactions to occur in the digestive system. End products of these reactions can be carcinogenic (e.g. nitrosamines)."

Patients also receive a daily coffee enema which Manner called "a coffee retention implant": "One cup of coffee (not instant) should be brewed and allowed to cool to body temperature. It is then injected into the rectum with a rectal syringe and retained for 15-30 minutes. The caffeine-stimulated secretion of bile is an important part of the detoxification plan as it helps to restore the alkaline condition of the small intestine." At the seminar, Manner acknowledged that he had been ridiculed for advocating coffee enemas. But he said, "When we talk about a coffee implant, we're talking about something that is solid science." When patients return home, Manner recommended that they continue one or two coffee enemas a week.

Patients also receive "digestive aids" and "pancreatic enzymes" with every meal. "These compounds contain hydrochloric acid, pepsin and enterically coated pancreatic enzymes," the cancer protocol states. "This will insure the proper digestion of ingested food." Manner told the workshop, "Most patients we see do not have a good digestive system." The regimen also calls for "anti-neoplastic enzymes" to remove protective shields so the tumor can be recognized by the immune system, the protocol states. Manner added that the enzymes help remove a fibrin coat that surrounds tumors, making them vulnerable to the other components of his treatment.

One of those components is vitamin A. "This should be given in an emulsified form to minimize liver involvement," the protocol states. "Two drops of Emulsified A are given in the morning juice and two drops in the evening juice to increase the number of circulating lymphocytes. This total of four drops will give the patient 60,000 International Units daily. Every second day an additional two drops should be added morning and evening. Classical signs of vitamin A toxicity should be watched for both by the patient and the physician. If any occur, discontinue vitamin A for one week. Return after one week with a two-weeks-on, two-weeks-off routine, employing a dosage 100,000 units lower per day than that which caused the toxic reaction."

"When we first started using vitamin A, people

thought we were mad," Manner told the Texas seminar. The clinic increases patients' daily doses of vitamin A from 100,000 International Units to 1 million. "That's enough vitamin A to kill," Manner noted. "How can we ever support these massive doses of vitamin A?" Because, he answered, in its emulsified form, the vitamin A bypasses the liver and does not poison the patients.

Benjamin Wilson, M.D., a surgeon in Dallas, Oregon, who has tracked Manner's activities for many years, states that Manner is dead wrong and that these vitamin A dosages can build up to toxic levels. In 1983, Charles and Paulette Peters of Midlothian, Illinois, sued Manner, the Metabolic Research Foundation, a Texas physician and two Illinois "nutritional consultants." According to the suit, Manner advised Mrs. Peters that it was safe to give large amounts of vitamin A to her 8-year-old son Charles, Jr., who had been diagnosed as having leukemia. After taking 120,000 IU of vitamin A daily for about a year, he developed headaches, extreme sensitivity to light, severe bone pain, headaches, mental confusion and a 10-pound weight loss caused by vitamin A poisoning [see NF 1:10]. The suit was settled out-of-court for an undisclosed sum.

At the seminar, Manner said that the vitamin A stimulates production of white blood cells, which can attack the tumor. His protocol adds that "lymphocytes are stimulated by the addition of thymosine. This hormone is present in raw thymus gland." Consequently, the clinic gives patients two thymus tablets three times a day.

The buildup of white blood cells has a drawback, Manner claimed. He said it causes a change in the oxygen in the bloodstream. An atom of oxygen normally has eight electrons in its outer ring, Manner said; however, a concentration of white blood cells causes two of the electrons to be thrown out, creating what he called an oxide radical. This oxide radical also is caused by ultraviolet light, microwave ovens, color television sets, x-rays and other radiation, Manner said. "We are being constantly bombarded with these rays." The resulting oxide radicals cause arthritis, rheumatism, lupus, sickle cell anemia and other diseases, he contended. So, three tablets of superoxide dismutase (SOD) should be given to "enable the body to convert any superoxide radicals present to water and pure oxygen."

Although enzymes taken by mouth are digested and don't actually enter the body, Manner told the Texas seminar that the SOD causes the oxide radicals to combine with hydrogen in the bloodstream, forming hydrogen peroxide, which boosts the blood's oxygen level. "Cancer cells thrive on carbon dioxide and die in an atmosphere of oxygen," he said.

The next part of Manner's therapy involves vitamin C "to inhibit tumor growth," the protocol says. "Start with five grams daily and increase by one gram per day until an acute diarrhea occurs. At this point,

drop back two grams and continue at this level throughout the treatment.

The protocol then calls for administration of amygdalin (laetrile) by mouth and later intravenously in a "Manner cocktail" containing 9 grams of amygdalin, 10 cc of DMSO, and 25 grams of vitamin C over 2-3 hours. Manner claimed that in the blood the amygdalin breaks down into: glucose, which gives patients a burst of energy; benzaldehyde, which alleviates their pain; and cyanide, which he said kills just cancer cells. However, according to the American Cancer Society, laetrile is toxic and cannot attack cancer cells selectively.

Manner's approach also calls for supplementation with selenium, zinc, spleen tablets, multivitamin/mineral tablets, and numerous other products. "There is no supplement which cannot be taken safely with the aforementioned plan," the protocol says. "In fact, one should supplement twelve tablets daily of the gland or organ tissue primarily affected." The clinic also puts cancer patients on a "natural food" diet which includes 32 ounces of raw vegetable juice a day. "A juice extractor should be purchased by the patient, and most of the vegetables in the diet should be juiced," the cancer protocol says. "In this way, all of the naturally occurring enzymes, minerals and vitamins will be present."

The clinic has whirlpools and Jacuzzis. Patients take "hydrotherapy," followed by a 45-minute massage, to stimulate the lymphatic system, Manner said. He said the clinic also holds inspirational sessions for its cancer patients. "If you believe that you only have three months to live, there is no treatment," Manner said. "When we begin to think we're going to make it, the body responds." The clinic tries to convince its patients that they can beat their cancer, said Miguel Lanzagorta, the clinic psychologist, who attended the Texas seminar. "As you think, so you become," he said. He touted "the power of thought," saying, "All power comes from within."

Seminar participants also received information on the "Manner 5" program, which Manner said was intended to augment the basic program with 21 days at the clinic plus 69 days of treatment at home. Its components include laetrile, various enzymes and supplements, an "anti-viral compound in the same class of interferon," a "lysing agent . . . designed to dissolve, decompose and disintegrate cancer cells," orange capsules to add oxygen to the blood, white-and-brown "antifermentation" capsules to "keep the carbon dioxide level in the blood low," and white-and-blue "anti-fibrinator" capsules that "strip cancer cells of their protective cocoon." Although literature referred to Manner 5 as "a new program that we feel will revolutionize cancer therapy," Manner said the program has been used for about five years and that the clinic's medical director, Gilberto Alvarez, recommends it for all cancer patients.

A testimonial

One of Manner's biggest boosters has been 51-year-old Ginny Davis, of Franklin, Wisconsin, whose testimonial story was distributed at the seminar. A pathology report attached to the testimonial indicates that in April 1985, a diagnosis of "infiltrating adenocarcinoma" was made in a polyp that was removed from Ms. Davis's large intestine. According to her testimonial, the surgeon advised Ms. Davis's family doctor that part of her large intestine should be removed, but she refused and chose instead to go to the Manner Clinic.

"It was a beautiful experience," Davis said in the testimonial. "I saw so much . . . Norma, with brain tumors, had been in a wheelchair for five months—walking with a cane in two weeks. Mike, with bone cancer, had been given only two weeks before he'd be flat in bed—and things were supposed to get worse from there. Instead, in two weeks he walked around the San Diego Zoo for four hours!"

"Now it is three years later. My latest colonoscopy report reads, 'Conclusion: normal colon' by my same specialist I original saw." Davis is more than a supporter of Manner; she is also listed on a map given out at the meeting as one of 12 distributors of Manner products. [Editor's note: The average layperson looking at Ms. Davis's story would probably conclude that her surgeon had wanted to remove part of her colon because her cancer had infiltrated into the colon. But the term "infiltrating carcinoma" merely meant that the cancer had infiltrated below the surface layer of the polyp—so that removal of the polyp would very likely cure the patient. The purpose of further surgery would have been to prevent new cancers from forming. Thus it is probable that Ms. Davis had been cured of her cancer before going to the Manner clinic.]

Arthritis regimen

The Manner Clinic also offers treatment for arthritis, including rheumatoid arthritis, gout and osteoarthritis. Contrary to the assertions of conventional physicians, "there is a known cause and there is a known cure," Manner said at the Texas seminar. He claimed that arthritis occurs when trauma from a fall, sprain, or everyday wear and tear injures a joint and the body's white blood cells rush to the area to clean up the damage. These white cells produce oxide radicals, which restrict movement in the joints, Manner contended. His arthritis patients go on a two-day juice fast, receive coffee enemas, follow a mainly vegetarian diet that includes numerous minerals and enzymes, receive 600,000 IU daily of emulsified vitamin A and 15 grams of vitamin C, and take other supplements such as thyroid, adrenal and liver tablets. Patients also get a slow-drip infusion containing 25 grams of vitamin C and 10 cc of dimethyl sulfoxide (DMSO), administered daily over 2-3 hours. They also receive 5 tablets a day of superoxide

dismutase, Manner said.

This therapy, he claimed, eliminates the oxide radicals that attack the lubricating fluids in the joint. But to eliminate the inflammation and prevent recurrence of arthritis, patients must take additional supplements, which he called Homeopathic Formulas No. 1, 11, 30 and 46. Each formula comes in a 1-ounce bottle that retails for \$8. Patients are told to continue these formulas along with SOD, digestive enzymes and other supplements for at least three months after returning from the clinic, Manner said. He also recommended that DMSO be diluted 1:1 with distilled water and patted gently on affected joints. "DMSO penetrates every cell in the body," he said. "It travels into and out of synovial cavities and, in so doing, removes toxic elements which may be present."

"As soon as we eliminate the inflammation, the arthritis should be gone and out of the body for the rest of the patient's life," although ingestion of red meat can retrigger the disease, Manner said. On the arthritis tape, he says the clinic has been using this therapy since 1984 and has a success rate of more than 80%. But no data to back this up were distributed at the seminar.

Multiple sclerosis regimen

Manner said the medical establishment is in the "dark ages" about multiple sclerosis, but he believed it is caused by a virus which produces (you guessed it) oxide radicals in the blood. "The treatment plan, based on this hypothesis, is a three-fold plan," the clinic's protocol for multiple sclerosis therapy states. "First, the virus must be removed from the body. This will be accomplished by using interferon stimulants and immunoglobulins. Secondly, the superoxide radical must be removed, utilizing the dismutation reaction. Thirdly, the physiological condition of the organ systems of the body must be restored to an optimum level."

The clinic's patients with multiple sclerosis do not receive a slow-drip infusion. However, along with the fast, coffee enemas, five SOD tablets three times a day, and a diet that includes "digestive aids," the patients take: two daily tablespoons of Imu-Gen, which Manner said is a colostrum from cows and is rich in immunoglobulins; 15 grams a day of vitamin C; 60,000 IU a day of emulsified vitamin A; 9 capsules a day of Prometal, which Manner said contains octacosanol, a wheat germ oil product that assists the neuromuscular system. After the patients leave the clinic, the Imu-Gen is administered on a three-weeks-on, three-weeks-off schedule; vitamin C is reduced to 5,000 mg per day; and vitamin A is cut to 25,000 units a day.

"Within a short time, they begin to feel a change, they begin to feel stronger," Manner said. "The results in some instances are unbelievable." He said the clinic has been treating multiple sclerosis for about two years. [Editor's note: In a 1984 TV broadcast he said he had been treating multiple sclerosis and claimed a 90% success

rate. However, since most patients with multiple sclerosis undergo several spontaneous remissions, no therapy for this condition can be evaluated without long-range controlled studies. Although Manner claimed high success rates for all of the conditions he treated, I have seen no evidence that he actually kept track of how his patients did after leaving his clinic. I believe that at least some of Manner's claims were outright lies.]

The clinic also offers two one-week programs, Manner told the Texas recruits. One is a "prevention program," which he said "also is covered by all the insurance policies." The program consists basically of the first week of the cancer therapy, but laetrile is omitted from the slow-drip infusion.

Cellular therapy (live cells therapy)

In October 1986, the clinic began offering "cellular therapy," based on the research of a German professor named Niehans, Manner said. In this therapy (which is on the American Cancer Society's "unproven methods" list), cells from an unborn or very young sheep are injected into the buttocks to revitalize the body's memory, sex drive and other characteristics. Manner claimed that the therapy has also been effective in reversing arteriosclerosis, Parkinson's disease, premature menopause, impotence, bronchial asthma, chronic indigestion and a long list of other problems. "Even in cases of chronic diseases which have persisted for many years and no longer respond to conventional medication, cell therapy can be beneficial because it activates the endogenous powers of resistance and revitalizes patients," Manner said. He recommended this treatment every five years for people between age 35 and 45 and every five years for older people. "This program is so well accepted that many American insurance companies may reimburse the complete cost of your treatment," a Manner brochure says.

Because of Manner's emphasis on strengthening the body's immune system to fight disease, several participants at the seminar asked whether he intended to develop a therapy for AIDS. Not surprisingly, he said yes, he had been thinking about opening an AIDS clinic in the Caribbean. He said he had been reluctant to treat AIDS at his Tijuana clinic because the thought of rubbing shoulders with AIDS patients might drive other patients away.

Throughout his presentation, Manner exuded optimism, self-confidence, and apparent sincerity—traits that enabled him to sell his bill of goods to many people. Calls to the toll-free number (1-800-433-4962) of Manner's public relations director, Nadine Rogers, are still answered with a recorded offer of a free information packet. But Manner himself shall quack no more. On October 11, he died of a massive heart attack.

Jeff South is a reporter for the Dallas Times-Herald.

BOGUS CLAIMS FOR H₂O₂ STOPPED

A U.S. Postal Service Judicial Officer has ordered Kurt W. Donsbach, founder of DRK Supplements, and his nephew, Richard Donsbach, the apparent owner since 1985, to stop representing in mail order sales that a 35% solution of hydrogen peroxide is effective against cancer and arthritis. (The hydrogen peroxide commonly used to clean wounds is a 3% solution.) The California-based company had been selling peroxide products while Kurt Donsbach promoted their use for health purposes in publications and in lectures at health fairs throughout the U.S. According to a Postal Service news release, DRK operated booths at some of these fairs and referred prospects for treatment at a Mexican hospital administered by Kurt Donsbach.

The cease and desist order, issued July 20, 1988, forbids DRK and the Donsbachs from falsely representing that: 1) hydrogen peroxide used orally or intra-

venously is effective in preventing the onset or spread of cancer or ridding the body of cancer; 2) hydrogen peroxide used topically, orally or intravenously is effective against the pain and inflammation of arthritis; and 3) food grade (35%) hydrogen peroxide is fit for human consumption. They are also prohibited from making unsubstantiated representations that hydrogen peroxide is effective against any other condition or that any other unproven remedy is effective against cancer or arthritis.

Earlier in the case, a federal court judge had issued a temporary restraining order permitting the Postal Service to stop mail to DRK containing remittances for hydrogen peroxide sales. Without acknowledging fault, the Donsbachs then agreed to the issuance of the cease and desist order rather than contest the charges further. [For information about Kurt Donsbach's many other activities, see the October 1987 Nutrition Forum.]

BRIEFS

"Fit for Life" update. Plans have been announced to market food items, personal health products, housewares, and other "natural items" based on the notions of *Fit for Life* authors Harvey and Marilyn Diamond. The products will be developed and promoted by the Howard Marlboro Group and its subsidiary, HMG Licensing of New York City. Although the book is filled with nonsensical ideas about nutrition [see NF 3:57-59], it has sold millions of copies.

Oat bran and cholesterol. Oat bran, the ground inner husk of the grain, has become popular as a means of lowering blood cholesterol levels. After reviewing the experimental evidence, *The Medical Letter* [December 2, 1988] has concluded: 1) limited short-term data indicate that large amounts of dietary oat bran, beans and possibly other sources of soluble fiber can lower serum cholesterol concentrations, including HDL-cholesterol; 2) small amounts of soluble dietary fiber may have little or no effect on cholesterol levels; 3) long-term effectiveness and safety of eating large amounts of soluble fiber have not been established; and 4) large amounts of oat bran and other dietary fiber can cause bloating.

Misleading ad endorsed. The Council of Better Business Bureau's Children's Advertising Review Unit (CARU) has concluded that a Kellogg Company television commercial linking breakfast cereal and athletic prowess was not misleading. The commercial featured a young boy talking to the animated character, "Tony the Tiger," on a basketball court. As the commercial opens, the boy is upset because he is unable to compete with the other basketball players. "Tony" consoles him and says, "What you need is a complete breakfast including my vitamin-packed Frosted Flakes. They bring out the tiger in you." While the boy practices baskets, voice-overs sing similar messages. Later the boy is shown shooting baskets and being carried off the court by other players as a hero. CARU expressed concern that the commercial implied that eating Frosted Flakes can directly lead to becoming a champion and that the benefits are attributable to its high vitamin concentration. Kellogg responded that the commercial's principal message was to believe in yourself and that another part of the message was to eat a balanced breakfast that includes Frosted Flakes. Kellogg also claimed that the commercial encouraged children to believe that practice and self-assurance can help them achieve their goals. *Editor's note:* Since eating Frosted Flakes has nothing whatsoever to do with basketball success, I fail to see how the commercial was anything but misleading.

NUTRITION, CHOLESTEROL AND HEART DISEASE PART I: RISK FACTORS

Mark A. Kantor, Ph.D.

The National Heart, Lung, and Blood Institute is coordinating an aggressive national campaign aimed at focusing public and professional attention on blood cholesterol levels. Participants in this campaign—called the National Cholesterol Education Program (NCEP)—include the American Heart Association, the American Medical Association, and other prominent medical groups as well as organizations from business and labor. These groups estimate that one out of four adults—about 40 million Americans—have cholesterol levels high enough to warrant further evaluation and possible medical intervention.

At the heart of this campaign is the belief that large numbers of Americans are at risk for heart disease and that dietary changes can lower their risk. During 1989, *Nutrition Forum* will explore this subject with a series of articles on the relationships between coronary heart disease, blood cholesterol, and diet.

Coronary Heart Disease (CHD)

Coronary heart disease is a condition of the heart and blood vessels in which the coronary arteries—the major arteries supplying blood to the heart—become clogged with a fatty, fibrous, cholesterol-laden deposit called plaque. The build-up of plaque over time gradually thickens the artery walls and narrows the channel inside. This condition, which is the chief cause of CHD, is called atherosclerosis, a term derived from the Greek words *athere* (gruel or paste) and *skleros* (hard).

While most Americans have some degree of atherosclerosis, the disease becomes dangerous when enough plaque accumulates to impede the flow of oxygen-rich blood through the arteries. Inadequate blood supply to the heart (ischemia) can cause chest pain (angina pectoris), which typically radiates to the left shoulder or arm during physical exertion. Although angina is an early indicator of CHD, it usually doesn't occur until the passageway through a coronary artery is reduced by at least 50%.

A heart attack occurs when one or more of the coronary arteries is abruptly sealed off by a blood clot, bleeding

into an atherosclerotic plaque, or coronary artery spasm. This kind of heart attack is called a myocardial infarction. When it occurs, part of the heart muscle may die from oxygen deprivation, or the heart may undergo a severe or fatal disturbance in rhythm (arrhythmia).

In most people, the process of atherosclerosis begins during childhood when “fatty streaks”—early cholesterol deposits that are nearly ubiquitous in the American population—begin developing within the arteries. Although these streaks don't always give rise to atherosclerosis later in life, they probably are forerunners of more advanced stages of atherosclerosis.

The early stages of coronary heart disease can be difficult to detect because they produce no symptoms. In many cases, the first indication is a heart attack, which may be fatal. In others, angina with exertion provides a warning that more serious problems loom ahead. The heart can also be damaged by ischemia that occurs without symptoms. The goal of the National Cholesterol Educational Program is to prevent heart attacks by identifying and treating individuals at risk for CHD before they suffer irreversible heart damage.

The death rate from cardiovascular disease has been declining steadily in the United States, especially since 1970, but it is still the nation's leading killer. Each year, about 1.5 million Americans suffer a heart attack, resulting in close to 760,000 hospitalizations. Coronary heart disease causes more than 500,000 deaths per year—nearly one per minute. It is responsible for more deaths than all forms of cancer combined and accounts for 30% of deaths beyond age 75. The economic cost is also staggering: about \$39 billion per year, a figure that includes physician and nursing services, hospital and nursing care, medications, and lost productivity from disability.

Risk Factors

Ten major risk factors for CHD are generally recognized. Most of these are considered “controllable” because they may be reduced or eliminated through medication or changes in lifestyle. The three most important controllable risk factors are cigarette smoking, high blood pressure (hyperten-

sion), and high blood cholesterol level (hypercholesterolemia). The other principal risk factors are obesity, diabetes, lack of exercise, stress, family history CHD, being male, and increasing age.

The risk factors for CHD are cumulative: the more risks an individual has, the greater the danger of having a heart attack. For example, a person who smokes and has high blood pressure and a high blood cholesterol level is eight times as likely to develop CHD as an individual with none of these risk factors. If the blood pressure and blood cholesterol level are very high, the risk may be 20 times as high.

Blood Cholesterol

Evidence has been accumulating for nearly a century that an elevated plasma cholesterol level is a major risk factor for CHD. As early as the 1920s, scientists observed that cholesterol was a principal component of the atherosclerotic plaque in rabbits. Over the years, metabolic studies using a variety of animal species consistently have shown a link between high blood levels of cholesterol and the pathogenesis of CHD.

Much of the research in humans has focused on individuals having genetic defects in cholesterol metabolism. Patients with abnormal cholesterol or triglyceride levels provide convenient models for studying the relationships between blood lipid and lipoprotein levels and the risk of CHD. For example, about one out of a million people is afflicted with a rare genetic defect in cholesterol metabolism called "homozygous familial hypercholesterolemia." Individuals born with this disease have extremely high levels of blood cholesterol, and inevitably succumb to CHD. Sometimes their first heart attack occurs by the age of two.

Numerous epidemiological studies, including the well-publicized Framingham Heart Study, have shown that as blood cholesterol levels rise, the heart attack rate also increases, especially at levels greater than 240 milligrams per deciliter (mg/dl).

The importance of cholesterol as a risk factor is illustrated by comparing the average cholesterol levels in American and Japanese men. The typical Japanese has a cholesterol value of about 150 mg/dl, nearly 70 mg/dl lower than his American counterpart. Accordingly, the incidence of CHD in Japan is one-tenth that of the United States. Although many Japanese smoke cigarettes and have high blood pressure, these risk factors—when not accompanied by a high blood cholesterol level—do not seem to significantly increase their risk of CHD. Therefore, a certain minimum level of cholesterol in the bloodstream is probably required for CHD to develop

even when other important risk factors are present. When the Japanese migrate to Hawaii or San Francisco and adopt American eating habits, their plasma cholesterol levels typically rise, as does their incidence of CHD.

Scientists had long suspected that if the blood cholesterol level in a population could be reduced, the CHD death rate also would come down. They had no direct proof for this so-called "cholesterol hypothesis," however, because of the difficulties in designing and implementing an appropriate experiment. Conducting a long-term diet study is extremely arduous because of problems with double-blinding and compliance. To achieve statistical validity, such an experiment requires large numbers of subjects and is extremely expensive.

Despite these inherent difficulties, a large-scale clinical trial was conducted by the National Institutes of Health (NIH) between 1973 and 1982. Called the Lipid Research Clinics-Coronary Primary Prevention Trial (LRC-CPPT), it provided the strongest evidence ever obtained for the importance of lowering cholesterol. The results of this study suggested that for each 1% reduction in the blood cholesterol level, the risk of CHD was decreased by 2% [*JAMA* 251:351-374, Jan. 20, 1984].

Although considered a landmark study, the LRC-CPPT has still generated considerable controversy. Since the study was performed only in male subjects who were at high risk for CHD because they had elevated cholesterol levels to begin with, the conclusions may not be valid for women or for individuals with lower cholesterol values. Furthermore, the drug cholestyramine was used together with diet to lower cholesterol levels. Therefore, the effectiveness of diet alone in reducing the incidence of CHD is uncertain. However, NIH experts believe that the results can be extrapolated to other segments of the population and that diet alone should be valuable in reducing heart disease risk.

Despite the overall success of the LRC-CPPT, a disturbing note emerged from the study. While the trial clearly demonstrated that lowering plasma cholesterol levels helped reduce the risk of CHD, the overall death rate was similar in both the experimental and control groups. The failure for mortality to decline as the incidence of CHD decreased was troubling because this same trend has been observed in other clinical trials as well. Researchers have no good explanation for this anomaly. Nevertheless, a nationwide effort is underway to persuade Americans to become aware of their cholesterol level and to take action if it exceeds recommended guidelines.

Dr. Kantor is an assistant professor and food and nutrition specialist with the University of Maryland's Cooperative Extension Service, and a regional communicator for the Institute of Food Technologists. His postdoctoral research was in cholesterol and lipoprotein metabolism.

BOOK REVIEW

Title: Complete Guide to Vitamins, Minerals & Supplements

Author: H. Winter Griffith, M.D.

Publisher: Fisher Books, Tucson, Arizona

Price: \$9.95, softcover

Reviewed by: Stephen Barrett, M.D.

The author is a former practitioner and family practice educator who devotes most of his time to writing medical-information books for the general public. He describes himself as taking a middle ground between the traditional medical establishment that usually cries, "Eat a well balanced diet and you'll get all the nutrients you need" and people who view supplements as miracle cures. He promises "no personal opinions . . . only the consensus of the majority of experts, presented as impartially as possible."

The book covers general advice (4 pages), vitamins (53 pages), minerals (122 pages), amino acids and nucleic acids (24 pages), other supplements (29 pages), "medicinal herbs" (202 pages), toxicity ratings for herbs (19 pages). It also includes a 10-page glossary and 7 pages listing the ingredients in brand-name supplement products. For each substance, the book contains 1-3 pages listing basic information, natural sources, reasons to use, unproved speculated benefits, who needs additional amounts, deficiency symptoms, unproved speculated symptoms, lab tests to detect deficiency, dosage and usage information, warnings and precautions, overdose/toxicity, adverse reactions or side effects, and in some cases, interactions with other substances.

Although the author's views are generally aligned with the scientific community, the book is mostly composed of lists with inadequate perspective. Under "reasons to use" it lists biochemical tidbits that have little or no practical value but might inspire readers to take unnecessary supplements. For example, "restores normal function of nerve cells, heart cells, skeletal muscle cells, kidneys and stomach juice secretion" is given as a reason to use potassium bicarbonate/chloride.

The passage on vitamin E contains a long list of deficiency symptoms and recommends "additional amounts" for people over 55; but it fails to mention that vitamin E deficiency on a dietary basis has never been reported in an American adult.

Even worse, the book contains many errors which suggest that the author does not understand the fine points of many of his topics or has failed to do his homework. For example, he describes the Recommended Dietary Allowances as "average amounts needed per day to maintain good health in the average healthy person" rather than the

amounts "adequate to meet the known nutritional needs of practically all healthy people."

The publicity for the book is particularly obnoxious. An ad in *Publishers Weekly* claims that, "No other book on the market covers this subject as completely, in an appealing, easy-access format." The ad also suggests that the reading public is hungry for information on "which vitamins and minerals will prevent, cure and relieve their problems." However, such information is listed only in the sections on "unproved speculative benefits." Although the ad says the book contains 600 pages, I can find only 516, including front matter.

It is possible that with appropriate expert review the book could be transformed into a useful reference for professionals. However, I don't see how it could be made useful to the general public in its present form, even if purged of its errors.

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 22 books including *Vitamins and "Health" Foods: The Great American Hustle*.

QUESTION BOX

Q. A product called Sweet Away is being marketed with claims that it causes a large percentage of the sugar you consume from being absorbed into the body. Company literature states that the product contains *Gymnema sylvestre*, which, when chewed, will make sweet things taste sour. According to the literature, a similar process takes place in the intestine to block absorption of sugar—with possible benefit to people with diabetes, obesity, hyperactive children, alcoholism, and hypoglycemia. The product is supposed to be taken with water "so, your taste buds are not affected; but the results are, while having wonderful meals and desserts, while the effect of sugar intake into the body is considerably reduced." Are any of these claims true?

A. It has been known since 1887 that chewing the leaves of *Gymnema sylvestre* can prevent one from experiencing the taste sensation of sweetness. However, we are aware of no reliable studies showing that *Gymnema sylvestre* blocks absorption of sugar into the body.

IRIDOLOGY: DO THE EYES HAVE IT?

By C. Eugene Emery, Jr.

The eyes are sometimes called the window to the soul. We watch them to determine whether a person is sincere or lying. When we encounter people, we usually notice their eyes first. So perhaps it's not surprising that some people believe that eyes provide a window to a person's health as well.

Signs of a few diseases—most notably atherosclerosis and Wilson's disease (a disorder of copper metabolism)—can appear in the colored portion of the eye (the iris). But iridologists profess that the iris can be used to diagnose virtually any disease. They claim that examination of eye markings can reveal not only current health problems but indications of past problems. Typically, they consider themselves "holistic" and recommend dietary supplements to correct whatever problems they see.

I first heard of this practice when a local television station aired a story featuring claims by a local iridologist who, according to the TV reporter, had successfully diagnosed someone's back problems. Another iridologist, in nearby Westerly, Rhode Island, was getting coverage in the New London Day newspaper. Subsequently, I discovered that a medical doctor also was dabbling in the field. I decided to investigate.

My first stop was an interview in Westerly with Joseph M. O'Reilly, Jr., a former judo and yoga teacher who called himself a "registered nutrition consultant" and said he had a "Ph.D." in nutrition from Donsbach University (an unaccredited correspondence school). Before getting into the nutrition field, O'Reilly said, he had been a parole officer in Florida and a certified sex educator.

O'Reilly told me that iridology could detect cancer with 99% accuracy. He said the shape of the eye and pupil could reveal psychological problems and be used to determine when a person is near death. He also reported that he discourages the use of drugs because "when you put drugs in the body, it just drives the illness deeper into the tissues and cells. You're just masking the symptoms. You're not getting to the cause."

When he examined my eyes, O'Reilly saw "caffeine spots from too much coffee," but said the spots could also be caused by too much alcohol. (I never drink coffee and, at most, drink one can of beer per month.)

The iridologist featured in the TV broadcast, Rosemary Hill, also taught at a local holistic health center. During her interview, she stressed that she doesn't diagnose diseases but "reads conditions in organs that could be construed as a weakness for a disease." But if you have a heart condition, she said, it would be obvious in the eyes. She also reported that she was in the process of changing her eye color from an unhealthy brown to a healthy blue.

When Hill examined my eyes, she reported some constipation (wrong), cardiovascular problems (nope), a high mucus and acid body (I have no idea how to measure this), stress in the foot area (not that I know of) and fatigue (sorry). She did say correctly that I ate lots of dairy, flour, red meat and sugar products, but that assessment would probably fit most Americans. Next I arranged a test with the help of Dr. Robert Bahr of the Rhode Island Ophthalmological Society, who took slides of the eyes of eight people with various medical

problems, such as lung disease, headaches, deafness, and a history of cancer. When I asked Hill to match the slides to the health problem, she declined, explaining that "I don't work that way." Instead, she suggested that I try to match her readings to the slides.

Working under those rules, Hill—who had said that iridology was accurate at least 75% of the time—missed the affected organs or body parts in 6 out of 8 slides. That's surprising if you consider the fact that each of her readings included many organ systems. For example, in the case of a nearsighted person with a history of fainting and a pulse of 54 when the slide was taken, Hill noted "severe acidosis," "not digesting proteins," "intestinal tract is a little depressed," "there is a difficult lung problem there," "probably tonsils in there too," "mucus throughout the system," "congestion in the head," "not absorbing nutrients," "esophageal, leg problems," "shoulder problem" and a "somewhat spastic colon."

In the two cases where Hill named an organ or body part that actually might be related to the patient's problem, she was still quite inaccurate. In the slide of a woman with daily headaches, Hill saw "toxins from the bowel dumping into the head area" and blamed "parasites" for the problem. For a woman with hypoglycemia, Hill cited an undefined "glandular problem," but she also reported a "possible thyroid problem" and "a lot of toxins in the blood stream."

The second person to take my test was Robert S. Carson, M.D., medical consultant for the holistic health center. "You can come out with some uncanny diagnoses by looking at the iris," he said. "The scientific evidence for this is very solidly based."

Unlike Hill, Carson did attempt to match the eye slides to the medical records. Despite at least two guesses in each case, he missed the fact that one woman had had a mastectomy and hysterectomy, that another had broken both arms and a leg, that another suffered from headaches and stomach prob-

Nutrition Forum (ISSN 0748-8165) is published bimonthly by J.B. Lippincott Company, Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740. lems, and another had hypoglycemia. He correctly matched the person with severe lung disease—on his second try.

My test also included a pair of slides showing a glass eye against a black background. Although the eye had no lashes and fingerprint ridges of one of the fingers holding it up to the camera were visible, neither of the iridologists mentioned anything amiss.

Bernard Jensen, D.C., the leading American iridologist, claims to have worked with over 350,000 patients during almost 50 years of active practice. He states that "Nature has provided us with a miniature television screen showing the most remote portions of the body by way of nerve reflex responses." He also claims that iridology reveals "tissue strengths and weaknesses" as well as "nutritional and chemical needs." His booklet, *Iridology Simplified*, relates more than 30 diseases and conditions (including arthritis, biliousness, gallstones, obesity and tuberculosis) to "mineral deficiencies." It also contains an "Iridology Nutrition Chart" for determining what vitamins, minerals and herbs to give "after determining those areas of the iris which show a need."

Jensen and two other practitioners were tested in a study published in the September 28, 1979 *Journal of the American Medical Association*. In this study, the iridologists were shown iris photographs of 143 patients, some with severe kidney disease and some with no evidence of kidney problems. The assessment of kidney problems was based on the levels of creatinine in the blood. When asked to identify the people with problems, all three iridologists failed the test.

Five Dutch iridologists failed a similar test last year when they tried to detect gallbladder disease by looking at slides of the iris of 39 patients with gallstones (proven by surgery the day after the slides were made) and 39 patients without gallstones (proven by ultrasound examination). The iridologists were correct only half the time (the result expected by chance), and did not agree among themselves about which patients had gallstones and which did not [*British Medical Journal* 297:1578-1581, Dec. 17, 1988].

Iridologists use detailed charts relating the location of various eye markings to problems in various parts of the body. In 1981, the AMA Council on Scientific Affairs noted that such charts are similar in concept to those used years ago in "phrenology," the pseudoscience that related protuberances of the skull to the mental faculties and character of the individual. Russell S. Worrell, an assistant clinical professor at the School of Optometry of the University of California, Berkeley, has noted that at least 19 iridology charts exist but that all have differences in the location and interpretation of many of their iris signs.

Despite all this, iridology apparently persists for some of the same reasons psychic practices and astrology remain popular.

First, since most ailments are self-limiting, most people who consult iridologists are likely to feel better with the passage of time. So if symptoms resolve while following an iridologist's advice, the iridologist will get the credit.

Second, iridologists are probably helped by feedback from their patients, and patients often take the iridologist's musings and fit them to events in their life.

Third, many of their claims are difficult or impossible for laypersons to evaluate. Hill, for example, contended that the iris not only reveals information about your present medical problems, but can reflect past and future problems as well. Thus, if she sees a back problem in your eyes, she can claim credit whether your back bothers you now, has bothered you in the past, or bothers you in the future. She also claimed that the structure of the iris can provide information about the health of your ancestors.

But from a practical standpoint—the ability to detect virtually any disease in the iris—the eyes clearly don't have it.

Mr. Emery is a science writer for the *Providence Journal*.

NEW FDA REPORT ON PESTICIDE LEVELS IN FOODS

Data from FDA's pesticide monitoring programs indicate there is no factual basis for widespread public concern that pesticides present a health hazard in the American diet.

Three federal agencies share the responsibility for monitoring pesticide levels in foods. The Environmental Protection Agency registers or approves the use of pesticides and establishes tolerances for those whose use may lead to residues in foods. The FDA is responsible for enforcing these tolerances for foods shipped in interstate commerce, except for meat and poultry, which are the responsibility of the U.S. Department of Agriculture. A tolerance is the maximum amount of residue expected in a food when a pesticide chemical is used according to the label directions, provided that the level does not present an unacceptable health risk. In 1987, there were 320 pesticide chemicals with established food and/or feed tolerances in the United States.

According to the latest FDA report—published in November 1988—data from over 25 years of monitoring show that above-tolerance levels are rarely found and indicate that pesticide chemicals are generally used according to label directions. Some violations result from misuse, unusual weather conditions, or poor agricultural practices. However, most violations involve foods that contain small amounts of pesticides for which no tolerance has been set. For example, if a pesticide registered for use in lettuce but not cabbage is found in cabbage, any amount is illegal even though it may not present a health risk.

Under its regulatory monitoring program, the FDA collects samples from individual lots of both domestically grown and imported food and analyzes them for pesticide residues. When violative residues are found, the agency can

stop the food from being marketed.

The FDA also does a Total Diet Study (also called a Market Basket Study) designed to estimate the dietary intakes of pesticide residues for eight age/sex groups from infants to senior citizens. Industrial chemicals, heavy metals, radionuclides and essential minerals are also measured. To obtain the samples, FDA personnel purchase foods from local supermarkets or grocery stores four times a year throughout the United States. Each market basket contains 234 individual items judged through nationwide dietary surveys to represent what Americans eat. The foods are prepared for eating and then analyzed for pesticide residues. The results of these analyses are combined with data on food consumption to estimate the actual amounts of pesticide residues in foods as they are usually eaten.

During Fiscal Year 1987, the FDA's regulatory monitoring program analyzed 14,992 samples, 6,503 produced in this country and 7,989 imported from 79 other countries. Residues were found in 42% of domestic samples and 44% of imported samples, but the levels involved were usually insignificant. Fewer than 1% of the samples contained residues that exceeded regulatory limits, but 81% of these were cases in which no tolerance had been established for a specific pesticide/commodity combination. These findings were supported by the Total Diet Study data, which showed that the dietary intake of pesticide residues was only a small fraction of acceptable limits.

Free copies of the FDA's report, *Residues in Foods—1987* are available on request from Norma J. Yess, HFF-420, FDA Division of Contaminants Chemistry, 200 C St., S.W., Washington, DC 20204.

BRIEFS

What's in a name? Currently, ice cream must contain at least 10% milkfat, while ice-cream products with 2-7% milkfat must be called "ice milk." Public Voice has petitioned the FDA to create a new standard for a "lite ice cream," which would be similar to ice cream but would contain 4-6% milkfat, while the name "ice milk" would be reserved for products containing less than 4% fat. (Whole milk contains 3.25% fat). Recently, in response to a Public Voice petition, the U.S. Department of Agriculture agreed to change the name of the lower-fat "good" grade of beef to "select."

FDA regulatory activity increased. According to a recent statement by NNFA attorney Scott Bass in *Health Foods Business*, the FDA has issued more regulatory letters and made more seizures involving health food industry products during the past year than during the previous six years. These actions charge that products are misbranded or are being marketed with illegal therapeutic claims. The products have included evening primrose oil, black currant oil, fish

oils, orotates, germanium, coenzyme Q₁₀, garlic, wheat grass and superoxide dismutase (SOD).

Drinking age raised. All 50 states now require that a person be at least 21 years old before buying or consuming alcoholic beverages. The impetus for this—in some states—was passage of the National Drinking Age Act (1984), which forced state officials to meet this standard or lose federal highway funds. Figures from a 13-state survey taken between 1975 and 1982 by the National Highway Traffic Safety Administration indicate that fatal accidents involving drivers under 21 years of age fell 13% after those states raised the drinking age to 21.

"Safe food" petition. Ralph Nader, former Senator George McGovern, and Americans for Safe Food (ASF) have launched a "safe food petition drive" calling for government promotion of food grown without the use of pesticides and synthetic fertilizers. The drive seeks to gather at least

250,000 signatures by early 1989 calling for "organic food" standards, help for "organic" farmers, taxes on farm chemicals to pay for low-chemical farming, and efforts by food retailers to test food for chemicals and bacteria. ASF, a coalition of over 80 groups, is a project of the Center for Science in the Public Interest (CSPI). CSPI has also published a guide to 85 "organic food" mail-order suppliers.

"Organic" certification laws. Although "organically grown" foods are not significantly different from conventionally grown foods, eleven states have established legal criteria for "organic" foods and six additional states are considering certification laws.

True believers. The degree of irrational belief related to nutrition that people can hold is illustrated in the January 1989 issue of *Bestways* (a health food magazine). One woman described how a clinical ecologist has been treating her for four years after telling her she was "allergic to all foods." Another woman said she had started the Coalition Against Sugar Abuse to educate the public about hypoglycemia, which she had gotten because she "wasn't absorbing anything" she ate.

Naturopath arrested. Gregory E. Caplinger of Blowing Rock, North Carolina, has been charged with practicing medicine without a license. According to local press reports, Caplinger claims to be a naturopath and has framed certificates from the N.C. Board of Naturopathic Physicians (although no such board exists), the American Nutritional Medical Association, the British Guild of Drugless Practitioners, and 20 other questionable sources. Caplinger told a reporter that his clinic has been operating for about four years and has treated more than 2,000 people.

Health food group wants nutrition center. The National Nutritional Foods Association (NNFA), the major trade organization for health food manufacturers, distributors and retailers, has announced plans to press for creation of a federal agency called the National Center for Nutrition and Health. The new agency would be responsible for setting standards and protocols for research into the role of nutrition in health, including the relationship between the consumption of specific nutrients and the occurrence or non-occurrence of disease. It would also operate a clearinghouse for research, disseminate information to professionals and the general public, and present nutrition and health information to government policymakers. The idea's originator, Richard Merriam of Global Marketing Associates (a germanium distributor) believes that establishment of such a center will gain "official recognition" of the health food industry from the federal government. NNFA plans to have bills introduced into both houses of Congress on or about March 1st. It also plans to distribute samples of natural food products with a questionnaire asking Congressmen where they receive information on nutrition and health.

NNFA petition denied. On October 14, 1988, the FDA denied a petition by the National Nutritional Foods Association to end FDA's program of collection reports of adverse reactions to vitamins and minerals.

"Organic" promoter honored. Garth Youngberg has been named a recipient of a \$150,000+ MacArthur Foundation fellowship award. He is a former U.S. Department of Agriculture official who promoted organic farming when he was with the agency. Since 1981 he has been executive director of the Institute for Alternative Agriculture, a nonprofit organization established "to encourage and facilitate low-cost, resource-conserving, and environmentally sound farming methods."

Advertising rule amended. The Federal Trade Commission has voted 3-2 to amend its Food Store Advertising Rule to permit grocers to offer rainchecks or comparable substitutes when they run out of advertised items. Compliance can also be achieved by advertising that items are available only in limited quantities or only at some stores. The current rule, adopted in 1971, required grocers to stock advertised items in sufficient quantities to meet reasonably anticipated demand. The purpose of the rule is to prevent grocers from luring customers by offering bargains that are actually not available or available in such small quantities that very few customers can obtain them.

Classic text revised. The fourth edition of the college textbook *Consumer Health—A Guide to Intelligent Decisions*, by Harold Cornacchia, Ed.D., and Stephen Barrett, M.D., had just been published by Times Mirror/Mosby (St. Louis). The 570-page book contains extensive information about nutrition and nutrition quackery. The book is available for \$28.95 postpaid from LVCAHF, P.O. Box 1747-N, Allentown, PA 18105.

Vitamin scams. Consumer protection officials in several states have warned consumers to be wary of expensive-sounding "gifts" or "prizes" offered in connection with vitamin sales. The typical sales pitch begins with a letter, post card or phone call announcing that the recipient has won one of several prizes or is entitled to a gift. To actually get the award, the recipient must pay several hundreds or even thousands of dollars for vitamins, using a credit card or paying for a COD delivery. Consumers have been offered such items as \$2,500 in cash, a fur coat, a new truck, or a 1988 Cadillac Seville. However, they either receive nothing or get the vitamins plus an item that is either worthless or worth far less than the cost of the vitamins. For example, a "Yamaha electric organ" turned out to be a 12" battery-powered toy.

Vitamin production. General Nutrition Corporation's latest mail-order catalog states that the company produces more vitamins than any other organization in the world: 6 billion tablets and capsules a year.

Nasal B₁₂ seized. In October 1988, a quantity of Ener-B was seized at Nature's Bounty, Bohemia, New York, on charges that the product was being illegally marketed. The product is a vitamin B₁₂ gel administered inside the nose, from which it is absorbed into the body. It was marketed with misleading claims that B₁₂ is "hard-to-get" and that "nutritional authorities have described vitamin B₁₂ as having the ability to restore or increase energy levels." In February

1987, a few months after marketing began, the FDA notified Nature's Bounty that Ener-B is an unapproved new drug that is illegal to market without agency approval. The company, which claimed it is a food, then petitioned the FDA to issue a regulation or guideline relating to food classification and methods of consumption and to refrain from enforcement action until the matter was resolved [NF 4:61]. In May 1988, the FDA denied the petition, noting that: 1) it knew of no food that is eaten through the nose; 2) people who eat normal diets don't need B₁₂ supplementation; and 3) claims for Ener-B suggested that it was intended for use as a drug.

Super carrot. The United States Agriculture Department's Agricultural Research Service has announced development of Super Carrot, a new carrot variety which contains 3-5 times the usual amount of beta-carotene.

Vitamins and birth defects. An epidemiological study has concluded that mothers who used vitamin supplements from three months before conception through the first three months of pregnancy gave birth to fewer infants with spinal bifida and other malformations of the nervous system [*JAMA* 260:3141-3145, 1988]. However, the authors cautioned that it is not yet possible to say whether this difference is the direct result of vitamin use or the result of other characteristics (such as a more healthy life-style) of women who use multivitamins. A randomized trial to test this is under way in Great Britain. Reprints of the study can be obtained from Joseph Mulinare, M.D., Division of Birth Defects and Devel-

opmental Disabilities, Centers for Disease Control, Atlanta, GA 30333.

Diet scam snuffed. The Iowa Attorney General has secured a consent judgment which it says will lead to the return of close to one million dollars to 28,000 consumers nationwide who responded to mailings for Neutralizer G.H. diet pills. The 4-page solicitation entitled "Obesity Eliminated in 1988" had represented that the pills would cause effortless and permanent weight loss. The defendants in the case were Austral Eagle Services, Ltd., also known as Calex and Pharmacal America, a Bermuda corporation owned by Irwin Dickstein a.k.a. Rudolph Klein. The defendants must pay \$18,000 to the Attorney General's Office and are permanently enjoined from claiming: 1) Neutralizer G.H. or any similar product can eliminate dieting, calorie counting, and strenuous exercise; 2) any such product can render calories fat-free; or 3) medical science has isolated the hormones that tell your body whether to be fat or thin. The Attorney General's action was brought under the Iowa Consumer Fraud Act.

NUTRITION, CHOLESTEROL AND HEART DISEASE PART II: STRUCTURE AND FUNCTIONS OF LIPOPROTEINS

Mark A. Kantor, Ph.D.

Last issue we discussed the risk factors for coronary heart disease, one of which is the blood cholesterol level. The cholesterol level in blood plasma (the fluid part of the blood) is determined partly by heredity and partly by the overall content of the diet. Other factors such as obesity and exercise level can also play a role. This article describes what happens to cholesterol within the body.

How Cholesterol Is Packaged

Cholesterol is found only in foods of animal origin and is part of every animal cell. It is essential to life, as the body uses cholesterol to make cell membranes, hormones, and bile acids, as well as for other functions. Because cholesterol is a fat-like substance and cannot mix with water, the body wraps it into protein-containing packages that can flow smoothly throughout the blood stream. These packages are called lipoproteins.

Lipoproteins are composed of various amounts of cholesterol, triglycerides (fats), phospholipids, and special proteins called apolipoproteins or apoproteins. They have two main sections: a hydrophobic ("water-hating") inner core and a hydrophilic ("water-loving") surface coat. The inner core is composed of triglycerides and cholesterol esters (cholesterol attached to fatty acids), while the surface layer is composed of phospholipids, free cholesterol, and apoproteins.

The phospholipids, and to some extent the apoproteins, serve as "detergents," enabling lipoprotein particles to remain suspended in the blood. The apoproteins serve three other functions as well: they impart stability to the lipoproteins, assist various metabolic reactions involving lipoproteins, and direct lipoproteins to specific cells and organs.

Apoproteins are designated by letter-number names, e.g., A-I, A-II, B-48, B-100, C-I, C-II. Evidence is accumulating that the levels of certain apoproteins in the blood stream may provide a better indication of coronary heart disease (CHD) risk than the concentrations of the entire lipoproteins. Thus apo A-I and apo A-II appear to protect against CHD, while apos B-48 and B-100 increase the risk.

Plasma lipoproteins are classified according to their density, with four major types generally recognized: chylomicrons, very-low-density lipoproteins (VLDL), low-density lipoproteins (LDL), and high-density lipoproteins (HDL). A fifth category called intermediate-density lipoproteins is also acknowledged, but some researchers consider IDL to be transitional particles rather than a discrete class of lipoproteins.

The density of lipoproteins varies according to their relative proportions of triglycerides and protein. The greater the amount of triglycerides and the lower the protein content, the lower the density.

One of the remarkable features of lipoproteins is that they are not static particles. Their composition continuously changes as they gain or lose some of their surface and core components, which are not tightly bound. In fact, during the normal metabolism of lipoproteins, one type (VLDL) is actually transformed into another type through the loss of surface and core materials and the action of certain enzymes.

Chylomicrons

Chylomicrons are the largest lipoproteins and have the lowest density. They are the chief vehicles for transporting dietary fat and cholesterol from the intestine to the rest of the body. Chylomicrons are necessary not only for the normal absorption of fat and cholesterol through the small intestine, but also for the absorption of fat-soluble vitamins.

After forming in the small intestine, chylomicrons pass through the villi of the intestinal wall, enter the lymphatic system, and then enter the general circulation. The triglycerides in chylomicrons are broken down by lipoprotein lipase (LPL), an enzyme bound to capillary cells of muscle and fatty tissue. The fatty acids released by this reaction enter nearby cells, where they are either oxidized for energy or converted back to triglycerides and stored for later use.

The LPL reaction removes most of the triglycerides from chylomicrons. Some of the surface phospholipids and apoproteins are also lost as the chylomicrons shrink. The

resulting "remnant" particles, which are high in cholesterol, are taken up by the liver. There, the cholesterol is either repackaged with triglycerides into VLDL or secreted into the small intestine, usually after being converted into bile acids. Much of the cholesterol and bile acids is reabsorbed through the intestine, enters the blood stream, and is returned to the liver in a process called the enterohepatic cycle. But about 5% escapes and is excreted in the feces during each cycle. It has been hypothesized that soluble dietary fiber enhances this excretion mechanism.

Chylomicrons disappear from the blood stream soon after being formed. The number of circulating particles is halved every 5–10 minutes. Within about an hour, virtually all have disappeared. Some chylomicron remnants may persist in the circulation for up to 12 hours, but these usually make no significant contribution to an individual's total blood cholesterol level.

Very-Low-Density Lipoproteins

VLDL usually contain 10–20% of the total serum cholesterol, depending upon a person's age and gender. They are produced by the liver, using fatty acids and cholesterol as the raw materials. The triglycerides in VLDL are synthesized by the liver from dietary carbohydrate and fat, while the cholesterol normally comes from chylomicron remnants. However, if the dietary intake of cholesterol is too low to satisfy the

liver's demand for cholesterol, the liver makes more by increasing the activity of HMG CoA reductase, the enzyme which controls the rate of cholesterol synthesis in the body. While almost every human cell has the ability to make cholesterol, most of it is made in the liver.

During the fasting state, VLDL are the major triglyceride-carrying lipoproteins in the blood stream. Therefore, the triglyceride level reported from a fasting blood test provides a good indication of how much VLDL is circulating.

Lipoprotein lipase, the enzyme that breaks down triglycerides in chylomicrons, is also responsible for breaking down the VLDL triglycerides. As the triglyceride core of VLDL is depleted by the action of LPL, the VLDL shrink and are transformed into intermediate-density lipoproteins (IDL), which are sometimes called VLDL remnants. Soon after being formed, some IDL particles are taken up by the liver and rapidly broken down. Those remaining in the circulation interact with nearby HDL particles, pick up large amounts of cholesterol esters, and eventually become transformed into LDL. Thus, most of the LDL in the circulation comes from the transformation of VLDL.

Low-Density Lipoproteins

Low-density lipoproteins contain about 60–70% of the cholesterol carried in the blood stream. Therefore, when a blood test indicates that total cholesterol is high, this usually

CHEMICAL COMPOSITION OF PLASMA LIPOPROTEINS (Percent Weight)

	Triglyceride	Cholesterol	Phospholipid	Protein	Major Apoproteins
Chylomicrons	90	5	3	2	A-I, A-IV, B-48, C-I, C-II, C-III
Very-low-density lipoproteins (VLDL)	60	12	18	10	B-100, C-I, C-II, C-III, E
Intermediate-density lipoproteins (IDL)	40	30	20	10	B-100, E
Low-density lipoproteins (LDL)	10	50	15	25	B-100
High-density lipoproteins (LDL)	5	20	25	50	A-I, A-II

The cholesterol in lipoproteins exists either as cholesterol esters or free cholesterol. Cholesterol esters and triglycerides are found in the core of lipoproteins, while free cholesterol, phospholipids and proteins (apoproteins) comprise the surface. IDL are sometimes considered transitional particles rather than a separate class of lipoproteins.

means that LDL is undesirably high, but some people (most notably endurance athletes) with high total cholesterol levels have high HDL rather than high LDL. Cholesterol has the same structure wherever it is found, but because the cholesterol from LDL tends to accumulate in the arteries as a component of atherosclerotic plaque, LDL is often called "bad cholesterol," while HDL is called "good cholesterol." (Actually, since their cholesterol is identical, it would be more accurate to refer to them as good or bad lipoproteins.)

Each LDL particle consists of about 1,500 cholesterol ester molecules in its oily core, with about 800 molecules of phospholipid, 500 molecules of unesterified cholesterol and one molecule of apoprotein B-100 in its detergent coat.

High-Density Lipoproteins

HDL usually contain 20–30% of the total serum cholesterol. People with high blood levels of HDL have a low risk of developing coronary heart disease, but how HDL provide this protection is not clear. While scientists still don't fully understand the exact role that HDL play in metabolism, they believe their primary function is to transport cholesterol out of the plasma and to the liver, where the cholesterol is either excreted in the feces or synthesized into bile acids. Presumably, this removal of cholesterol from the blood stream helps prevent the formation of atherosclerotic plaque. HDL probably have some ability to remove cholesterol that has already been deposited in plaque.

HDL are synthesized mainly in the liver and the small intestine, but some are made in the plasma from surface material that originally belonged to chylomicrons and VLDL. Researchers have identified two major HDL subfractions, designated as HDL₂ and HDL₃. The HDL₂ particles are larger and contain more lipid and less protein. The HDL₂ subfraction seems more important in providing protection against CHD and also accounts for most of the variability in plasma HDL levels seen in the general population. For example, long-distance runners and other endurance athletes have higher HDL levels than sedentary individuals mainly because their HDL₂ levels are higher. The levels of HDL₃ in athletes and non-exercisers are similar.

Development of Coronary Heart Disease

The development of atherosclerosis can be viewed as having three stages:

Early Stage. Atherosclerosis begins when the layer of endothelial cells (the cells lining the inner surface of an arterial blood vessel) becomes damaged or injured by such factors as high blood pressure or high circulating levels of LDL. As a result, smooth muscle cells beneath the point of injury begin to divide rapidly and bulge into the channel of the blood vessel.

Endothelial cells normally produce a prostaglandin compound called prostacyclin, whose main function is to keep blood flowing smoothly by preventing blood platelets from accumulating inside the blood vessel. When the endothelial cell layer is damaged, production of prostacyclin is also disturbed. This allows platelets to clump together where the injury has

occurred, further impeding the flow of blood. As platelets continue to pile up inside the vessel, they secrete a hormone that stimulates growth of the underlying smooth muscle cells, which further narrows the channel of the blood vessel.

Middle Stage. Circulating LDL particles that flow near the damaged endothelial cells are attacked by white blood cells called monocytes, which become transformed into scavenger cells known as macrophages. The chief function of macrophages is to attack invading cells such as bacteria that pose a threat to the body. But macrophages also ingest LDL and chylomicron remnants. In so doing, the macrophages are transformed into foam cells: large, cholesterol-laden cells that are classic components of atherosclerotic plaque. Macrophages also secrete a growth factor that enhances the proliferation of smooth muscle cells.

Advanced stage. During this stage, additional LDL, foam cells, platelets, collagen, fat, calcium, other minerals, and other cellular debris accumulate inside the artery. Smooth muscle cells in the layer below the endothelium continue to multiply and migrate into the damaged area, further narrowing the channel. The resultant mass of material is called atherosclerotic plaque. Eventually, the deposit may become large enough to cut off the flow of blood and trigger a heart attack.

LDL Regulation

A high level of LDL in the circulation is an absolute requirement for the formation of plaque and subsequent development of atherosclerosis. But what causes an individual to have high LDL levels? There are several possibilities, arising either from increased LDL production or decreased removal from the plasma.

The mystery of how the body regulates plasma LDL was solved by Michael S. Brown, M.D., and Joseph L. Goldstein, M.D., who shared the 1985 Nobel Prize in Medicine for their remarkable research. They discovered that most circulating LDL is removed by specialized cell components called LDL receptors. The great majority of LDL receptors are located on the surface of liver cells, but some are found on cells in the intestine, spleen, and adrenal glands.

LDL receptors work by attracting and binding to apoprotein B-100 on the surface of LDL. After LDL becomes bound to a receptor, it enters the cell where an enzyme-rich structure (lysosome) breaks it down to release its cholesterol. The cell then uses this cholesterol to make membranes, steroid hormones, or other substances.

If too much cholesterol accumulates in the cell, three events can take place: 1) The excess may be esterified and stored in the cell; 2) the cell's own synthesis of cholesterol may be shut off through the inhibition of HMG CoA reductase; or 3) the genes responsible for synthesizing LDL receptors may be switched off. Consequently, fewer LDL receptors will be made, and less LDL will be taken into the cell. These mechanisms enable a cell to regulate its supply of cholesterol.

In addition to taking LDL out of the circulation, LDL receptors also remove IDL. Thus, a lack of LDL receptors slows the removal of IDL by the liver and enables more IDL to be converted to LDL.

One important way that LDL levels are influenced is through diet. Certain dietary components may raise or lower

LDL levels by decreasing or increasing the number of LDL receptors. A deficiency in LDL receptors can also be inherited, as occurs in familial hypercholesterolemia (FH). This disease varies in severity, depending on whether one or both parents pass on a defective gene. When both parents are transmitters, which is rare, the offspring will have few or no LDL receptors. Victims of this condition (homozygous FH) have cholesterol levels about four times higher than average and a high incidence of heart attacks during childhood.

In the more common form of the disease, only one mutant gene is inherited (heterozygous FH). Individuals afflicted with this condition have plasma LDL levels about twice the normal value and usually begin having heart attacks by the

age of 35. Such cases occur in about one of every 500 people in most ethnic groups. There are also other genetic types of hyperlipidemia characterized by various defects in lipid and lipoprotein metabolism.

In the next issue we will discuss how diet affects plasma cholesterol levels.

Dr. Kantor is an assistant professor and food and nutrition specialist with the University of Maryland's Cooperative Extension Service, and a regional communicator for the Institute of Food Technologists. His postdoctoral research was in cholesterol and lipoprotein metabolism.

BRIEFS

Food allergy brochure. The International Life Sciences Institute-Nutrition Foundation, with help from the American Academy of Allergy and Immunology, has produced an attractive brochure on food allergies. A free copy can be obtained by sending a self-addressed stamped envelope to Karen Taylor, ILSI- NF, 1126 16th St., N.W., Suite 300, Washington, DC 20036.

Stuart Berger's theory attacked. The New York Academy of Medicine has blasted cytotoxic testing and the theory in *Dr. Berger's Immune Power Diet* that obesity is related to food allergy. In a position statement, the Academy has concluded: 1) cytotoxic testing remains unproved and misleading with respect to the diagnosis of food allergy; 2) since the results of this test do not correlate with the presence of absence of food allergy, reliance on it may result in a dangerous allergic reaction in allergic individuals or in unnecessary food deprivation in the nonallergic; 3) there is no scientific basis for the claim that obesity can result from binging on foods to which one is allergic; and 4) there is no evidence that cytotoxic testing is of any use in the diagnosis or treatment of obesity [*Bulletin of the New York Academy of Medicine* 64(1):117-120, 1988]. Cytotoxic testing involves adding a suspension of a patient's white blood cells to slides containing dried food extract and examining them under a microscope to see whether the cells deteriorate. All attempts to confirm the validity of this test in controlled studies have failed.

Nutrition monitoring vetoed. Before leaving office, President Reagan vetoed the National Nutrition Monitoring and Research Act of 1988, a bill intended to ensure more complete information while reducing duplication of efforts among government agencies studying the eating habits of Americans. The bill had passed the U.S. House of Representatives by a vote of 331-84 and passed in the Senate by voice vote during October. The legislation has been reintroduced as S 253 and HR 677 in the current Congressional session.

Discrimination against vegetarians. According to an article in *Vegetarian Times*, laboratories that use experimental animals are being warned not to hire vegetarians because they may turn out to be animal-rights activists seeking to document conditions of abuse or cause other difficulty.

Health food store sales. *Health Foods Business'* annual survey estimates that during 1988 there were about 7,200 health food stores with total sales of \$2.98 billion. Included in this figure were \$894 million for vitamins and supplements; \$265 million for herbal products, including teas; and \$6 million for books. These figures were considerably above those from the magazine's 1987 survey, but were in line with previous surveys, suggesting that the 1987 figures resulted from unrepresentative sampling rather than a sharp drop in sales.

Nutrition Forum (ISSN 0748-8165) is published bimonthly by J.B. Lippincott Company, Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740. Business offices are located at East Washington Square, Philadelphia, PA 19015. Printed in the U.S.A. Copyright 1989 by J.B. Lippincott Company. Annual Subscription Rates: U.S. \$25.00 individual, \$25.00 institution; all other countries except Japan, India, Nepal, Bangladesh, and Sri Lanka, \$29.00 individual, \$29.00 institution. Single copies \$5.00. Rates for airmail delivery available upon request. Subscriptions, orders, or changes of address (except Japan, India, Nepal, Bangladesh, and Sri Lanka) Journal Fulfillment Department, J.B. Lippincott, Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740, or call 1-800-638-3030; in Maryland call collect 301-824-7300. In Japan, Woodbell Incorporated, 4-22-11, Kitakasai, Edogawaku, Tokyo 134, Japan. In India, Nepal, Bangladesh, and Sri Lanka, Universal Subscription Agency Pvt. Ltd., 101-102 Community Centre (F.F.) Saket, New Delhi-110017, India. Copies will be replaced without charge if the publisher receives a request within 60 days of the mailing date in the U.S. or within 5 months in all other countries. Editorial correspondence should be sent to Stephen Barrett, M.D., P.O. Box 1747, Allentown, PA 18105. POSTMASTER: Send address changes to Nutrition Forum, Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740.

Vitamin scams proliferating. The Florida Division of Consumer Services has received complaints on over 200 companies that have been sending out "prize" announcements as a come-on for overpriced vitamins. The same promotional technique is also being used to sell water purification systems with exaggerated claims.

Rent a goat? The Supreme Court of Virginia has ruled that an arrangement under which people bought partial ownership in a goat still violated a state regulation forbidding the sale of unpasteurized milk. In 1983, the court had ruled that the regulation prevented Christine Solem from "renting" one of her goats for \$3/day in return for the "by-products" of that goat. She then began selling 24% interests in her goats which, upon payment of a \$3/day "maintenance" fee, entitled the purchaser to a gallon of milk each day. Although a lower court ruled in Solem's favor, the Supreme Court reasoned that the maintenance fee was "nothing more than a sham for payment" for each gallon of milk received. The sale of raw milk is illegal within 25 states and in interstate commerce.

"Nutrition" school denied accreditation. The National Home Study Council has denied accreditation to the National Institute of Nutrition Education (NINE), a correspondence school intended to provide credentials for health food retailers. Founded by the National Nutritional Foods Association, the school offers a course leading to designation as a "Certified Nutritional Counselor."

Campbell's—in the soup? The Federal Trade Commission has issued an administrative complaint charging Campbell Soup Co. with making deceptive and unsubstantiated claims. As part of its "Soup is Good Food" campaign, the company has been advertising that most of its soups are low in fat and cholesterol and that soups—as part of a diet low in fat and cholesterol—may help reduce the risk of some forms of heart disease. However, according to the FTC complaint, the ads are deceptive because they don't state that the soups are high in sodium and that diets high in sodium can cause problems for some individuals with heart disease. According to trade sources, Campbell controls two-thirds of the \$2.2 billion retail soup market in the United States. The FTC's action was stimulated by a petition filed in February 1988 by the Center for Science in the Public Interest.

What's in a name? The makers of Aids appetite suppressants have spent \$200,000 for package redesign and a new name to shake customer confusion of their product with the disease AIDS. According to an article in *American Medical News*, the change was motivated by a 40% drop in sales. The new product will be called Diet Aids.

Lipid labeling proposed. The Low Cholesterol Consumer Education Act of 1989—introduced in March as S 623 and HR 1441—would require that total fat, saturated fat, and cholesterol content be specified on the label of foods for which comparative claims are made about cholesterol content and vegetable fats.

U.S. food budget. According to data recently released by the U.S. Department of Agriculture, typical American shoppers spent 9.6% of their disposable income for food in 1987, down from 12.5% in 1977, 20% in 1947, and 40% at the turn of the century. If eating out is added, the 1987 total is \$14.3%, down from 16.7% in 1977.

Movie "ads" attacked. The Center for Science in the Public Interest (CSPI) believes that movie-makers should be required to tell their audiences when manufacturers of such items as cigarettes, soft drinks, and beer have paid to have their products shown on screen. CSPI has suggested to federal officials that contracts between film-makers and manufacturers constitute paid advertising that, in the case of cigarettes, may violate federal laws when the films are shown on television. CSPI has also asked state attorneys general to determine whether the undisclosed placement of commercial products in films constitutes deceptive advertising that violates state laws and whether placing ads for cigarettes and alcoholic beverages should be prohibited in films whose target audiences are too young to buy such products legally. CSPI expressed concern because the movie *Bull Durham* included 21 shots of Miller Lite beer, the Marlboro cigarette logo was featured in *Superman II*, and Reese's Pieces and Coors beer appeared repeatedly in *E.T., the Extra-Terrestrial*.

New report on food irradiation. The American Council on Science and Health has issued a 35-page booklet strongly supporting the use of food irradiation. A copy can be obtained by sending \$3 plus a self-addressed, stamped (65¢ postage), 4" x 9½" envelope to ACSH, 1995 Broadway, 16th Floor, New York, NY 10023.

EDITORIAL BOARD

EDITOR: Stephen Barrett, M.D. **SENIOR ASSOCIATE EDITOR:** Manfred Kroger, Ph.D. **ASSOCIATE EDITORS:** Michael Botts, Esq., Darlene Forester, Ph.D., R.D.; Mary Abbott Hess, R.D., M.S.; William T. Jarvis, Ph.D.; James Lowell, Ph.D.; **CONTRIBUTING EDITORS:** John Cunningham, Ph.D.; Johanna Dwyer, Sc.D., R.D.; Mark Fuerst; Kathy King Helm, R.D.; Victor Herbert, M.D., J.D.; James J. Kenney, Ph.D., R.D.; Barbara Levine, Ph.D., R.D.; Kathleen A. Meister, M.S.; Grace Powers Monaco, Esq.; Anita Owen, R.D., M.A.; Zev Remba (Washington Correspondent); Sheldon Rovin, D.D.S., M.S.; Varro E. Tyler, Ph.D.; Eleanor N. Whitney, Ph.D., R.D.; Eleanor A. Young, Ph.D., R.D.; Jack Z. Yetiv, M.D., Ph.D.; and staff members of The Pennsylvania State University Nutrition Information and Resource Center.

AARP appoints nutrition advisory board. Apparently in response to criticism by *Consumer Reports* magazine [Oct. 1986] and Dr. Stephen Barrett [NF 3:76-78], the American Association of Retired Persons Pharmacy Service has appointed an advisory board to offer advice and consumer messages about vitamin, mineral, and supplement products. Acting on the board's advice, products with potentially toxic doses of vitamin A were reformulated, misleading product claims were stopped, and a few worthless products (such as Bee Pollen Plus Royal Jelly) were withdrawn from the pharmacy service's catalog. Lecithin, l-lysine, l-tryptophan, bone meal, dolomite, garlic capsules, brewer's yeast, desiccated liver, kelp and alfalfa, and protein tablets and powder are still being sold, but the page listing them contains a disclaimer: "Considerable controversy exists among experts on the merits of the nutritionals listed on this page. We offer quality products such as those as a convenience to our members."

Misleading vitamin ad stopped. Following a complaint by Dr. Stephen Barrett to the National Advertising Division (NAD) of the Council of Better Business Bureaus, E.R. Squibb & Sons has pledged to revise a television commercial for its Theragran-M. The commercial, which showed individuals involved in various energetic activities, had stated: ". . . If only you had more energy. This kind of energy comes from eating a balanced diet with vitamin B-Complex and Biotin—the energy releasers. To be sure you're getting enough energy releasers take Theragran-M high potency multivitamins . . . Unleash your energy." In support of these claims, Squibb's attorney provided chapters from nutrition texts explaining how energy refers to the chemical energy locked in foods. Siding with Dr. Barrett, however, NAD expressed concern that consumers viewing the commercial would understand "energy" to mean the physical energy that enables people to engage in strenuous activities.

SCREWED UP PRIORITIES

Stephen Barrett, M.D.

Self, the only fitness magazine that carries cigarette ads, hit a new high (or low) in its August 1988 issue. Among its 12 pages of cigarette ads was a 4-page spread from R.J. Reynolds that is probably the most conspicuous ad ever published in a magazine.

The four pages were made of cardboard so resilient that it was impossible to riffle through the magazine without landing in the middle of the ad. But the maximum effect would hit readers who began on its first page, which said: "Here's an offer that'll shake you up! See inside. . ." When I turned to the next page, a 3" x 3" octahedron attached to an elastic band was pulled out of its protective slot and unflattened with a loud pop. All this to offer a free T-shirt from Salem cigarettes to smokers at least 21 years old who call 1-800-GET-TEES. The T-shirt pictured a cork popping out of a bottle plus the message: "Salem—the Refreshest." Once out of its slot, the pop-up—which depicted a cork—would dangle outside of the magazine until torn out by the reader.

The magazine's cover story was a 14-page "health-packed report on aging—from 20 to 60," which contained eight articles. The first pictured a 1-year-old girl who would "probably live to 120 healthily and disease-free" by following a personal nutrition plan, using sunscreens, engaging in moderate aerobics, and working out her mind at intellectual fitness clubs. The next five articles covered causes of "face-aging," how to keep skin looking young, "anti-aging" exercises, maintaining body architecture, and determining ideal weight. In these 11½ pages, cigarette smoking got exactly six sentences. The article on skin aging mentioned that smokers get early lines around the lips, and the discussion of ideal weight explained that studies relating longevity to weight need careful interpretation because smokers tend to weigh less and die earlier than nonsmokers.

Then came an article called "The 19 longevity nutrients," which began: "Did you know you're probably running

low on a few key nutrients? Women especially are prone to gaps because of dieting, the Pill, pregnancy, breastfeeding, and menopause all take a bite . . . as do smoking, stress and certain over-the-counter drugs. As a result, your skin, hair, energy levels may be sagging. Even more vital, you're leaving yourself open to three serious threats, heart disease, diabetes, and osteoporosis. The chart zeros in on the 19 vitamins and minerals that commonly come up scarce." The next article, "Eat right, stay young? Put medicine's next 'miracle drugs' on your dinner table tonight," talked about "working longevity nutrients into your diet." A final article, "Life-stretching food moves," was based on the U.S. Dietary Guidelines.

Although the advice on food selection was reasonably accurate, the reasons behind some of the choices were absurd. Women are not at special risk for 19 nutrients, and neither smoking nor "stress" creates any special need for nutrients. Nor is sagging of the skin, hair, or energy levels likely to be due to nutrient deficiency. Suggesting one serving of fruit daily to be sure to get enough boron is idiotic. And advice to "drizzle oil over an E-rich leafy green salad" to ensure an adequate supply of vitamin E is foolish because no case of E-deficiency on a dietary basis has ever been reported in this country.

One final noteworthy message for *Self's* beauty-conscious readers was an ad for Topol, the special toothpaste for "coffee, tea, wine, and tobacco stains."

I find it puzzling that a magazine specializing in health, fitness and beauty can present foods as "miracle drugs" while saying almost nothing about the leading destroyer of all three. Are *Self's* editors ignorant? Or do they care more about tobacco advertising dollars than accuracy?

Dr. Barrett, a practicing psychiatrist and consumer advocate, is co-author/editor of 22 books including *Vitamins and "Health" Foods: The Great American Hustle*.

SURGEON GENERAL ISSUES LENGTHY REPORT

The U.S. Surgeon General has issued a thoroughly referenced 750-page report focused primarily on the relationship of diet and the occurrence of chronic diseases. The report was prepared primarily for policymakers, but states that its lessons can be directly applied to the public. More than 250 experts participated in its preparation or review process.

The report includes chapters on the relationships of diet to coronary heart disease, high blood pressure, cancer, diabetes, obesity, skeletal diseases, dental diseases, kidney diseases, gastrointestinal diseases, infections and immunity, anemia, neurological disorders, behavior, and aging. It also contains chapters on maternal and child nutrition, alcohol use, drug-nutrient interactions, and dietary fads and frauds. The key recommendations are:

ISSUES FOR MOST PEOPLE

Fats and cholesterol: Reduce consumption of fat (especially saturated fat) and cholesterol. Choose foods relatively low in these substances, such as vegetables, fruits, whole grain foods, fish, poultry, lean meats, and low-fat dairy products. Use food preparation methods that add little or no fat.

Energy and weight control: Achieve and maintain a desirable body weight. To do so, choose a dietary pattern in which energy (caloric) intake is consistent with energy expenditure. To reduce energy intake, limit consumption of foods relatively high in calories, fats, and sugars, and minimize alcohol consumption. Increase energy expenditure through regular and sustained physical activity.

Complex carbohydrates and fiber: Increase consumption of whole grain foods and cereal products, vegetables (including dried beans and peas), and fruits.

Sodium: Reduce intake of sodium by choosing foods relatively low in sodium and limiting the amount of salt added in food preparation and at the table.

Alcohol: To reduce the risk for chronic disease, take alcohol only in moderation (no more than two drinks a day), if at all. Avoid drinking any alcohol before or while driving, operating machinery, taking medications, or engaging in any other activity requiring judgment. Avoid drinking alcohol while pregnant.

OTHER ISSUES FOR SOME PEOPLE

Fluoride: Community water systems should contain fluoride at optimal levels for prevention of tooth decay. If such water is not available, use other appropriate sources of fluoride.

Sugars: Those who are particularly vulnerable to dental caries (cavities), especially children, should limit their consumption and frequency of use of foods high in sugars.

Calcium: Adolescent girls and adult women should increase consumption of foods high in calcium, including low-fat dairy products.

Iron: Children, adolescents, and women of childbearing age should be sure to consume foods that are good sources of iron, such as lean meats, fish, certain beans, and iron-enriched cereals and whole grain products. This issue is of special concern for low-income families.

Misinformation Attacked

Regarding dietary fads and frauds, the report notes: "Food faddism in America had its roots in Great Britain, where patent medicines were advertised and sold by everyone from hairdressers to goldsmiths. . . . Today, the patent medicine man has been largely replaced by the highly skilled and organized use of electronic means to promote fraudulent marketing—computers, customized mailing lists, national advertisements, WATS banks of telephone lines, and other mass media. The medium and the details have changed, but the message and goals remain. It is difficult for consumers to evaluate the validity of health claims perpetrated by quacks and faddists."

Regarding supplements, the report states: "Nutrient supplements are usually safe in amounts corresponding to the RDA, but the RDAs are already set to provide maximum benefit consistent with safety. Thus, there is no reason to think that larger doses will improve health in already healthy people, and excess intake can be harmful."

The report also attacked the concepts of "natural vitamins" and "organic" foods and labeled the following as "fraudulent":

Superoxide dismutase (SOD) and nucleic acids (RNA and DNA) as anti-aging remedies;

Bee pollen as a source of youth and health and as an energy pill for athletes;

Lethicin plus vinegar, kelp, and vitamin B₆ for the prevention and cure of heart disease and as a diet aid;

Spirulina and glucomannan as diet aids;

Ginseng as a panacea for many ailments;

Alfalfa tablets for treatment of arthritis;

Aloe vera for treatment of an array of unrelated medical conditions;

Para-aminobenzoic acid (PABA) as an essential or curative nutrient;

Pangamic acid (vitamin B₁₅) as an essential nutrient;

Hair analysis for determination of nutritional status;

Oral chelation products as treatment for heart disease.

In addition to harming its victims, the report notes, nutrition fraud can hurt responsible members of the food industry by reducing consumers' trust of the regular food supply.

Copies of *The Surgeon General's Report on Diet and Health* (1988) [Publ. No. 017-001-00465-1] are available for \$22.00 from the Supt. of Documents, Government Printing Office, Washington, DC 20402. Copies of the report's 79-page *Summary and Recommendations* [Publ. No. 017-001-0466-9] cost \$2.75.

OVERUSE OF B₁₂ SHOTS REPORTED

A study of the records of 1,222 patients at a newly purchased rural satellite clinic revealed that 120 (10%) of them had been receiving vitamin B₁₂ shots on a regular basis, but that only 4 (3%) met accepted criteria for its administration [JAMA 261:1920-1923, 1989]. Interviews with 48 of these patients revealed that they had received the shots for an average (mean) of 9.9 years for 3.3 symptoms, the most common of which were weakness and fatigue. These patients ranged in age from 46 to 96 years, with an average age of 74.4.

After being informed that the appropriate reasons for B₁₂ injections are limited to conditions (such as pernicious anemia) in which B₁₂ absorption from the intestine is impaired, 25 (52%) of these patients agreed to discontinue the injections or to enter a double-blind study to test whether they were actually beneficial. However, 18 patients who were younger (average age 68) and reported greater symptom relief said they would actively seek a physician who would continue to administer the shots.

Noting that the doctor who had ordered the injections was well respected, the researchers speculated that the injections might have been part of an approach whose effective mechanism was emotional support through discussion of personal problems. They concluded: "Our findings suggest that patients who have been receiving [B₁₂] injections without evidence of deficiency will respond favorably to a program to

discontinue them. We believe . . . that explanations must be compatible with the patient's health belief system and must attempt to preserve the credibility of the physician or physicians who originally prescribed the injections." A reprint of the article can be obtained by writing to Larry Lawhorne, M.D., Fayette Medical Clinic, Elm and Church Streets, Fayette, MO 65248.

Editor's comment: The study's authors seem to have bent over backwards to avoid suggesting that most of the patients studied had been mistreated. I believe that treating an emotional problem as physical makes it more difficult for the patient to identify and resolve the underlying cause of the symptoms. Placebo therapy also fosters unhealthy dependence. Some patients may do better with a placebo than with counseling, but I believe it is unfair to divert anyone who might benefit from counseling from the opportunity to have it. I agree with the authors that patients who have received B₁₂ shots for years from a doctor they trust must be educated carefully, particularly because criticism of the previous doctor may cause the patient to distrust and abandon the new doctor. One way to wean patients who might be emotionally dependent on B₁₂ shots is to suggest that they may have received enough and that it would be worth trying to stop them or space them further apart.

HEALTH FOOD INDUSTRY GROUP FORMED TO FIGHT FDA

FDA action against illegally marketed "food supplements" has increased considerably since John M. Taylor became Associate Commissioner for Regulatory Affairs. In fiscal year 1988 the agency's health fraud staff approved 62 regulatory letters and 22 seizures, up from 15 regulatory letters and 7 seizures during the previous fiscal year.

Upset with the large number of recent FDA enforcement actions, supplement manufacturers have formed the Dietary Supplement Coalition, a nonprofit group intended to defend the health food industry and individual companies against product seizures which they believe are beyond what current laws allow.

According to an article in *Whole Foods* magazine, the group is asking retailers to chip in toward its 1989 goal of \$1.5 million. A Coalition leader cited in the article said, "Everyone realizes that the life of an industry is at stake. We will be the most powerful and pragmatic group in the industry." The group plans to issue a "white paper" criticizing FDA enforcement actions based on the concept that various nonvitamin supplements are "unsafe food additives."

According to an ad in *Natural Foods Merchandiser*, members will receive legal support if the FDA "takes regulatory

action with reference to the unsafe food additive issue" but not in defense of drug claims made in literature or packaging. The ad lists seven companies as founding members and invites health food retailers to contact Michael Schwartz for further information. (Schwartz, a naturopath, is president of Michael's Health Products, of San Antonio, Texas.) In December 1987, Schwartz was ordered by the FDA to stop making drug claims in promotional materials for Diab Tabs (for diabetes), Artho Tabs (for arthritis), Manpower (for sexual dysfunction), or other products. Yet his current literature offers "naturopathic programs for every condition" and makes drug claims for more than 20 "nutritional" products, including those cited by the FDA.

NUTRITION, CHOLESTEROL AND HEART DISEASE PART III: HOW DIET AFFECTS BLOOD CHOLESTEROL LEVELS

Mark A. Kantor, Ph.D.

In the past two issues we have discussed the risk factors for coronary heart disease (one of which is blood cholesterol level) and the structure and function of lipoproteins. This article covers how dietary fats and cholesterol affect the blood cholesterol level.

Types of Dietary Fat

Dietary fat exists mainly in the form of triglycerides, molecules composed of a glycerol "backbone" to which three fatty acids are attached. Fatty acids in food usually contain from 10 to 22 carbon atoms arranged together with their accompanying hydrogen atoms in a straight chain. The carbons are chemically linked to each other by either a single or double bond. If all the chemical bonds are single, the fatty acid retains the maximum number of hydrogen atoms possible and is said to be saturated (with hydrogen atoms). Monounsaturated fatty acids contain one double bond and have two fewer hydrogen atoms than saturated fatty acids of the same chain length. Polyunsaturated fatty acids have two or more double bonds, each of which displaces two hydrogen atoms.

Animal products usually contain a higher percentage of saturated fats than do plant products. At room temperature, most saturated fats are solid, whereas all unsaturated fats are liquid. The chief exceptions to this rule are three tropical oils—coconut, palm, and palm kernel oil—which, despite their plant origin, are highly saturated. Monounsaturated fatty acids are distributed widely in plants, animals, and seafood. Generally, the longer the chain length of a saturated fatty acid, the more solid its texture. That's why coconut oil, which contains some short-chain fatty acids having only six and eight carbon atoms, remains a liquid at room temperature although it is highly saturated.

All food triglycerides are made up of both saturated and unsaturated fatty acids. If the saturated fatty acids predominate, as they do in butter and beef fat, the fat is considered saturated. Hence, butterfat is considered saturated although only two-thirds of its fatty acids are actually saturated. If polyunsaturated fatty acids are present in large amounts—as

they are in corn and safflower oils—the oil is called polyunsaturated. Oils high in monounsaturated and low in saturated fatty acids—as are olive oil, canola (rapeseed) oil, and some margarines—are described as good sources of monounsaturates. The percentages of the different types of fatty acids in common fats, oils, and spreads are shown in the accompanying table.

Saturated vs. Polyunsaturated Fats

Contrary to popular belief, the amount and type of dietary fat eaten—not the amount of cholesterol consumed—have the greatest impact on the blood cholesterol level. In most people, saturated fats raise the plasma cholesterol level, while polyunsaturated fats lower it. Dietary cholesterol also affects the level of blood cholesterol, but to a lesser and more variable extent than does the fat content of the diet.

The effect of dietary fat on blood cholesterol levels was described in an equation developed by Ancel Keys and co-workers more than 30 years ago. They proposed that for every 1% increase in calories coming from saturated fat, the plasma total cholesterol level was increased by about 2.7 mg. In contrast, each 1% increase in calories derived from polyunsaturated fatty acids substituted for saturated fat lowered the plasma cholesterol level by about 1.4 mg. Therefore, saturated fat raised the blood cholesterol level about twice as much as polyunsaturated fat substitution lowered it. The Keys equation assumed that monounsaturated fats had no effect on the blood cholesterol level, but this assumption has been challenged by recent studies showing that monounsaturated fats do have the ability to lower cholesterol.

The decrease in plasma cholesterol levels that occurs when polyunsaturated fats are eaten results from a decrease in both LDL and HDL. Dietary saturated fat, on the other hand, raises both LDL and HDL levels, but LDL is elevated to a relatively greater extent. Therefore, dietary saturated fat is considered to be atherogenic.

The individual fatty acids comprising dietary fats also influence blood cholesterol levels. Whereas lauric (12-carbons), myristic (14-C), and palmitic (16-C) acids increase plasma cholesterol levels, saturated fatty acids having a chain length of

greater than 16 or less than 12 carbon atoms do not appreciably raise the cholesterol level. Short- and medium-chain fatty acids having less than 12 carbon atoms probably are delivered directly to the liver's portal vein without first being packaged into chylomicrons, so these fatty acids have little effect on blood cholesterol levels.

Stearic acid (18-C) recently was found to lower the level of plasma cholesterol when it replaced palmitic acid in the diet, perhaps because stearic acid is metabolized to oleic acid, an 18-C monounsaturated fatty acid. Cocoa butter, a saturated fat containing 35% stearic acid, also does not seem to appreciably affect cholesterol levels. In several dietary feeding studies, cocoa butter increased the plasma cholesterol level by only half the amount expected from the Keys formula.

These findings could have important implications for the food industry. For example, food technologists could formulate margarines that are high in stearic acid, creating products having a more desirable taste and texture than conventional margarines made with vegetable oils. But experts caution that these research results should not be construed as an endorsement for the public to eat more beef and chocolate. Although beef tallow and cocoa butter are relatively high in stearic acid, they also contain substantial amounts of palmitic acid, which does raise blood cholesterol levels. Therefore, the recommendation to eat less red meat and more fish and poultry is still appropriate for people on a cholesterol-lowering diet.

Not only is the type of fat an important determinant of the blood cholesterol level, but the total amount of fat eaten also affects cholesterol metabolism. After a fatty meal, the small intestine secretes large amounts of chylomicrons, which results in the increased production of chylomicron remnants. These remnants are thought to be atherogenic because they are capable of transferring their cholesterol esters to macrophages, transforming these white blood cells into plaque-forming foam cells. Furthermore, because dietary fat is such a concentrated source of calories and is easily converted into body fat, a diet habitually high in total fat increases the likelihood of obesity, which is a risk factor for coronary heart disease (CHD).

Another thing to consider about dietary fat composition is the ratio of polyunsaturated to saturated fatty acids (the P/S ratio). This ratio is sometimes used (mainly by research scientists) to estimate how a diet will affect the blood cholesterol level. For example, a diet having a P/S ratio greater than 2.0 is usually effective in lowering blood cholesterol, while a ratio of less than 0.4 probably will raise the cholesterol level. Unfortunately, the P/S ratio of the typical American diet is about 0.5, which may explain why CHD is so prevalent in the United States.

More recently, discussions of dietary fats have focused on the percentages of calories coming from the different types rather than the P/S ratio. The National Cholesterol Education Program and other health groups recommend that the saturated fat content of the diet should be less than 10% of calories, and less than 7% if previous dietary attempts to lower blood cholesterol levels have failed. The total fat intake should account for less than 30% of the daily calories, while the calories derived from polyunsaturated and monounsaturated fatty acids should be 10% or less and 10–15%, respectively.

Why does the type of fat in the diet affect the blood cholesterol level? Although researchers have shown repeatedly

that substituting polyunsaturated for saturated fat in the diet lowers plasma cholesterol levels in most people—particularly LDL levels—the mechanism remains unclear.

One possibility is that the liver is better able to synthesize VLDL using saturated fatty acids than it can from polyunsaturated fats. Therefore, a diet low in saturated fats

FATTY ACID COMPOSITION OF SELECTED FATS, OILS, SPREADS AND DRESSINGS

might induce the liver to produce less VLDL for transport. Fewer circulating VLDL particles would in turn result in lower LDL levels, since most LDL is derived directly from the breakdown of VLDL. Also, polyunsaturated fats may prevent the formation of VLDL by inhibiting the synthesis of apoprotein-B, one of the components of VLDL.

Another possible mechanism to explain the ability of saturated fat to raise cholesterol levels is that saturated fatty acids may suppress the activity of LDL receptors in the liver or reduce their number. Either of these circumstances would diminish the liver's ability to remove LDL particles from the circulation, leading to an increase in plasma LDL levels. Presumably, polyunsaturated and monounsaturated fatty acids do not affect LDL receptors in this manner. Finally, polyunsaturated fatty acids may help lower blood cholesterol levels by augmenting the excretion of cholesterol and bile acids.

Monounsaturated Fats

For many years, nutritionists have considered monounsaturated fatty acids to have little or no effect on blood cholesterol levels, but recent studies have demonstrated that monounsaturated fats do have the ability to lower cholesterol. In one experiment, 12 male subjects were each fed three different diets containing 40% of calories as fat. In each diet, the type of fat was composed principally of either saturated, monounsaturated, or polyunsaturated fatty acids. All diets were consumed for a period of 4 weeks.

After the subjects consumed the mono- and polyunsaturated fat diets, their average LDL levels were 31 and 30 mg/dl lower, respectively, than values resulting from the saturated fat diet. But while nine of the 12 subjects who ate the polyunsaturated fat diet also had significantly lower HDL levels, only four showed a decrease in HDL after consuming the monounsaturated fat diet. In two subjects, the high-mono

diet actually produced an increase in HDL levels [Journal of Lipid Research 26:194-202, 1985].

This study suggested that monounsaturated fats might have a major advantage over polyunsaturated fats: while polyunsaturated fatty acids lower both LDL and HDL levels, monounsaturated fats selectively decrease LDL levels. Several other research groups have confirmed this finding. In another recent experiment, a diet containing 40% fat—much of it composed of monounsaturated fatty acids—was just as effective in reducing LDL levels as a diet that was very low in fat (20% of calories) and high in carbohydrates. But whereas this low-fat, high-carbohydrate diet also decreased HDL levels, the diet high in monounsaturated fats did not [American Journal of Clinical Nutrition 47:965-969, 1988]. The authors proposed that, over the long run, the increased use of monounsaturated fats may be more acceptable to many people trying to lower their cholesterol levels than the traditional approach of eating a high-fiber, low-fat diet.

In addition to lowering HDL, the excessive use of dietary polyunsaturated fats has generated concern for other reasons. Researchers suspect these fats are capable of suppressing the immune system in experimental animals, possibly increasing the risk of cancer. Also, polyunsaturated fats may promote the formation of highly reactive, cell-damaging compounds called free radicals, which are also linked to cancer. Scientists also are concerned that polyunsaturated fats may increase the risk of gallstone formation, and perhaps adversely alter the composition of cell membranes. Furthermore, during their normal metabolism in the body, polyunsaturated fats may be transformed into a group of compounds called eicosanoids, some of which may exert deleterious effects on the body.

Not only do monounsaturated fats have none of these disadvantages, but they have a long history of safe use in the Mediterranean region. Olive oil has been consumed for thousands of years in Spain, Greece, and Italy, countries that have a lower incidence of both CHD and cancer than the United States. In addition, researchers from Stanford University recently reported that monounsaturated fats may have the ability to lower blood pressure. When the dietary habits of a group of sedentary middle-aged men were examined, the individuals who ate the most monounsaturated fats had the lowest systolic and diastolic blood pressures [JAMA 257:3251-3256, 1987].

The principal monounsaturated fatty acid in food is oleic acid, which has 18 carbon atoms and 1 double bond. Olive oil, composed of about 77% oleic acid, is the major dietary source of this fatty acid. Other good dietary sources of oleic acid include canola (rapeseed) oil, avocado oil, margarines and shortenings made with hydrogenated soybean and hydrogenated cottonseed oils, and peanut oil (see Table).

Canola oil is produced from a hybrid of rapeseed, a member of the mustard family. Because early varieties of rapeseed oil contained erucic acid, a chemical damaging to the heart, they had been banned for use in food in the United States. But canola is a new, low-erucic acid variety of rapeseed, also called LEAR, that was developed in Canada and approved by the FDA in 1985. It is now being marketed by the Procter and Gamble Company as Puritan Oil. Besides being high in monounsaturated and low in saturated fatty acids, it also contains 6% of omega-3 fatty acids, whose benefits will be described in a future article.

In addition to rapeseed, scientists also are genetically manipulating sunflower and safflower seeds to increase the concentration of monounsaturated fatty acids in the oil. When available, these oils will probably be less expensive than olive oil. New studies also are underway to see if the amount of monounsaturated fatty acids in beef and pork can be increased by feeding livestock animals a diet rich in monounsaturated fats.

Dietary Cholesterol

The typical American consumes 350–450 mg of cholesterol per day, all from animal products. Despite advertising claims that imply otherwise, cholesterol is never found in plant products. Scientists are uncertain how much of the cholesterol eaten is actually absorbed by the human intestine, with estimates ranging from 25% to 75%. The body's ability to absorb cholesterol appears to be inversely related to the amount consumed.

Cholesterol that has either been ingested in the diet or synthesized by the body has several possible fates: 1) it may be synthesized into hormones (such as estrogens) or other steroid compounds; 2) it may be taken up by cells and become a part of cell membranes or the myelin sheath of nerve cells; 3) it may be excreted in the stool without prior conversion to bile acids; or 4) it may be converted into bile acids in the liver, which then enter the enterohepatic cycle.

The role of dietary cholesterol in human atherosclerosis is complex and not yet clear. Scientists have long known that omitting cholesterol from the diets of experimental animals markedly reduces the amount of atherosclerosis that develops, but they are not sure why. They suspect that, acting similarly to the action of saturated fat, dietary cholesterol has the ability to suppress the number of LDL receptors in the animal liver, thereby raising the level of LDL in the bloodstream. This mechanism probably operates in humans as well as animals. But dietary cholesterol's ability to elevate blood cholesterol generally is less potent in people than in laboratory animals, and the effect is more variable.

While some human feeding studies have shown that the addition of cholesterol to the diet increases the blood cholesterol level, other studies have not been able to demonstrate this. The data are conflicting because the ability of dietary cholesterol to affect an individual's blood cholesterol level depends on several factors.

One consideration is the total composition of the diet, especially the fat content. Eating saturated fat together with cholesterol seems to potentiate the effect of just eating cholesterol alone.

In addition, some researchers have hypothesized that individuals are either "responders" or "nonresponders" to dietary cholesterol, a trait that is inherited. While responders show a rise in blood cholesterol levels after consuming a diet

rich in cholesterol, nonresponders compensate for any dietary increase by absorbing less cholesterol or synthesizing less. This happens because the synthesis of cholesterol in the liver is controlled by a feedback inhibition process that shuts off cholesterol production when a certain dietary intake is exceeded. Consequently, even when the dietary intake of cholesterol is high, there may be little change in the blood cholesterol level.

But other researchers suggest that when the cholesterol intake is initially low, virtually all people will exhibit a rise in plasma cholesterol if they begin eating a cholesterol-rich diet. This finding has been demonstrated over the years in a number of carefully controlled studies. The results of these investigations suggest that for every 100 mg of dietary cholesterol per 1000 calories consumed in the daily diet, plasma total cholesterol levels rise by about 10 mg/dl. (Values in the literature range from 4 to 12 mg/dl.) Furthermore, even a nonresponder cannot completely compensate for a diet that is habitually high in cholesterol. Such an individual eventually will show a rise in plasma cholesterol, despite the body's attempt to excrete more bile acids or synthesize less cholesterol in the liver.

The ability of dietary cholesterol to affect the blood cholesterol level also may depend upon the range of cholesterol consumed. According to one hypothesis, if a diet initially contains no cholesterol at all, a threshold amount of dietary cholesterol must be exceeded before the plasma cholesterol level will start to rise. For most people, this quantity is about 100 mg/day. As the amount of dietary cholesterol increases above this threshold level, the plasma cholesterol concentration also rises until a "ceiling" level is reached, usually corresponding to a dietary intake of about 300–400 mg of cholesterol per day. Above this amount, eating more cholesterol will produce little if any additional increase in the plasma cholesterol level.

This model may explain why dietary cholesterol failed to increase the plasma cholesterol level in some egg feeding studies. If several egg yolks are added to a diet already high in cholesterol—that is, above the ceiling level—no further increase in the plasma cholesterol level should be expected.

In addition to raising the level of LDL in the blood stream, dietary cholesterol may have other detrimental effects. A diet rich in cholesterol increases the amount of cholesterol esters in chylomicron and VLDL remnants, making these particles more atherogenic. Also, some researchers have suggested that dietary cholesterol can induce the formation of unusual lipoprotein species—new types of lipoproteins that may induce the formation of plaque.

In the next issue, we will discuss how dietary fiber affects blood cholesterol levels.

Dr. Kantor is an assistant professor and food and nutrition specialist with the University of Maryland's Cooperative Extension Service, and a regional communicator for the Institute of Food Technologists. His postdoctoral research was in cholesterol and lipoprotein metabolism.

RAW MILK CREAMED IN CALIFORNIA COURT

On April 10, California Superior Court Judge John Sutter ruled that Alta-Dena Certified Dairy and its affiliate Steuve's Natural must stop advertising that their raw milk products are safe and healthier than pasteurized milk. After 54 days of trial with over 800 exhibits, Judge Sutter concluded that "overwhelming evidence . . . proved . . . that Alta-Dena's raw (unpasteurized) milk frequently contains dangerous bacteria that cause serious illness. Pasteurization kills such bacteria. Yet for 35 years, Alta-Dena carried out a false and misleading advertising campaign touting its raw milk now sold under the 'Steuve's Natural' label as 'safe,' the 'safest,' and superior to pasteurized milk."

The judge's decision requires that for 10 years, the company's milk containers must carry a conspicuous warning:

WARNING: THIS MILK MAY CONTAIN DANGEROUS BACTERIA. THOSE FACING THE HIGHEST RISK OF DISEASE OR DEATH INCLUDE BABIES, PREGNANT WOMEN, THE ELDERLY, ALCOHOLICS, THOSE WITH CANCER, AIDS OR REDUCED IMMUNITY, AND THOSE TAKING CORTISONE, ANTIBIOTICS OR ANTACIDS. QUESTIONS REGARDING THE USE OF RAW CERTIFIED MILK SHOULD BE DIRECTED TO YOUR PHYSICIAN.

The judge also ordered that all the company's advertising with health and nutrition claims during the next 10 years must state:

WARNING: THE FOOD AND DRUG ADMINISTRATION (FDA) HAS DETERMINED THAT THERE IS NO SATISFACTORY SCIENTIFIC PROOF TO SUPPORT CLAIMS THAT PASTEURIZATION SIGNIFICANTLY REDUCES THE NUTRITIONAL VALUE OF MILK AND THAT THE RISKS ASSOCIATED WITH CONSUMING RAW CERTIFIED MILK OUTWEIGH ANY OF ITS ALLEGED HEALTH BENEFITS.

The suit was filed in 1985 by Consumers Union, publisher of Consumer Reports, and the American Public Health Association, who quickly won a preliminary injunction against advertising that raw milk is ideal for infants and invalids. Later, the public interest groups were joined by the Alameda County District Attorney, who enforces consumer protection laws.

The judge's 34-page analysis of the case includes the following conclusions based on evidence presented at the trial:

- Steuve's Natural is "certified," which means it is produced under the standards of the Association of Medical Milk Commissions (AAMMC). The only such commission in California is the Los Angeles Milk Commission (LAMC), which regulates Alta-Dena and no other dairy. However, there is considerable evidence that both AAMMC and LAMC are "captives" of Alta-Dena, which pays all or most of their expenses.

- A laboratory hired by LAMC has sampled Steuve's Natural milk and isolated Salmonella dublin bacteria on numerous occasions without either the laboratory or LAMC notifying state authorities of the findings—which would have been legally obligated to prohibit sale or use of the infected milk.

- On more than 40 occasions between 1982 and 1984, Alta-Dena's own laboratories had positive tests for salmonella in its milk but failed to report this to the state. But in 1984, AAMMC and LAMC complied with a request from Alta-Dena to drop the requirement that raw milk be tested for salmonella. In September 1987, the dairy stopped testing for salmonella, citing "costs" as the reason. *Editor's note:* In December 1988, despite the obvious conflicts of interest and LAMC's failure to report previous test results, the California Department of Food and Agriculture transferred its program of testing raw milk to LAMC!]

- Despite ample evidence to the contrary, the dairy advertised that raw milk is "the ideal formula for babies . . . and for the same reason, a basic food for invalids." The dairy continued to promote raw milk for infants despite specific warnings from the California Department of Health. Moreover, long after learning of reports of infant botulism caused by the ingestion of honey, Alta-Dena continued to suggest in advertising that its formula should be made with honey.

- Between 1971 and 1984, 31 people died in California of illnesses associated with raw milk consumption.

- In 1983, Alta-Dena commissioned a panel of experts to evaluate the safety of its raw milk. Although the study confirmed other studies showing that raw milk poses a great risk to immune-deficient people, the dairy did not follow the recommendation of the study's authors to warn about this on its product labels.

The judge's order prohibits Alta-Dena from making more than 40 specific claims related to health, safety, nutrition, and quality control of its products—including whole milk, nonfat milk, cream, butter, buttermilk, kefir, and cottage cheese. The dairy was also ordered to pay \$23,000 to Alameda County as a penalty for false advertising, \$100,000 in restitution to the Attorney General's consumer law section, and plaintiffs' attorney fees, which could be quite high.

Alta-Dena is appealing the judge's decision.

QUESTION BOX

Q. What happens if a person's percentage of body fat becomes very low?

A. Men and women differ with regard to percentage of body fat that would be considered too low. The average man is composed of 12–15% fat, 3% of which is essential, with the remainder being normal storage fat. Women average 22–25% fat, of which 12% is essential and the remainder is normal storage fat. Body fat is needed to cushion vital organs (e.g., heart, liver, spleen, kidneys, etc.), to insulate against heat loss, and to contribute to hormone synthesis. Allowing the percentage of body fat to fall below levels considered essential can result in decreased ability to protect vital organs from damage, decreased adaption to temperature variations, and inadequate hormone synthesis.

BRIEFS

Astrology for weight control? Since September 1988, *Weight Watchers* magazine has carried a "horoscope" column that contains tips and encouragement for dieters. Its words of wisdom have included: "try a wild new recipe" (Taurus); "tempt your taste buds with low-calorie seafood dishes" (Pisces); "join an exercise class and learn new tricks" (Gemini); "let your mate help with your diet—it's easier with support" (Libra); "incorporate an exotic food into your menu" (Aquarius); "vitamin-rich veggies get you through the flu season snuffle-free" (Sagittarius); "the planets bring you an energy boost—use it constructively to reach fitness goals" (Aries); and "though you feel others haven't noticed your weight-loss achievements, a good friend has been singing your praises" (Aries). The magazine also carries cigarette ads.

New hope for diabetics. *Medical World News* has reported that in studies at several centers, about half of 55 insulin-dependent diabetics who received transplants of fetal cells related to insulin production have been able to reduce their insulin dosage.

Light exercise may protect the heart. A 20-year study of 3,043 middle-aged white male railroad workers has found that even light physical activity may protect the heart as well as general health [*Circulation* 79:304-311, 1989]. The project began in the late 1950s when the men were given fitness tests to establish their condition as they entered the study. They were also interviewed about their leisure-time physical activities, which were classified as light, moderate, or intense. The researchers subsequently inquired about the leisure-time activities and compared them to the causes of death among those who died during the study period. It was found that death rates from diseases of the heart and blood vessels were lower for men who expended 1,000 or more calories per week in leisure-time physical activity—the equivalent of 30 minutes a day in a moderately intense activity such as playing softball or weeding the garden. But after taking into account such primary risk factors as smoking, high blood pressure, and elevated blood cholesterol, the researchers concluded that "the greatest increase in protection was between those men who were sedentary and those who had some activity." According to the report, the overall death rate decreased from nearly 30% in those who expended less than 250 calories per week (the equivalent of walking 10 minutes a day at 3 miles per hour on a level surface) to about 25% in the more active men. The authors conclude: "Physical activity appears directly related to the development of coronary heart disease . . . These data show that increasing physical activity, particularly of a light-to-moderate intensity, is appropriate to prevent disease and promote health." Reprints can be obtained from Martha L. Slattery, Ph.D., Dept. of Family and Community Medicine, University of Utah Medical School, 50 N. Medical Drive, Salt Lake City, UT 84132.

Illegal "infant formula" manufacturer prosecuted. In January 1989, Michael J. Potter, president of Eden Foods, became the first person found guilty and sentenced to prison for violating the Infant Formula Act of 1980. In 1983, the company began marketing a soybean product named Edensoy with claims that it was free of cholesterol, rich in iron, and good for babies as a "quality," "easily digested," and "preferred" substitute for mother's milk and was suitable for children who could not tolerate cows' milk or other liquid or powdered formulas. Later that year, FDA investigators informed Potter that his company's promotional claims made Edensoy subject to FDA regulation, that it lacked the minimum levels of vitamins, minerals, and protein specified under the Infant Formula Act, and that it could cause severe malnutrition and even death if used as the only food fed to an infant. According to a report in the May 1989 *FDA Consumer*, although Potter said he would stop promoting Edensoy as an infant formula, FDA investigators continued to find such promotional literature in health food stores, where clerks were advising customers that Edensoy and similar products were suitable for infants. After a Canadian infant raised on Edensoy was hospitalized with rickets and other signs of severe malnutrition, Eden Foods recalled its promotional literature and relabeled Edensoy to emphasize that it was not suitable as an infant formula or as a sole source of nutrition. The company was charged with selling at least 53,482 cartons of the soy drink illegally between July 1983 and June 1985. Potter pleaded guilty to one count of violating the Infant Formula Act and was sentenced to 1 year in prison with all but 30 days suspended. He was also fined \$25,000 and placed on probation for 2 years. Eden Foods, which pleaded guilty on 12 counts, was fined the full \$110,000 permitted under the law.

Nutrition Forum (ISSN 0748-8165) is published bimonthly by J.B. Lippincott Company, Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740. Business offices are located at East Washington Square, Philadelphia, PA 19105. Printed in the U.S.A. Copyright 1989 by J.B. Lippincott Company. Saket, New Delhi-110017, India. Copies will be replaced without charge if the publisher receives a request within 60 days of the mailing date in the U.S. or within 5 months in all other countries. Editorial correspondence should be sent to Stephen Barrett, M.D., P.O. Box 1747, Allentown, PA 18105. POSTMASTER: Send address changes to Nutrition Forum, Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740.

AMA cholesterol campaign. The American Medical Association is spearheading a major public education campaign aimed at educating Americans about the risk of high blood cholesterol and showing how to lower that risk. The campaign includes a book (*Count out Cholesterol* by Arthur Ulene, M.D.) and an audiocassette program containing a behavioral program for cholesterol reduction and information about the medical therapies available for treating high blood cholesterol. During the first half of 1989, mass media will be used, including national television programming, a special section in the March issue of *Good Housekeeping* magazine, a ten-city tour by Dr. Ulene, distribution of more than 40 million promotional inserts to American households, and educational displays in thousands of grocery stores. Beginning in April, a 5-week course offering personalized instruction and counseling to people with high blood cholesterol levels is being offered in many communities throughout the country. Physicians interested in participating in the campaign have received kits containing educational and motivational materials. The campaign is co-sponsored by Feeling Fine, the Kellogg Company, Pam (no-stick cooking spray), and Merck, Sharp & Dohme (maker of the cholesterol-lowering drug Mevacor). Pam and Kellogg's cereals are offering five-dollar cholesterol screening rebate coupons on the back of their products. Although not part of the AMA campaign, General Foods Corporation is also offering information and a five-dollar rebate coupon on the back of its Post Oat Flakes.

Court approves feeding tube removal. A Florida appeals court has granted the right to order removal of a feeding tube to the guardian of an 89-year-old woman who was neither brain dead nor comatose. According to an article in *American Medical News*, the woman had suffered a stroke and could neither move nor swallow. But she had specified in a living will that she did not want tube-feeding or any heroic measures done to save her life.

Death caused by hydrogen peroxide. The FDA has reported that last September two children in Texas were severely injured after their mother poured drinks for them from a bottle containing 35% hydrogen peroxide that she thought was water. Another child, who was a neighbor, also was given the highly corrosive peroxide solution and died as a result. Literature sold with the product claimed it could be used for sprouting seeds, purifying meat, and for the treatment of acne, gum disease, athlete's foot, colic, headache, varicose veins, AIDS, and cancer.

Chilean fruit update. On April 14th the FDA ended its requirement that importers of Chilean fruit carry out intensive monitoring triggered by the finding of two cyanide-tainted grapes on March 12th. According to the agency, the amount of cyanide found in the grapes was far below the amount that would sicken a child but was more than is known to be present naturally. Detection of the cyanide followed an anonymous warning to the U.S. Embassy in Santiago, Chile, which was considered likely to be a hoax. But after the tainted grapes were found, the agency ordered all Chilean fruit in the hands of retailers, wholesalers, and importers destroyed and stepped up monitoring of new imports for several weeks.

Notable quote. "If every threat causes flights to be canceled or fruit to be removed from grocery shelves, terrorists and psychotics will soon be able to grind society to a halt . . . The public must recognize that a risk-free society is not only impossible, but intolerably expensive."—Daniel E. Koshland, Jr., in "Scare of the Week," an editorial in the April 7 issue of *Science*.

Sales aids for health food stores. Two of the leading health food industry trade publications publish one-page "consumer education" articles with space on the page for the store's name and address. Most "health food" magazines sell reprints of their articles, and one offers a monthly news summary which retailers can reproduce as a flyer. These publications typically contain false or unproven claims for foods or food supplements that would be illegal in advertising or on a product label. But if the flyers are not used directly in the sale of a product, the claims they make are protected under freedom of the press.

Licensing update. Dietitians have now gained passage of laws to regulate nutritionists in 23 states, Puerto Rico, and the District of Columbia. Some make it illegal for unqualified persons to call themselves dietitians or nutritionists, while others define nutrition practice and who is eligible to do it. Since 1986, the American Dietetic Association has collected 449 case reports of people harmed by inappropriate advice from bogus "nutritionists," health food store operators, and others. Information about licensure and the ADA's Questionable Nutritional Practices System ("QUEST System") is available from Michele Mathieu-Harris, American Dietetic Association, 216 W. Jackson Blvd., Chicago, IL 60606.

NATIONAL RESEARCH COUNCIL ISSUES MASSIVE REPORT ON DIET AND HEALTH

In the most comprehensive scientific analysis to date of potential health risks and benefits stemming from diet, the Committee on Diet and Health of the National Research Council/National Academy of Sciences has concluded that Americans can substantially reduce their risk of heart disease, cancer, and many other chronic diseases through specific changes in eating habits. The analysis was based on 3 years of study funded by the W.K. Kellogg Foundation, the Henry J. Kaiser Family Foundation, the Pew Charitable Trusts, the Fannie E. Rippel Foundation, Occidental Petroleum Corporation, and the National Research Council Fund.

In preparing its report, the Committee systematically examined competing disease risks from various dietary modifications and sought to balance them in a set of dietary recommendations:

- Reduce total fat consumption to 30% or less of calories, saturated fatty acids to less than 10% of calories, and cholesterol to less than 300 milligrams daily. The intake of fat and cholesterol can be reduced by substituting fish, poultry without skin, lean meats, and low- or nonfat dairy products for fatty meats and whole-milk dairy products; by choosing more vegetables, fruits, cereals, and legumes; and by limiting oils, fats, egg yolks, and fried and other fatty foods.

- Eat five or more daily servings of vegetables and fruits, especially green and yellow vegetables and citrus fruits. Also increase intake of starches and other complex carbohydrates by eating six or more daily servings of a combination of breads, cereals, and legumes. Carbohydrates should total more than 55% of calories.

- Maintain protein intake at moderate levels—approximately the current Recommended Dietary Allowance for protein (0.8 mg/kg of body weight for adults), but not exceeding twice that amount.

- Balance food intake and physical activity to maintain appropriate body weight.

- We do not recommend alcoholic beverages. If you do drink, limit yourself to less than one ounce of pure alcohol daily—equivalent to two cans of beer, two small glasses of wine, or two average cocktails. Pregnant women should avoid alcoholic beverages altogether.

- Limit total daily intake of salt (sodium chloride) to 6 grams or less. Limit the use of salt in cooking and avoid adding it to food at the table. Salty, salt-preserved, and salt-pickled foods should be consumed sparingly.

- Maintain adequate calcium intake.

- Avoid taking dietary supplements in excess of the Recommended Dietary Allowances for one day.

- Maintain an optimal intake of fluoride, particularly during the years of primary and secondary tooth formation and growth.

The Committee cautioned that although data were insufficient to estimate the total percentage of chronic disease that might be avoided by following its recommendations, its suggested reductions in fat and cholesterol could be expected

to reduce the incidence of coronary heart disease by at least 20%. While the percentage of avoidable cancers is also impossible to estimate, the Committee noted that several countries with dietary patterns similar to those recommended by its report have about half the U.S. rates of diet-associated cancers.

Generally, the Committee's recommendations agree with those of other expert panels in the United States and abroad but include more specific quantitative recommendations. Implementing them will require individuals to devote more time and attention to their daily diet and will require professionals to help the public in dietary planning. The Committee expects that the food processing industry, restaurants, and school cafeterias will be required to alter recipes and menus, while government agencies will need to consider changes in food and nutrition programs and policies. However, the Committee noted, U.S. dietary habits are already changing in many ways consistent with its recommendations.

Regarding supplement use, the Committee concluded:

- A large percentage of the U.S. population consumes some vitamin or mineral supplement daily. These supplements are often self-prescribed and not based on known nutrient deficiencies.

- Some population subgroups (such as those suffering from malabsorption syndromes) may require supplements, but they should take them only under professional supervision.

- A single daily dose of a multiple vitamin-mineral supplement containing 100% of the RDA is not known to be harmful or beneficial; however, vitamin-mineral supplements that exceed the RDA and other supplements (such as protein powders, single amino acids, fiber, and lecithin) not only have no known health benefit for the population but their use may be detrimental to health.

- The desirable way for the general public to obtain recommended levels of nutrients is by eating a wide variety of foods.

- It is not known what, if any, benefits or risks accrue to individuals or the general population from taking small doses of supplements.

- It is important for further research to determine whether: 1) long-term supplement use (at both high and low levels) can affect mortality or general health; 2) supplements can help to prevent or treat health problems in the general population or in particular population subgroups; and 3) any population groups might be particularly vulnerable to health risks from the use of supplements. Research is also needed to explore the quality of dietary formulations—including their potency, nutrient balance, nutrient bioavailability, and possible contamination with other substances.

Copies of the final 996-page NRC report, *Diet and Health: Implications for Reducing Chronic Disease Risk*, are available for \$49.95 (prepaid) from the National Academy Press, 2101 Constitution Ave., N.W., Washington, DC 20418.

NUTRITION, CHOLESTEROL AND HEART DISEASE PART IV: THE ROLE OF DIETARY FIBER

Mark A. Kantor, Ph.D.

In previous issues, we have discussed the risk factors for coronary heart disease, the structure and function of lipoproteins, and how dietary fats and cholesterol affect blood cholesterol levels. This article covers how dietary fiber affects blood cholesterol.

Dietary fiber is not a single material but a mixture of chemically complex substances found in plants. All components except one (lignin) that make up dietary fiber are carbohydrates composed of polysaccharide chains—multiple units of sugars and related compounds linked together. Lignin, a three-dimensional network of phenylpropane units derived from several different alcohols, is chiefly responsible for the rigid texture of woody plants.

Definition and Measurement

Because of fiber's heterogeneous nature, scientists have had difficulty defining it. Definitions for fiber have been proposed to take into account both its chemical and biological properties. One common definition based on chemical structure is "the sum of lignin and nonstarch polysaccharides in foods." The nonstarch components are frequently divided into two subgroups, cellulosic fibers and noncellulosic fibers. Cellulose, an unbranched polymer consisting of about 3,000 glucose units, is the main structural component of plant cell walls. The other nonstarch components have side chains and are composed of a variety of polysaccharides.

The chief difference between fiber and other carbohydrates, such as sugar and starch, is that fiber is not appreciably broken down by enzymes and microorganisms in the human digestive tract. This has led to the widely accepted biological definition of dietary fiber: "The plant polysaccharides and lignin that are resistant to hydrolysis (breakdown) by human digestive enzymes."

Until recently, scientists believed that dietary fiber was not degraded at all by intestinal microorganisms. But new research has shown that microbial enzymes can break down certain kinds of fiber, particularly those not made of cellulose. These microbial reactions produce pyruvate, a metabolic

by-product that can be absorbed through the large intestine (colon) and used as an energy source. However, the amount of calories contributed by dietary fiber is negligible.

Developing procedures to accurately measure dietary fiber has been as tricky as defining it. Originally, the fiber content of food was expressed as "crude" fiber. This term refers to the residue after a food sample is exposed to strong acid and alkali. But since this chemical treatment is much harsher than the biological reactions that actually occur during digestion, the crude fiber content of food always is substantially lower than the dietary fiber level.

Because the crude fiber content of food has little nutritional significance, it is no longer widely used (except in animal nutrition). However, some older food composition tables still use this term. Unfortunately, values for dietary fiber cannot be predicted from measurements of crude fiber. A standard method has been developed for measuring the total dietary fiber concentration in food and the amounts coming from its different components. But because of the complexity of the procedure, analytical results from different laboratories often vary. Therefore, even some of the recently published values for dietary fiber may not be consistent. Researchers are continuing to develop simpler and more reproducible procedures for analyzing dietary fiber.

Soluble vs. Insoluble Fiber

Today, dietary fiber frequently is subdivided into two major categories: soluble and insoluble. These subgroups have different chemical, physical, and biological properties.

The substances comprising soluble fiber include pectin, gums (such as guar gum and locust bean gum), mucilages, and some hemicelluloses. Pectin, which is found in many fruits and vegetables (especially the peel of citrus fruits), helps maintain the structure of plants by serving as an "intracellular cement." It also gives fruits the ability to form gels, a property exploited in making jams and jellies.

The other types of soluble fiber help repair injuries to plant cells or serve as stored energy for plants and seeds. As

its name implies, soluble fiber is able to dissolve in water. In the intestines, it soaks up water like a sponge and swells, forming gels.

Insoluble fiber, on the other hand, is unable to dissolve in water but can bind and hold onto water to some extent. Its main role in nature is to maintain the structural integrity of plants. The chief types of insoluble fibers are cellulose, lignin, and nonsoluble hemicelluloses.

Both soluble and insoluble fibers have desirable physiological effects. Insoluble fiber adds moisture and bulk to the stools and increases the rate at which food moves through the colon. This decreases the intestinal "transit time," helping to prevent constipation and diverticulosis, an outpouching of the intestinal wall that can lead to diverticulitis (an inflammation). Some researchers believe that insoluble fiber also may help prevent colon cancer, but this relationship is controversial because of conflicting scientific data.

Soluble fiber has none of the above capabilities but has two very important metabolic functions of its own: 1) it can lower the total amount of cholesterol circulating in the bloodstream, especially the LDL level; and 2) it can help diabetics regulate their blood glucose level and diminish their insulin requirement. (Wheat bran also can do this by delaying the absorption of glucose.) Some studies suggest that soluble fiber can reduce serum triglycerides, especially in diabetics. Both soluble and insoluble fiber can help promote weight loss.

Soluble Fiber and Coronary Heart Disease

The health benefits of soluble fiber now being publicized are not a new discovery. Reports that rolled oats or pectin could reduce serum cholesterol levels and inhibit the development of atherosclerosis began appearing in the scientific literature in the early 1960s. But the current frenzy about oat bran and other sources of soluble fiber—and the rush by food companies to market these ingredients in new products—stems largely from investigations by Dr. James Anderson and his colleagues at the University of Kentucky that began in the 1970s.

In one such study, a group of 20 men with high levels of blood cholesterol (above 260 mg/dl) were given diets containing 17 grams per day of soluble fiber, derived either from oat bran (100 grams/day dry weight) or pinto and navy beans (115 grams/day dry weight). Subjects on the oat diet consumed 1 cup of hot oat bran cereal each day plus five oat bran muffins. Those eating beans were served cooked beans and bean soup. After consuming these high-fiber diets for three weeks, subjects in both groups showed favorable changes in their cholesterol levels. Total cholesterol was reduced by about 19%, while LDL levels decreased by approximately 24%. Although the average HDL levels also decreased slightly in this study, other researchers have shown that HDL usually increases modestly or does not change when subjects increase their soluble fiber intake [American Journal of Clinical Nutrition 40:1146-1155, 1984].

In a similar study by different researchers, a group of middle-aged men and women added 2 ounces daily of either oat bran or oatmeal (to provide 5.6 and 2.7 grams of soluble fiber per day, respectively) to their diets, which already were low in fat and cholesterol. After 6 weeks, subjects in both groups

lowered their plasma cholesterol levels by an additional 5-7 mg/dl beyond the reduction they achieved by just restricting saturated fat and cholesterol. The effects of oat bran and oat meal were similar in this study. Both lowered total blood cholesterol levels by about 3% [Journal of the American Dietetic Association 86:759-764, 1986].

In a follow-up investigation, the same authors found that the inclusion of 2 ounces of oatmeal each day again enhanced the serum cholesterol response in individuals eating diets containing 30% or fewer calories as fat. The oatmeal significantly lowered total cholesterol after 4 weeks, with the greatest reduction occurring in individuals who had the highest cholesterol levels to begin with. The authors concluded that a "moderate daily ingestion of oatmeal in combination with a fat-modified diet is a practical and palatable means of lowering serum cholesterol, at least in the short term." Their studies suggest that people who include a bowl of oatmeal or oat bran cereal as part of a nutritionally well-balanced diet should expect to see a decline in blood cholesterol by an additional 3% over what can be achieved on a low-fat, low-cholesterol diet that does not emphasize soluble fiber [Preventive Medicine 17:377-386, 1988].

It is difficult to draw firm conclusions about how soluble fiber affects blood cholesterol levels because the diet studies reported to date have varied in: 1) the sources and amounts of soluble fiber they used; 2) the methods used for analyzing soluble fiber; 3) the age and initial cholesterol levels of their subjects; 4) overall dietary composition; and 5) duration. However, the following are probably true:

- If people eating a typical American diet (37% of calories from fat; cholesterol over 300 mg/day) include 1½ cups of dry oat bran (four 1-ounce servings or 114 grams) in their daily diet, blood cholesterol levels should decline about 20% in one month. The same result should be expected from eating 1/2 cup (4 ounces or 114 grams dry weight) of pinto, navy, or kidney beans. Half a cup of dried beans, peas, or lentils is equivalent in volume to about 1¼ cups of the cooked product. However, some soluble fiber may be lost in the cooking water.

POSTMASTER: Send address changes to Nutrition Forum, Downsville Pike, Route 3, Box 20-B, Hagerstown, MD 21740.

- Eating smaller portions of oats and beans than described above will produce smaller but still significant reductions in cholesterol levels. For example, Dr. Anderson's group found that 50 grams of oat bran added to the typical diets of college students lowered their cholesterol levels by 12% after 6 weeks. Thus the ability of soluble fiber to reduce cholesterol levels is somewhat dose-dependent.

- The inclusion of oats and beans in a diet moderate in fat (less than 30% of total calories) and cholesterol (under 300 mg/day) will further reduce total and LDL-cholesterol levels, but the change will be more modest than if the diet had been high in fat and cholesterol.

- Most of the cholesterol-lowering effects of soluble fiber can be apparent in 1 month. One 2-year study found little additional reduction beyond what was achieved after 3 weeks.

- Soluble fiber does not seem to significantly affect HDL levels.

- Lentils and most types of beans and peas, canned or dry, also are good sources of soluble fiber (see table). Although fewer data are available on these foods, they probably are effective in lowering blood cholesterol levels.

An equation has been developed to predict the percent decrease in blood cholesterol that can be expected in about 1 month from the daily addition to the diet of a given quantity of oat bran: $\text{PERCENT DECREASE IN TOTAL CHOLESTEROL LEVEL} = 0.156 \times \text{GRAMS OF OAT BRAN PER DAY} + 1.0$ [Western Journal of Medicine 148:299-302, 1988]. However, many researchers feel that more data are needed before equations of this type can be used with confidence. Such equations are difficult to develop because individuals are known to vary in their response to oat bran, and the overall composition of the diet must be taken into account.

Proposed Mechanisms of Action

The mechanism by which soluble fiber lowers plasma cholesterol levels is unclear, but several hypotheses have been proposed. One scenario is that soluble fiber binds to bile acids, causing an increase in bile acid excretion and interrupting the body's ability to reabsorb and reuse bile acids via the enterohepatic cycle. To replenish the lost bile acids, the liver synthesizes new ones from its internal stores of cholesterol. But then, to renew its cholesterol supply, the liver must draw more cholesterol out of the blood stream. It does this by increasing either the number or activity of its LDL receptors, which lowers the amount of LDL in the circulation.

Through this process, soluble fiber may act similarly to the bile acid sequestrant drugs cholestyramine and colestipol, which also lower cholesterol by binding and removing bile

acids. But remedying high blood cholesterol with diet instead of medications offers two major advantages: it eliminates the common problem of side effects that accompany drug usage, and it is much less expensive. Researchers estimate that oat bran costs only one-tenth as much as cholestyramine when used to treat high blood cholesterol over an individual's lifetime.

While oat bran does seem to increase fecal bile acid excretion, other sources of soluble fiber, such as beans, do not. Scientists have proposed two other mechanisms for soluble fiber's ability to lower cholesterol. Some bacteria naturally present in the colon ferment soluble fiber, producing several types of short-chain fatty acids, including acetic, propionic, and butyric acids. These fatty acids may inhibit the production of cholesterol in the liver and therefore reduce the cholesterol concentration in the bloodstream. The other hypothesis is that soluble fiber may prevent dietary cholesterol from being absorbed by "trapping" it and carrying it away in the stool.

Scientists believe that the major cholesterol-lowering component in oats is a water-soluble polysaccharide gum having a chemical structure known as "beta-glucan." Because the amount of beta-glucan varies among different varieties of oats, researchers are planning to screen large numbers of oat varieties to identify those with naturally high levels. These oat varieties could be selectively bred to further enhance their beta-glucan content, or the concentration of beta-glucan could be augmented through genetic engineering. Barley is another good source of beta-glucan.

Corn bran, rice bran, carrots, and several citrus fruits have been investigated recently for their ability to lower cholesterol. While the results have been encouraging, more research is needed on these products before any specific recommendations can be made on their use.

Another source of dietary fiber that has been shown to effectively lower cholesterol is psyllium hydrophilic mucilloid, a type of mucilage derived from husks of the psyllium seed. It contains both soluble and insoluble fibers and is marketed chiefly as a laxative. It is available commercially as Metamucil (Procter and Gamble Co.), Fiberall (Rydelle Laboratories, Inc.), and Serutan (Beecham Products, USA). A recent study found that men eating a typical American high-fat diet (40% of calories from fat) who took about 10 grams of Metamucil each day for 2 months showed a 15% drop in their total cholesterol level (248-211 mg/dl) and a 20% reduction in LDL. [Archives of Internal Medicine 148:292-296, 1988]. Other researchers have found that psyllium produced more moderate decreases in total and LDL-cholesterol levels (about 5% and 8%, respectively) in subjects eating a 30% fat diet. [JAMA 261:3419-3423, 1989]. In both studies, HDL did not change.

DIETARY FIBER CONTENT OF SELECTED FOODS (GRAMS PER SERVING)

	Total Weight	Total Fiber	Soluble Fiber		Total Weight	Total Fiber	Soluble Fiber
<i>Cereal Products</i>				Pinto beans, canned, 1/2 cup	85	4.34	1.01
All-Bran, 1/3 cup	28	8.61	1.43	Pinto beans, dried, cooked, 1/2 cup	85	5.90	1.84
40% Bran flakes, 2/3 cup	28	4.29	.43	Pinto beans, dried, raw, 1/6 cup	32	6.22	2.39
Corn bran, 2/3 cup	28	22.83	.31	Pork and beans, canned, 1/2 cup	90	3.74	1.84
Corn grits, 3 tbsps	28	.62	.10	White beans, canned, 1/2 cup	90	4.98	1.50
Cornflakes (Kellogg's), 1 cup	28	.44	.13	White beans, dried, cooked, 1/2 cup	90	5.07	1.48
Fiber 1, 1/2 cup	28	11.87	.84	White beans, dried, raw, 1/6 cup	30	5.30	1.31
Graham crackers, 2 2½" squares	28	.67	.33	<i>Other Vegetables</i>			
Grapenuts, 1/4 cup	28	2.82	.83	Asparagus, canned, 1/2 cup	121	2.84	.51
Macaroni, raw, 1/4 cup	21	.63	.34	Beets, canned, 1/2 cup	85	2.21	.68
Oat bran, 1/3 cup	28	4.03	2.01	Broccoli, frozen, 1/2 cup	78	2.18	.98
Product 19, 1 cup	28	1.22	.30	Brussel sprouts, frozen, 1/2 cup	78	3.53	1.42
Puffed rice, 1 cup	14	.18	.05	Cabbage, raw, 1 cup	70	1.46	.55
Puffed wheat, 1 cup	14	1.01	.48	Carrots, raw, 1/2 cup	55	1.76	.84
Rice Krispies, 1 cup	28	.33	.09	Cauliflower, frozen, 1/2 cup	66	1.69	.57
Rolled oats, 1/3 cup	27	2.58	1.33	Corn, canned, whole kernel, 1/2 cup	82	1.52	.20
Saltine crackers, 6	17	.51	.29	Kale, frozen, 1/2 cup	65	2.48	.74
Spaghetti, white, raw, 1/4 cup	21	—	.36	Lettuce, iceberg, 1/2 cup	28	.25	.06
Spaghetti, whole wheat, raw 1/4 cup	21	1.99	.36	Potato, white, raw, 1/2 cup	75	1.49	.77
Special K, 1 cup	28	.89	.16	Spinach, frozen, 1/2 cup	78	1.70	.39
Wheaties, 2/3 cup	28	2.31	.66	Squash, frozen, 1/2 cup	65	.68	.25
White bread, 1 slice	28	.57	.28	Sweet potato, canned, 1/2 cup	98	1.20	.46
White flour, 2½ tbsps	18	.66	.28	Tomato, raw, 1 medium	123	1.02	.17
White rice, raw, 1/6 cup	28	—	.25	<i>Fruits</i>			
Whole wheat bread, 1 slice	28	1.53	.34	Apple, raw, 1 small	138	2.76	.97
Whole wheat flour, 2½ tbsps	19	2.08	.35	Applesauce, unsweetened, canned, 1/2 cup	122	1.96	.76
<i>Legumes</i>				Banana, raw, 1/2 small	57	1.09	.32
Black-eyed peas, canned, 1/2 cup	83	3.21	.35	Grapefruit, Florida yellow, 1/2 medium	118 ¹	1.46	.90
Garbanzo beans, canned, 1/6 cup	40	1.40	.16	Orange, Calif. seedless naval, 1 small	140 ²	1.94	1.13
Green beans, canned, 1/2 cup	68	2.03	.49	Peach, canned, 1/2 cup	122	1.93	.78
Green peas, canned, 1/2 cup	85	3.22	.45	Pear, canned, 1/2 cup	122	3.69	.79
Kidney beans, canned, 1/2 cup	93	5.75	1.45	Pineapple, canned, 1/3 cup	82	1.35	.17
Lentils, dried, cooked, 1/2 cup	99	5.22	.56	Plum, canned, purple, 1/2 cup	125	2.74	1.19
Lentils, dried, raw, 1/6 cup	32	3.66	.38	¹ with refuse, 241 grams ² with refuse, 206 grams			
Lima beans, canned, 1/2 cup	85	3.02	.79				
Navy beans, dried, cooked, 1/2 cup	95	6.78	2.29				

Data supplied by Susan R. Lawrence, M.S., R.D., and James W. Anderson, M.D.; modified from Anderson, J.W. and Bridges, S.R.: Dietary fiber content of selected foods. *American Journal of Clinical Nutrition* 47:440-447, 1988.

Fiber Pills

Nutrition experts generally discourage the use of fiber pills, recommending instead that healthy Americans obtain their fiber from food. The amount of fiber required to lower blood cholesterol levels can be obtained without too much difficulty from the diet. Moreover, fiber supplements have several potential disadvantages: they may inhibit the absorption of certain minerals; they don't provide other nutrients as food does; the long-term effects of using fiber supplements are not known; and they add unnecessary cost to a cholesterol-lowering program. In addition, users may develop a dependency on fiber pills to maintain "regularity."

Food Products

While food manufacturers are capitalizing on the favorable publicity about soluble fiber by introducing new breakfast

cereals, baked goods, and other products made with oat bran, consumers need to realize that the amount of soluble fiber contained in many of these items is too low to positively affect their cholesterol levels. Based on the results of the abovementioned studies, the average person consuming a diet that is reasonably low in saturated fat and cholesterol needs to eat about 35 grams of oat bran or oatmeal every day for 4-6 weeks to lower blood cholesterol by about 3%. A typical serving of most commercially available breakfast cereals, muffins, or cookies falls short of this amount. In addition, some companies have been marketing oat cereals that also are high in saturated fats because they contain tropical oils. Such foods may not be effective in lowering blood cholesterol levels.

In evaluating products, shoppers should check food labels to see if oat bran, rolled oats, or another source of soluble fiber is located near the top of the ingredient list. They also need to be wary of products made with coconut oil or other highly saturated fats. Most important, consumers need to realize that, despite all the encouraging research results, foods

containing oat bran, beans, or other sources of soluble fiber are not "magic bullets." These products should be considered only one part of an overall cholesterol-lowering diet.

Practical Tips
