Friedberg F.		An Overview of Psychometric Assessment	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 161	The assessment of a number of behavioral and psychosocial domains may be important in baseline and outcome evaluations of CFS patients. These domains include mood disturbance, functional status, sleep disturbance, global well-being (i.e., psychiatric status), pain, behavioral coping, social support, locus of control, illness behavior and illness attribution. This article describes a variety of pen-and-paper measures designed to assess these behavioral dimensions and summarizes their psychometric properties and applicability to CFS populations.
Fulcher KY, White PD.	National Sports Medicine Institute, St Bartholomew's and the Royal London School of Medicine and Dentistry, Charterhouse Square, London EC1M 6BQ, UK.		J Neurol Neurosurg Psychiatry 2000 Sep;69(3):302-7Comment in: J Neurol Neurosurg Psychiatry. 2000 Sep;69(3):289 Strength and physiological response	OBJECTIVE: To measure strength, aerobic exercise capacity and efficiency, and functional incapacity in patients with chronic fatigue syndrome (CFS) who do not have a current psychiatric disorder. METHODS: Sixty six patients with CFS without a current psychiatric disorder, 30 healthy but sedentary controls, and 15 patients with a current major depressive disorder were recruited into the study. Exercise capacity and efficiency were assessed by monitoring peak and submaximal oxygen uptake, heart rate, blood lactate, duration of exercise, and perceived exertion during a treadmill walking test. Strength was measured using twitch interpolated voluntary

			to exercise in patients with chronic fatigue syndrome.	isometric quadriceps contractions. Symptomatic measures included physical and mental fatigue, mood, sleep, somatic amplification, and functional incapacity. RESULTS: Compared with sedentary controls, patients with CFS were physically weaker, had a significantly reduced exercise capacity, and perceived greater effort during exercise, but were equally unfit. Compared with depressed controls, patients with CFS had significantly higher submaximal oxygen uptakes during exercise, were weaker, and perceived greater physical fatigue and incapacity. Multiple regression models suggested that exercise incapacity in CFS was related to quadriceps muscle weakness, increased cardiovascular response to exercise, and body mass index. The best model of the increased exercise capacity found after graded exercise therapy consisted of a reduction in submaximal heart rate response to exercise. CONCLUSIONS: Patients with CFS were weaker than sedentary and depressed controls and as unfit as sedentary controls. Low exercise capacity in patients with CFS was related to quadriceps muscle weakness, low physical fitness, and a high body mass ratio. Improved physical fitness after treatment was associated with increased exercise capacity. These data imply that physical deconditioning helps to maintain physical disability in CFS and that a treatment designed to reverse deconditioning helps to improve physical function.
Fulle S, Mecocci P, Fano G, Vecchiet I, Vecchini A, Racciotti D, Cherubini A, Pizzigallo E, Vecchiet L, Senin U, Beal MF.	Lab. Interuniversitario di Miologia, Dip. Biologia Cellulare e Molecolare, Universita di Perugia, Perugia, Italy.	Specific oxidative alterations in vastus lateralis muscle of patients with the diagnosis of chronic fatigue syndrome.	Free Radic Biol Med 2000 Dec 15;29(12):1252-9	Chronic fatigue syndrome (CFS) is a poorly understood disease characterized by mental and physical fatigue, most often observed in young white females. Muscle pain at rest, exacerbated by exercise, is a common symptom. Although a specific defect in muscle metabolism has not been clearly defined, yet several studies report altered oxidative metabolism. In this study, we detected oxidative damage to DNA and lipids in muscle specimens of CFS patients as compared to age-matched controls, as well as increased activity of the antioxidant enzymes catalase, glutathione peroxidase, and transferase, and increases in total glutathione plasma levels. From these results we hypothesize that in CFS there is oxidative stress in muscle, which results in an increase in antioxidant defenses. Furthermore, in muscle membranes, fluidity and fatty acid composition are significantly different in specimens from CFS patients as compared to controls and to patients suffering from fibromyalgia. These data support an organic origin of CFS, in which muscle suffers oxidative damage.
Furst G.		Measuring Fatigue in Chronic Fatigue Syndrome: Why and How	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 55	Fatigue is a common symptom occurring in a wide range of acute and chronic illnesses. It is multidimensional and subjective and because of this it has been difficult to define and quantify. Fatigue is one of several significant symptoms in diseases such as rheumatoid arthritis and multiple sclerosis, but for persons with chronic fatigue syndrome (CFS), it is often the most debilitating symptom. The need for valid and reliable assessments of fatigue is necessary for health care providers as we are increasingly required to document outcomes of care for professional and insurance purposes.

Gimenez HB, Cash P, Laing RBS, Douglas JG.		Cytokine Expression and Morphology of in vitro Grown Monocytes from Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 5(1): 47	Although underlying metabolic cause of chronic fatigue syndrome (CFS) is unknown, specific defects have been proposed to exist in the skeletal muscle, the immune system and the neuroendocrine system. Peripheral blood mononuclear cells from CFS patients and healthy controls were fractionated as adherent cells (monocyte-enriched fraction) and non-adherent cells. We have investigated some activities of the former during in vitro culture. It was observed that the morphology (shape and size) of adherent cells from CFS patients, co-cultivated with homologous non-adherent cells, differed between CFS patients and healthy controls for 21 out of 25 (84%) paired samples (i.e., CFS patient and healthy control). Cytokine expression was examined for the adherent cell population collected from 14 CFS patients and 12 healthy controls. Unstimulated and LPS stimulated tumour necrosis factor-a (TNFa) expression was higher for monocytes from 7 out of 14 CFS patients. Unstimulated interleukin-1b (IL-1b) expression was higher for monocytes from 10 out of 14 CFS patients, whereas LPS-stimulated IL-1b expression was higher for 8 out of 14 CFS patients. The proportional increase of IL-1b and TNFa following LPS stimulation was lower for the majority of the CFS patients studied, suggesting that the monocytes from CFS patients were less responsive to LPS than the respective healthy controls. The basis for the abnormal in vitro monocyte maturation, the elevated unstimulated levels of IL-1b expression and the abnormal response of the monocytes to LPS is unknown. The relevance of these findings to CFS pathogenesis is discussed.
Glass RT.		The Human/Animal Interaction in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: A Look at 127 Patients	Journal of Chronic Fatigue Syndrome 2000; 6(2): 65	Objective: To evaluate the interaction between Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) patients and domestic animals (pets). Design: Retrospective study of criteria-met ME/CFS patients using a standardized questionnaire which included patient comments. Setting: University medical center and ME/CFS support groups throughout the United States. Patients: A total of 127 patients met the surveillance criteria of the Centers for Disease Control and Prevention (CDC) for the establishment of the diagnosis of ME/CFS and were included in the study. Measurements: Information from the standardized questionnaire was compiled and appropriate statistical tests, including mean, median, Z test, multivariant analysis, and Chi-square test, were used. This information was compared to national statistical information on animal interaction compiled by the American Veterinary Medicine Association. Results: The most striking result of the study was the association between ME/CFS patients and animals (usually indoor pets) and the

				number of animals per ME/CFS patient. 97% of the ME/CFS patients had animal contact (expected national contact: 57.9%), with only 2 males and 2 females not reporting animal contact. Reported dog ownership/household for ME/CFS males was 9.5 and for ME/CFS females was 7.9 (expected national average: 1.52). Reported cat ownership/household for ME/CFS males was 6.1 and for ME/CFS females was 8.7 (expected national average: 1.95). 106 of the respondents (83.5%) reported that their animals (pets) had atypical diseases with symptoms which mimicked ME/CFS in humans. Of the 106 ME/CFS patients, 100 (94.3%) either were the primary caregiver for the sick animals or had intimate contact (sleeping with, being bitten or scratched by, or kissing the animal). Conclusions: ME/CFS patients have a significant animal interaction and a large number of these animals have atypical or unusual diseases which at least mimic ME/CFS.
Glass RT.		Abnormal Signs Found in Animals of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome Patients: A Look at 463 Animals	Journal of Chronic Fatigue Syndrome 2000; 6(2): 73	Objective: To evaluate the abnormal signs found in the domestic animals (pets) of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) patients. Design: Retrospective study of the domestic animals (pets) of criteria-met ME/CFS patients using a standardized questionnaire which included patient comments. Setting: University medical center and ME/CFS support groups throughout the United States. Patients: A total of 127 patients met the surveillance criteria of the Centers for Disease Control and Prevention (CDC) for the establishment of the diagnosis of ME/CFS and were included in the study. This group of patients had a total of 463 domestic animals (pets), of which 348 animals demonstrated abnormal signs and 115 were considered healthy. Measurements: Information from the standardized questionnaire was compiled and appropriate statistical tests, including mean, median, Z test, multivariant analysis, and Chi-square test, were used. Results: One hundred six (83%) of the 127 ME/CFS surveyed reported that at least one of their animals (predominantly domestic pets) showed a wide range of unusual or atypical signs, many of which mimicked the signs and symptoms of ME/CFS. The sick animals' signs were divided into General (40%), Neurological (35%), Gastrointestinal (10%), Reticuloendothelial/Blood (9%), Neoplasia (4%), and Endocrine (2%). One of the most striking result of the study was that 113 of the 127 ME/CFS patients surveyed felt their ME/CFS symptoms were somehow associated with their animals contact. Ninety (71%) of the 127 ME/CFS patients reported that they were the primary caretakers for multiple animals. Other less common findings were: the onset of ME/CFS being associated with obtaining the animal; the onset of ME/CFS being associated with a flea bite episode; prior residents having sick animals and ME/CFS; other family member contracting ME/CFS from their close association with the sick animal (as opposed to their association with the family members who had ME/CFS); ME/CFS symptoms decreasing after the pet leaving or dying. Conclusions: A large number of animals of ME/CFS patients have atypical or unusual diseases which at least mimic ME/CFS. Most of the 127 ME/CFS patients surveyed have significant animal

				interactions.
Goodwin SS.	Pacific Lutheran University, Tacoma, WA 98447, USA. goodwisd@plu.edu	Couples' perceptions of wives' CFS symptoms, symptom change, and impact on the marital relationship.	Issues Ment Health Nurs 2000 Jun;21(4):347-63	The purpose of this descriptive correlational study was to describe the differences in couples' perceptions of wives' Chronic Fatigue Syndrome (CFS) symptoms and to describe the relationship between changing symptoms and the marital relationship. The convenience sample of 131 wives with CFS and their spouses reported symptom changes similarly. However, wives reported significantly higher problem levels for constitutional, fatigue, cognition, central nervous system (CNS), musculoskeletal, and allergy symptom domains and significantly less problem levels of mood disturbance domain than their husbands. Husbands who reported more symptom changes also reported lower marital adjustment, less empathy and support from their wives, and more conflict within the relationship. Wives who reported more symptom changes reported lower marital adjustment, less empathy for their husbands, and more conflict within the relationship and had husbands who reported lower marital adjustment and less empathy and support by the wives.
Gordon R, Michalewski HJ, Nguyen T, Starr A.		Premovement and Cognitive Brain Potentials in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 137	Brain potentials from normals and patients with Chronic Fatigue Syndrome (CFS) were recorded in four different experimental tasks: (1) Auditory target detection, (2) Short-term memory scanning, (3) Fore-warned reaction time (contingent negative variation) and, (4) Self-paced movement. In the auditory target detection task, a slow negative potential shift (maximum at Cz), appears prior to stimulus onset in normals, but is markedly reduced in amplitude in patients with CFS. However, all other sensory and cognitive brain potentials do not differ between normals and CFS. Reaction times are slower in CFS compared to normals. In the memory task, a slow negative shift associated with memory scanning is reduced in patients with CFS. For the fore-warned reaction time and self-paced movement tasks, no differences were found between the patients and normals. The finding of premovement related potential abnormalities in CFS supports the concept that central motor preparation and execution are impaired in CFS. In certain tasks, measures of neural processes related to sensory processing and attention are normal for these patients. Results from the memory task suggest that neural processes related to short-term memory are also altered in CFS.
Goudsmit E.		Chronic fatigue syndrome and depression	Br J Psychiatry 2000 Nov;177:470 Comment on: Br J Psychiatry. 2000 Jun;176:550-6.	
Green J, Romei J, Natelson BH.		Stigma and Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 5(2): 63	We predicted that the largely female population seeking relief from the incapacitating symptoms of chronic fatigue syndrome (CFS), an enigmatic illness, would feel stigmatized, and that attribution of CFS symptoms to psychological causes by physicians would contribute significantly to the CFS-related stigma. Most subjects scored high on measures of stigma: 95% had feelings of estrangement, 70% believed that others attributed their CFS symptoms to psychological causes, 77% coped by

				using an educational strategy (disclosure) and 39% saw a need to be secretive about their symptoms in some circumstances. Most subjects (77%) were labeled as `psychological cases' by one or more of the physicians (mean = 8) consulted, but of the 4 stigma measures, only disclosure was related to physician labeling. Such factors as duration of illness and unemployment, dissatisfaction with spouse, and symptom severity correlated significantly with measures of stigma. That many physicians were reportedly ignorant or skeptical of CFS (male more so than female M.D.'s) may influence attempts of CFS patients to legitimize their symptoms by disclosure and lead to high rates of health care system use.
Greenlee JE, Rose JW.	Neurology Service, Veterans Affairs Medical Center and Department of Neurology, University of Utah Health Science Center, Salt Lake City 84148-001, USA.	Controversies in neurological infectious diseases.	Semin Neurol 2000;20(3):375-86	The past several years have seen major advances in our understanding of neurological infectious diseases, their diagnosis, and their treatment. Along with these advances, however, new information about infectious agents and new therapeutic options have also introduced both uncertainty and controversy in the approach and management of patients with diseases of the central nervous system. Here, we discuss six such areas: the long-term efficacy of HAART therapy in treatment of HIV infection; the role of viral infection in chronic fatigue syndrome; Rasmussen's encephalitis as an infectious or autoimmune disease; the spectrum of neurological diseases caused by rickettsial infection; the role of Mycoplasma pneumoniae in human central nervous system disease; and the possible association of Chlamydia pneumoniae and human herpesvirus 6 with multiple sclerosis. Review, Academic
Grimaud J.	Service de Neurologie A, Hopital Neurologique et Neurochirurgical Pierre Wertheimer, Lyon.	[Relationship between fatigue in multiple sclerosis and the chronic fatigue syndrome].[article in French]	Rev Neurol (Paris) 2000 Nov;156(11):1044-5	
Hack AD.		Divalent Cations, Hormones, Psyche and Soma: Four Case Reports	Journal of Chronic Fatigue Syndrome 2000; 6(3/4): 117	Objectives: The steroid hormone, vitamin D and the peptide hormone, parathormone are reported to influence not only bone metabolism, but also other metabolic and nervous, cardiovascular and immune functions, and mood. Regular actions of these hormones depend highly on intracellular magnesium content. Although symptoms are recognized, they usually are not correlated to these hormones. Foregoing case studies have revealed that vitamin D and/or parathormone disorders are common causes of CFS-fibromyalgia like symptoms. Methods: Four patients with chronic fatigue-like symptoms and vitamin D (25OHD3) and parathormone (PTH intact) disorders are illustrated to demonstrate conflicting laboratory results. Patients were treated with 5,000 to 10,000 IU cholecalciferol, plus multiminerals and trace elements. Clinical outcome was assessed and treatment difficulties are reported. Results: Diagnostic pitfalls are shown. Vitamin D and parathormone disorders are not completely detectable by calcium and phosphate screening. In 2 of this 4

				demonstrated cases treatable diagnosis would have been missed without endocrinological screening. In the case of undetected long-standing disorder of these hormones, intracellular mineral derangement follows, thus inducing vitamin D resistance and parathormone ineffectiveness which makes therapy difficult. Combining vitamin D therapy with multiminerals possibly may overcome these obstacles. Conclusions: Vitamin D and parathormone disturbance should not be overlooked in chronic fatigue. Appropriate therapy is easy, inexpensive and harmless. Early diagnosis and treatment might be essential to avoid chronic fatigue syndrome. The complexity of diagnosis, therapy and scientific background may lead to a new understanding of ``psycho-somatic'' disease. The relation between intracellular minerals, trace elements, cellular energy supply and responsible hormones should become clearer.
Hadzi-Pavlovic D, Hickie IB, Wilson AJ, Davenport TA, Lloyd AR, Wakefield D.	Mood Disorders Unit, Prince of Wales Hospital, Randwick, NSW, Australia. D.Hadzi-Pavlovic@unsw.edu.au	Screening for prolonged fatigue syndromes: validation of the SOFA scale.	Soc Psychiatry Psychiatr Epidemiol 2000 Oct;35(10):471-9	BACKGROUND: The identification of syndromes characterised by persistent and disabling mental and/or physical fatigue is of renewed interest in psychiatric epidemiology. This report details the development of two specific instruments: the SOFA/CFS for identification of patients with chronic fatigue syndrome (CFS) in specialist clinics and the SOFA/GP for identification of prolonged fatigue syndromes (PFS) in community and primary care settings. METHODS: Patients with clinical diagnoses of CFS (n = 770) and consecutive attenders at primary care (n = 1593) completed various self-report questionnaires to assess severity of current fatigue-related symptoms and other common somatic and psychological symptoms. Quality receiver operating characteristic curves were used to derive appropriate cut-off scores for each of the instruments. Comparisons with other self-report measures of anxiety, depression and somatic distress are noted. Various multivariate statistical modelling techniques [latent class analysis (LCA), longitudinal LCA] were utilised to define the key features of PFS and describe its longitudinal characteristics. RESULTS: The SOFA/CFS instrument performs well in specialist samples likely to contain a high proportion of patients with CFS disorders. Cut-off scores of either 1/2 or 2/3 can be used, depending on whether the investigators wish to preferentially emphasise false-negatives or false-positives. Patients from these settings can be thought of as consisting not only of those with a large number of unexplained medical symptoms, but also those with rather specific musculoskeletal and pain syndromes. The SOFA/GP instrument has potential cut-off scores of 1/2 or 2/3, with the latter preferred as it actively excludes all non-PFS cases (sensitivity = 81%, specificity = 100%). Patients with these syndromes in the community represent broader sets of underlying classes, with the emergence of not only musculoskeletal and multisymptomatic disorders, but also persons characterised by significant cognitive subjective impairment. Twelve-month longitudinal analyses of the primary care sample indicated that the underlying class structure was preserved over time. Comparisons with other measures of psychopathology indicated the relative

				independence of these constructs from conventional notions of anxiety and depression. CONCLUSIONS: The SOFA/GP instrument (which is considerably modified from the SOFA/CFS in terms of anchor points for severity and chronicity) is preferred for screening in primary care and community settings. Patients with PFS and CFS present a range of psychopathology that differs in its underlying structure, cross-sectionally and longitudinally, from coventional notions of anxiety and depression.
Hannan KL, Berg DE, Baumzweiger W, Harrison HH, Berg LH, Ramirez R, Nichols D.	Osceola Hospital, Kissimmee, Orlando, Florida, USA.	Activation of the coagulation system in Gulf War Illness: a potential pathophysiologic link with chronic fatigue syndrome. A laboratory approach to diagnosis.	Blood Coagul Fibrinolysis 2000 Oct;11(7):673-8	Most symptoms of Gulf War Illness (GWI) are similar to Chronic Fatigue Syndrome (CFS) and/or Fibromyalgia (FM). We investigated whether these symptoms are associated with an activated coagulation system as has been reported in some cases of CFS/FM. The coagulation assays include activation markers of the cascade, platelet activation and hereditary risk factors. Our findings show activation of the coagulation system in GWI. This evidence of a hypercoagulable state suggests that symptoms may be due to poor blood flow and, therefore, a basis for the potential utility of anticoagulant therapy.
Hart B, Grace VM.	Department of Feminist Studies, University of Canterbury, Christchurch, New Zealand. blossom@expansive.co.nz	Fatigue in chronic fatigue syndrome: a discourse analysis of women's experiential narratives.	Health Care Women Int 2000 Apr-May;21(3):187-201	Chronic fatigue syndrome (CFS) is a debilitating condition. Approximately 75% of sufferers are women. The etiology of CFS is debated, but remains inconclusive. "Fatigue" is ill defined and conceptually problematic. The international multidisciplinary literature on CFS reveals a paucity of studies on women. Qualitative research to analyze women's discourses on CFS is virtually absent. Eleven New Zealand women of European descent with experience of CFS were interviewed in depth. Within the complex facets of CFS, this article reports specifically on an analysis of discourses on "fatigue." The predominant theme that emerged was that fatigue is articulated as "lack" or absence, which is not representable as an identifiable entity in biomedical terms. Parallels with chronic pain are briefly drawn. We conclude that approaches to CFS must respond to the diverse and complex constructions of the experience of fatigue evident in women's narratives.
Hazendonk KM, Crowe SF.	School of Psychological Science, La Trobe University, Bundoora, Victoria, Australia.	A neuropsychological study of the postpolio syndrome: support for depression without neuropsychological impairment.	Neuropsychiatry Neuropsychol Behav Neurol 2000 Apr;13(2):112-8	OBJECTIVE: This study aimed to examine cognitive functioning in postpolio syndrome (PPS) after controlling for the effects of depression and illness behavior. BACKGROUND: Few studies have investigated the possible cognitive sequelae of PPS, despite widespread documented subjective complaints of "mental fatigue." METHOD: A total of 23 PPS sufferers, 20 polio survivors without PPS, and 22 matched controls were compared using the Beck Depression Inventory-II; the Illness Behaviour Questionnaire; a chronic fatigue syndrome symptom checklist; and several measures of memory, attention, and concentration, including the Brown-Petersen Task, Stroop Test, Austin Maze, California Verbal Learning Test, Trail Making Test, Controlled Oral Word Association Test, and Symbol-Digit Modalities Test. RESULTS: In those participants with a medically confirmed diagnosis of PPS, there was a significantly higher level of depressive and hypochondriacal symptomatology as compared with the other two groups. Nevertheless, no significant differences existed between the three groups on neuropsychological measures. CONCLUSIONS: These results indicate

				that the attention and memory difficulties reported by PPS sufferers may be linked to the physical or psychological manifestations of the illness rather than to objective decrements in cognitive performance.
Heim C, Ehlert U, Hellhammer DH.	Center for Psychobiological and Psychosomatic Research, University of Trier, Germany.	The potential role of hypocortisolism in the pathophysiology of stress-related bodily disorders.	Psychoneuroendocrinology 2000 Jan;25(1):1-35	Representing a challenge for current concepts of stress research, a number of studies have now provided convincing evidence that the adrenal gland is hypoactive in some stress-related states. The phenomenon of hypocortisolism has mainly been described for patients, who experienced a traumatic event and subsequently developed post-traumatic stress disorder (PTSD). However, as presented in this review, hypocortisolism does not merely represent a specific correlate of PTSD, since similar findings have been reported for healthy individuals living under conditions of chronic stress as well as for patients with several bodily disorders. These include chronic fatigue syndrome, fibromyalgia, other somatoform disorders, rheumatoid arthritis, and asthma, and many of these disorders have been related to stress. Although hypocortisolism appears to be a frequent and widespread phenomenon, the nature of the underlying mechanisms and the homology of these mechanisms within and across clinical groups remain speculative. Potential mechanisms include dysregulations on several levels of the hypothalamic-pituitary adrenal axis. In addition, factors such as genetic vulnerability, previous stress experience, coping and personality styles may determine the manifestation of this neuroendocrine abnormality. Several authors proposed theoretical concepts on the development or physiological meaning of hypocortisolism. Based on the reviewed findings, we propose that a persistent lack of cortisol availability in traumatized or chronically stressed individuals may promote an increased vulnerability for the development of stress-related bodily disorders. This pathophysiological model may have important implications for the prevention, diagnosis and treatment of the classical psychosomatic disorders.
Hickie IB, Wilson AJ, Wright JM, Bennett BK, Wakefield D, Lloyd AR.	School of Psychiatry, University of New South Wales, Sydney, Australia. i.hickie@unsw.edu.au	A randomized, double-blind placebo-controlled trial of moclobemide in patients with chronic fatigue syndrome.	J Clin Psychiatry 2000 Sep;61(9):643-8	BACKGROUND: Chronic fatigue syndrome is characterized by prolonged and disabling fatigue and a range of neuropsychiatric symptoms including depressed and/or irritable mood. To date, no medical or psychotropic therapies have provided clear symptomatic benefit. METHOD: Ninety patients with chronic fatigue syndrome, diagnosed with our system that approximates CDC criteria, participated in a randomized, placebo-controlled, double-blind trial of 450 to 600 mg/day of moclobemide, a novel reversible inhibitor of monoamine oxidase-A. RESULTS: Fifty-one percent (24/47) of patients receiving moclobemide improved compared with 33% (14/43) of patients receiving placebo (odds ratio = 2.16, 95% confidence interval [CI] = 0.9 to 5.1). Drug response was best characterized symptomatically by an increase in the subjective sense of vigor and energy rather than a reduction in depressed mood. The effect of moclobemide on subjective energy was detectable within the first 2 weeks of treatment and increased across the course of the study. The greatest reduction in clinician-rated disability was in patients with concurrent

				immunologic dysfunction (mean difference in standardized units of improvement = 0.8, 95% CI = 0.03 to 1.6). CONCLUSION: Moclobemide produces some improvement in key symptoms experienced by patients with chronic fatigue syndrome. This effect is not dependent on the presence of concurrent psychological distress and is likely to be shared with other monoamine oxidase inhibitors.
Hoskin L, Clifton-Bligh P, Hansen R, Fulcher G, Gates F.	Department of Diabetes, Endocrinology, and Metabolic Medicine, Royal North Shore Hospital, St. Leonards, New South Wales, Australia. lhoskin@doh.health.nsw.gov.au	Bone density and body composition in young women with chronic fatigue syndrome. Huber M.	Institut und der Poliklinik fur Psychosomatik und Psychotherapie der Universitat zu Koln.	[Aspects of occupational disability in psychosomatic disorders].[article in German]	Versicherungsmedizin 2000 Jun 1;52(2):66-75	In 1997, 30% of the persons going into early retirement because of occupational disability and received pensions were psychosomatically ill. An additional large number of retirees suffered from untreatable pain such as chronic low back pain, some of them might as well have a chronic somatoform pain disorder. The article describes frequent psychosomatic diseases like somatization disorder, fibromyalgia and chronic fatigue syndrome with respect to their pathophysiology and psychological aspects as well as therapeutic advancements. It is postulated that an interdisciplinary access to these patients early in the course of their illness involving both somatic medical and psychiatric competence is the most promising means to tackle this enormous medical and health protection problem.
Hurwitz BE, Brownley KA, Fletcher MA, Klimas NG.		Chronic Fatigue Syndrome: Evidence Supporting the Hypothesis of a Behaviorally-Activated Neuromodulator of Fatigue	Journal of Chronic Fatigue Syndrome 2000; 6(2): 45	Chronic Fatigue Syndrome (CFS) is a disorder characterized by a prolonged, debilitating fatigue of unknown etiology. In addition, patients with CFS frequently report enhanced fatigue symptoms following even mild physical exertion, and their tolerance for physical exercise is limited relative to healthy individuals. The physiological mechanisms underlying the excessive fatigue and weakness common to this disorder remain an issue of scientific debate. Collectively, the available data suggest that fatigue in CFS is not due to any neuromuscular dysfunction, per se, but possibly is caused or influenced by some centrally acting mediator that is released during behavioral activities that require physical or mental exertion. In addition to persistent fatigue, there is growing evidence that many CFS patients exhibit alterations in hypothalamic-pituitary-adrenal (HPA) axis and autonomic function, including the inability to maintain the blood pressure response to orthostatic challenge. When an individual engages in mental or physical behavioral activation, there is a release of numerous centrally acting neuromodulators, some of which have been postulated to influence fatigue. This paper examines the evidence supporting a

				common pathway through which these centrally-mediated psychological and autonomic abnormalities may be linked. It is hypothesized that as a consequence of behavioral activation there is an abnormality in neuromodulator release or action in individuals with CFS, and that this abnormal neuromodulator activity results in increased fatigue. Furthermore, it is postulated that the CNS initiates a counter-regulatory mechanism to reduce the activity of those systems responsible for the production of the neuromodulator; and that the consequence of this counter-regulatory maneuver is the prevailing dysregulation of the autonomic and HPA axes and other dysfunctional cardiovascular and immunological sequelae.
Jadin CL.		Common Clinical and Biological Windows of CFS and Rickettsial Diseases	Journal of Chronic Fatigue Syndrome 2000; 6(3/4): 133	From 1991, links between CFS and Rickettsial Diseases were uncovered because of their similar clinical presentation. Further research linked them even more. Five Rickettsia strains, suspected to be the cause, or an important factor in CFS, were identified by means of the Giroud Micro-Agglutination test and were widely found to be positive in patients' serum, diagnosed as suffering from CFS, Fibromyalgia, Rheumatoid Arthritis, Multiple Sclerosis, Depression, Psychosis, Heart Diseases, and Auto-Immune Diseases. This finding leads us to submit those originally differently diagnosed patients to the same Tetracycline treatment. This proved to be a great success. The increasing number of patients gave us the opportunity to establish a biological checklist (regardless of the diversity of the pathology) of infections, organs' functions and auto-immune profile. We found the differences in positivity to depend on four factors: length of illness, virulence of germs, cohabitation of germs, and the state of the host immune system. These studies suggest that auto-immune diseases could have an infectious origin. Better knowledge and mastery of the co-factors would be determinant in speeding recovery. With this approach, CFS patients are being treated for the cause of their illness rather than symptomatically.
Jason LA, Fennell PA, Klein S, Fricano G, Halpert J.		An Investigation of the Different Phases of the CFS Illness	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 35	The present study examined the factor structure of the Fennell Phase Inventory, an instrument designed to measure the phases of the illness known as chronic fatigue syndrome. Four hundred participants were recruited and randomly assigned to two equally sized groups. A similar three-factor solution emerged for both samples, suggesting that three phases characterize this illness: a Crisis phase, a Stabilization phase, and an Integration phase. Factor scores on the Crisis Factor were significantly related to levels of fatigue and disability. The Fennell Phase Inventory appears to be a promising way of differentiating the different phases that are experienced by patients with CFS. The implications of these findings are discussed.
Jason LA, Fennell PA,Taylor RR, Fricano G, Halpert JA.		An Empirical Verification of the Fennell Phases of the CFS Illness	Journal of Chronic Fatigue Syndrome 2000; 6(1): 47	The Fennell Phase Inventory is an instrument designed to measure the phases typically experienced by individuals with chronic fatigue syndrome. In a previous study, a three-factor solution emerged. A cluster analysis was then conducted using the three mean scores for each individual, and four clusters emerged. These clusters matched the four phases predicted by Fennell. The Fennell Phase Inventory appears to be a promising way of differentiating the phases that are experienced by

				individuals with CFS.
Jason LA, Fricano G, Taylor RR, Halpert J, Fennell PA, Klein S, Levine S.	Department of Psychology, DePaul University, Chicago, IL 60614, USA. ljason@wppost.depaul.edu	Chronic fatigue syndrome: an examination of the phases.	J Clin Psychol 2000 Dec;56(12):1497-508	The present study examined the Fennell Phase Inventory, an instrument designed to measure the phases typically experienced by individuals with chronic fatigue syndrome (CFS). This inventory yields three factor scores of Crisis, Stabilization, and Integration. These factor scores have been employed in a cluster analysis, yielding four clusters that matched the four phases predicted by Fennell: Crisis, Stabilization, Resolution, and Integration. The present study represents a partial replication study of a prior investigation of the Fennell Phase Inventory by Jason et al. (in press), but that earlier study did not have an independent physician examination to diagnose patients with CFS. In the present study, 65 patients diagnosed with chronic fatigue syndrome by a physician were recruited and administered the Fennell Phase Inventory and other measures assessing CFS-related symptoms, disability, and coping. Each of the 65 patients was classified into one of four predefined clusters measuring a Crisis phase, a Stabilization phase, a Resolution phase, and an Integration phase. Relationships were explored between three of these cluster groupings and measures of symptoms, disability, and coping. Results confirmed Fennell's model, revealing significant differences between the three clusters in terms of levels of disability and modes of coping. Results suggest that the Fennell Phase Inventory accurately differentiates phases of adaptation to illness experienced by individuals with CFS.
Jason LA, King CP, Taylor RR, Kennedy C.		Defining Chronic Fatigue Syndrome: Methodological Challenges	Journal of Chronic Fatigue Syndrome 2000; 7(3): 17	Accurate diagnosis of Chronic Fatigue Syndrome (CFS) is greatly complicated by the vague wording of many of the major diagnostic criteria (i.e., substantial reductions in previous levels of occupational, educational, social, or personal activities) and the absence of guidelines for health care professionals to follow. The lack of operationally explicit criteria has forced health care professionals to rely heavily on their own clinical judgement, which may be biased by personal and highly idiosyncratic factors. Thus, in the case of CFS, the lack of consensus among clinicians regarding the interpretation and application of the diagnostic criteria has likely produced problems in diagnostic reliability. Data from a recent community based epidemiologic study are presented to illustrate these problems and provide recommendations for improving criterion reliability.
Jason LA, King CP, Richman JA, Taylor RR, Torres SR, Song S.		U.S. Case Definition of Chronic Fatigue Syndrome: Diagnostic and Theoretical Issues	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 3	In 1994, researchers from the U.S. Centers for Disease Control and Prevention developed a revised case definition of chronic fatigue syndrome (CFS) (1), a complex illness characterized by debilitating fatigue and a number of accompanying flu-like symptoms. Although Fukuda and associates intended to resolve complexities surrounding the classification of individuals with CFS stemming from previous definitional criteria (1), significant problems with the revised criteria endure. This article highlights reliability issues and other conceptual and operational difficulties inherent in the current U.S. definition of CFS (1). We employ case studies derived from a community-based epidemiological study of chronic fatigue syndrome (2) to

				illustrate examples of the potential for misclassification of individuals with CFS using the current U. S. criteria (1). Moreover, we suggest alternative approaches to classification and ways to operationalize specific concepts embedded in the current U.S. criteria (1).
Jason LA, Taylor RR, Kennedy CL, Jordan K, Song S, Johnson DE, Torres SR.	Department of Psychology, DePaul University, Chicago, Illinois 60614, USA.	Chronic fatigue syndrome: sociodemographic subtypes in a community-based sample.	Eval Health Prof 2000 Sep;23(3):243-63	Most chronic fatigue syndrome (CFS) studies are based on information about patients from primary or tertiary care settings. These patients might not be typical of patients in the general population. This investigation involved examinations of individuals with CFS from a community-based study. A random sample of 18,675 in Chicago was interviewed by telephone. Individuals with chronic fatigue and at least four minor symptoms associated with CFS were given medical and psychiatric examinations. A group of physicians then diagnosed individuals with CFS, who were then subclassified based on three sociodemographic categories--gender, ethnicity, and work status. Sociodemographic subgroups were analyzed in terms of symptom severity, functional disability, coping, optimism, perceived stress, and psychiatric comorbidity. Women, minorities, and nonworking individuals with CFS reported greater levels of functional disability, symptom severity, and poorer psychosocial functioning than men, Caucasians, and working individuals, suggesting sociodemographic characteristics may be associated with poorer outcomes in urban, community-based samples of CFS individuals.
Jason LA, Taylor RR, Kennedy CL, Song S, Johnson D, Torres S.	Department of Psychology, DePaul University, Chicago, Illinois 60614, USA.	Chronic fatigue syndrome: occupation, medical utilization, and subtypes in a community-based sample.	J Nerv Ment Dis 2000 Sep;188(9):568-76	Most studies of chronic fatigue syndrome (CFS) have been based on patients recruited from primary or tertiary care settings. Patients from such settings might not be typical of patients in the general population. The present investigation involved examining individuals with CFS from a community-based study. A random sample of 18,675 respondents in Chicago was first interviewed by telephone. A group of individuals with chronic fatigue accompanied by at least four minor symptoms associated with CFS were given medical and psychiatric examinations. From this sample, a physician review group diagnosed individuals with CFS. Those diagnosed with CFS were subclassified based on a variety of categories, including duration of illness, mode of illness onset, and presence or absence of a stressful life event directly preceding onset. In addition, we examined medical utilization among those diagnosed with CFS, as well as whether individuals with CFS were disproportionately represented in health care professions. Important differences emerged on measures of sociodemographics, symptoms, and functional disability. The implications of these findings and others are discussed.
Jason LA, Taylor RR, Kennedy CL.	Department of Psychology, DePaul University, Chicago 60614, IL, USA. ljason@wppost.depaul.edu	Chronic fatigue syndrome, fibromyalgia, and multiple chemical sensitivities in a community-based	Psychosom Med 2000 Sep-Oct;62(5):655-63	OBJECTIVE: The aim of this study was to determine illness comorbidity rates for individuals with chronic fatigue syndrome (CFS), fibromyalgia (FM), and multiple chemical sensitivities (MCS). An additional objective was to identify characteristics related to the severity of fatigue, disability, and psychiatric comorbidity in each of these illness groups. METHODS: A random sample of 18,675 residents in Chicago, Illinois, was first interviewed by telephone. A control group and a group of individuals

		sample of persons with chronic fatigue syndrome-like symptoms.		with chronic fatigue accompanied by at least four minor symptoms associated with CFS received medical and psychiatric examinations. RESULTS: Of the 32 individuals with CFS, 40.6% met criteria for MCS and 15.6% met criteria for FM. Individuals with MCS or more than one diagnosis reported more physical fatigue than those with no diagnosis. Individuals with more than one diagnosis also reported greater mental fatigue and were less likely to be working than those with no diagnosis. Individuals with CFS, MCS, FM, or more than one diagnosis reported greater disability than those with no diagnosis. CONCLUSIONS: Rates of coexisting disorders were lower than those reported in prior studies. Discrepancies may be in part attributable to differences in sampling procedures. People with CFS, MCS, or FM endure significant disability in terms of physical, occupational, and social functioning, and those with more than one of these diagnoses also report greater severity of physical and mental fatigue. The findings illustrate differences among the illness groups in the range of functional impairment experienced.
Jay SJ.		Tobacco use and chronic fatigue syndrome, fibromyalgia, and temporomandibular disorder.	Arch Intern Med 2000 Aug 14-28;160(15):2398, 2401 Comment on: Arch Intern Med. 2000 Jan 24;160(2):221-7	
Jiaxu C, Weiyi Y.		Treatment of Chronic Fatigue Syndrome with Chinese Medicine	Journal of Chronic Fatigue Syndrome 2000; 5(1): 61	Chronic fatigue syndrome (CFS) is a severe, debilitating disorder, which prominently features self-reported impairments in concentration and short-term memory, and disturbances in sleep and emotions, all of which can affect any one and seriously affect quality of life. In 1987, the Centers for Disease Control and Prevention (CDC) defined CFS as persistent or relapsing fatigue, with at least 50% reduction of baseline activity level lasting for at least 6 months, as one of the main symptoms. Since its cause is still unknown, treatment of CFS has been palliative and has included usually orally administered products, such as vitamin B12, vitamin C, folic acid, iron, magnesium, essential fatty acids, coenzyme Q10 and nicotinamide adenine dinucleotide (NADH), among others. The latter therapeutic modalities can only relieve some symptoms to some extent, but cannot fundamentally eliminate fatigue. It is, therefore, urgent to seek safe and effective drugs for the treatment of fatigue. We propose here that regulating homeostasis and enhancing immunity are important for the treatment of fatigue. In China, many Chinese herbs with such functions have been proven effective, an observation which opens the possibility of a new therapeutic method of eliminating fatigue with traditional Chinese medicine (TCM).
Jordan KM, Ayers PM. Jahn SC, Taylor KK, Huang C-F, Richman J, Jason LA.		Prevalence of Fatigue and Chronic Fatigue Syndrome-Like Illness in Children and	Journal of Chronic Fatigue Syndrome 2000; 6(1): 3	A community-based screening of over 12,000 households was conducted in order to determine the prevalence of fatigue and CFS-like illness in a sample of 5 to 17 year olds. Results indicate that over 4% of the sample was fatigued and that 2. 05% were diagnosed with CFS-like illness. Adolescents had a slightly higher rate of CFS-like

		Adolescents		illness (2.91%) than did pre-pubescent children (1.96%). Those with CFS-like illness were almost evenly divided between male (47.5%) and female (52. 5%). Youngsters of Latino origin had the highest representation in the CFS-like group. Symptom data, family patterns, and other data are presented for both the CFS-like group and the entire sample.

Kaur G, Kulkarni SK.		Comparative Study of Antidepressants and Herbal Psychotropic Drugs in a Mouse Model of Chronic Fatigue	Journal of Chronic Fatigue Syndrome 2000; 6(2): 23	This study examined the effects and comparative efficacy of various antidepressants and herbal psychotropic drugs in a mouse model of chronic fatigue. Animals were subjected daily to forced swimming (Porsolt's forced swimming test) and the duration of the immobility period was recorded in 6-minute sessions on each day for 7 days. Chronic forced swimming resulted in significant increases in immobility time on day 7 as compared to day 1 in control mice. Pretreatment with imipramine (10 mg/kg, i.p.), desipramine (10 mg/kg, i.p.), tranylcypromine (10 mg/kg, i.p.), alprazolam (0.5 mg/kg, i.p.), fluoxetine (10 mg/kg, i.p.) and melatonin (10 mg/kg, i.p.) produced significant decreases in immobility time as compared to controls on each day. Similar decreases in immobility periods were observed with herbal psychotropic preparations-Withania somnifera root extract (100 mg/kg, p.o.), BR-16AR (200 mg/kg, p.o.), siotoneR granules (200 mg/kg, p.o.) and evening primrose oil (0.2 ml/20g, p.o.). However, trazodone and idazoxan failed to modify the immobility times on all the days. The present observations underscore the established use of antidepressants in providing symptomatic relief of fatigue in Chronic Fatigue Syndrome (CFS) patients and further reinforce the potential therapeutic usefulness of herbal psychotropic preparations in CFS patients.
Kavelaars A, Kuis W, Knook L, Sinnema G, Heijnen CJ.	Department of Pediatric Immunology, Wilhelmina Children's Hospital of the University Medical Center Utrecht, The Netherlands. a.kavelaars@wkz.azu.nl	Disturbed neuroendocrine-immune interactions in chronic fatigue syndrome.	J Clin Endocrinol Metab 2000 Feb;85(2):692-6	The present study was designed to investigate the interaction between neuroendocrine mediators and the immune system in chronic fatigue syndrome (CFS). We examined the sensitivity of the immune system to the glucocorticoid agonist dexamethasone and the beta2-adrenergic agonist terbutaline in 15 adolescent girls with CFS and 14 age- and sex-matched controls. Dexamethasone inhibits T-cell proliferation in healthy controls and in CFS patients. However, the maximal effect of dexamethasone on T-cell proliferation is significantly reduced in CFS patients as compared with controls. The beta2-adrenergic receptor agonist terbutaline inhibits tumor necrosis factor-alpha production and enhances interleukin-10 production by monocytes. Our data demonstrate that the capacity of a beta2-adrenergic agonist to regulate the production of these two cytokines is also reduced in CFS patients. We did not observe differences in baseline or CRH-induced cortisol and ACTH between CFS patients and controls. Baseline noradrenaline was similar in CFS and controls, whereas baseline adrenaline levels were significantly higher in CFS patients. We conclude that CFS is accompanied by a relative resistance of the

				immune system to regulation by the neuroendocrine system. Based on these data, we suggest CFS should be viewed as a disease of deficient neuroendocrine-immune communication.

Antibodies to parvovirus B19 non-structural protein are associated with chronic but not acute arthritis following B19 infection.	Rheumatology (Oxford) 2000 Aug;39(8):903-8	OBJECTIVE: To determine the incidence and significance of antibodies to the parvovirus B19 non-structural (NS1) protein in B19-infected persons during acute infection and convalescence. METHODS: The B19 NS1 protein was expressed in SF9 cells using the baculovirus expression system and was used to prepare immunofluorescence slides. These were used in a fluorescent antibody test to determine anti-B19 NS1 IgG in a well-characterized cohort of 53 persons at the time of acute B19 infection and again after a follow-up period of 26-85 months. Results were examined for statistical significance by the use of Fisher's exact test. RESULTS: NS1 antibodies were detected in five of 32 persons with acute B19 infection (four with arthritis) and 10 of 53 persons with past B19 infection (six with chronic arthritis and two with chronic arthritis and chronic fatigue syndrome). Regarding the correlation of NS1 antibodies and arthritis, at the time of acute infection four of 24 persons with arthritis had NS1 antibodies detected compared with one of eight persons with any other symptoms (P: = 1). During convalescence, eight of 20 persons with chronic arthritis had NS1 antibodies compared with two of 33 with symptoms of any other category (all except one were asymptomatic) (P: = 0.007). All 10 patients with NS1 antibodies during convalescence had arthritis during acute infection, which persisted in eight persons until the time of follow-up. CONCLUSION: Antibodies to parvovirus B19 NS1 protein are associated with chronic but not with acute arthritis after B19 infection.

High nocturnal melatonin in adolescents with chronic fatigue syndrome.	J Clin Endocrinol Metab 2000 Oct;85(10):3690-2	Decreased quality of sleep is frequently reported by chronic fatigue syndrome (CFS) patients. The pineal hormone melatonin is involved in regulation of sleep. We analyzed the nocturnal rise in melatonin in 13 adolescent CFS patients and 15 healthy age-matched controls. Saliva samples were collected at hourly intervals between 1700 and 0200 h. Nocturnal saliva melatonin levels were significantly higher in CFS patients, compared with controls, at midnight, 0100 h, and 0200 h ($P < 0.001$). No differences were observed in timing of melatonin increase in saliva between patients and controls. Time of sleep onset and duration of sleep did not differ significantly between patients and controls. However, all CFS patients and only one of the controls in our study group reported unrefreshing sleep. Our data demonstrate that sleep problems in adolescents with CFS are associated with increased melatonin levels during the first part of the night. Based on these data, we suggest that there is

				no indication for melatonin supplementation in adolescents with CFS.

Korszun A, Young EA, Engleberg NC, Masterson L, Dawson EC, Spindler K, McClure LA, Brown MB, Crofford LJ.	Department of Psychological Medicine, University of Wales College of Medicine, Cardiff, UK. akorszun@umich.edu	Follicular phase hypothalamic-pituitary-gonadal axis function in women with fibromyalgia and chronic fatigue syndrome.	J Rheumatol 2000 Jun;27(6):1526-30	OBJECTIVE: Fibromyalgia (FM) and chronic fatigue syndrome (CFS) are clinically overlapping stress associated disorders. Neuroendocrine perturbations have been noted in both syndromes, and they are more common in women, suggesting abnormalities of gonadal steroid hormones. We tested the hypothesis that women with FM and CFS manifest abnormalities of the hypothalamic-pituitary-gonadal (HPG) hormonal axis. METHODS: We examined the secretory characteristics of estradiol, progesterone, follicle stimulating hormone (FSH), and luteinizing hormone (LH), including a detailed analysis of LH in premenopausal women with FM (n = 9) or CFS (n = 8) during the follicular phase of the menstrual cycle compared to matched healthy controls. Blood was collected from an indwelling intravenous catheter every 10 min. over a 12 h period. LH was assayed from every sample; pulses of LH were identified by a pulse-detection program. FSH and progesterone were assayed from a pool of hourly samples for the 12 h period and estradiol from samples pooled over four 3 h time periods. RESULTS: There were no significant differences in FSH, progesterone, or estradiol levels in patients versus controls. There were no significant differences in pulsatile secretion of LH. CONCLUSION: There is no indication of abnormal gonadotropin secretion or gonadal steroid levels in this small, but systematic, study of HPG axis function in patients with FM and CFS.
Korszun A.	Department of Psychological Medicine, University of Wales College of Medicine, Heath Park Cardiff CF4 4XN, UK. akorszun@umich.edu	Sleep and circadian rhythm disorders in fibromyalgia.	Curr Rheumatol Rep 2000 Apr;2(2):124-30	Fibromyalgia (FM) is a syndrome of generalized muscle pain that is also associated with equally distressing symptoms of sleep disturbance and fatigue. FM shows clinical overlap with other stress-associated disorders, including chronic fatigue syndrome (CFS) and depression. All of these conditions have the features of disrupted sleep patterns and dysregulated biologic circadian rhythms, such as stress hormone secretion. This review focuses on the role of sleep and circadian rhythm disorders in FM and, in the absence of any specific treatment for FM, presents a pragmatic therapeutic approach aimed at identifying and treating comorbid sleep and depressive disorders, optimizing sleep habits, and judicious use of pharmacologic agents.

The difference in patterns of motor and cognitive function in chronic fatigue syndrome and severe depressive illness.	Psychol Med 2000 Mar;30(2):433-42	BACKGROUND: Chronic fatigue syndrome (CFS) and major depressive disorder (MDD) share many symptoms and aetiological factors but may have different neurobiological underpinnings. We wished to determine the profile of the biological variables disturbed in CFS and MDD, and identify any critical factors that differentiate the disorders. METHODS: Thirty patients with CFS, 20 with MDD and 15 healthy controls matched group-wise for age and sex were recruited. Subjects were given a detailed battery of motor and cognitive tests, including measures of psychomotor speed, memory and maximal voluntary muscle contraction in both the morning and evening that were balanced to avoid order effects. RESULTS: CFS patients generally performed worse on cognitive tests than healthy controls, but better than patients with MDD. Both patient groups had markedly impaired motor function compared with healthy controls. MDD subjects showed a significantly greater diurnal improvement in maximal voluntary contraction than healthy controls. CONCLUSIONS: Patients with CFS and MDD show similarly substantial motor impairment, but cognitive deficits are generally more marked in MDD. Diurnal changes in some functions in MDD may differentiate the disorder from CFS.
Laylander JA.		A Nutrient/Toxin Interaction Theory of the Etiology and Pathogenesis of Chronic Pain-Fatigue Syndromes: Part I	Journal of Chronic Fatigue Syndrome 2000; 5(1): 67	Recent research suggests that Chronic Fatigue Syndrome (CFS), Fibromyalgia Syndrome (FMS), and Persian Gulf Syndrome (PGS) may represent the effects of dysfunctions involving the central and/or peripheral nervous system, neuroendocrine system, neuromuscular system, immune system, metabolism, or sleep patterns. Each systemic dysfunction is accepted here as being central to these syndromes but not causal. This two-part review introduces the theory that the syndromes listed above represent finitely variable combinations of multiple systemic dysfunctions which all share a common underlying etiology at the subcellular level: magnesium deficiency plus concomitant fluoride excess (MDFE). The theory is introduced in Part I; detailed evidence which supports the theory is presented in Part II. Treatment suggestions are

				listed at the end of Part II through a call for clinical trials to test this theory.
Laylander JA.		A Nutrient/Toxin Interaction Theory of the Etiology and Pathogenesis of Chronic Pain-Fatigue Syndromes: Part II	Journal of Chronic Fatigue Syndrome 2000; 5(1): 93	This second part of the review paper covers the evidence in favor of the theory which proposes that Chronic Fatigue Syndrome, Fibromyalgia Syndrome, and Persian Gulf Syndrome represent finitely variable combinations of multiple systemic dysfunctions which share a common underlying etiology at the subcellular level: magnesium deficiency plus concomitant fluoride excess (MDFE). Treatment suggestions are listed at the end of the manuscript through a call for clinical trials to test the theory presented.
Le Bon O, Hoffmann G, Murphy J, De Meirleir K, Cluydts R, Pelc I.	Brugmann University Hospital, Brussels 1020, Belgium. lebono@resulb.ulb.ac.be	How significant are primary sleep disorders and sleepiness in the chronic fatigue syndrome?	Sleep Res Online 2000;3(2):43-8	In order to study both the prevalence of Primary Sleep Disorders (PSD) and sleepiness, and their association to the Chronic Fatigue Syndrome (CFS), 46 unselected outpatients (34 women, mean age 36.5) were examined clinically and underwent two nights of all-night polysomnography and multiple sleep latency tests (MSLT). Forty-six percent presented with a Sleep Apnea/Hypopnea Syndrome Index (AHI>=5), 5% with a Periodic Limb Movements syndrome. No subject received a diagnosis of Narcolepsy or Idiopathic Hypersomnia. Thirty percent showed the presence of objective sleepiness as measured by MSLT<10 minutes. Objective and subjective measures of sleepiness were not associated with CFS, nor with the double diagnosis of CFS and a PSD. The presence of PSD or sleepiness was not associated with any of the clinical scales that were used to measure anxiety, depression, somatisation, physical or mental fatigue, or functional status impairment. Fifty-four percent of CFS patients had no PSD, and 69% no sleepiness. These patients could not be distinguished clinically from patients having a PSD or from those with sleepiness. Therefore, it is unlikely that CFS is simply a somatic expression of any PSD observed in our sample or of sleepiness per se.
Lee S, Yu H, Wing Y, Chan C, Lee AM, Lee DT, Chen C, Lin K, Weiss MG.	Department of Psychiatry, The Chinese University of Hong Kong, Prince of Wales Hospital, Shatin. singlee@cuhk.edu.hk	Psychiatric morbidity and illness experience of primary care patients with chronic fatigue in Hong Kong.	Am J Psychiatry 2000 Mar;157(3):380-4	OBJECTIVE: The authors' goal was to examine the prevalence and experience of psychiatric morbidity among primary care patients with chronic fatigue in Hong Kong. METHOD: One hundred adult patients with medically unexplained fatigue for 6 or more months were assessed with the Explanatory Model Interview Catalogue, psychopathological rating scales, and an enhanced version of the Structured Clinical Interview for DSM-III-R. RESULTS: The lifetime prevalence of DSM-III-R depressive and anxiety disorders was 54%. Current depressive and anxiety disorders were identified in 28 patients, who exhibited more psychopathology and functional impairment than other patients. Thirty-three patients had somatoform pain disorder, and 30 had undifferentiated somatoform disorder, but most of them could also be diagnosed as having shenjing shuairuo (weakness of nerves) and, to a lesser extent, ICD-10 neurasthenia. Chronic fatigue syndrome diagnosed according to the 1988 Centers for Disease Control criteria was rare (3%) and atypical. Generally, patients mentioned fatigue if asked, but pains (36%), insomnia (20%), and worries (13%) were the most troublesome symptoms. Most patients attributed illness onset to psychosocial sources. CONCLUSIONS: Psychiatric morbidity was common among primary care

				patients with chronic fatigue. Subthreshold psychiatric morbidity was very common and was more validly represented by the disease construct of shenjing shuairuo or neurasthenia than somatoform disorder.
Leonhardt T.	Medicinkliniken i Vanersborg-Trollhattan.	[Chronic fatigue syndrome--old wine in new bottles].[article in Swedish]	Lakartidningen 2000 Jan 19;97(3):182-4	
Levine PH, Clauw DJ, Claman HC, Robertson AD, Ketch L.		Silicone Breast Implants, Chronic Fatigue Syndrome and Fibromyalgia	Journal of Chronic Fatigue Syndrome 2000; 7(1): 53	Clinical studies have continued to suggest a relationship between silicone breast implants and chronic fatigue syndrome. Extensive epidemiologic studies, however, indicate that such a relationship is likely to be by chance and the successful lawsuits against producers of silicone breast implants are based on factors other than scientific proof. We present several perspectives on this issue which are probably relevant to other reports of putative etiologic agents for chronic fatigue syndrome.
Levine PH, Pilkington D, Strickland P, Peterson D.		Chronic Fatigue Syndrome and Cancer	Journal of Chronic Fatigue Syndrome 2000; 7(1): 29	Several studies have indicated a link between chronic fatigue syndrome (CFS) and cancer, most of them based on anecdotal observations. We have attempted to use more population-based data to determine if the reported relationship is meaningful. Two outbreaks of a fatiguing illness which included well documented cases of CFS were evaluated ten years after the reported outbreak for long-term effects, particularly cancer. We found an unusual pattern of cancer which, in view of an increased incidence of brain tumors and non-Hodgkin's lymphoma (NHL) reported in other studies involving CFS, indicates the need for further study. At the present time this link, which is often presumed to be due to immune dysfunction, has not yet been documented. Not all CFS patients have apparent dysregulation of the immune system and a single causative agent is highly unlikely, making the study of two heterogeneous illnesses, CFS and cancer, highly problematic. With the continuing focus on subgroups, however, this area of research may prove to be more productive.
Levine S.		Borna Disease Virus Proteins in Patients with CFS	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 199	Bornavirus is a member of a newly recognized virus family, Bornaviridae, and is neurotropic for a wide range of animal species, including birds, rodents, horses, and humans. Although little is known about its mode of transmission and it has not been clearly linked to any human disease, an association between bornaviruses and neuropsychiatric disorders has been suggested. Several researchers have also isolated this organism from patients who meet the clinical criteria for the Chronic Fatigue Syndrome (CFS). However, due to non-standardization of assay protocols, lack of a large study population and the possibility of contamination in certain laboratory settings, the true prevalence of Bornaviral proteins and their possible role in the pathogenesis of at least a subgroup of CFS patients remains undefined. We analyzed the serum immune reactivity to Borna Disease Virus (BDV) in 77 CFS patients and in 33 healthy normal controls using an ELISA based assay of 3 different recombinant BDV proteins. Of the 6 samples that displayed immunoreactivity to 2 or

				more BDV proteins, S were from patients (83.3%). Two samples, both from CFS patients, displayed immunoreactivity to 3 BDV proteins.

Lofqvist AH.		Functional Somatic Syndromes-A Matter of Stress Response Patterns?	Journal of Chronic Fatigue Syndrome 2000; 7(2): 75	This hypothesis deals with reactions described in functional somatic syndromes and postulates that these reactions be described in terms of active/passive and external/internal. The reflex character of these reactions explain the variation in symptom intensity which in turn is projected to doctors as feelings of lacking understanding, especially when disease parameters are normal.
Loganovsky KN.		Vegetative-Vascular Dystonia and Osteoalgetic Syndrome or Chronic Fatigue Syndrome as a Characteristic After-Effect of Radioecological Disaster: The Chernobyl Accident Experience	Journal of Chronic Fatigue Syndrome 2000; 7(3): 3	The aim of this study was to determine whether the Chronic Fatigue Syndrome (CFS) definition could be applicable to the assessment of the medical aftermath of radioecological disasters and to investigate a possible psychophysiological basis of fatigue in Chernobyl accident survivors. One hundred randomly selected clean-up workers of the Chernobyl accident who presented with complains of fatigue were examined neuropsychiatrically using MMPI profiles, Quantitative Electroencephalography (QEEG) and Somatosensory evoked potentials (SSEP). Twenty-six percent of them met the CFS diagnostic criteria. Their absorbed radiation doses were less than 0.3 Sv, an exposure level that is not expected to produce a clear deterministic radiation effect. Clinical symptomatology included persistent fatigue, odd skin sensations, bizarre feelings in bones, muscles and joints, irritability, headache, vertigo, pain in the chest area, emotional lability, irritability, lack of concentration and memory, cognitive deterioration, depression signs and sleep disorders. Liquidators with CFS had the characteristic MMPI profile with increased hypochondria, depression, clear hypochondria, schizophrenia, hysteria, psychasthenia, and bizarre sensory perception scales. Spectral analysis of QEEG showed lateralised (left-sided) increase of q-power ($P < 0.001$) and lateralised (left-sided) decrease of a-power ($P < 0.001$) and lateralised (left-sided) increase of b-power ($P < 0.01$). SSEP were characterized by increased latencies and decreased amplitudes. SSEP significantly differed by topographic abnormalities in the left temporoparietal area in liquidators with CFS. Associations between schizophrenia-like, hypochondriac and psychasthenic psychopathology and an increase of latency of

				SSEP P300 and N400 in liquidators with CFS were revealed. Thus, ``Vegetative-Vascular Dystonia'' and ``Osteoalgetic Syndrome'' cases following exposure to ionizing radiation as a result of the Chernobyl accident can be classified as CFS cases. The psychophysiological basis of fatigue in liquidators consists of dysfunction of the cortico-limbical structures of the left, dominating, hemisphere. CFS is one of the most important consequences of radioecological disaster, which results from an interaction of different hazardous environmental factors.
MacHale SM, Lawrie SM, Cavanagh JT, Glabus MF, Murray CL, Goodwin GM, Ebmeier KP.	University Department of Psychiatry, Royal Edinburgh Hospital.		192: Br J Psychiatry 2000 Jun;176:550-6Comment in: Br J Psychiatry. 2000 Nov;177:470 Cerebral perfusion in chronic fatigue syndrome and depression.	BACKGROUND: Patients with chronic fatigue syndrome (CFS) and depressive illness share many, but not all, features. AIMS: To test the hypothesis that patients with CFS have abnormal cerebral perfusion, that differs from that in patients with depressive illness. METHOD: We recruited 30 patients with CFS who were not depressed, 12 depressed patients and 15 healthy volunteers. Regional cerebral perfusion at rest was assessed using region of interest (ROI) and voxel-based statistical parametric mapping (SPM) techniques. RESULTS: On SPM analysis there was increased perfusion in the right thalamus, pallidum and putamen in patients with CFS and in those with depressive illness. CFS patients also had increased perfusion in the left thalamus. Depressed patients differed from those with CFS in having relatively less perfusion of the left prefrontal cortex. The results were similar on ROI analysis. CONCLUSIONS: Abnormal cerebral perfusion patterns in CFS subjects who are not depressed are similar but not identical to those in patients with depressive illness. Thalamic overactivity may be a correlate of increased attention to activity in CFS and depression; reduced prefrontal perfusion in depression may be associated with the greater neuropsychological deficits in that disorder.
Mahowald ML, Mahowald MW.	Department of Medicine, Minneapolis Veteran's Administration Medical Center, University of Minnesota Medical School, MN, Minneapolis, USA	Nighttime sleep and daytime functioning (sleepiness and fatigue) in less well-defined chronic rheumatic diseases with particular reference to the 'alpha-delta NREM sleep anomaly'	1389-9457 2000 Jul 1;1(3):195-207	For the past 25 years, the 'alpha-delta NREM sleep abnormality' has been used by some as a defining or legitimizing marker for poorly defined rheumatic diseases such as fibromyalgia and chronic fatigue syndrome. Comprehensive review of the literature reveals no support for such a conclusion. Most studies involve small numbers of patients. The lack of control subjects, non-standardized recording techniques, and confusion between tonic and phasic alpha frequency activity patterns make comparison difficult. There is much evidence that this sleep EEG pattern is not only non-specific, but may actually reflect a sleep maintaining process. The 'sleep fragmentation' theory of the complaint of non-restorative sleep in this patient population is invalidated by the fact that conditions characterized by severe sleep fragmentation, such as obstructive sleep apnea, are not associated with musculoskeletal symtoms. It is difficult to attribute musculoskeletal symptoms to disorders of sleep in view of the fact that the only organ of the body known to benefit from sleep, or to be adversely affected by lack of sleep, is the brain. It is concluded that fibromyalgia and chronic fatigue syndrome are associated with subjective sleep complaints, but do not represent sleep disorders.

Review Review, Tutorial		syndrome: the fundamentals still apply	Feb;108(2):172-3Comment in: Am J Med. 2000 Aug 15;109(3):257-9 and Am J Med. 2000 Feb;108(2):99-105.	
Manuel y Keenoy B, Moorkens G, Vertommen J, Noe M, Neve J, De Leeuw I.	Laboratory of Endocrinology, University of Antwerp, Belgium.	Magnesium status and parameters of the oxidant-antioxidant balance in patients with chronic fatigue: effects of supplementation with magnesium.	J Am Coll Nutr 2000 Jun;19(3):374-82	OBJECTIVE: Magnesium deficiency and oxidative stress have both been identified as pathogenic factors in aging and in several age-related diseases. The link between these two factors is unclear in humans although, in experimental animals, severe Mg deficiency has been shown to lead to increased oxidative stress. METHODS: The relationship between Mg body stores, dietary intakes and supplements on the one hand and parameters of the oxidant-antioxidant balance on the other was investigated in human subjects. RESULTS: The study population consisted of 93 patients with unexplained chronic fatigue (median age 38 years, 25% male, 16% smokers and 54% with Chronic Fatigue Syndrome (CFS). Mg deficient patients (47%) had lower total antioxidant capacity in plasma (p=0.007) which was related to serum albumin. Mg deficient patients whose Mg body stores did not improve after oral supplementation with Mg (10 mg/kg/day) had persistently lower blood glutathione levels (p=0.003). In vitro production of thiobarbituric acid reactive substances (TBARS) by non-HDL lipoproteins incubated with copper was related to serum cholesterol (p<0.001) but not to Mg or antioxidants and did not improve after Mg supplementation. In contrast, velocity of formation of fluorescent products of peroxidation (slope) correlated with serum vitamin E (p<0.001), which was, in turn, related to Mg dietary intakes. Both slope and serum vitamin E improved after Mg supplementation (p<0.001). CONCLUSIONS: These results show that the lower antioxidant capacity found in moderate Mg deficiency was not due to a deficit in Mg dietary intakes and was not accompanied by increased lipid susceptibility to in vitro peroxidation. Nevertheless, Mg supplementation was followed by an improvement in Mg body stores, in serum vitamin E and its interrelated stage of lipid peroxidation.
Maquet D, Croisier JL, Crielaard JM.	Universite de Liege, Medecine de l'Appareil Locomoteur.	[Fibromyalgia in the year 2000].[article in French]	Rev Med Liege 2000 Nov;55(11):991-7	Musculoskeletal pain is common in the population. Several pathologies like fibromyalgia (FM), chronic fatigue syndrome (CFS) or spasmophilia are associated with functional myalgia. The etiology of FM remains elusive, but the diagnosis is well established. The criteria for the classification are widespread pain combined with tenderness at 11 or more of the 18 specific tender points sites. The prevalence is 2% in the general population. This article reviews recent data on the pathophysiology and treatment of FM.
Martinsen EW.	Psykiatrisk klinikk, Sentralsjukehuset i Sogn og Fjordane, Forde.	[Physical activity for mental health].[article in Norwegian]	Tidsskr Nor Laegeforen 2000 Oct 20;120(25):3054-6	BACKGROUND: About 50% of the population will be affected by a mental disorder during their lifetime; the most common forms are mood and anxiety disorders and abuse of or dependence on drugs or alcohol. The standard forms of therapy are medication and various forms of psychotherapy. The cost of treating disease is

	egilwm@online.no			escalating, and the health care system will never be able to meet the need for treatment in this large group of patients. Hence, development of effective self help strategies is important. MATERIAL AND METHODS: In this paper, the scientific basis for promoting exercise as treatment for mental disorders is evaluated on the basis of a review of the literature. RESULTS: Beneficial psychological effects of exercise are best documented for mild to moderate forms of unipolar depression and chronic fatigue syndrome; in these disorders, exercise is an alternative to traditional forms of treatment. A therapeutic effect may also be achieved in panic and generalised anxiety disorder, schizophrenia, conversion and somatoform pain disorder, and alcohol abuse and dependence. INTERPRETATION: Beneficial effects of exercise are well documented. A simple and inexpensive approach like exercise is helpful and might be important for public health.
McGregor NR, Niblett S, Clifton Bligh P, Dunstan RH, Fulcher G, Hoskin L, Butt HL, Roberts TK,King K, Klineberg I.		The Biochemistry of Chronic Pain and Fatigue	Journal of Chronic Fatigue Syndrome 2000; 7(1): 3	Background: Chronic pain and fatigue represent major reasons for seeking medical treatments, however, the mechanisms are poorly understood. Onset of these disorders has been associated with events (infections, trauma, stress) which initiate a host response requiring increased energy demands. Objectives: To investigate the biochemical mechanisms of chronic pain and fatigue. Methods: Data will be presented from 4 separate investigations of CFS and myofascial pain syndrome (MFPS) patients, and from age/sex-matched controls, using metabolite profiling techniques. Results: Several types of chronic pain and fatigue disorders were discerned on the basis of their biochemistry. The metabolic events associated with chronic pain were distinct from those associated with chronic fatigue. The investigations have shown that chronic pain was associated with reductions in serum sodium, changes in urinary volume and output of amino and organic acids, increases in levels of markers of tissue damage (ALT, AST), and increases in the tyrosine: leucine ratio, which represents alterations in protein turnover. Fatigue was associated with alterations in urine excretion of amino and organic acids associated with tricarboxylic acid cycle (TCA) function. Levels of RNase-L were correlated with the expression of chronic fatigue related symptoms and were a good marker for CFS. Increased carriage of toxin-producing coagulase negative staphylococci was evident in MFPS and CFS patients, and this carriage was correlated with increased tyrosine: leucine ratios and pain severity. The toxin producing staphylococci appear to be a co-morbid pathogen that contributes to CFS patient morbidity. Conclusion: These studies indicated that changes in nitrogen homeostasis were associated with pain and fatigue symptoms and carriage of certain pathogens may sustain or exaggerate the chronic disorder.
McKenzie R, Reynolds JC, O'Fallon A, Dale J, Deloria M, Blackwelder W, Straus	Division of Microbiology and Infectious Diseases, National Institute of	Decreased bone mineral density during low dose glucocorticoid	J Rheumatol 2000 Sep;27(9):2222-6	OBJECTIVE: While osteoporosis and bone fractures are clearly recognized side effects of high dose glucocorticoids, the effect of low dose glucocorticoids remains controversial. We investigated the effect of 3 months of low dose hydrocortisone on bone mineral density (BMD). METHODS: Subjects, 18 to 55 years old with chronic

SE.	Allergy and Infectious Diseases, National Institute of Health, Bethesda, Maryland , USA.	administration in a randomized, placebo controlled trial.		fatigue syndrome and no medical or psychiatric illness requiring medication, were randomized in a double blind, placebo controlled trial to receive oral hydrocortisone, 13 mg/m2 body surface area every morning and 3 mg/m2 every afternoon (25 to 35 mg/day, equivalent to about 7.5 mg prednisone/day) or placebo for 12 weeks. Before and after treatment BMD of the lumbar spine was measured by dual energy x-ray absorptiometry. RESULTS: We studied 23 subjects (19 women, 4 men). For the 11 hydrocortisone recipients there was a mean decrease in BMD: mean change from baseline of the lateral spine was -2.0% (95% CI -3.5 to -0.6. p = 0.03) and mean change of the anteroposterior spine was -0.8% (95% CI -1.5 to -0.1, p = 0.06). Corresponding changes for the 12 placebo recipients were +1.0% (95% CI -1.0 to 3.0, p = 0.34) and +0.2% (95% CI -1.4 to 1.5, p = 0.76). CONCLUSION: A 12 week course of low dose glucocorticoids given to ambulatory subjects with chronic fatigue syndrome was associated with a decrease in BMD of the lumbar spine. This decrease was statistically significant in lateral spine measurements and nearly so in anteroposterior spine measurements.

Moorkens G, Berwaerts J, Wynants H, Abs R.	Departments of Internal Medicine; Endocrinology, University Hospital Antwerp, Belgium.	Characterization of pituitary function with emphasis on GH secretion in the chronic fatigue syndrome.	Clin Endocrinol (Oxf) 2000 Jul;53(1):99-106	OBJECTIVE: Previous studies have revealed that hormonal disturbances may accompany the chronic fatigue syndrome (CFS). Changes in the secretion of the pituitary-adrenal axis have been demonstrated, as well as abnormalities in the GH-IGF-I axis. However, data have not always been well characterized and were sometimes conflicting. The small number of CFS patients investigated in earlier studies may have played a role in the interpretation of the results. SUBJECTS AND DESIGN: Hormonal testing was performed in 73 nonobese CFS patients and nonobese 21 age-and gender-matched healthy controls. We investigated GH, ACTH and cortisol responses to insulin-induced hypoglycaemia. In a subgroup of patients arginine and clonidine stimulation for GH was also performed. Nocturnal secretion of GH, ACTH and cortisol were determined. Serum levels of IGF-I, prolactin, TSH, and free thyroxine were also measured. Visceral fat mass was assessed by CT scanning. RESULTS: GH response to insulin induced hypoglycaemia assessed by peak value (17.0 +/- 13.1 microg/l vs. 22. 1 +/- 9.8 microg/l; P = 0.01) and by AUC (450.0 +/- 361.3 microg/l vs. 672.3 +/- 393.0 microg/l; P = 0.002) was significantly decreased in CFS patients vs. controls. Nocturnal GH secretion assessed by GH peak value (5.4 +/- 3.7 vs. 9.0 +/- 5.1 microg/l; P = 0.44) and by AUC (34.4 +/- 20.2 vs. 67.4 +/- 43.1; P = 0.045) was also significantly impaired in CFS patients. Arginine and clonidine administration showed no differences in GH secretion between CFS patients and controls. In the CFS group, GH peak values were significantly higher after ITT than

				after arginine (P = 0.017) or clonidine (P = 0.001). No differences in serum IGF-I levels were found between CFS patients and controls. Except for a significantly lower nocturnal cortisol peak value, no differences were found in ACTH and cortisol secretion between CFS patients and controls. Significantly higher serum prolactin levels (7.4 +/- 4.7 microg/l vs. 4.4 +/- 1.3 microg/l; P = 0.004) and significantly higher serum TSH levels (1.6 +/- 1.0 mU/l vs. 1.0 +/- 0.4 mU/l; P = 0.011) were found in CFS patients. Serum free thyroxine was comparable in both groups. Visceral fat mass was significantly higher in CFS patients (86.6 +/- 34.9 cm2 vs. 51.5 +/- 15.7 cm2; P < 0.001). CONCLUSIONS: We observed a significant impairment of GH response during insulin-induced hypoglycaemia and a low nocturnal GH secretion in CFS patients. These changes did, however, not lead to different concentrations in serum IGF-I. The clinical expression of this inadequate GH secretion can thus be questioned, although the alteration in body composition may be related to this relative GH deficiency. Significantly increased prolactin and TSH levels were found when compared to controls. These findings give support to the hypothesis of a decreased dopaminergic tone in CFS. Further investigations are required in order to identify specific adaptations within the neurotransmitter system in CFS and to determine the clinical importance of the impaired GH homeostasis.
Naschitz JE, Rosner I, Rozenbaum M, Gaitini L, Bistritzki I, Zuckerman E, Sabo E, Yeshurun D.	Department of Internal Medicine A, Bnai Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel.	The capnography head-up tilt test for evaluation of chronic fatigue syndrome.	Semin Arthritis Rheum 2000 Oct;30(2):79-86	OBJECTIVES: To compare the hemodynamic and ventilatory responses to autonomic challenge evoked by upright tilt table testing in patients with chronic fatigue syndrome (CFS) to healthy individuals. METHODS: Thirty-two consecutive patients with CFS and 32 healthy volunteers were evaluated with the aid of the recently introduced capnography head-up tilt test (CHUTT). The main outcome measures were values of blood pressure (BP), heart rate (HR), respiratory rate (RR), and end-tidal pressure of co2 (ETPco2) recorded during recumbence and tilt. In addition, the end points of vasodepressor and cardioinhibitory reactions, hyperventilation (defined by ETPco2 <25 mm Hg) and the postural tachycardia syndrome, were recorded. RESULTS: The BP, HR, RR, and ETPco2 recorded during recumbence were similar in both groups. During tilt, patients with CFS developed significantly lower systolic BP, diastolic BP, and ETPco2, and a significant rise in HR and RR (P<.01). In CFS patients, the postural tachycardia syndrome occurred in 44%, vasodepressor reaction in 41%, cardioinhibitory reaction in 13%, and hyperventilation in 31% of cases. One or more end points of the CHUTT were reached in 78% of patients with CFS but in none of the controls (P<.0001). CONCLUSIONS: In most patients with CFS, a spectrum of abnormal homeostatic reactions is diagnosed with the aid of the CHUTT. Data provided by the CHUTT may reinforce the clinical diagnosis by adding objective and unbiased criteria to the subjective assessment of CFS.
Nawab SS, Miller CS, Dale JK, Greenberg BD, Friedman TC, Chrousos	Section on Biological Rhythms, National Institute of Mental	Self-reported sensitivity to chemical exposures in five	Psychiatry Res 2000 Jul 24;95(1):67-74	Two hundred and twenty-five subjects, including normal volunteers and patients with previously documented seasonal affective disorder (SAD), chronic fatigue syndrome (CFS), Cushing's syndrome, Addison's disease and obsessive-compulsive disorder

GP, Straus SE, Rosenthal NE.	Health, Bethesda, MD 20892-1390, USA. ssnawab@hotmail.com	clinical populations and healthy controls.		(OCD), completed a self-rated inventory of reported sensitivity to various chemical exposures. Patients with CFS, Addison's disease and SAD self-reported more sensitivity to chemical exposures than normal controls. In addition, women reported more sensitivity than men. This report suggests that chemical sensitivity may be a relevant area to explore in certain medical and psychiatric populations. A possible relationship between reported chemical sensitivity and hypothalamic-pituitary-adrenal (HPA)-axis functioning is discussed.
Neeck G, Crofford LJ.	Department of Rheumatology, University of Giessen, Bad Nauheim, Germany. gunther.neeck@kerckhoff.med.uni-giessen.de	Neuroendocrine perturbations in fibromyalgia and chronic fatigue syndrome.	Rheum Dis Clin North Am 2000 Nov;26(4):989-1002	A large body of data from a number of different laboratories worldwide has demonstrated a general tendency for reduced adrenocortical responsiveness in CFS. It is still not clear if this is secondary to CNS abnormalities leading to decreased activity of CRH- or AVP-producing hypothalamic neurons. Primary hypofunction of the CRH neurons has been described on the basis of genetic and environmental influences. Other pathways could secondarily influence HPA axis activity, however. For example, serotonergic and noradrenergic input acts to stimulate HPA axis activity. Deficient serotonergic activity in CFS has been suggested by some of the studies as reviewed here. In addition, hypofunction of sympathetic nervous system function has been described and could contribute to abnormalities of central components of the HPA axis. One could interpret the clinical trial of glucocorticoid replacement in patients with CFS as confirmation of adrenal insufficiency if one were convinced of a positive therapeutic effect. If patient symptoms were related to impaired activation of central components of the axis, replacing glucocorticoids would merely exacerbate symptoms caused by enhanced negative feedback. Further study of specific components of the HPA axis should ultimately clarify the reproducible abnormalities associated with a clinical picture of CFS. In contrast to CFS, the results of the different hormonal axes in FMS support the assumption that the distortion of the hormonal pattern observed can be attributed to hyperactivity of CRH neurons. This hyperactivity may be driven and sustained by stress exerted by chronic pain originating in the musculoskeletal system or by an alteration of the CNS mechanism of nociception. The elevated activity of CRH neurons also seems to cause alteration of the set point of other hormonal axes. In addition to its control of the adrenal hormones, CRH stimulates somatostatin secretion at the hypothalamic level, which, in turn, causes inhibition of growth hormone and thyroid-stimulating hormone at the pituitary level. The suppression of gonadal function may also be attributed to elevated CRH because of its ability to inhibit hypothalamic luteinizing hormone-releasing hormone release; however, a remote effect on the ovary by the inhibition of follicle-stimulating hormone-stimulated estrogen production must also be considered. Serotonin (5-HT) precursors such as tryptophan (5-HTP), drugs that release 5-HT, or drugs that act directly on 5-HT receptors stimulate the HPA axis, indicating a stimulatory effect of serotonergic input on HPA axis function. Hyperfunction of the HPA axis could also reflect an elevated serotonergic tonus in the

				CNS of FMS patients. The authors conclude that the observed pattern of hormonal deviations in patients with FMS is a CNS adjustment to chronic pain and stress, constitutes a specific entity of FMS, and is primarily evoked by activated CRH neurons.
Neerinckx E, Van Houdenhove B, Lysens R, Vertommen H, Onghena P.	Department of Psychosomatic Rehabilitation, University Hospital Katholieke Universiteit Leuven, Belgium. eneerinckx@mail.phlimburg.be	Attributions in chronic fatigue syndrome and fibromyalgia syndrome in tertiary care.	J Rheumatol 2000 Apr;27(4):1051-5	OBJECTIVE: To evaluate the attributions of patients with chronic fatigue syndrome (CFS) and fibromyalgia (FM) consulting at a university fatigue and pain clinic. METHODS: Consecutive attenders (n = 192) who met the CFS criteria (n = 95) or FM criteria (n = 56) or who had medically unexplained chronic pain and/or fatigue without meeting both criteria (CPF) (n = 41) were evaluated. All subjects completed an extended form of the Cause of Illness Inventory. Descriptive statistics, frequency analyses, chi-square tests, one-way analysis of variance, and sequential Fisher least significant difference tests were performed. RESULTS: In total, 48 patients reported physical causes only and 10 patients psychosocial causes only; the majority (70%) mentioned both types of causes. With regard to the contents, "a chemical imbalance in my body" (61%), "a virus" (51%), "stress" (61%), and "emotional confusion" (40%) were reported most frequently. The diagnostic label did not have a significant influence on number and type of attributions. Small to moderate effect sizes were registered concerning the association of specific attributions and diagnosis, sex, duration of the symptoms, contact with a self-help group, and premorbid depression. CONCLUSION: The majority of patients with CFS, FM, and CPF reported a great diversity of attributions open to a preferably personalized cognitive behavioral approach. Special attention should be paid to patients with symptoms existing for more than one year and those who had previous contacts with a self-help group. They particularly show external, stable, and global attributions that may compromise feelings of self-efficacy in dealing with the illness.
Nicolson GL. Nasralla MY, Franco AR, De Meirleir K, Nicolson NL, Ngwenya R, Haier J.		Role of Mycoplasmal Infections in Fatigue Illnesses: Chronic Fatigue and Fibromyalgia Syndromes, Gulf War Illness and Rheumatoid Arthritis	Journal of Chronic Fatigue Syndrome 2000; 6(3/4): 23	Bacterial and viral infections are purported to be associated with several fatigue illnesses, including Chronic Fatigue Syndrome (CFS), Fibromyalgia Syndrome (FMS), Gulf War Illnesses (GWI) and Rheumatoid Arthritis (RA), as causative agents, cofactors or opportunistic infections. We and others have looked for the presence of invasive pathogenic mycoplasmal infections in patients with CFS, FMS, GWI and RA and have found significantly more mycoplasmal infections in CFS, FMS, GWI and RA patients than in healthy controls. Most patients had multiple mycoplasmal infections (more than one species). Patients with chronic fatigue as a major sign often have different clinical diagnoses but display overlapping signs/symptoms similar to many of those found in CFS/FMS. When a chronic fatigue illness, such as GWI, spreads to immediate family members, they present with similar signs/symptoms and mycoplasmal infections. CFS/FMS/GWI patients with mycoplasmal infections generally respond to particular antibiotics (doxycycline, minocycline, ciprofloxacin, azithromycin and clarithromycin), and their long-term administration plus nutritional support, immune enhancement and other supplements appear to be necessary for

				recovery. Examination of the efficacy of antibiotics in recovery of chronic illness patients reveals that the majority of mycoplasma-positive patients respond and many eventually recover. Other chronic infections, such as viral infections, may also be involved in various chronic fatigue illnesses with or without mycoplasmal and other bacterial infections, and these multiple infections could be important in causing patient morbidity and difficulties in treating these illnesses.
Nisenbaum R, Jones A, Jones J, Reeves W.	Centers for Disease Control and Prevention, Atlanta, GA, USA	Longitudinal analysis of symptoms reported by patients with chronic fatigue syndrome.	Ann Epidemiol 2000 Oct 1;10(7):458	PURPOSE: To determine the effect of chronic fatigue syndrome (CFS) illness duration and onset type on the likelihood of reporting a symptom during successive follow-up periods.METHODS: In 1997, a two-phase RDD survey in Wichita, Kansas, was conducted to estimate the prevalence of CFS. Phase I identified 56,154 respondents 18-69 years of age and screened for severe fatigue, extreme tiredness or exhaustion lasting for 1 month or longer. In phase II an equal number of fatigued (n = 7,176) and randomly selected non-fatigued subjects were asked about 8 CFS and 13 non-CFS symptoms, as well as the presence of specific medical and psychiatric conditions. Eligible respondents were clinically evaluated to establish CFS diagnosis. Phase II respondents were re-contacted at 12- (n = 4,331) and 24-months (n = 4,266) for additional follow-up and diagnosis. In this study we considered symptoms reported as being present most of the time during each successive observation period. Generalized estimating equations were used to model symptoms over time and to address study questions. Such a model accounts for correlations among repeated symptoms for each subject. We used an auto-regressive structure for the correlation matrix, assuming the correlations between each pair of repeated symptoms should decrease as the time between symptoms increased.RESULTS: There were 74 CFS patients who had been ill for 1 to 20 years (median = 6.3 years). Among these, 46 reported gradual and 28 reported sudden onset. Symptoms fluctuated over the course of illness. However, only stomach pain (non-CFS symptom) was more likely to be reported as duration of illness increased ($p < 0.05$). There was no association between onset type and the likelihood of reporting a symptom during an interview, except that chills and severe headaches were more likely to be reported by sudden cases.CONCLUSIONS: The likelihood of expressing CFS and non-CFS symptom "most of the time" is the same across years of illness. More analyses are warranted to consider expression of symptoms for >/=6 months and severe symptoms.
Nores J-M.		The Philosophy of Pain: New Concepts	Journal of Chronic Fatigue Syndrome 2000; 5(2): 99	This article examines the concept of physical pain and its relationship to philosophy within the context of ethics. The first question posing a problem is: should pain be added to or included in the list of the five senses? Whether sensation is present or not, pain does exist. Pain is part of the ``immediate data of consciousness'' dear to philosophers. Pain is at the heart of ontology, philosophy of the being and existential ontology, which places existence above essence. Pain is mine and teaches me that I exist. Pain conveys my existence more than thought. Why shouldn't we enrich Descartes's cogito? ``I suffer, therefore I exist'' rather than ``I think, therefore I exist''

				or even ``I am something which suffers'' rather than ``I am a thing which thinks'' by Descartes. As pain is the witness of their existence, other beings resemble me. The use of physical pain to cause harm is the best transition towards the following question, that is, what is the relationship between pain and evil or harm? This is a question which is primordial and concerns philosophers, moralists and theologians. There is just pain which is harmful and is our enemy to be conquered. This would seem to be what philosophy has to teach those of us who are doctors fighting pain.

Pall ML.		Elevated Peroxynitrite as the Cause of Chronic Fatigue Syndrome: Other Inducers and Mechanisms of Symptom Generation	Journal of Chronic Fatigue Syndrome 2000; 7(4): 45	In an earlier paper, I proposed that chronic fatigue syndrome (CFS) is caused by a response to infection, involving the induction of inflammatory cytokines which induce, in turn, the inducible nitric oxide synthase, producing elevated nitric oxide. Nitric oxide reacts with superoxide to form the potent oxidant, peroxynitrite. Six positive feedback loops were proposed by which peroxynitrite may stay elevated, acting to increase levels of both nitric oxide and superoxide, which react to form more peroxynitrite. This vicious cycle based on known biochemistry is proposed to be the central cause of CFS. The current paper discusses additional inducers which may act by increasing nitric oxide (physical or psychological trauma) or increasing superoxide (hypoxia) and the role of orthostatic intolerance, Ehlers-Danlos syndrome, excessive exercise, exercise intolerance and carbon monoxide in inducing hypoxia and consequently superoxide and peroxynitrite. The major symptoms of CFS can all be interpreted as relatively direct consequences of the pathophysiology predicted by the elevated peroxynitrite theory of CFS. Attractive mechanisms are proposed by which elevated peroxynitrite, nitric oxide and/or related physiological changes may induce CFS symptoms including fatigue, immune dysfunction, learning and memory dysfunction, multi-organ pain, exercise intolerance/postexertional malaise and orthostatic intolerance. Roles are discussed for six factors likely to influence the frequency of CFS induction in response to infection or other inducing events.
Pall ML.	Department of Biochemistry/Biophysics and Program in Basic	Elevated, sustained peroxynitrite levels as the cause of chronic	Med Hypotheses 2000 Jan;54(1):115-25	The etiology of chronic fatigue syndrome (CFS) has been both obscure and highly contentious, leading to substantial barriers to both clear diagnosis and effective treatment. I propose here a novel hypothesis of CFS in which either viral or bacterial

	Medical Sciences, Washington State University, Pullman 99164-4660, USA. pall@mail.wsu.edu	fatigue syndrome.		infection induces one or more cytokines, IL-1beta IL-6, TNF-alpha and IFN-gamma. These induce nitric oxide synthase (iNOS), leading to increased nitric oxide levels. Nitric oxide, in turn, reacts with superoxide radical to generate the potent oxidant peroxynitrite. Multiple amplification and positive feedback mechanisms are proposed by which once peroxynitrite levels are elevated, they tend to be sustained at a high level. This proposed mechanism may lower the HPA axis activity and be maintained by consequent lowered glucocorticoid levels. Similarities are discussed among CFS and autoimmune and other diseases previously shown to be associated with elevated peroxynitrite. Multiple pharmacological approaches to the treatment of CFS are suggested by this hypothesis.
Patarca-Montero R, Mark T, Fletcher MA, Klimas NG.		Immunology of Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 6(3/4): 69	A review of the literature on the immunology of CFS reveals that people who have Chronic Fatigue Syndrome (CFS) have two basic problems with immune function that have been documented by most research groups: 1. immune activation, as demonstrated by elevation of activated T lymphocytes, including cytotoxic T cells, as well as elevations of circulating cytokines; and 2. poor cellular function, with low natural killer cell cytotoxicity (NKCC), poor lymphocyte response to mitogens in culture, and frequent immunoglobulin deficiencies, most often IgG1 and IgG3. These findings have a waxing and waning temporal pattern which is consistent with episodic immune dysfunction (with predominance of so called T-helper type 2 and proinflammatory cytokines and low NKCC and lymphoproliferation) that can be associated as cause or effect of the physiological and psychological function derangement and/or activation of latent viruses or other pathogens. The interplay of these factors can account for the perpetuation of disease with remission/exacerbation cycles. Therapeutic intervention aimed at induction of a more favorable cytokine expression pattern and immune status is discussed.
Pearn J.		Differential Diagnosis: The Challenge of Chronic Fatigue	Journal of Chronic Fatigue Syndrome 2000; 7(4): 17	The chronic fatigue syndrome comprises one of the most challenging issues in contemporary medicine. The condition remains distressing for patients and perplexing to medical science. Clinicians face a management path which has no ``gold standard'' of investigational mileposts; and are locked into a progression where the extremes of either undertreatment or over-investigation may lead to iatrogenic disaster. The themes of investigation, diagnosis and management of patients with the chronic fatigue syndrome remain controversial. This condition joins in historical perspective a series of other diseases such as pink disease, post traumatic stress disorder (by a variety of names), the Royal Free disease, Q Fever, Ross River disease and chronic ciguatera-all of which have occupied windows of historical time in the twentieth century during which their genesis remained an enigma. In some cases, they still do. New and puzzling diseases will undoubtedly arise in the future. Both patients and medical science are best served if the formal discipline of differential diagnosis is followed unswervingly under these circumstances or ``new'' diseases. The rigour of this discipline-the rank listing of formal possibilities after the clinical

				history and objective signs have been elicited-forms the pivot of best-practice contemporary medicine. An example of its power is no more dramatically illustrated by the example of a ``new'' enigmatic disease, chronic ciguatera, which ``reappeared'' in the 1950s. Ciguatoxins are some of the most potent biological substances known. Their neurotropic effects produce a protean array of symptoms which are distressing in the acute-phase syndrome and which are enervating throughout the often-prolonged progression of convalescence. It is now appreciated that such effects are due to sodium channel activation and subsequent dysfunction at the receptor sites on the cell surface of all excitable tissues. Dr. A. Melvin Ramsay, the Honorary Consultant Physician in Infectious Diseases at the Royal Free Hospital in London, was at the clinical epicentre of the presentation of another new disease in July 1955. His approach to its diagnosis, in the best traditions of differential diagnosis, is an exemplar of the objective response to the appearance of a new or enigmatic disease; and especially to that type in which experience has not generated sufficient case familiarity to define syndrome barriers or to establish pathogenesis. Under such conditions, the correct diagnostic paradigm is to follow the discipline of differential diagnosis, an evolved phenomenon of the last one hundred years of medicine. This paper traces the evolution of the process of differential diagnosis, in the perspective of the enigma of chronic fatigue, which remains an unmet challenge today.
Pearn J.	Australian Defence Force, Royal Children's Hospital, Brisbane, Queensland, Australia.	Traumatic stress disorders: a classification with implications for prevention and management.	Mil Med 2000 Jun;165(6):434-40	The management and prevention of acute and post-traumatic stress disorders are current themes of great importance to the defense health services of many nations. Currently, between 2% and 8% of service members deployed on combat operations, United Nations peacekeeping tasks, and humanitarian and disaster relief operations present with one or more stress disorders within 3 years of deployment. The management of acute stress disorders and the prevention and management of post-traumatic stress disorders necessitate an understanding of the nosology of this group of illnesses. Research into some preventive options--such as critical incident stress debriefing--also necessitates the selection of syndrome-specific subjects during case finding if controversies about the efficacy of such interventions are to be resolved. Diagnostic features, a summary of the nosological evolution, and key points of differential treatment options are presented for 5 acute operational stress disorders (acute combat stress disorder, conversion reactions, the counter-disaster syndrome, peacekeeper's acute stress syndrome, and the Stockholm syndrome) and for 11 post-traumatic disorders, including classic post-traumatic stress disorder, chronic fatigue syndrome, Gulf War syndrome, peacekeeper's stress syndrome, survivor's guilt syndrome, and the syndrome of lifestyle and cultural change.
Peckerman A, LaManca JJ, Smith SL, Taylor A, Tiersky L, Pollet C, Korn LR,	Center for Environmental Hazards Research, Environmental and	Cardiovascular stress responses and their relation to symptoms in Gulf War veterans	Psychosom Med. 2000 Jul-Aug;62(4):509-16.	OBJECTIVE: The objective of this study was to examine whether inappropriate cardiovascular responses to stressors may underlie symptoms in Gulf War veterans with chronic fatigue. METHODS: Psychophysiological stress testing was performed on 51 Gulf War veterans with chronic fatigue (using the 1994 case definition of the

Hurwitz BE, Ottenweller JE, Natelson BH.	Occupational Health Sciences Institute, Robert Wood Johnson Medical School, Piscataway, NJ, USA. apeckerm@nbunj.jvnc.net	with fatiguing illness.		Centers for Disease Control and Prevention) and 42 healthy veterans. Hemodynamic responses to cold pressor, speech, and arithmetic stressors were evaluated using impedance cardiography. RESULTS: Veterans with chronic fatigue had diminished blood pressure responses during cognitive (speech and arithmetic) stress tests due to unusually small increases in total peripheral resistance. The cold pressor test, however, evoked similar blood pressure responses in the chronic fatigue and control groups. Low reactivity to cognitive stressors was associated with greater fatigue ratings among ill veterans, whereas an opposite relation was observed among healthy veterans. Self-reported neurocognitive decline was associated with low reactivity to the arithmetic task. CONCLUSIONS: These results suggest a physiological basis for some Gulf War veterans' reports of severe chronic fatigue. A greater deficit with responses processed through cerebral centers, as compared with a sensory stimulus (cold pressor), suggests a defect in cortical control of cardiovascular function. More research is needed to determine the specific mechanisms through which the dissociation between behavioral and cardiovascular activities identified in this study may be contributing to symptoms in Gulf War veterans.
Petzke F, Clauw DJ.	Division of Rheumatology, Immunology, and Allergy, Georgetown University Medical Center, LL Gorman Building, 3800 Reservoir Road NW, Washington, DC 20007. petzkef@gusun.georgetown.edu	Sympathetic nervous system function in fibromyalgia.	Curr Rheumatol Rep 2000 Apr;2(2):116-23	This review focuses on studies of the sympathetic nervous system in fibromyalgia (FM). First, a brief review of the sympathetic system, and its relationship to the human stress response, is outlined. Then various studies of functional assessment of sympathetic function in FM are highlighted. Certain methods of assessment (eg, heart rate variability, biochemical, and psychophysical responses to various stressors) that we believe to be of specific importance for future research are discussed in greater detail. Finally, findings on autonomic function in related disorders--specifically, chronic fatigue syndrome, irritable bowel syndrome, and migraine--will be briefly presented.
Podell RN.		Chronic fatigue syndrome: the fundamentals still apply.	Am J Med 2000 Jun 1;108(8):677	
Poole J, Herrell R, Ashton S, Goldberg J, Buchwald D.	Harborview Medical Center, 325 Ninth Ave, Box 359780, Seattle, WA 98104, USA.	Results of isoproterenol tilt table testing in monozygotic twins discordant for chronic fatigue syndrome.	Arch Intern Med 2000 Dec 11-25;160(22):3461-8	BACKGROUND: The pathogenesis of chronic fatigue syndrome (CFS) is unknown. Neurally mediated hypotension (NMH) has been suggested as a common comorbid condition or a potential underlying cause. METHODS: We conducted a cotwin control study of 21 monozygotic twins who were discordant for CFS. One twin met the 1994 Centers for Disease Control and Prevention criteria for CFS, and the other twin was healthy and denied chronic fatigue. The twins were selected from a volunteer twin registry in which at least 1 member reported persistent fatigue. As part of a 7-day clinical evaluation, all 21 twin pairs were evaluated with a 3-stage tilt table test with isoproterenol hydrochloride for the assessment of NMH. The presence of NMH was

				defined as syncope or presyncope associated with a decrease of 25 mm Hg in blood pressure and no associated increase in heart rate. RESULTS: A positive tilt table test result was observed in 4 twins with CFS (19%) and in 4 healthy twins (19%). This difference was not statistically significant (matched pair odds ratio, 1.0; 95% confidence interval, 0.2-5.4; P>.90). Compared with the healthy twins, the twins with CFS reported more severe symptoms of CFS and NMH both in the week before and during the tilt table test. CONCLUSIONS: These results do not support a major role for NMH in CFS. They highlight the importance of selecting well-matched control subjects, as well as the unique value of the monozygotic cotwin control design in the study of this illness. Arch Intern Med. 2000;160:3461-3468.
Price JR, Couper J.	Department of Psychiatry, University of Oxford, The Warneford Hospital, Oxford, UK, OX3 7JX. jonathan.price@psych.ox.ac.uk	Cognitive behaviour therapy for adults with chronic fatigue syndrome.	Cochrane Database Syst Rev 2000;(2):CD001027	OBJECTIVES: 1. To systematically review all randomised controlled trials of cognitive-behaviour therapy (CBT) for adults with chronic fatigue syndrome (CFS); 2. To test the hypothesis that CBT is more effective than orthodox medical management or other interventions in adults with CFS. SEARCH STRATEGY: 1. Electronic searching of bibliographic databases, including Medline, PsycLIT, Biological Abstracts, Embase, SIGLE, Index to Theses, Index to Scientific and Technical Proceedings, and Science Citation Index, using multiple search terms in order to perform a highly sensitive search. 2. Electronic searching of the Trials Register of the Depression, Anxiety and Neurosis group. 3. Citation lists of relevant studies and reviews were perused for other relevant trials. 4. Contact with the principal authors of relevant studies, and with researchers in the field. SELECTION CRITERIA: All randomised controlled trials were included in which - adult patients with CFS; - received CBT or a control intervention, being either orthodox medical management or another intervention; - and whose outcomes were assessed in an appropriate way. CBT could be either type 'A' (encouraging return to 'normal' levels of rest and activity) or type 'B' (encouraging rest and activity which were within levels imposed by the disorder). DATA COLLECTION AND ANALYSIS: The two reviewers worked independently throughout the selection of trials and data extraction, comparing findings only when there was disagreement. Relevant trials were allocated to one of three quality categories. Full data extraction, using a standardised data extraction sheet, was performed on studies which were of high or moderate quality. Trials of low quality were excluded from the review. The comparisons made to test the review hypothesis were of type 'A' CBT versus other intervention(s), and of type 'B' CBT versus other intervention(s). Functional outcome was used as the main outcome for comparison, but other appropriate outcomes were compared where possible. Results were synthesised using the Review Manager software. For dichotomous data, the odds ratio was calculated for each study. For continuous data, effect sizes were obtained and the standardised mean difference, with 95% confidence intervals, was calculated. MAIN RESULTS: Only three relevant trials of adequate quality were found. These trials demonstrated that CBT significantly benefits physical functioning in adult out-

				patients with CFS when compared to orthodox medical management or relaxation. It is necessary to treat about two patients to prevent one additional unsatisfactory physical outcome about six months after treatment end. CBT appeared highly acceptable to the patients in these trials. There is no satisfactory evidence for the effectiveness of CBT in patients with the milder forms of CFS found in primary care or in patients who are so disabled that they are unable to attend out-patients. Additionally, there is no satisfactory evidence for the effectiveness of group CBT. REVIEWER'S CONCLUSIONS: Cognitive behaviour therapy appears to be an effective and acceptable treatment for adult out-patients with chronic fatigue syndrome. CFS is a common and disabling disorder. Its sufferers deserve the medical profession to be more aware of the potential of this therapy to bring lasting functional benefit, and health service managers to increase its availability. Further research is needed in this important area. Trials should conform to accepted standards of reporting and methodology. The effectiveness of CBT in more and less severely disabled patients than those usually seen in out-patient clinics needs to be assessed. Trials of group CBT and in-patient CBT compared to orthodox medical management, and of CBT compared to graded activity alone, also need to be conducted. Review, Academic
Prins JB, Bleijenberg G, Rouweler EK, van Weel C, van der Meer JWM.		Doctor-Patient Relationship in Primary Care of Chronic Fatigue Syndrome: Perspectives of the Doctor and the Patient	Journal of Chronic Fatigue Syndrome 2000; 7(4): 3	Background: Chronic Fatigue Syndrome (CFS) is characterized by severe debilitating fatigue for at least six months. The lack of a known origin could have consequences for the way general practitioners deal with the diagnosis CFS and their perception of CFS patients. The aims of the study were to investigate the use of the diagnosis CFS by GPs and their reactions to self-diagnosis and to explore opinions of GPs about causes of CFS and the communication with CFS patients as well as opinions of CFS patients about their GPs. Method: One hundred twenty-one GPs completed questionnaires and 12 were interviewed. Data of 211 CFS patients were analyzed as well. Results: Only half of the GPs used the diagnosis CFS. The main reason for not diagnosing CFS was ignorance of the criteria. GPs reported self-diagnosis in 68% of the CFS patients. More than half of the GPs could sympathize less with the complaints of CFS patients compared with other patients. These GPs experienced more problems in communicating with CFS patients and judged co-operation and contact as poor. As to the causes for CFS a discrepancy was found. GPs mainly attributed the complaints to psychosocial factors, whereas patients mainly had physical attributions. Conclusion: In CFS, GPs should be explicit about the diagnosis. As to the discrepancy in presumed causes of CFS between GPs and CFS patients, it may be helpful for GPs to discuss the distinction between initiating and perpetuating factors of CFS. We argue that this attitude of GPs would be beneficial to the course of the complaints of CFS patients.
Racciatti D, Barberio A,Vecchiet J, Pizzigallo E.		Clinical and Pathogenetical Characterization of 238	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 61	Prolonged fatigue is a common complaint in the community and is usually transitory. If fatigue continues for more than six months, is disabling, and is accompanied by other constitutional and neuropsychiatric symptoms, then a diagnosis of chronic

		Patients of a Chronic Fatigue Syndrome Italian Center		fatigue syndrome (CFS) should be considered. CFS probably is an heterogeneous disease, maybe multifactorial, or it includes different pathologies which manifest with the same symptoms. In some cases, the mode of presentation of the illness implicate the exposure to chemical and/or food toxins as precipitating factors (e.g., ciguatera poisoning, Gulf War Syndrome, etc.). In other CFS cases, the etiology is still unknown: there are various hypotheses on pathogenetic events which, alone or in association with each other, may precipitate the illness. In fact, it is probable an involvement of multiple events in CFS onset where different precipitating factors can interact each other, even if not always all present in the single patient: latent and/or chronic viral infections, immunologic and neuroendocrine dysfunctions, psychological, environmental and mood factors. In accordance to this theory, we consider various subgroups of CFS patients on the basis of the pathway and the mode of presentation of the disease. The Clinic of Infectious Diseases of ``G. D'Annunzio'' University of Chieti is one of the main National Reference Centers for the CFS Study in Italy. From January 1992 to January 1998, 238 patients came to our observation: 89 of them met CDC criteria for CFS (1994), 127 did not; the other 22 patients are still under evaluation. Our patients underwent physical examination (including tests for searching for the possible coexistence of a fibromyalgia syndrome), psychiatric interview with several neuropsychological tests, laboratory tests (including magnesium determination on serum), neuroendocrine evaluation (circadian rhythm of several hormones, buspirone challenge test), SPECT scans to evaluate cerebral perfusion, and other examinations where necessary in according to the symptomatology of each patient (e.g., orthopedic, ORL, EMG, muscle biopsy, etc.). According to our preliminary results, we subdivided our patients in different subgroups and we studied them comparatively. We report the more significant data collected from this evaluation that might lead to a better understanding of the syndrome and in particular of its pathways course, a knowledge that will help is choosing appropriate therapies for each subgroups.
Rangel L, Garralda E, Levin M, Roberts H.	Academic Unit of Pediatrics, Imperial College School of Medicine, London, UK.	Personality in adolescents with chronic fatigue syndrome.	Eur Child Adolesc Psychiatry 2000 Mar;9(1):39-45	Our aim was to study the presence of personality traits and disorder in adolescents with Chronic Fatigue Syndrome (CFS). Personality was then compared to other measures of functioning such as presence of psychiatric disorder and rating on the Child Behavior Checklist 4-18 (CBCL) and in relation to CFS outcome. Twenty-five adolescents with CFS followed-up after contacts with tertiary paediatric/psychiatric clinics were compared with 15 matched healthy controls. Interviews and questionnaires from parents and youngsters included Personality Assessment Schedule (PAS), Kiddie-SADS Psychiatric Interview, Child Behavior Checklist. CFS subjects were significantly more likely than controls to have personality difficulty or disorder. Personality features significantly more common amongst them were conscientiousness, vulnerability, worthlessness and emotional lability. There was a nonsignificant association between personality disorder and worse CFS outcome.

				Personality difficulty or disorder was significantly associated with psychological symptoms and decreased social competence on the CBCL but it was distinguishable from episodic psychiatric disorder. Personality difficulty and disorder are increased in adolescents with a history of CFS. Personality disorder may be linked to poor CFS outcome.
Rangel L, Garralda ME, Levin M, Roberts H.	Academic Unit of Child and Adolescent Psychiatry, Imperial College School of Medicine, St Mary's Hospital, London, UK.		J R Soc Med 2000 Mar;93(3):129-34Comment in: J R Soc Med. 2000 Jun;93(6):337-8 The course of severe chronic fatigue syndrome in childhood.	Little has been reported on prognostic indicators in children with chronic fatigue syndrome (CFS). We used interviews with children and parents, a mean of 45.5 months after illness onset, to follow up 25 cases of CFS referred to tertiary paediatric psychiatric clinics. At its worst, the illness had been markedly handicapping (prolonged bed-rest and school absence in two-thirds); mean time out of school was one academic year. Two-thirds, however, had recovered and resumed normal activities--mean duration of illness to recovery/assessment 38 months--and none had developed other medical conditions. Recovery was associated with specific physical triggers to the illness, with start of illness in the autumn school term and with higher socioeconomic status. Severe fatigue states in children can cause serious and longlasting handicap but most children recover.
Ray DE.	Medical Research Council Toxicology Unit, Leicester, United Kingdom. der@le.ac.uk	Pesticide neurotoxicity in Europe: real risks and perceived risks.	Neurotoxicology 2000 Feb-Apr;21(1-2):219-21	The same classes of pesticides are used all over the world, but conditions of use vary widely, and public perceptions of risk vary more widely still. Within Western Europe pesticide residues in commercially traded foodstuffs are subject to international standards and are closely monitored. Hence risks to consumers from such foods are negligible. The major hazards are poisoning associated with high acute/chronic operator exposures due to occasional pesticide misuse. In addition pesticides provide a convenient means of attempting suicide in agricultural areas. In contrast, public perception of risks from pesticides centres on low level exposures, and is heightened by several factors. These are: poisonings associated with pesticide misuse; the indirect nature of the benefit to the consumer (cf. medicines or public health uses); and commercially motivated marketing of pesticide-free produce. In press reports pyrethroid insecticides have been linked to "Multiple Chemical Sensitivity" in Germany, and organophosphates to "Chronic Fatigue Syndrome" in the UK. A number of pressure groups are actively campaigning to ban all uses of organophosphorus pesticides. Unfortunately evaluation of the real risks of pesticide exposure is rendered less certain by the lack of any very useful retrospective exposure measures with which biological effects of uncertain aetiology might be correlated. This means that although we can be sure that pesticides pose no gross threat to health in the general population, subtle effects on more highly exposed sub-populations are, as yet, more difficult to rule out.
Redman DA.	American University, Washington, DC, USA.	Ruscus aculeatus (butcher's broom) as a potential treatment for orthostatic	J Altern Complement Med 2000 Dec;6(6):539-49	CONTEXT: Chronic orthostatic hypotension (OH) is frequently a severely debilitating disease that affects large groups of the population with autonomic insufficiency--the elderly; patients with diabetes, Parkinson's disease, and chronic fatigue syndrome; and anyone on drugs that affect the autonomic nervous system. Unfortunately, even

		hypotension, with a case report.		though more than 60 medications are currently being used to treat OH, none of them is particularly or consistently effective. Ruscus aculeatus, a phytotherapeutic agent that is well known in Europe, may, however, change this. Its vasoconstrictive and venotonic properties make it ideally suited to treat the pooling of blood in the limbs, lack of venous tone, and lack of neurally mediated vasoconstriction that frequently characterize OH. Although it has never been suggested as a treatment for OH, it already has a long, proven record of use in Europe for treating a variety of circulatory disorders. OBJECTIVE: To provide evidence for what appears to be an effective, safe, inexpensive botanical therapy for OH and encourage further studies on the efficacy of Ruscus for OH patients. DESIGN: Review of OH and therapies currently available for OH and evaluation of the properties of Ruscus aculeatus, its mechanism of action, and its suitability as a therapeutic agent for treatment of OH. RESULTS: A review of the many pharmacologic and nonpharmacologic agents for treating OH reveals that all of the drug therapies are disappointing and marginally useful. Although nonpharmacologic management is preferred, in the many cases in which OH becomes debilitating, pharmacologic intervention becomes a last resort. But drug therapy may not always be necessary, because Ruscus aculeatus, a phytotherapeutic agent containing ruscogenins and flavonoids, may prove useful for the treatment of OH if denervation is not so advanced that it has compromised receptor activity at the venous wall. Ruscus aculeatus is an alpha-adrenergic agonist that causes venous constriction by directly activating postjunctional alpha1- and alpha2-receptors, in turn stimulating the release of noradrenaline at the level of the vascular wall. It also possesses venotonic properties: it reduces venous capacity and pooling of blood in the legs and exerts protective effects on capillaries, the vascular endothelium, and smooth muscle. Its flavonoid content strengthens blood vessels, reduces capillary fragility, and helps maintain healthy circulation. Unlike most of the drug therapies used to treat OH, Ruscus aculeatus does not cause supine hypertension. It also appears to do something no other therapy can offer--alleviate the worsening effects of OH in environmentally hot conditions. Finally, it is an extremely safe, inexpensive, over-the-counter botanical medicine. CONCLUSION: With proven phlebotherapeutic properties, including vasoconstrictive action and venotonic properties, Ruscus aculeatus shows great promise for ameliorating the symptoms of OH and improving the quality of life for large groups in the population. It clearly deserves to be the object of wider research and study as a treatment for OH.
Reeves WC, Stamey FR, Black JB, Mawle AC, Stewart JA, Pellett PE.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and	Human herpesviruses 6 and 7 in chronic fatigue syndrome: a case-control study.	Clin Infect Dis 2000 Jul;31(1):48-52	We conducted this study to determine whether infection with human herpesvirus (HHV) 6A, HHV-6B, or HHV-7 differed between patients with chronic fatigue syndrome and control subjects. We recruited 26 patients and 52 nonfatigued matched control subjects from Atlanta. Serum samples were tested by enzyme immunoassay for seroreactivity to HHV-6, and all were seropositive. Lymphocyte specimens were cocultivated with cord blood lymphocytes and assayed for HHV-6

	Prevention, Atlanta, GA, 30333, USA. wcr1@cdc.gov			and HHV-7; neither virus was isolated. Finally, lymphocytes were tested by use of 3 polymerase chain reaction methods for HHV-6A, HHV-6B, and HHV-7 DNA. HHV-6A or HHV-6B DNA was detected in 17 (22.4%) of 76 samples, and there were no significant differences (by matched analyses) between patients (3 [11.5%] of 26) and control subjects (14 [28%] of 50). HHV-7 DNA was detected in 14 subjects, and although control subjects (12 [24%]) were more likely than patients (2 [7.7%]) to be positive, the difference was not statistically significant. We found no evidence that active or latent infection with HHV-6A, HHV-6B, HHV-7, or any combination these 3 HHVs is associated with chronic fatigue syndrome.
Regland B.		[Two contributions on chronic fatigue syndrome: biological causes are involved in most cases]. [Article in Swedish]	Lakartidningen 2000 Mar 8;97(10):1168

Reyes M, Dobbins JG, Nisenbaum R, Subedar NS, Randall B, Reeves C.		Chronic Fatigue Syndrome Progression and Self-Defined Recovery: Evidence from the CDC Surveillance System	Journal of Chronic Fatigue Syndrome 2000; 5(1): 17	Objective: To examine the presence of symptoms associated with chronic fatigue syndrome (CFS) over the course of the illness and determine the probability of self-defined recovery by duration of illness. Design: Follow-up study. Subjects: One hundred fifty-five CFS patients enrolled in the Centers for Disease Control and Prevention's (CDC) CFS surveillance system between August 1989 and July 1993 and followed to November 1997. Measurements: Presence of symptoms, a self-defined period of recovery from CFS, and demographic differences between patients reporting and not reporting recovery. Period life-table methods were used to compute the probability of recovery from CFS for specific years of illness duration. Results: At illness onset, the most commonly reported CFS symptoms (w 45%) were sore throat, fever, tender lymph nodes, general weakness, and muscle pain. As the illness progressed, the percentages of patients reporting symptoms fluctuated. At illness onset, patients with a sudden onset of CFS reported significantly higher frequencies of sore throat, fever, tender lymph nodes, chills, hypersomnia, difficulty thinking or concentrating, and depression when compared to patients with a gradual onset. As the illness progressed, these differences disappeared, but gradual onset cases reported more hypersomnia than sudden onset cases (p = 0.001). The cumulative probability of recovery from CFS was 31.4% during the first 5 years of illness and 48.1% during the first 10 years of illness. For each year of illness through

				year 15, both sudden and gradual onset cases had similar recovery probabilities. Thereafter, gradual onset cases had higher recovery probabilities, but these differences were not statistically significant. Patients reporting recovery and those remaining ill were similar demographically. Conclusions: A period of recovery could be reported at any time during the course of CFS, but was more likely in the early years. Additional longitudinal studies are required to adequately describe the course of CFS in the early stages of illness, determine if the illness recurs over time, and predict the occurrence of symptoms over the course of illness. We recommend that researchers develop a standard definition of recovery from CFS and that future studies take into account the variable duration of illness and follow-up
Richards RS, Roberts TK, Dunstan RH, McGregor NR, Butt HL.	Department of Biological Sciences, University of Newcastle, New South Wales, Australia.	Free radicals in chronic fatigue syndrome: cause or effect?	Redox Rep 2000;5(2-3):146-7	We have demonstrated that certain morphological and biochemical changes occur in chronic fatigue syndrome (CFS) and in rheumatoid arthritis (RA). These changes in RA can be explained by the well-established inappropriate increase in free radical generation. The similar changes in CFS suggest a similar explanation and a possible role for free radicals in the aetiology of this condition.
Richards RS, Roberts TK, Mathers D, Dunstan RH, McGregor NR, Butt HL.		Erythrocyte Morphology in Rheumatoid Arthritis and Chronic Fatigue Sydrome: A Preliminary Study	Journal of Chronic Fatigue Syndrome 2000; 6(1): 23	Erythrocyte deformability and erythrocyte membrane stability are dependent on the erythrocyte cytoskeleton and its relationship with the contents of the cell. Certain internal occurrences such as oxidation of sulphydryl groups on the membrane cytoskeleton or the haemoglobin molecule could alter this relationship and as a consequence, alter the membrane properties and the shape of the cell. It is thus conceivable that in conditions where there is a potential increase in the generation of free radicals, erythrocyte shape could be altered. We investigated the possibility that predictable shape changes occur in erythrocytes from patients with rheumatoid arthritis (RA), a condition associated with free radical damage. We also investigated this possibility in patients with chronic fatigue syndrome (CFS) and whether any such change could be correlated with those seen in RA. Patients with CFS could be divided into two groups based on their erythrocyte morphology. Patients in one of these groups had increased numbers of stomatocytes. Patients with RA had increased numbers of leptocytes.
Richards RS, Roberts TK, Mathers D, Dunstan RH, McGregor NR, Butt HL.		Investigation of Erythrocyte Oxidative Damage in Rheumatoid Arthritis and Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 6(1): 37	A role of free radical scavenging for erythrocytes has previously been demonstrated, which is additional to their established role of gas exchange. In carrying out this role, erythrocytes become damaged by oxidation, which consumes endogenous reducing substances. It was therefore proposed that there exists a link between erythrocyte metabolism (particularly redox metabolism) and erythrocyte shape and that both of these should be related to erythrocyte deformability. To look for evidence of oxidative damage in vivo, the erythrocytes were assessed for reduced glutathione (GSH), malondialdehyde (MDA), methaemoglobin (metHb) and 2,3-diphosphoglyceric acid (2,3-DPG) in patients suffering from rheumatoid arthritis (RA), chronic fatigue syndrome (CFS) and healthy control subjects. Full blood counts, serum vitamin B12, erythrocyte folate, serum ferritin, serum iron, serum iron binding capacity and

				erythrocyte magnesium were also performed on all samples. Patients with RA had increased 2, 3-DPG, GSH and metHb when compared with the control group as well as the expected decreased haemoglobin, haematocrit, and serum iron. There was evidence of oxidative damage in CFS with 2,3-DPG metHb and MDA increased in this group. An increase in GSH could also be demonstrated in a sub-group of the CFS patients. This damage may explain the shape changes (presumably accompanied by increased rigidity) that have been reported in erythrocytes in patients suffering from CFS and suggests a role for free radicals in the pathogenesis of CFS.
Richards RS, Roberts TK, McGregor NR, Dunstan RH, Butt HL.	Department of Biological Sciences, University of Newcastle, Australia.	Blood parameters indicative of oxidative stress are associated with symptom expression in chronic fatigue syndrome.	Redox Rep 2000;5(1):35-41	Full blood counts, ESR, CRP, haematinics and markers for oxidative stress were measured for 33 patients diagnosed with chronic fatigue syndrome (CFS) and 27 age and sex matched controls. All participants also completed symptom questionnaires. CFS patients had increases in malondialdehyde (P <0.006), methaemoglobin (P <0.02), mean erythrocyte volume (P <0.02) and 2,3-diphosphoglycerate (P <0.04) compared with controls. Multiple regression analysis found methaemoglobin to be the principal component that differentiated between CFS patients and control subjects. Methaemoglobin was found to be the major component associated with variation in symptom expression in CFS patients (R(2) = 0.99, P <0.00001), which included fatigue, musculoskeletal symptoms, pain and sleep disturbance. Variation in levels of malondialdehyde and 2,3-diphosphoglycerate were associated with variations in cognitive symptoms and sleep disturbance (R(2) = 0.99, P <0.00001). These data suggest that oxidative stress due to excess free radical formation is a contributor to the pathology of CFS and was associated with symptom presentation.
Richardson J.		Four Cases of Pesticide Poisoning, Presenting as ``ME,'' Treated with a Choline and Ascorbic Acid Mixture	Journal of Chronic Fatigue Syndrome 2000; 6(2): 11	Objectives: 1. To demonstrate in four patients, in whom the correct diagnosis of pesticide poisoning had been missed, the injustices inflicted on them when they are told ME does not exist. 2. To show how closely the features of such poisoning, especially by organochlorines, resemble those of the much more classic ME which is usually due, at least in the author's practice in the northern region of the UK, to persistent enteroviral infection. 3. To draw attention to a new and apparently successful form of treatment with an oral mixture of choline and ascorbic acid. 4. To suggest reasons why this treatment merits further scientific investigation. Setting: A charity based private practice involved in the investigation of viral mediated disease. Subjects: Four patients, two male and two female, each referred with a diagnosis of ME. Intervention: a. Samples of blood were sent to Biolab Medical Unit where a variety of pesticide residues, including the very persistent organochlorines, were identified, and progress in detoxification was monitored. b. All four cases were treated orally with a choline and ascorbic acid mixture. Results: After a variable number of months, during the early phase of which the blood levels of some of the toxins rose, possibly due to mobilization from fatty stores, all symptoms cleared as blood levels fell. KEY Messages: The term ME comprises a number of clinical features, characterizing a patient who is ill. To refuse to recognize their existence does the

				patient much injustice. Some cases of ME may be found to have pesticide poisoning. The possibility of it should always be borne in mind. The source may be either in the UK or abroad. A positive enquiry and a single blood test will provide a diagnosis. Organochlorines may persist in the body for many years, as may the symptoms derived from them. A detoxification program based on oral administration of a choline and ascorbic acid mixture has shown much promise and deserves verification of its value. Conclusions: Amongst the group of clinical features known as ME, the possibility of pesticide poisoning should always be borne in mind. Treatment with choline and ascorbic acid mixture is worth trying, pending its more formal investigation.
Richman JA, Jason LA, Taylor RR, Jahn SC.	Department of Psychiatry, University of Illinois, Chicago 60612, USA. JRichman@uic.edu	Feminist perspectives on the social construction of chronic fatigue syndrome.	Health Care Women Int 2000 Apr-May;21(3):173-85	We contrast Western medical views of chronic fatigue syndrome (CFS) etiology, diagnosis, and treatment with views maintained by a predominantly female CFS population. We argue that the failure of Western medicine to demonstrate a viral etiology for CFS led to a paradigmatic shift in research perspectives, which then embraced psychiatric and sociocultural explanations for CFS. As a result, CFS was delegitimized as a biomedical phenomenon within medical, academic, governmental, and public arenas. We compare alternative social constructions of CFS with issues pertaining to multiple sclerosis (MS), an illness that similarly predominates among women. Patient perspectives suggest that the history of medical attitudes toward CFS may eventually parallel the transformations that occurred in relation to MS. In particular, the discovery of biological markers for CFS may lay to rest the categorization of CFS as largely within the psychiatric realm. Review Literature

Rowe KS.		Five-Year Follow-Up of Young People with Chronic Fatigue Syndrome Following the Double Blind Randomised Controlled Intravenous Gammaglobulin Trial	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 97	Three and 5 year follow-up studies of eighty-nine young people with Chronic Fatigue Syndrome who completed a double blind randomized controlled trial of intravenous gammaglobulin has been conducted to determine whether the improvement following the intravenous gammaglobulin was sustained. Initial telephone contact and a questionnaire that assessed functional outcomes including, physical activity, social activities, work/school attendance and work/school workload was used. Strategies and treatment that were found helpful and ways to improve management were also asked. Follow-up data were obtained on 86 of 89 after the study concluded. The 3-year follow-up yielded a 75% response to the questionnaire. A 78% follow up response rate at 5 years was achieved for those enrolled in the study with 84% (n = 74) of those who completed the study being traced. The mean follow-up time from commencement of illness was 56 months (s.d. 25 months), range 15-112 months. There was no persistent deterioration in function related to CFS in any young person. Four had reported recurrence of symptoms lasting 3-8 months and

				again improved. Others remained `improved' or continued to improve. Seventeen per cent of those who responded were still moderately unwell with another 23% `not back to normal yet.' Sixty per cent of participants considered they were `well' at the last follow-up with 45% scoring 10/10. Seventeen (20%) had another condition during or after their illness. Anergy or hypoergy did not predict functional outcome at five years after the trial, although an earlier improvement was noted in those who were anergic and who received gammaglobulin. There was no deterioration in overall function over the 5 years following participation in the gammaglobulin trial, and young people continued to improve although a significant number were still disabled. The significance of the abnormal delayed type hypersensitivity reaction for the response to gammaglobulin is uncertain and warrants further investigation.
Sachs L, Evengard B.	Tema Kommunikation, Linkopings universitet.	[The special physician-patient relation in connection to chronic fatigue syndrome. Anthropologists and physicians search for a new contact-model].[article in Swedish]	Lakartidningen 2000 Jan 19;97(3):176-8, 181	
Sadlier M, Evans JR, Phillips C, Broad A.		A Preliminary Study into the Effectiveness of Multi-Convergent Therapy in the Treatment of Heterogeneous Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 7(1): 93	In this preliminary study twenty-eight heterogeneous Chronic Fatigue Syndrome (CFS) patients were treated with Multi-Convergent Therapy (MCT). This form of therapy has been used successfully for over ten years in the treatment of Irritable Bowel Syndrome, Tinnitus, Hyperventilation Syndrome, Chronic Pain and Anxiety Disorders. This small study was undertaken to assess whether MCT is effective in the treatment of CFS and to examine whether a more extensive investigation is warranted. Due to heterogeneity of symptoms, outcome measures were established on the basis of a shared decision-making process between patient and therapist. One patient dropped out of the study. All twenty-seven remaining patients achieved significant recoveries. Twelve patients recorded a mean improvement on baseline symptoms of 61%, eight patients who completed a Quality of Life questionnaire demonstrated a mean change from 2.4 to 6.3 (out of 10). Five patients reported a return to full normal function and two patients returned to school or work and regular exercise. At follow up nine-months to one-year later all eighteen patients who responded reported either continued improvements or maintenance of a well state. The findings of this study support the use of MCT in the management of patients with Chronic Fatigue Syndrome and justify the implementation of a major clinical trial.
Schmaling KB, Smith WR, Buchwald DS.	University of Washington, Seattle	Significant other responses are	Psychosom Med 2000 May-Jun;62(3):444-50	OBJECTIVE: The predictive power of partners' responses to illness behavior for illness outcomes was investigated among couples in which one person had chronic fatigue

	98195-6560, USA. karens@u.washington.edu	associated with fatigue and functional status among patients with chronic fatigue syndrome.		syndrome (CFS). METHODS: One hundred nineteen participants who met case-definition criteria for CFS and were living with a significant other (SO) completed self-report measures of relationship satisfaction, responses of their SO to fatigue symptoms, and outcome measures of fatigue and functional status. RESULTS: The results indicated that more frequent solicitous SO responses to illness behavior were predictive of greater fatigue-related severity and bodily pain. Solicitous SO responses to fatigue behavior were particularly influential in the context of a satisfactory relationship. In highly satisfactory relationships, solicitous SO responses were associated with significantly greater fatigue severity and fatigue-related disability than in relationships characterized by low or average satisfaction. CONCLUSIONS: Solicitous SO responses to CFS-related symptoms are associated with poorer patient outcomes, especially in the context of a satisfactory intimate relationship. Because of the cross-sectional nature of the study, the direction of effects cannot be interpreted unambiguously. SOs may be inadvertently positively reinforcing illness-related behavior: Solicitous partners may help the patient more with tasks of daily living, thereby decreasing the patient's activity level, which may lead to deconditioning and disability. Alternatively, patients with more severe symptoms and disability may present more opportunities for concerned SO responses, which again may be heightened in the context of a caring, satisfactory relationship. In either case, the results suggest that additional research on the role of solicitous SO responses is warranted.
Schwartz SN, Jones R.		Measuring Outcomes of Treatment in Chronic Fatigue Syndrome: A Comparison of Simple Questioning vs. Use of a Validated Outcome Instrument (Short Form 36)	Journal of Chronic Fatigue Syndrome 2000; 6(2): 3	Purpose: To compare the outcome of treatment of chronic fatigue syndrome measured by a validated outcome instrument to patients' perception of outcome based on simple questioning. Subjects and Methods: Results of a single self-report question (``Are you much better, better, about the same, worse or much worse?'') at the end of approximately one year of treatment of 45 patients were compared to results of the Short Form 36 obtained at the beginning and end of that year. Results: There was no correlation between the results of the single self-report question and the interval change in the Short Form 36 summary scales and 7 of 8 component scales. Conclusions: Appropriate outcomes measurements can increase reliability of clinical practice results as well as treatment trials. Studies based only on answers to simple self-report questions may yield unreliable results.
Scott LV, Svec F, Dinan T.	Department of Psychiatry, Trinity College Medical School, St. James' Hospital, 8, Dublin, Ireland.	A preliminary study of dehydroepiandrosterone response to low-dose ACTH in chronic fatigue syndrome and in healthy subjects.	Psychiatry Res 2000 Dec 4;97(1):21-8	Abnormalities of the production of dehydroepiandrosterone (DHEA), the adrenal androgen, have been linked with disorders such as obesity and psychological disorders such as major depression. Adrenocorticotropin (ACTH) is the primary stimulant of DHEA, and cortisol, from the adrenal. We chose to examine the DHEA and DHEA/cortisol response to the novel low-dose ACTH test in healthy subjects and a cohort with chronic fatigue syndrome (CFS): this test is useful in assessing subtle irregularities of pituitary-adrenal activity. Nineteen CFS subjects (diagnosed by CDC criteria) and 10 healthy subjects were examined. We demonstrated that 1 &mgr;g

				ACTH significantly elevates DHEA levels, with no difference in output between CFS and healthy subjects. The DHEA/cortisol ratio decreased in response to ACTH stimulation in healthy subjects but not in the CFS cohort. We suggest this divergence of response between the two groups represents an imbalance in the relative synthetic pathways of the CFS group which, if present chronically and if comparable to daily stressors, may manifest itself as an inappropriate response to stress. This difference may be important in either the genesis or propagation of the syndrome.
Shannon M, Clovis LL.		Health Care Workers, Predominant Gender Females at High Risk: Turning the Spotlight on the Endocrine System	Journal of Chronic Fatigue Syndrome 2000; 7(1): 75	``Cluster Outbreaks'' of Chronic Fatigue (Immune Dysfunction) Syndrome CFIDS)/ Myalgic Encephalomyelitis (ME) have been well documented in the Healthcare professions. Large bodies of scientific evidence suggest that the endocrine system is very involved. In fact, it may be the most critical piece of the puzzle that needs to be examined in all future research. Although some subtle immunologic changes have been documented in persons with ME/CFIDS, recent studies on the endocrine system suggest that several hormonal abnormalities may account for the myriad of symptoms. Calkins and colleagues at Johns Hopkins have found that most patients have delayed orthostatic hypotension. Streeten and Bell extended these studies finding that most patients studied have severe hypovolemia. Hormones that prevent these conditions in healthy people are controlled by the pituitary and hypo-thalamus. It is interesting that the symptoms experienced by patients with Pan-Hypothyroidism are virtually identical to CFIDS/ME Endocrine research shows that most patients have low Cortisol levels. Overwhelming research shows a similar pattern to the many autoimmune diseases that occur predominantly in females. What looks like a multi-systemic disease, therefore, could be an endocrine disorder and could possibly explain the predisposition of the female gender. As health care professionals living with the disease, we would like to bridge the gap and help you help us return to our normal, pre-CFIDS/ME lives as best we can.
Soderlund A, Skoge AM, Malterud K.	Department of Public Health and Primary Health Care, University of Bergen, Norway.	"I could not lift my arm holding the fork...". Living with chronic fatigue syndrome.	Scand J Prim Health Care 2000 Sep;18(3):165-9	OBJECTIVES: To explore and describe symptoms and their consequences for patients suffering from chronic fatigue syndrome (CFS). DESIGN: Qualitative data from a group interview, written answers to a questionnaire and a follow-up meeting analysed in accordance with Giorgi's phenomenological approach. SUBJECTS: Purposeful sample of 10 women and 2 men of various ages recruited from the local self-help patient organisation. MAIN OUTCOME MEASURES: Descriptions reflecting the nature, extent and consequences of symptoms regarded as the most substantial by the informants across the group. RESULTS: Extreme exhaustion exceeding the nature of everyday weariness was reported as the worst symptom. The informants perceived reduced muscular strength, continuous weakness and recurrent pain, problems related to memory and concentration, sleep disturbances and excessive sensitivity towards smell, light and sound. Learning abilities had deteriorated, and housework, conversation, reading and watching TV were characterised as exhausting, leading to an unpredictability of everyday life-disturbing social relations. CONCLUSION: The

				extent and nature of symptoms suggest that CSF is an essentially different and far more serious condition than the strains of everyday life. Our findings suggest immunological processes affecting the neuromuscular and central neural system comparable to the effects of cytostatic medication.
Soetekouw PM, Wevers RA, Vreken P, Elving LD, Janssen AJ, van der Veen Y, Bleijenberg G, van der Meer JW.	Department of Medicine, Division of General Internal Medicine 541, University Medical Center St. Radboud, P.O. Box 9101, 6500 HB, Nijmegen, The Netherlands. p.soetekouw@aig.azn.nl	Normal carnitine levels in patients with chronic fatigue syndrome.	Neth J Med 2000 Jul;57(1):20-4	BACKGROUND: Patients with chronic fatigue syndrome (CFS) complain of muscle pain and impaired exercise tolerance. Previous studies show that this is due to systemic carnitine deficiency. We investigated the hypothesis that carnitine deficiency plays an important role in CFS in female CFS patients and compared their results with neighbourhood controls. METHODS: The level of total carnitine, free carnitine, acylcarnitine and carnitine esters were measured in 25 female CFS patients and 25 healthy matched neighbourhood controls in a blinded fashion. RESULTS: The previously reported decreased level of acylcarnitine in CFS patients was not confirmed. There were also no significant differences in levels of total carnitine, free carnitine and 20 carnitine esters between CFS patients and controls. CONCLUSIONS: The present study demonstrates that serum carnitine deficiency does not contribute to or causes the symptoms in many CFS patients.
Spath M, Welzel D, Farber L.	Friedrich-Baur-Institut, University of Munich, MunchenGermany. Michael.Spaeth@LRZ.uni-muenchen.de	Treatment of chronic fatigue syndrome with 5-HT3 receptor antagonists--preliminary results.	Scand J Rheumatol Suppl 2000;113:72-7	OBJECTIVE: The serotonin system presumably is involved in the pathogenesis of chronic fatigue syndrome (CFS). Results from a few studies led to the hypothesis of a "postsynaptic hyperresponsiveness" in CFS. Therefore we intended to evaluate the efficacy of 5-HT3 receptor antagonists in the treatment of CFS. PATIENTS AND METHODS: 2 patient groups (10 patients each; CFS according to the CDC classification criteria) received either oral tropisetron (5 mg once daily) or oral ondansetron (2 x 8 mg daily), open-labelled. Treatment duration was 15 days. Treatment response was evaluated by visual analog scales (VAS) for fatigue and capability. RESULTS: 19 patients finished their respective study. In the tropisetron group 6/9 (VAS fatigue) and 7/9 (VAS capability) patients documented benefit, 8/10 rsp. 8/10 patients in the ondansetron group. The score changes (VAS before and after treatment) in case of response were more pronounced in the tropisetron group. The frequency of concomitant symptoms did not differ significantly in the treatment groups. The overall analysis of both studies showed a remarkable improvement (> or = 35%) of approximately one third of the patients in both VAS. Treatment was well tolerated. CONCLUSION: Our preliminary results encourage to perform placebo-controlled, double-blind studies to further evaluate the efficacy of 5-HT3 receptor antagonists in the treatment of CFS.

Starr A, Scalise A, Gordon R, Michalewski HJ, Caramia MD.	Department of Neurology, University of California, Irvine, CA 92697-4290, USA. astarr@uci.edu	Motor cortex excitability in chronic fatigue syndrome.	Clin Neurophysiol 2000 Nov;111(11):2025-31	OBJECTIVE: To use transcranial magnetic stimulation (TMS) to define motor cortical excitability in chronic fatigue syndrome (CFS) subjects during a repetitive, bilateral finger movement task. METHODS: A total of 14 CFS patients were tested and compared with 14 age-matched healthy control subjects. TMS of the motor cortex (5% above threshold) was used to elicit motor evoked potentials (MEPs). Subjects performed regular (3-4/s) repetitive bilateral opening-closing movements of the index finger onto the thumb. MEPs of the first dorsal interosseus (FDI) were measured before, immediately following exercise periods of 30, 60 and 90 s, and after 15 min of rest. RESULTS: Performance, defined by rate of movement, was significantly slower in CFS subjects (3.5/s) than in controls (4. 0/s) independent of the hand measured. The rate, however, was not significantly affected by the exercise duration for either group. The threshold of TMS to evoke MEPs from the FDI muscle was significantly higher in CFS than in control subjects, independent of the hemisphere tested. A transient post-exercise facilitation of MEP amplitudes immediately after the exercise periods was present in controls independent of the hemisphere tested, but was absent in CFS subjects. A delayed facilitation of MEPs after 15-30 min of rest was restricted to the non-dominant hemisphere in controls; delayed facilitation was absent in CFS subjects. CONCLUSIONS: Individuals with CFS do not show the normal fluctuations of motor cortical excitability that accompany and follow non-fatiguing repetitive bimanual finger movements.
Steven ID, McGrath B, Qureshi F, Wong C, Chern I, Pearn-Rowe B.	Royal Australian College of General Practitioners, South Australia.	General practitioners' beliefs, attitudes and reported actions towards chronic fatigue syndrome.	Aust Fam Physician 2000 Jan;29(1):80-5	OBJECTIVE: To undertake a survey of Australian general practitioners (GPs) to explore their beliefs, attitudes and reported actions with respect to chronic fatigue syndrome (CFS). METHOD: A random sample of 2090 Australian GPs, stratified by state, was surveyed in May-August 1995. RESULTS: A 77% response rate was obtained. For the majority of practitioners who pursue a diagnosis of CFS, six symptoms were considered to be of significance: chronic unremitting fatigue for over 6 months; failure to recover energy after rest; reduced exercise tolerance; prostration for several days after exercise; generalised myalgia and poor concentration. Individual counselling was the most frequently used treatment. Thirty-one percent of practitioners reported that they did not believe that CFS is a distinct syndrome. Of these, 70% reported that the most likely cause of chronic fatigue was depression. CONCLUSION: There is considerable diversity of opinion between practitioners about CFS. The diversity extends from questioning whether the syndrome even exists to different strategies for diagnosis and management.
Stewart JM.	Department of Pediatrics, The Center for Pediatric Hypotension, New York Medical College, Valhalla 10595, USA.	Autonomic nervous system dysfunction in adolescents with postural orthostatic tachycardia syndrome and chronic fatigue	Pediatr Res 2000 Aug;48(2):218-26	The objective was to determine the nature of autonomic and vasomotor changes in adolescent patients with orthostatic tachycardia associated with the chronic fatigue syndrome (CFS) and the postural orthostatic tachycardia syndrome (POTS). Continuous electrocardiography and arterial tonometry was used to investigate the heart rate and blood pressure responses before and 3-5 min after head-up tilt in 22 adolescents with POTS and 14 adolescents with CFS, compared with control subjects

		syndrome is characterized by attenuated vagal baroreflex and potentiated sympathetic vasomotion.		comprising 10 healthy adolescents and 20 patients with simple faint. Heart rate and blood pressure variability, determined baroreceptor function using transfer function analysis, and measured cardiac vagal and adrenergic autonomic responses were calculated using timed breathing and the quantitative Valsalva maneuver. Two of 10 healthy controls and 14 of 20 simple faint patients experienced vasovagal syncope during head-up tilt. By design, all CFS and POTS patients experienced orthostatic tachycardia, often associated with hypotension. R-R interval and heart rate variability were decreased in CFS and POTS patients compared with control subjects and remained decreased with head-up tilt. Low-frequency (0.05-0.15 Hz) blood pressure variability reflecting vasomotion was increased in CFS and POTS patients compared with control subjects and increased further with head-up tilt. This was associated with depressed baroreflex transfer indicating baroreceptor attenuation through defective vagal efferent response. Only the sympathetic response remained. Heart rate variability declined progressively from normal healthy control subjects through syncope to POTS to CFS patients. Timed breathing and Valsalva maneuver were most often normal in CFS and POTS patients, although abnormalities in select individuals were found. Heart rate and blood pressure regulation in POTS and CFS patients are similar and indicate attenuated efferent vagal baroreflex associated with increased vasomotor tone. Loss of beat-to-beat heart rate control may contribute to a destabilized blood pressure resulting in orthostatic intolerance. The dysautonomia of orthostatic intolerance in POTS and in chronic fatigue are similar.
Stough C, Withers G.		Sleep Disturbance in Patients with Chronic Fatigue Syndrome and Chronic Fatigue	Journal of Chronic Fatigue Syndrome 2000; 6(2): 37	To examine whether the identification of patients with Chronic Fatigue Syndrome can be made using more objective criteria than presently available (1), we compared 14 patients with Chronic Fatigue Syndrome and 12 patients with chronic fatigue (but who did not meet the criteria for Chronic Fatigue Syndrome) on sleep architecture, continuity, and sleep abnormalities from polysomnography recordings. No differences in sleep continuity or architecture were found between the two groups, except that patients with Chronic Fatigue Syndrome recorded significantly increased sleep latencies. There were no differences in the frequency of sleep disorders. Results indicated that apart from sleep latency, other sleep variables do not adequately differentiate patients with CFS from those with chronic fatigue and that other variables should be examined, which may validly diagnose patients with CFS.
Streeten DH, Thomas D, Bell DS.	Department of Medicine, State University of New York Health Science Center, Syracuse 13210, USA.	The roles of orthostatic hypotension, orthostatic tachycardia, and subnormal erythrocyte volume in the pathogenesis of the chronic fatigue	Am J Med Sci 2000 Jul;320(1):1-8	BACKGROUND: Orthostatic hypotension during upright tilt is an important physical disorder in patients with chronic fatigue syndrome. We have tested its occurrence during prolonged standing, whether it is correctable, and whether reduced circulating erythrocyte volume is present. METHODS: Fifteen patients were randomly selected from a large population of patients with chronic fatigue syndrome, studied, and observed for several years (by DSB). Blood pressure (BP) and heart rate (HR) measured with Dinamap every minute for 30 minutes supine and 60 minutes standing were compared with these findings in 15 healthy age- and gender-matched

		syndrome.		control subjects and later during lower body compression with military antishock trousers (MAST). Plasma catecholamines and circulating erythrocyte and plasma volumes were also measured by isotopic dilution methods. RESULTS: Abnormal findings in the patients included excessive orthostatic reductions in systolic (P < 0.001) and diastolic BP (P < 0.001) and excessive orthostatic tachycardia (P < 0.01), together with presyncopal symptoms in 11 of the 15 patients and in none of the control subjects after standing for 60 min. Lower body compression with the MAST restored all orthostatic measurements to normal and overcame presyncopal symptoms within 10 min. Circulating erythrocyte but not plasma volumes were subnormal in the 12 women (P < 0.01) and plasma norepinephrine concentration rose excessively after standing for 10 min. CONCLUSION: Delayed orthostatic hypotension and/or tachycardia caused by excessive gravitational venous pooling, which is correctable with external lower-body compression, together with subnormal circulating erythrocyte volume, are very frequent, although not invariably demonstrable, findings in moderate to severe chronic fatigue syndrome. When present, they may be involved in its pathogenesis.
Suhadolnik RJ, Peterson DL, Cheney PR, Horvath SE, Reichenbach NL, O'Brien K, Lombardi V, Welsch S, Furr EG, Charubala R, Pfleiderer W.		Biochemical Dysregulation of the 2-5A Synthetase/RNase L Antiviral Defense Pathway in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 223	The aim of the current study was to examine the biochemical defects in KEY components of the 2i,5i-oligoadenylate (2-5A) synthetase/RNase L antiviral pathway in an extended cohort of patients with chronic fatigue syndrome (CFS) from two sites. CFS patients, who met the CDC criteria for CFS, and matched controls were assessed with respect to their general health, depression, and pain. Biochemical assays were completed for three blood draws over a period of one year. Analysis of the mean values for bioactive 2-5A, RNase L activity, low molecular weight (LMW) RNase L in CFS PBMC extracts confirmed the statistically significant upregulation of the 2-5A synthetase/RNase L pathway compared to control PBMC extracts (p = .001, .002, and .007, respectively). Clinical correlates to the biochemical findings included a negative correlation between Karnofsky Performance Score and bioactive 2-5A (p = .025) or RNase L activity (p = .002) and positive correlation between Metabolic Screening Questionnaire and RNase L activity (p = .01) and between interferon- and LMW RNase L (p = .05). The evidence presented in this study more firmly establishes the dysregulation of the 2-5A synthetase/RNase L pathway in CFS.

Takahashi Y, Ohta S, Sano A, Kuroda Y, Kaji Y, Matsuki M, Matsuo M.	Department of Pediatrics, Tenri Hospital, Nara, Japan.	Does severe nutcracker phenomenon cause pediatric chronic fatigue?	Clin Nephrol 2000 Mar;53(3):174-81	BACKGROUND: In the past five years we experienced 9 fatigued disabled children who were intermittently or persistently absent from school. PATIENTS: They had been suspected to be burdened with psychosomatic disorders, having orthostatic hypotension, postural tachycardia, or other autonomic dysfunction symptoms.

				RESULTS: Investigating the cause of moderate orthostatic proteinuria in some of them, we found by chance severe typical nutcracker phenomenon (NC), which was present in all 9 children complaining of chronic fatigue. CONCLUSION: Their symptoms filled the criteria of chronic fatigue syndrome or idiopathic chronic fatigue (CFS/CF). An association between severe NC and autonomic dysfunction symptoms in children with CFS/CF has been presented.

Taylor RR, Jason LA, Torres A.	Department of Psychology, DePaul University, Chicago, IL 60614, USA.	Fatigue rating scales: an empirical comparison.	Psychol Med 2000 Jul;30(4):849-56	BACKGROUND: There has been limited research comparing the efficacy of different fatigue rating scales for use with individuals with chronic fatigue syndrome (CFS). This investigation explored relationships between two commonly-used fatigue rating scales in CFS research, the Fatigue Scale and the Fatigue Severity Scale. Theoretically, these scales have been described as measuring different aspects of the fatigue construct. The Fatigue Scale was developed as a measure of the severity of specific fatigue-related symptoms, while the Fatigue Severity Scale was designed to assess functional outcomes related to fatigue. METHODS: Associations of these scales with the eight definitional symptoms of CFS and with eight domains of functional disability were examined separately in: (1) an overall sample of individuals with a wide range of fatigue severity and symptomatology; (2) a subsample of individuals with CFS-like symptomatology, and, (3) a subsample of healthy controls. RESULTS: Findings revealed that both scales are appropriate and useful measures of fatigue-related symptomatology and disability within a general population of individuals with varying levels of fatigue. However, the Fatigue Severity Scale appears to represent a more accurate and comprehensive measure of fatigue-related severity, symptomatology, and functional disability for individuals with CFS-like symptomatology.
Tomoda A, Miike T, Yamada E, Honda H, Moroi T, Ogawa M, Ohtani Y, Morishita S.	Department of Child Development, Kumamoto University School of Medicine, Japan. tomo@kaiju.medic.kumamoto-u.ac.jp	Chronic fatigue syndrome in childhood.	Brain Dev 2000 Jan;22(1):60-4	Chronic fatigue occurring in previously healthy children and adolescents is one of the most vexing problems encountered by pediatric practitioners. We report three cases, 11, 12 and 13-year-old children, with chronic fatigue syndrome (CFS). They initially developed a low grade fever and generalized fatigue, followed by sleep disturbance and psychosomatic symptoms, and their performance ability deteriorated. They were diagnosed as having CFS on the basis of criteria. To investigate the brain function in CFS patients, we examined the regional cerebral blood flow by single-photon emission-computed tomography (SPECT) with 111 MBq [123I]-iodoamphetamine (123I-IMP) or xenon-computed tomography (Xe-CT), and brain metabolic levels by MR spectroscopy (MRS). Blood flow, expressed as the corticocerebellar ratio (CCR), in

				the left temporal and occipital lobes was markedly lower in cases 2 and 3 than that in healthy subjects reported by another investigator. In case 1, however, blood flow in the left basal ganglia and thalamus was markedly higher than in healthy subjects. The MR spectroscopy (MRS) study revealed remarkable elevation of the choline/creatine ratio in the patients with CFS. None of our patients exhibited evidence of focal structural abnormalities on MRI. These findings suggest that the various clinical symptoms in CFS patients may be closely related to an abnormal brain function.
Treib J, Grauer MT, Haass A, Langenbach J, Holzer G, Woessner R.	Department of Neurology, University Hospital of the Saarland, Homburg, Germany.	Chronic fatigue syndrome in patients with Lyme borreliosis.	Eur Neurol 2000;43(2):107-9	Several authors have reported a chronic fatigue-like syndrome in patients that have suffered from Lyme borreliosis in the past. To further investigate this suspicion of an association without sample bias, we carried out a prospective, double-blind study and tested 1, 156 healthy young males for Borrelia antibodies. Seropositive subjects who had never suffered from clinically manifest Lyme borreliosis or neuroborreliosis showed significantly more often chronic fatigue (p = 0.02) and malaise (p = 0.01) than seronegative recruits. Therefore we believe it is worth examining whether an antibiotic therapy should be considered in patients with chronic fatigue syndrome and positive Borrelia serology. Copyright 2000 S. Karger AG, Basel.
Tuck I, Wallace D, Casalnuova G, May B.		Psychosocial Response of Sufferers of Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 7(3): 49	Chronic Fatigue Syndrome (CFS) is a chronic debilitating disease that affects two to five million persons in the United States. Previous studies examined theories of etiology and have resulted in contradictory findings. This study explored the psychosocial factors associated with CFS. Questionnaires were administered to 49 CFS sufferers and a matched sample of non-CFS sufferers. Significant differences were found in the perception of stress and its causes, coping styles, and emotional responses to affective states as measured by the Ways of Coping, Derogatis Stress, Trait Anger, Perceived Stress, and Profile of Moods scales. Groups were not different on the measure of trait anger. The findings indicated that associated psychosocial factors do influence the illness trajectory and the quality of life of CFS sufferers. These findings have implications for nursing practice.
Tuck I, Wallace D.	School of Nursing, Virginia Commonwealth University, 1220 East Broad Street, P.O. Box 980567, Richmond, VA 23298-0567, USA. ituck@hsc.vcu.edu	Chronic fatigue syndrome: a woman's dilemma.	Health Care Women Int 2000 Jul-Aug;21(5):457-66	Chronic Fatigue Syndrome (CFS) is an illness characterized by fatigue with varying levels of disability. According to the Centers for Disease Control (CDC) there are 2 to 5 million people in the United States who suffer from CFS and a disproportionate number are women. There are many theories of etiology of the condition and controversy has surrounded recommendations for diagnosis and treatment. CFS can mimic other diseases and women are doubly affected since many have comorbid conditions. While diagnoses and treatment are critical to the health of women, having the disease and coping with the symptoms may have a greater impact on their well-being and quality of life. The authors report qualitative data describing the experience of having CFS (N = 22) and quantitative responses of 42 CFS sufferers reporting psychosocial factors. The psychosocial factors were measured by the Derogatis Stress Profile (DSP), Spielberger Trait-Anger Scale, Ways of Coping Survey, Profile of Moods States (POMS) Survey, and the Perceived Stress Scale. The findings

				indicate that CFS changes the lives of women who suffer with the disease and disrupts their relationships, careers, and perceptions of themselves.

van der Steen WJ.	Faculties of Biology and Philosophy, Vrije Universiteit, Amsterdam, The Netherlands. wvds@bio.vu.nl	Chronic fatigue syndrome: a matter of enzyme deficiencies?	Med Hypotheses 2000 May;54(5):853-4	The etiology of chronic fatigue syndrome (CFS) remains an enigma. But literature concerning chronic fatigue which does not focus on CFS points to all sorts of enzyme deficiencies as possible causes. The deficiencies are probably dismissed as causes of CFS because other characteristic symptoms are lacking in CFS patients. But these symptoms are often also lacking in patients with a deficiency. Symptom patterns in enzyme deficiencies are extremely variable. Therefore, patients with CFS should be screened systematically for enzyme deficiencies. Copyright 2000 Harcourt Publishers Ltd.
van der Werf SP, Prins JB, Jongen PJ, van der Meer JW, Bleijenberg G.	Department of Medical Psychology, University Hospital Nijmegen, The Netherlands.	Abnormal neuropsychological findings are not necessarily a sign of cerebral impairment: a matched comparison between chronic fatigue syndrome and multiple sclerosis.	Neuropsychiatry Neuropsychol Behav Neurol 2000 Jul;13(3):199-203	OBJECTIVE: The aim of this study was to assess the potential impact of effort in comparative studies assessing neurocognitive dysfunction in patients with and without a neurologic diagnosis. BACKGROUND: It was hypothesized that a subgroup within a group of patients with prominent neurocognitive complaints but without a neurologic diagnosis would have impaired performance on a task originally designed to detect malingering. METHOD: We compared the neuropsychological performance of a group of 40 patients with a definite diagnosis of multiple sclerosis (MS) with that of 67 patients with chronic fatigue syndrome (CFS). The Amsterdam Short-Term Memory Test, a forced-choice memory task, served as measure to detect submaximal effort. In addition, we administered a regular neuropsychological task generally considered to be sensitive for cognitive deterioration. RESULTS: Compared with the MS group (13%), a larger proportion of the matched CFS group (30%) obtained scores indicative of reduced effort. In contrast, the proportions of patients scoring below the cutoff value on a conventional neuropsychological test did not differ significantly (17% of MS patients and 16% of CFS patients). CONCLUSIONS: The results obtained raise the question of to what extent abnormal test findings in the absence of documented neurologic impairment should be interpreted as a sign of cerebral

				impairment. The suggestion has been made to screen more often for biased results in comparative research studies so as to enhance valid interpretation of neuropsychological findings.
van der Werf SP, Prins JB, Vercoulen JH, van der Meer JW, Bleijenberg G.	The Netherlands Fatigue Research Group Nijmegen, Department of Medical Psychology and Internal Medicine, University Hospital Nijmegen, Post Box 9101, 6500 HB, Nijmegen, The Netherlands. s.vanderwerf@cksmps.azn.nl	Identifying physical activity patterns in chronic fatigue syndrome using actigraphic assessment.	J Psychosom Res 2000 Nov;49(5):373-9	OBJECTIVE: Changes in physical activity are thought to play an important role in maintaining symptoms in chronic fatigue syndrome (CFS). The aim of this study was to describe intraindividual physical activity patterns in more detail and to identify pervasively passive patients. METHODS: With help of a movement-sensing device, physical activity levels were registered continuously over a 12-day period in 277 CFS patients. Within this registration period, the 10 largest activity peaks were computed. The intensity and duration of these activity peaks and their subsequent rest periods were described and compared to those of 47 healthy controls. In addition, the patients' 12 daily activity scores were used to identify patients who were characterised by low levels of physical activity throughout the registration period. RESULTS: The CFS sample had less intense and shorter activity peaks, while the average rest periods that followed these peaks lasted longer. Approximately one-fourth of the CFS sample differed distinctly from the control group and was labelled as pervasively passive. CONCLUSION: The measurements and classification of actual physical activity levels were found to reduce heterogeneity in the CFS population and therefore could provide the opportunity to optimise behavioural intervention protocols for CFS.

Visser JT, De Kloet ER, Nagelkerken L.	TNO Prevention and Health, Division of Immunological and Infectious Diseases, P.O. Box 2215, 2301 CE Leiden, The Netherlands.	Altered glucocorticoid regulation of the immune response in the chronic fatigue syndrome.	Ann N Y Acad Sci 2000;917:868-75	It is increasingly recognized that glucocortiocoids (GCs) can have subtle modulatory effects in immunoregulation rather than having generalized immunosuppressive effects. GCs suppress Th1 cells and cellular immunity, but may favor Th2 responses and humoral immunity. The chronic fatigue syndrome (CFS) appears to be associated with a disturbed HPA-axis. Moreover, CFS patients show several immunological changes suggestive of decreased cellular immunity. It is postulated herein that in CFS patients a decreased Th1/Th2 balance may be the result of selective effects of GC on the IL-10/IL-12 regulatory circuit.
Vojdani A, Franco R.		Muliplex PCR for the Detection of Mycoplasma	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 187	A multiplex polymerase chain reaction (PCR) was used to detect mycoplasma infection in human DNA samples of patients with CFS and related illnesses. One set of oligonucleotide primers which are specific for a highly conserved region among all

		fermentans, M. hominis, and M. penetrans in Patients with Chronic Fatigue Syndrome, Fibromyalgia, Rheumatoid Arthritis, and Gulf War Syndrome		members of the genus Mycoplasma along with three other primer sets which are specific for Mycoplasma fermentans, M. hominis, and M. penetrans species were used in this assay. The sensitivity of detection was determined by adding known mycoplasma DNA copy numbers to 1 mg of genomic DNA from healthy subjects. Each sample was subjected to 40 cycles of amplification. The detection level was determined to be 7, 7, 9, and 15 mycoplasma DNA copies per mg of human genomic DNA for M. genus, M. fermentans, M. hominis, and M. penetrans, respectively. The assay was applied to DNA extracted from the PBMCs of individuals suffering from chronic fatigue syndrome (CFS) (n = 100), fibromyalgia (FMS) (n = 40), rheumatoid arthritis (RA) (n = 60), and gulf war syndrome (GWS) (n = 60) and compared to age- and sex-matched healthy individuals (n = 160). The percentage of M. genus infection detected in CFS, FMS, RA, and GWS was 52, 54, 49, and 55%, respectively. M. fermentans was detected in 32, 35, 23, and 36%, M. hominis was detected in 9, 8, 11, and 5%, and M. penetrans was detected in 6, 4, 7, and 3% of CFS, FMS, RA, and GWS patients, respectively. M. genus, M. fermentans, M. hominis, and M. penetrans were detected in 15, 8, 3, and 2% of healthy matched controls. This assay provides a rapid and cost efficient procedure to screen clinical samples for the presence of three potentially pathogenic species of Mycoplasma with a high level of sensitivity and specificity.
Vojdani A, Lapp CW.		The Relationship Between Chronic Fatigue Syndrome and Chemical Exposure	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 207	Overlapping symptomatologies between chronic fatigue syndrome (CFS) and chemical sensitivity have been observed by different investigators. Interferon-induced proteins 2-5A synthetase and protein kinase RNA (PKR) have been implicated in the viral induction of CFS. The objective of this study was to measure 2-5A and PKR activity in patients with CFS and toxic chemical exposure. Based on the CDC definition and criteria, twenty CFS patients who were positive for viral genome(s) (mainly HHV6; HTLV II, EBV, and CMV) and did not have any history of exposure to toxic chemicals were included in this study. As a comparison, the second group of patients consisted of twenty individuals from the same geographical area who were negative for viral genomes but had been exposed to methyl tertiary-butyl ether concentration of up to 70 ppb and benzene concentration up to 14 ppb. All patients complained of fatigue and other symptoms overlapping between the two groups. From all 40 patients, blood was drawn, leukocyte extract was prepared and assayed for 2-5A synthetase and PKR activity. Clinical specimens which were positive for viral genomes showed from 2. 2-38.7 fold increase in 2-5A activity and 1.3-13.5 fold increase in PKR activities over the background of the healthy controls. Similarly, the second group (negative for viral genomes, but exposed to chemicals) showed a 1.1-29.2 fold increase for 2-5A synthetase and a 1.3-11.6 fold increase for PKR when they were compared to healthy subjects. To elucidate mechanisms involved in viral versus chemical induction of 2-5A synthetase and PKR, MDBK cell lines were cultured either in the presence or absence of HHV6, MTBE, or benzene. 2-5A and PKR activities were

				measured in all the above conditions. A clear induction of 2-5A and PKR was observed when MDBK cells were exposed to HHV6, MTBE, and benzene indicating that induction of interferon-induced proteins are not unique to viruses. We conclude that 2-5A and PKR are not only biomarkers for viral induction of CFS, but biomarkers to other stressors that include MTBE and benzene.
Waxman SG, Ptacek LJ.		Chronic fatigue syndrome and channelopathies	Med Hypotheses 2000 Nov;55(5):457Comment in: Med Hypotheses. 2000 Dec;55(6):524 and Med Hypotheses. 2000 Jan;54(1):59-63.	
Werbach MR.	UCLA School of Medicine, California, USA.	Nutritional strategies for treating chronic fatigue syndrome.	Altern Med Rev 2000 Apr;5(2):93-108	Despite considerable worldwide efforts, no single etiology has been identified to explain the development of chronic fatigue syndrome (CFS). It is likely that multiple factors promote its development, sometimes with the same factors both causing and being caused by the syndrome. A detailed review of the literature suggests a number of marginal nutritional deficiencies may have etiologic relevance. These include deficiencies of various B vitamins, vitamin C, magnesium, sodium, zinc, L-tryptophan, L-carnitine, coenzyme Q10, and essential fatty acids. Any of these nutrients could be marginally deficient in CFS patients, a finding that appears to be primarily due to the illness process rather than to inadequate diets. It is likely that marginal deficiencies not only contribute to the clinical manifestations of the syndrome, but also are detrimental to the healing processes. Therefore, when feasible, objective testing should identify them and their resolution should be assured by repeat testing following initiation of treatment. Moreover, because of the rarity of serious adverse reactions, the difficulty in ruling out marginal deficiencies, and because some of the therapeutic benefits of nutritional supplements appear to be due to pharmacologic effects, it seems rational to consider supplementing CFS patients with the nutrients discussed above, along with a general high-potency vitamin/mineral supplement, at least for a trial period.
White C, Schweitzer R.	Department of Psychology and Counselling, Queensland University of Technology, Brisbane, Australia.	The role of personality in the development and perpetuation of chronic fatigue syndrome.	J Psychosom Res 2000 Jun;48(6):515-24	OBJECTIVES: Qualitative evidence suggests that personality may have special relevance to the predisposition, precipitation and perpetuation of chronic fatigue syndrome (CFS). This study compares three dimensions of personality - perfectionism, self-esteem, and emotional control in the personality profiles of CFS patients (N=44) and a control group (N=44) without a history of CFS, matched for age and gender. METHODS: Participants were assessed on the MPS [Frost RO, Marten P, Lahart C, Rosenblate R. The dimensions of perfectionism. Cognit Ther Res 1990;14:449-468.]; the Rosenberg Self-Esteem Scale [Rosenberg M. Society and the Adolescent Self-image. Princeton, NJ: Princeton Univ Press, 1965.]; the Courtauld Emotional Scale [Watson M, Greer S. Development of a questionnaire measure of emotional control. J Psychosom Res 1983;27:299-305.] and the Marlowe-Crowne

				Social Desirability Scale [Crowne DP, Marlowe D. A new scale of social desirability independent of psychopathology. J Consult Psychol 1960;24:349-354.]. RESULTS: Analyses revealed that the CFS group reported higher levels than the control group on the Total Perfectionism score and Doubts about Actions and the Concern over Mistakes subscales. Furthermore, the CFS group also reported lower self-esteem than the control group. No difference between the two groups was found on the dimensions of emotional control and social desirability response bias. CONCLUSION: A developmental model of CFS, which considers the predisposing, precipitating, and perpetuating factors that may account for the course of the disorder irrespective of etiology, is proposed. In the context of the results, recommendations for practice and future research are discussed.
White KP, Speechley M, Harth M, Ostbye T.	Department of Medicine, University of Western Ontario, London, Canada. kevin.white@lhsc.on.ca	Co-existence of chronic fatigue syndrome with fibromyalgia syndrome in the general population. A controlled study.	Scand J Rheumatol 2000;29(1):44-51	OBJECTIVE: To determine the proportion of adults with fibromyalgia syndrome (FMS) in the general population who also meet the 1988 Centre for Disease Control (CDC) criteria for chronic fatigue syndrome (CFS). METHODS: Seventy-four FMS cases were compared with 32 non-FMS controls with widespread pain and 23 with localized pain, all recruited in a general population survey. RESULTS: Among females, 58.0% of fibromyalgia cases met the full criteria for CFS, compared to 26.1% and 12.5% of controls with widespread and localized pain, respectively (p=0.0006). Male percentages were 80.0, 22.2, and zero, respectively (p=0.003). Compared to those with FMS alone, those meeting the case definitions for both FMS and CFS reported a worse course, worse overall health, more dissatisfaction with health, more non-CFS symptoms, and greater disease impact. The number of total symptoms and non-CFS symptoms were the best predictors of co-morbid CFS. CONCLUSIONS: There is significant clinical overlap between CFS and FMS.

Wittrup IH, Christensen LS, Jensen B, Danneskiold-Samsee B, Bliddal H, Wiik A.	Parker Research Institute, Dept. of Rheumatology, Frederiksberg University Hospital, Copenhagen, Denmark. Irenewittrup@fh.hosp.dk	Search for Borna disease virus in Danish fibromyalgia patients.	Scand J Rheumatol 2000;29(6):387-90	OBJECTIVE: The purpose of this study was to look for Borna disease virus (BDV) in 18 patients with acute onset of fibromyalgia (FMS) following a "flu-like" episode. BDV is a neurotropic RNA virus affecting horses and sheep. Infections in animals have been reported to cause immune mediated disease characterized by abnormalities in behavior. A possible link between BDV and neuropsychiatric diseases in man has been described, and lately a connection to chronic fatigue syndrome (CFS) has been suggested. METHODS: A BDV-specific nested PCR (RT-PCR) was performed on serum and spinal fluid. RESULTS: The BDV genome was not detected in any of the FMS cases. CONCLUSION: Although BDV was not demonstrated in spinal fluid or serum from the tested patients with FMS, we believe that it is important to report our results, since FMS can exhibit many manifestations in common with CFS. Possible reasons for the discrepant findings are discussed.
Woo SB, Schacterle RS,	Dept of Oral Medicine	Salivary gland changes	Oral Surg Oral Med	OBJECTIVE: The purpose of this preliminary study is to compare labial salivary gland

Komaroff AL, Gallagher GT.	and Diagnostic Sciences, Harvard School of Dental Medicine, Brigham and Women's Hospital, USA.	in chronic fatigue syndrome: a case-controlled preliminary histologic study.	Oral Pathol Oral Radiol Endod 2000 Jul;90(1):82-7	changes of 11 patients with chronic fatigue syndrome with control subjects. STUDY DESIGN: Changes in labial salivary glands were graded from 0 to 3+ for acinar dilatation, ductal dilatation, periductal fibrosis, plasmacytic infiltrate, lymphocytic infiltrate, mast cell infiltrate, and lymphocytic aggregates or foci. RESULTS: Four of the 11 subjects had 2+ to 3+ changes in at least 4 of the 7 parameters examined. Only the presence of mast cells was statistically significant between the 2 groups. Two of these 4 patients had 1 lymphocytic focus per 4 mm(2) of tissue. CONCLUSIONS: The salivary gland changes in patients with chronic fatigue syndrome show varying degrees of ductal and acinar dilatation, periductal fibrosis, lymphoplasmacytic infiltrates, and occasional lymphocytic foci, all suggestive of primary gland damage. The one parameter that showed statistical significance was the presence of mast cells (Fisher exact test, 0.0125).
Zhang QW, Natelson BH, Ottenweller JE, Servatius RJ, Nelson JJ, De Luca J, Tiersky L, Lange G.	Department of Neurosciences, University of Medicine and Dentistry-New Jersey Medical School, Newark, USA.	Chronic fatigue syndrome beginning suddenly occurs seasonally over the year.	Chronobiol Int 2000 Jan;17(1):95-9	The fact that many patients with chronic fatigue syndrome (CFS) have an infectious like sudden onset to their illness has led to the hypothesis that CFS is a medical illness. If CFS were, on the other hand, a psychiatric disorder related to symptom amplification, one would expect illness onset to occur randomly over the calendar year. This study tested that hypothesis with 69 CFS patients whose illness was on the more severe side of the illness spectrum; all patients reported sudden illness onset with the full syndrome of sore throat, fatigue/malaise, and diffuse achiness developing over no longer than a 2-day period. Date of illness onset was distinctly nonrandom. It peaked from November through January and was at its lowest from April through May. These data support the hypothesis that an infectious illness can trigger the onset of CFS.

Arpino C, Carrieri MP, Valesini G, Pizzigallo E, Rovere P, Tirelli U, Conti F, Dialmi P, Barberio A, Rusconi N, Bosco O, Lazzarin A, Saracco A, Moro ML, Vlahov D.	Laboratorio di Epidemiologia e Biostatistica, Istituto Superiore di Sanita, Rome, Italy.	Idiopathic chronic fatigue and chronic fatigue syndrome: a comparison of two case-definitions.	Ann Ist Super Sanita 1999;35(3):435-41	The aim of the study was to compare the signs and symptoms of individuals meeting two different definitions of chronic fatigue syndrome (CFS). Ninety-four patients fitting the eligibility criteria for idiopathic fatigue were enrolled into the study. Of the 94 patients, 48 met the 1988 definition of CFS, 20 the 1994 (but not the 1988) definition of CFS, and 26 met neither definition. The 1994 defined cases were more likely than 1988 defined cases, and non-syndromal individuals to be male, married, and high school educated. The 1994 cases were less likely than 1988 cases to present acute onset, self reported sore throat, mild fever lymphadenopathy, pharyngitis. In conclusion, the 1994 criteria increased the number of patients classified as CFS; however, those who fit only the 1994 criteria were less likely to have an acute symptomatic onset and signs and symptoms suggestive of an infectious process.
Ax S		Coping Differences Between Chronic Fatigue Syndrome Sufferers and Their Carers	Journal of Chronic Fatigue Syndrome 1999: 5(2): 27 - 62	The main objective of the present study was to describe the extent to which CFS sufferers and their carers reported to have used a number of coping strategies over the course of the illness, and to find out if reports of coping differed between groups of these. In addition, associations between married sufferers and carers were investigated. From a methodological point of view, the factorial structure and the usefulness of the Ways of Coping Questionnaire (Folkman & Lazarus, 1988) in CFS was studied. The results indicated no gender differences. There were also no differences between sufferers supported and not supported by a carer. However, the results indicated reduced coping responses of carer husbands. From a methodological point of view, the emergence of comparable factors for sufferers and carers, which were also closely related to the original emotion and problem-focused factors, suggested that the use of the questionnaire was appropriate. The importance of these findings for coping research and therapy are discussed.
Barsky AJ, Borus JF.	Division of Psychiatry, Brigham and Women's Hospital, Boston, Massachusetts 02115, USA.	Functional somatic syndromes.	Ann Intern Med 1999 Jun 1;130(11):910-21Comment in: Ann Intern Med. 2000 Feb 15;132(4):327-8; discussion 329-30 Ann Intern Med. 2000 Feb 15;132(4):327; discussion 329-30 Ann Intern Med. 2000 Feb 15;132(4):328-9; discussion 329-30 Ann Intern Med. 2000 Feb 15;132(4):328;	The term functional somatic syndrome has been applied to several related syndromes characterized more by symptoms, suffering, and disability than by consistently demonstrable tissue abnormality. These syndromes include multiple chemical sensitivity, the sick building syndrome, repetition stress injury, the side effects of silicone breast implants, the Gulf War syndrome, chronic whiplash, the chronic fatigue syndrome, the irritable bowel syndrome, and fibromyalgia. Patients with functional somatic syndromes have explicit and highly elaborated self-diagnoses, and their symptoms are often refractory to reassurance, explanation, and standard treatment of symptoms. They share similar phenomenologies, high rates of co-occurrence, similar epidemiologic characteristics, and higher-than-expected prevalences of psychiatric comorbidity. Although discrete pathophysiologic causes may ultimately be found in some patients with functional somatic syndromes, the suffering of these patients is exacerbated by a self-perpetuating, self-validating cycle in which common, endemic, somatic symptoms are incorrectly attributed to serious

			discussion 329-30 Ann Intern Med. 2000 Feb 15;132(4):329; discussion 329-30	abnormality, reinforcing the patient's belief that he or she has a serious disease. Four psychosocial factors propel this cycle of symptom amplification: the belief that one has a serious disease; the expectation that one's condition is likely to worsen; the "sick role," including the effects of litigation and compensation; and the alarming portrayal of the condition as catastrophic and disabling. The climate surrounding functional somatic syndromes includes sensationalized media coverage, profound suspicion of medical expertise and physicians, the mobilization of parties with a vested self-interest in the status of functional somatic syndromes, litigation, and a clinical approach that overemphasizes the biomedical and ignores psychosocial factors. All of these influences exacerbate and perpetuate the somatic distress of patients with functional somatic syndromes, heighten their fears and pessimistic expectations, prolong their disability, and reinforce their sick role. A six-step strategy for helping patients with functional somatic syndromes is presented here. Review, Academic

Chronic Fatigue Syndrome and Primary Fibromyalgia Syndrome as recognized by GPs.	Fam Pract 1999 Dec;16(6):602-4	BACKGROUND: Prevalence studies on Chronic Fatigue Syndrome (CFS) are rare. Because of the similarity in symptoms, the prevalence of Primary Fibromyalgia Syndrome (PFS) was investigated at the same time. OBJECTIVES: To determine the prevalence of CFS and PFS as recognized by GPs in The Netherlands and to inform them of the existence of CFS. METHODS: A postal questionnaire was sent to all GPs. RESULTS: The questionnaire was returned by 60% of the GPs. Seventy-three per cent reported one or more CFS patients and 83% one or more PFS patients in their practice. CONCLUSION: The estimated prevalence of CFS as recognized by GPs of 112 (PFS 157) patients per 100,000 is a minimum estimate.
Bell IR, Richard R. Bootzin, Gary E. R. Schwartz, Carol M. Baldwin RN, Faith Ballesteros		Differing Patterns of Cognitive Dysfunction and Heart Rate Reactivity in Chemically-Intolerant Individuals With and Without Lifestyle Changes	Journal of Chronic Fatigue Syndrome 1999: 5(2): 3 - 25	The purpose of the present study was to compare specific neuropsychological, psychological, and family history patterns, as well as cardiovascular reactivity of three community-recruited groups of nonsmoking, nonalcoholic middle-aged individuals with and without the symptom of intolerance to low levels of environmental chemicals (CI). CI is a common symptom in chronic fatigue syndrome and fibromyalgia. The groups included: (i) CI who had made associated lifestyle changes because of the CI (CI/LSC); (ii) CI who had not made such changes (CI); and (iii) normals without CI (N). All subjects underwent an evaluation session followed by two laboratory cognitive and psychophysiological test sessions one week apart. The CI/LSC diverged from the other groups in exhibiting poorer performance on the Continuous Visual Memory Test (CVMT) in terms of more false alarms and fewer correct hits, but normal performance on a visuospatial test of divided attention

				(DAT). In contrast, the CI group showed progressively poorer performance on the DAT with practice, but were like the N on the CVMT. The CI group showed a complex sensitization (amplification) of heart rate response to the DAT over time. In addition, the CI/LSC had the highest rate of family histories of alcohol problems and of attention deficit disorder, as well as of antihypertensive medication treatment and self-reported past emotional/physical abuse. Taken together, the data suggest that individuals with CI comprise a heterogeneous population requiring careful definition of subtypes for future studies.
Bell IR, Szarek MJ, Dicenso DR, Baldwin CM, Schwartz GE, Bootzin RR.	Department of Psychology, The University of Arizona, Tucson 85721, USA. IBELL@U.ARIZONA.EDU	Patterns of waking EEG spectral power in chemically intolerant individuals during repeated chemical exposures.	Int J Neurosci 1999 Mar;97(1-2):41-59	Previous studies indicate that low level chemical intolerance (CI) is a symptom of several different controversial conditions with neuropsychiatric features, e.g., chronic fatigue syndrome, fibromyalgia, multiple chemical sensitivity, and "Persian Gulf Syndrome". Prior studies suggest that limbic and/or mesolimbic sensitization may contribute to development of CI. The purpose of this report was to document the waking electroencephalographic (EEG) patterns of individuals with CI during chemical exposures presented over repeated sessions. Three groups of adult subjects who were recruited from the community participated in the study: self-reported CI who had made associated lifestyle changes due to their intolerance (CI/ LSC), self-reported CI who had not made such changes (CI), and normal controls without self-reported CI. Subjects underwent two sessions involving one-minute EEG recordings during exposures to low level chemical odors (a probe for limbic activation). The CI, but not the CI/ LSC, subjects had increased absolute delta power after the chemical exposures during the second, but not the first, session. The findings support the neural sensitization hypothesis for intolerance to low levels of environmental chemicals in vulnerable individuals. As in human studies of stimulant drug sensitization, those with the strongest past history with sensitizing agents may not show-term sensitization to low level exposures in the laboratory.
Berg D, Berg LH, Couvaras J, Harrison H.	HEMEX Laboratories, Inc., Phoenix, Arizona 85021, USA.	Chronic fatigue syndrome and/or fibromyalgia as a variation of antiphospholipid antibody syndrome: an explanatory model and approach to laboratory diagnosis.	Blood Coagul Fibrinolysis 1999 Oct;10(7):435-8	Chronic Fatigue and/or Fibromyalgia have long been diseases without definition. An explanatory model of coagulation activation has been demonstrated through use of the ISAC panel of five tests, including, Fibrinogen, Prothrombin Fragment 1+2, Thrombin/ AntiThrombin Complexes, Soluble Fibrin Monomer, and Platelet Activation by flow cytometry. These tests show low level coagulation activation from immunoglobulins (Igs) as demonstrated by Anti-B2GPI antibodies, which allows classification of these diseases as a type of antiphospholipid antibody syndrome. The ISAC panel allows testing for diagnosis as well as monitoring for anticoagulation protocols in these patients.

Blenkiron P, Edwards R, Lynch S.	Division of Psychiatry and Behavioural	Associations between perfectionism, mood,	J Nerv Ment Dis 1999 Sep;187(9):566-70	This study investigated possible associations between perfectionistic personality traits, mood, and fatigue in chronic fatigue syndrome (CFS). Forty CFS sufferers

	Sciences in Relation to Medicine, St. James's University Hospital, Leeds, United Kingdom.	and fatigue in chronic fatigue syndrome: a pilot study.		referred to tertiary care and 31 control healthy subjects completed the Multidimensional Perfectionism Scale (MPS), Chalder Fatigue Questionnaire, and Hospital Anxiety and Depression (HAD) scale. Total perfectionism scores did not correlate with fatigue, anxiety, or depression in either group. Other-oriented MPS scores were significantly lower among CFS sufferers (p = .0019), especially women, and correlated negatively with physical fatigue levels overall (R = -0.27, p = .02). Total and socially prescribed MPS scores correlated with age for the CFS group alone (p = .05). Possible reasons why this study did not confirm a positive association between perfectionism and CFS are discussed. The finding that CFS sufferers set lower standards and have lower expectations for significant others may have implications for rehabilitation and recovery from this disorder.
Bounous G, Molson J.	Department of Surgery, McGill University, and Medical Research Council of Canada.	Competition for glutathione precursors between the immune system and the skeletal muscle: pathogenesis of chronic fatigue syndrome.	Med Hypotheses 1999 Oct;53(4):347-9	The chronic fatigue syndrome (CFS) is typically associated or follows a recognized or presumed infection. Abnormalities of both humoral and cellular immunity have been demonstrated in a substantial proportion of patients with CFS. The most consistent findings are of impaired lymphocyte responses to mitogen. As an antioxidant, glutathione (GSH) is essential for allowing the lymphocyte to express its full potential without being hampered by oxiradical accumulation. Hence, protracted challenge of the immunocytes may lead to cellular GSH depletion. Because GSH is also essential to aerobic muscular contraction, an undesirable competition for GSH precursors between the immune and muscular systems may develop. It is conceivable that the priority of the immune system for the survival of the host has drawn to this vital area the ever-diminishing GSH precursors, thus depriving the skeletal muscle of adequate GSH precursors to sustain a normal aerobic metabolism resulting in fatigue and eventually myalgia.
Breau LM, McGrath PJ, Ju LH.	Department of Psychology, Dalhousie University, Halifax, Canada.	Review of juvenile primary fibromyalgia and chronic fatigue syndrome.	J Dev Behav Pediatr 1999 Aug;20(4):278-88	This article reviews the current literature on childhood fibromyalgia and chronic fatigue syndrome. In doing so, it questions assumptions about the presumed nature of the disorders-that they are distinct from each other and are duplicates of their adult counterparts. It also attempts to synthesize the available data to reach some preliminary judgments about these disorders: that fibromyalgia and chronic fatigue syndrome may be related in children and may not be duplicates of the adult disorders; that psychological and psychosocial factors are unlikely contributors to the etiology of these disorders; and that the evidence is increasingly pointing to a role for genetic factors in their etiology. A discussion of the research into treatments for childhood fibromyalgia and chronic fatigue syndrome highlights the lack of well-designed, controlled studies. Finally, directions for future research are offered where results of the current literature are unclear.
Brunello N, Akiskal H, Boyer P, Gessa GL, Howland RH, Langer SZ, Mendlewicz J, Paes	Center of Neuropharmacology, Institute of Pharmacological	Dysthymia: clinical picture, extent of overlap with chronic fatigue syndrome,	J Affect Disord 1999 Jan-Mar;52(1-3):275-90	Dysthymia, as defined in the American Psychiatric Association and International Classification of Mental Disorders, refers to a prevalent form of subthreshold depressive pathology with gloominess, anhedonia, low drive and energy, low self-esteem and pessimistic outlook. Although comorbidity with panic, social phobic, and

de Souza M, Placidi GF, Racagni G, Wessely S.	Sciences, University of Milan, Italy. brunello@isfunix.farma.unimi.it	neuropharmacological considerations, and new therapeutic vistas.		alcohol use disorders has been described, the most significant association is with major depressive episodes. Family history is loaded with affective, including bipolar, disorders. The latter finding explains why dysthymia, especially when onset is in childhood, can lead to hypomanic switches, both spontaneously and upon pharmacologic challenge in as many as 30%. Indeed, antidepressants from different classes -tricyclic antidepressants (TCAs), monoamine oxidase inhibitors (MAOIs), reversible inhibitors of monoamine oxidase A (RIMAs), selective serotonin-reuptake inhibitors (SSRIs) and, more recently, amisulpride, and spanning noradrenergic, serotonergic as well as dopaminergic mechanisms of action - have been shown to be effective against dysthymia in an average of 65% of cases. This is a promising development because social and characterologic disturbances so pervasive in dysthymia often, though not always, recede with continued pharmacotherapy beyond acute treatment. Despite symptomatic overlap of dysthymia with chronic fatigue syndrome - especially with respect to the cluster of symptoms consisting of low drive, lethargy, lassitude and poor concentration - neither the psychopathologic status, nor the pharmacologic response profile of the latter syndrome is presently understood. Chronic fatigue today is where dysthymia was two decades ago. We? submit that the basic science - clinical paradigm that has proven so successful in dysthymia could, before too long, crack down the conundrum of chronic fatigue as well. At a more practical level, we raise the possibility that a subgroup within the chronic fatigue group represents a variant of dysthymia.
Buchwald D, Herrell R, Ashton S, Belcourt M, Schmaling K, Goldberg J.	Department of Medicine, University of Washington, Seattle, USA. dedra@u.washington.edu	The Chronic Fatigue Twin Registry: method of construction, composition, and zygosity assignment.	Twin Res 1999 Sep;2(3):203-11	Chronic fatigue syndrome (CFS) and the symptom of chronic fatigue are conditions of unknown etiology. The Centers for Disease Control and Prevention (CDC) define CFS as an illness characterized by > or = 6 months of disabling fatigue associated with muscle pain, pharyngitis, and alterations in mood, sleep and neurocognition. We constructed a registry of twins with chronic fatigue to facilitate research on the impact of illness, the associated medical and psychosocial factors, and the heterogeneous proposed mechanisms for these conditions. We have recruited 204 twin pairs in which one or both members reported persistent fatigue through patient support group newsletters (60%), clinicians/researchers familiar with CFS (12%), notices placed on electronic bulletin boards for CFS (11%), twin organizations and researchers (6%), relatives and friends (3%) and other sources (8%). Complete data are available for 177 pairs (87%). Twins completed an extensive questionnaire booklet that included measures of physical and mental health, functional status, and psychosocial factors; a structured psychiatric interview was also conducted by telephone. Twins were classified using three increasingly more stringent diagnostic criteria for chronic fatigue: 1) > or = 6 months of fatigue (115 discordant and 61 concordant pairs); 2) chronic fatigue with additional symptoms and application of the medial exclusions of the CDC CFS case definition as obtained by self-report (92 discordant and 41 concordant pairs) and; 3) chronic fatigue with additional symptoms

				unexplained by self-reported medical conditions and psychiatric diagnoses as determined by the structured interview (69 discordant pairs and 25 concordant pairs). Despite the limitations of a volunteer registry, the Chronic Fatigue Twin Registry promises to be an important resource for research on CFS and chronic fatigue.
Buckley L, MacHale SM, Cavanagh JT, Sharpe M, Deary IJ, Lawrie SM.	Department of Psychiatry, University of Edinburgh and Royal Edinburgh Hospital, UK.	Personality dimensions in chronic fatigue syndrome and depression.	J Psychosom Res 1999 Apr;46(4):395-400	Chronic fatigue syndrome (CFS) is a poorly understood condition. Possible etiological factors include infectious agents, psychiatric disorders, and personality characteristics. We examined personality dimensions in 30 nondepressed patients with CFS, 20 patients with major depressive disorder (MDD), and 15 healthy controls. On the NEO-FFI, patients with CFS scored significantly lower than healthy controls on the extroversion subscale. On the neuroticism dimension of the Eysenck Personality Questionnaire (EPQ), patients with MDD scored higher than those with CFS, who in turn scored significantly higher than the healthy controls. CFS patients rated themselves as higher on neuroticism and less extroverted when ill than when they were well. Our results suggest that high scores on neuroticism and low scores on extroversion in CFS could be a reaction to chronic illness. Controlled Clinical Trial
Buskila D.	Department of Medicine B, Soroka Medical Center, Beer Sheva, Israel.	Fibromyalgia, chronic fatigue syndrome, and myofascial pain syndrome.	Curr Opin Rheumatol 1999 Mar;11(2):119-26	Fibromyalgia was almost completely absent from an urban affluent population compared with poor urban and rural communities. Seventeen percent of Gulf War veterans with soft tissue syndromes had fibromyalgia, a much higher rate than was seen in previous studies of rheumatic disease in the military population. A state of central hyperexcitability in the nociceptive system was reported in fibromyalgia. Altered functioning of the stress-response system has been further documented in fibromyalgia and chronic fatigue syndrome. Administration of growth hormone to patients with fibromyalgia who have low levels of insulin-like growth factor 1 resulted in improvement in their symptoms and tenderness. An association between chronic fatigue syndrome and initial infections was demonstrated. A correlation between particular immunologic abnormalities and measures of disease severity was documented in chronic fatigue syndrome. Concomitant fibromyalgia in other rheumatic diseases was a major contributor to poor quality of life. A favorable outcome of fibromyalgia in children was reported; the majority of patients improved over 2 to 3 years of follow-up. Treatment of patients with fibromyalgia continues to be of limited success.
Cannon JG, Angel JB, Ball RW, Abad LW, Fagioli L, Komaroff AL.	Department of Medicine, New England Medical Center, Boston, Massachusetts 02111, USA. jgc2@psu.edu	Acute phase responses and cytokine secretion in chronic fatigue syndrome.	J Clin Immunol 1999 Nov;19(6):414-21	This study addresses the hypothesis that clinical manifestations of chronic fatigue syndrome (CFS) are due in part to abnormal production of or sensitivity to cytokines such as interleukin-1beta (IL-1beta) and IL-6 under basal conditions or in response to a particular physical stress: 15 min of exercise consisting of stepping up and down on a platform adjusted to the height of the patella. The study involved 10 CFS patients and 11 age-, sex-, and activity-matched controls: of these, 6 patients and 4 controls were tested in both the follicular and the luteal phases of the menstrual cycle, and the remainder were tested in only one phase, for a total of 31 experimental sessions.

				Prior to exercise, plasma concentrations of the acute phase reactant alpha2-macroglobulin were 29% higher in CFS patients (P < 0.008) compared to controls. Secretion of IL-6 was generally higher for CFS patients (approximately 38%), however, this difference was statistically significant only if all values over a 3-day period were analyzed by repeated-measures ANOVA (P = 0.035). IL-6 secretion correlated with plasma alpha2-macroglobulin in control subjects at rest (R = 0.767, P = 0.001). Immediately after exercise, the CFS patients reported greater ratings of perceived exertion (P=0.027) compared to the healthy control subjects. Ratings of perceived exertion correlated with IL-1beta secretion by cells from healthy control subjects (R = 0.603, P = 0.022), but not from CFS patients, and IL-1beta secretion was not different between groups. Exercise induced a slight (< 12%) but significant (P = 0.006) increase in IL-6 secretion, but the responses of the CFS patients were not different than controls. Furthermore, no significant exercise-induced changes in body temperature or plasma alpha2-macroglobulin were observed. These data indicate that under basal conditions, CFS is associated with increased IL-6 secretion which is manifested by chronically elevated plasma alpha2-macroglobulin concentrations. These modest differences suggest that cytokine dysregulation is not a singular or dominant factor in the pathogenesis of CFS.
Castell LM, Yamamoto T, Phoenix J, Newsholme EA.	University Department of Biochemistry, Oxford, UK. cat@bioch.ox.ac.uk	The role of tryptophan in fatigue in different conditions of stress.	Adv Exp Med Biol 1999;467:697-704	Tryptophan is the precursor for the neurotransmitter 5-hydroxytryptamine (5-HT), which is involved in fatigue and sleep. It is present in bound and free from in the blood, where the concentration is controlled by albumin binding to tryptophan. An increase in plasma free tryptophan leads to an increased rate of entry of tryptophan into the brain. This should lead to a higher level of 5-HT which may cause central fatigue. Central fatigue is implicated in clinical conditions such as chronic fatigue syndrome and post-operative fatigue. Increased plasma free tryptophan leads to an increase in the plasma concentration ratio of free tryptophan to the branched chain amino acids (BCAA) which compete with tryptophan for entry into the brain across the blood-brain barrier. The plasma concentrations of these amino acids were measured in chronic fatigue syndrome patients (CFS) before and after exercise (Castell et al., 1998), and in patients undergoing major surgery (Yamamoto et al., 1997). In the CFS patients, the pre-exercise concentration of plasma free tryptophan was higher than in controls (p < 0.05) but did not change during or after exercise. This might indicate an abnormally high level of brain 5-HT in CFS patients leading to persistent fatigue. In the control group, plasma free tryptophan was increased after maximal exercise (p < 0.001), returning towards baseline levels 60 min later. The apparent failure of the CFS patients to change the plasma free tryptophan concentration or the free tryptophan/BCAA ratio during exercise may indicate increased sensitivity of brain 5-HT receptors, as has been demonstrated in other studies (Cleare et al., 1995). In post-operative recovery after major surgery plasma free tryptophan concentrations were markedly increased compared with baseline

				levels; the plasma free tryptophan/BCAA concentration ratio was also increased after surgery. Plasma albumin concentrations were decreased after surgery: this may account for the increase in plasma free tryptophan levels. Provision of BCAA has improved mental performance in athletes after endurance exercise (Blomstrand et al., 1995, 1997). It is suggested that BCAA supplementation may help to counteract the effects of an increase in plasma free tryptophan, and may thus improve the status of patients during or after some clinically stressful conditions.
Charnock D, Shepperd S, Needham G, Gann R.	University of Oxford, Division of Public Health and Primary Health Care, Institute of Health Sciences.	DISCERN: an instrument for judging the quality of written consumer health information on treatment choices.	J Epidemiol Community Health 1999 Feb;53(2):105-11	OBJECTIVE: To develop a short instrument, called DISCERN, which will enable patients and information providers to judge the quality of written information about treatment choices. DISCERN will also facilitate the production of new, high quality, evidence-based consumer health information. DESIGN: An expert panel, representing a range of expertise in consumer health information, generated criteria from a random sample of information for three medical conditions with varying degrees of evidence: myocardial infarction, endometriosis, and chronic fatigue syndrome. A graft instrument, based on this analysis, was tested by the panel on a random sample of new material for the same three conditions. The panel re-drafted the instrument to take account of the results of the test. The DISCERN instrument was finally tested by a national sample of 15 information providers and 13 self help group members on a random sample of leaflets from 19 major national self help organisations. Participants also completed an 8 item questionnaire concerning the face and content validity of the instrument. RESULTS: Chance corrected agreement (weighted kappa) for the overall quality rating was kappa = 0.53 (95% CI kappa = 0.48 to kappa = 0.59) among the expert panel, kappa = 0.40 (95% CI kappa = 0.36 to kappa = 0.43) among information providers, and kappa = 0.23 (95% CI kappa = 0.19 to kappa = 0.27) among self help group members. Higher agreement levels were associated with experience of using the instrument and with professional knowledge of consumer health information. Levels of agreement varied across individual items on the instrument, reflecting the need for subjectivity in rating certain criteria. The trends in levels of agreement were similar among all groups. The final instrument consisted of 15 questions plus an overall quality rating. Responses to the questionnaire after the final testing revealed the instrument to have good face and content validity and to be generally applicable. CONCLUSIONS: DISCERN is a reliable and valid instrument for judging the quality of written consumer health information. While some subjectivity is required for rating certain criteria, the findings demonstrate that the instrument can be applied by experienced users and providers of health information to discriminate between publications of high and low quality. The instrument will also be of benefit to patients, though its use will be improved by training.

Christodoulou C, Deluca J, Johnson SK, Lange G, Gaudino EA, Natelson BH.	University of Medicine and Dentistry of New Jersey, New Jersey Medical School, Newark, USA. cchristo@kmrrec.org	Examination of Cloninger's basic dimensions of personality in fatiguing illness: chronic fatigue syndrome and multiple sclerosis.	J Psychosom Res 1999 Dec;47(6):597-607	Relatively few studies have examined the personality characteristics of patients with chronic fatigue syndrome (CFS). The personality profiles of 38 CFS subjects were compared with 40 healthy controls and 40 subjects with multiple sclerosis (MS), a chronic illness that shares many symptoms with CFS (e.g., fatigue), but has a known neurological substrate. Subjects were examined within Cloninger's biosocial theory of personality, which delineates basic dimensions of temperament. Both illness groups displayed similarly elevated levels of Harm Avoidance, and lower levels of Reward Dependence as compared with healthy controls. The MS group showed a lower level of Persistence than controls and CFS subjects. Implications for the relationship between chronic illness and personality are discussed.
Clapp LL, Richardson MT, Smith JF, Wang M, Clapp AJ, Pieroni RE.	Health, Physical Education, and Recreation Department, Southwest Texas State University, San Marcos 78666, USA. ll12@swt.edu	Acute effects of thirty minutes of light-intensity, intermittent exercise on patients with chronic fatigue syndrome.	Phys Ther 1999 Aug;79(8):749-56Comment in: Phys Ther. 2000 Jan;80(1):115	BACKGROUND AND PURPOSE: Currently, there is no consensus on exercise prescription for patients with chronic fatigue syndrome (CFS). This investigation examined whether light-intensity, intermittent physical activity exacerbated symptoms in patients with CFS immediately following exercise to 7 days following exercise. Subjects. Subjects were 9 women (mean age=44.2 years, SD=8.4, range=29-56; mean weight=74.2 kg, SD=18.8, range=56.36-110.91; and mean height=1.63 m, SD=0.8, range=1.55-1.78) and 1 man (age=48 years, weight=97.1 kg, and height= 1.98 m) who met the Centels for Disease Control and Prevention's criteria fi)r (FS. METHODS: Subjects performed 10 discontinuous 3-minute exercise bouts (separated by 3 minutes of recovery) at a self-selected, comfortable walking pace on a treadmill. Oxygen consumption, minute ventilation, respiratory exchange ratio, and heart rate were measured every minute during the exercise session. To assess degree of disability, general health status, activity level, symptoms, and mood, subjects completed various questionnaires before and after exercise. RESULTS: Results indicated that degree of disability, general health status, symptoms, and mood did not change immediately and up to 7 days following exercise. CONCLUSION AND DISCUSSION: Thirty minutes of intermittent walking did not exacerbate symptoms in subjects with CFS. The physiological data did not show any abnormal response to exercise. Although this study did not determine whether 30 minutes of continuous versus intermittent exercise would exacerbate symptoms, all 10 subjects felt that they could not exercise continuously for 30 minutes without experiencing symptom exacerbation. Despite this limitation, the results indicate that some individuals with CFS may be able to use low-level, intermittent exercise without exacerbating their symptoms.
Clarke JN.	Department of Sociology and Anthropology, Wilfrid Laurier University,	Chronic fatigue syndrome: gender differences in the search for legitimacy.	Aust N Z J Ment Health Nurs 1999 Dec;8(4):123-33	This study employs qualitative research methods to describe and compare the experiences of men and women with chronic fatigue syndrome (CFS), focusing on respondents' self-perceived illness experience and relationship with medical practitioners. Data were collected from 59 respondents (18 male, 41 female) in

	Waterloo, Ontario, Canada.			telephone interviews using an open-ended focus interview schedule. While respondents explained the causes of the disease in ways that were largely gender appropriate, they did not experience the disease itself in gender different ways. The evidence of the study points to a clear dichotomy between ways in which men and women experience the disease and differences in the ways in which they are treated by the medical profession.
Cleare AJ, Heap E, Malhi GS, Wessely S, O'Keane V, Miell J.	Department of Psychological Medicine, Guy's King's and St Thomas' School of Medicine and the Institute of Psychiatry, London, UK. a.cleare@iop.bpmf.ac.uk	Low-dose hydrocortisone in chronic fatigue syndrome: a randomised crossover trial.	Lancet 1999 Feb 6;353(9151):455-8Comment in: Lancet. 1999 Feb 6;353(9151):424-5 Lancet. 1999 May 8;353(9164):1618-9; discussion 1619-20 Lancet. 1999 May 8;353(9164):1618; discussion 1619-20 Lancet. 1999 May 8;353(9164):1619-20	BACKGROUND: Reports of mild hypocortisolism in chronic fatigue syndrome led us to postulate that low-dose hydrocortisone therapy may be an effective treatment. METHODS: In a randomised crossover trial, we screened 218 patients with chronic fatigue. 32 patients met our strict criteria for chronic fatigue syndrome without co-morbid psychiatric disorder. The eligible patients received consecutive treatment with low-dose hydrocortisone (5 mg or 10 mg daily) for 1 month and placebo for 1 month; the order of treatment was randomly assigned. Analysis was by intention to treat. FINDINGS: None of the patients dropped out. Compared with the baseline self-reported fatigue scores (mean 25.1 points), the score fell by 7.2 points for patients on hydrocortisone and by 3.3 points for those on placebo (paired difference in mean scores 4.5 points [95% CI 1.2-7.7], p=0.009). In nine (28%) of the 32 patients on hydrocortisone, fatigue scores reached a predefined cut-off value similar to the normal population score, compared with three (9%) of the 32 on placebo (Fisher's exact test p=0.05). The degree of disability was reduced with hydrocortisone treatment, but not with placebo. Insulin stress tests showed that endogenous adrenal function was not suppressed by hydrocortisone. Minor side-effects were reported by three patients after hydrocortisone treatment and by one patient after placebo. INTERPRETATION: In some patients with chronic fatigue syndrome, low-dose hydrocortisone reduces fatigue levels in the short term. Treatment for a longer time and follow-up studies are needed to find out whether this effect could be clinically useful.

Faculty of Medicine and Pharmacy, Vrije Universiteit Brussel, Belgium. pdbeck@minf.vub.ac.be	Dehydroepiandrosterone (DHEA) response to i.v. ACTH in patients with chronic fatigue syndrome.	Horm Metab Res 1999 Jan;31(1):18-21Comment in: Horm Metab Res. 1999 Jul;31(7):439	Previous studies have demonstrated concentrating neuroendocrinological disturbances in chronic fatigue syndrome (CFS) patients, concentrating in particular on low cortisol levels and a hypothalamic deficiency. In order to investigate the dynamic response of the adrenal glands, we measured dehydroepiandrosterone (DHEA) in serum after adreno-corticotropic hormone (ACTH) stimulation during 60 minutes in 22 CFS-patients and 14 healthy controls. We found normal basal DHEA levels, but a blunted serum DHEA response curve to i.v. ACTH injection. This

				observation adds to the large amount of evidence of endocrinological abnormalities in CFS. Relative glucocorticoid deficiency might contribute to the overall clinical picture in CFS, and could explain some of the immunological disturbances observed in this syndrome.

Doyle JP, Frank E, Saltzman LE, McMahon PM, Fielding BD.	Division of General Medicine, Rollins School of Public Health, Emory University School of Medicine, Atlanta, Georgia 30303, USA.	Domestic violence and sexual abuse in women physicians: associated medical, psychiatric, and professional difficulties.	J Womens Health Gend Based Med 1999 Sep;8(7):955-65	Physicians have been called on to identify victims of domestic violence (DV) and sexual abuse (SA). Few data exist, however, on the prevalence of DV and SA in physicians themselves or on the personal or professional sequelae of such experiences. We determined the reported lifetime prevalence of DV and SA among women physicians and the personal characteristics, health-related factors, and work-related factors associated with these forms of abuse. We used data from the Women Physicians' Health Study, a large (n = 4501 respondents), nationally distributed questionnaire study that included questions on DV and SA histories, personal characteristics, and psychiatric, medical, and work-related histories. We compared the characteristics of women physicians with and without histories of DV or SA. The logistic models indicate that women physicians reporting DV histories (3.7% of the population) were significantly ($p < 0.05$) less likely to be single and significantly more likely to report depression histories, suicide attempts, substance abuse, current or past cigarette smoking, severe daily stress at home, chronic fatigue syndrome, and DV experienced by their mothers. Women physicians reporting SA histories (4.7% of the population) were significantly more likely to be younger than 60 years, identify themselves as homosexual or bisexual, to have specialized in psychiatry, obstetrics and gynecology, or emergency medicine, and to report histories of depression, suicide attempts, eating disorders, and fair or poor perceived health status. Although the reported lifetime prevalence of DV and SA among women physicians is below other reported figures, such experiences are associated with medical and psychiatric difficulties that could negatively affect them personally and professionally.
Duncan RB		Latency Immunity and Therapy: A Clinical Study of Latent Epstein Barr Virus Incidence in 297 Idiopathic Chronic Fatigue Patients with Plausible Hypotheses	Journal of Chronic Fatigue Syndrome 1999: 5(2): 77 - 95	Organ cells of the body retain an Immune Activity System comparable to protozoa. The cells' immunity memory templates are latent proteins, microbes, their toxins and chemicals (latentees). Excess latentees are detected and excreted by latency therapy. Their excretion induces immediate and/or delayed symptoms and signs recognized by the patient. Foreign latent materials (latentors) enter the body and bypass the natural immune system to be taken up selectively by organ cell groups. Active infection/disease and allergens (antigens) involve the natural immune system antibodies. Latent infection/disease and allergens (latentors) involve the Organ Cell

				Immunity as intracellular latentees. Clinical laboratory testing is inappropriate. This Clinical Anecdotal Study compiles 297 patients who obtained little or no relief from conventional and alternative medicine (duration: 63% > three years). Patients provoked symptoms to two or more of 16 viruses, in particular Epstein Barr Virus. Latency therapy (heat, saunas, massage, tolerated exercise and sweating during sleep, the auto-sauna) dilutions stimulated excretion until symptoms/signs cleared. The principals were Epstein Barr Virus 67.3%, 200 patients; 13 individual viruses 30.0%, 89 patients; non-viral 2.6%, 8 patients. Latency therapy < 50% improvement = 16.5%; 50% to 80% = 26.6%; 80% to 100% = 46.7%; failures = 11%. Fourteen patients gave positive Epstein Barr Virus serology. A latency immunity concept explains affected subjective symptoms and illnesses and offers a treatment which complements related medical therapies
Elkins LE, Pollina DA, Scheffer SR, Krupp LB.	Department of Neurology, State University of New York at Stony Brook 11794-8121, USA.	Psychological states and neuropsychological performances in chronic Lyme disease.	Appl Neuropsychol 1999;6(1):19-26	The neuropsychiatric sequelae of chronic Lyme disease remains unclear. This study sought to characterize the psychological status of a group of participants who met criteria for post-Lyme syndrome (PLS). These measures were then used to examine the influence of psychological status on neuropsychological performances. Thirty PLS participants completed a structured psychiatric interview, the Positive and Negative Affect Schedule, the Lyme Symptom Checklist, and a battery of neuropsychological tests. As a group, the PLS participants did not appear to have an elevated incidence of psychiatric disorders, and psychiatric history was not useful for understanding neuropsychological performances or symptom reports. The mood of the PLS participants was characterized by lowered levels of positive affect (PA) and typical levels of negative affect. This combination can be distinguished from depression and is consistent with previous findings of affect patterns in individuals with chronic fatigue syndrome. PA was also linked to both total symptom severity and severity of cognitive complaints, but not to duration of illness, neurological manifestations at initial diagnosis, or treatment history. Relative to published normative data, neuropsychological performances were not in the impaired range on any measure. Neither psychological status nor symptom report were useful for understanding any aspect of cognitive functioning. It is concluded that decreased PA is the most useful marker of psychological functioning in PLS.
Endicott NA.	Department of Research, Assessment & Training, New York State Psychiatric Institute, New York, USA.	Chronic fatigue syndrome in private practice psychiatry: family history of physical and mental health.	J Psychosom Res 1999 Oct;47(4):343-54	Forty-five psychiatric patients with chronic fatigue syndrome (CFS) were compared, using the case-control method, to two control groups selected from the same practice and matched on age, gender, and psychiatric diagnosis. The first control group (C-I, N=90) was selected on the basis of relatively good physical health. The second control group (C-II, N=45) was selected without regard to physical health. The reported family history of physical health revealed: the CFS mothers died at a younger age than the C-II mothers; both parents died before age 65 among the CFS parents more frequently than did the C-I parents; and the CFS parents had an increased prevalence of cancer, autoimmune disorders, and CFS-like conditions as

				compared to the families of one or both control groups. The reported family history of mental disorders revealed no significant differences in any of these conditions between the CFS patients and either control group.
Evengard B, Briese T, Lindh G, Lee S, Lipkin WI.	Department of Immunology, Microbiology, Pathology and Infectious Diseases, Clinic for Infectious Diseases, Karolinska Institutet at Huddinge University Hospital.	Absence of evidence of Borna disease virus infection in Swedish patients with Chronic Fatigue Syndrome.	J Neurovirol 1999 Oct;5(5):495-9	Chronic Fatigue Syndrome (CFS) is characterized by debilitating fatigue, somatic symptoms and cognitive impairment. An infectious basis has been proposed; candidate agents include enteroviruses, herpesviruses, retroviruses and Borna disease virus (BDV), a novel neurotropic virus associated with neuropsychiatric disorders. Sera and peripheral blood mononuclear cells (PBMC) from Swedish CFS patients were assayed for evidence of infection using ELISA and Western immunoblot for detection of antibodies to BDV proteins N, P and gp18; and using nested reverse transcriptase polymerase chain reaction (RT-PCR) for detection of BDV N- and P-gene transcripts. No specific immunoreactivity to BDV proteins was found in sera from 169 patients or 62 controls. No BDV N- or P-gene transcripts were found through RT-PCR analysis of PBMC from 18 patients with severe CFS. These results do not support a role for BDV in pathogenesis of CFS.
Evengard B, Komaroff AL.	Infektionskliniken, Huddinge sjukhus.	[Chronic fatigue syndrome does exist. Changes of biological parameters are measurable].[article in Swedish]	Lakartidningen 1999 Jun 30;96(26-27):3166-9	Chronic fatigue syndrome is a debilitating condition characterised by neurocognitive and somatic symptoms. Although many patients report an infectious onset, there is no unequivocal evidence to support this. The immune system is activated, and the hypothalamic-pituitary-adrenal axis is involved. The aetiology is complex, and its understanding may require modification of our views on ill-health and disease.
Evengard B, Schacterle RS, Komaroff AL.	Division of Infectious Diseases, Department of Immunology, Karolinska Institute at Huddinge University Hospital, Huddinge, Sweden. birgitta.evengardinfect.hs.sll.se	Chronic fatigue syndrome: new insights and old ignorance.	J Intern Med 1999 Nov;246(5):455-69	Chronic fatigue syndrome (CFS) is a condition characterized by impairment of neurocognitive functions and quality of sleep and of somatic symptoms such as recurrent sore throat, muscle aches, arthralgias, headache, and postexertional malaise. A majority of patients describe an infectious onset but the link between infections and CFS remains uncertain. Findings show an activation of the immune system, abberations in several hypothalamic-pituitary axes and involvement of other parts of the central nervous system. The origin is bound to be complex and it may well be that the solution will come together with a more generally altered view about mind-body dualism, and the concept of illness and disease.
Forsyth LM, Preuss HG, MacDowell AL, Chiazze L Jr, Birkmayer GD, Bellanti JA.	Department of Pediatrics, Georgetown University School of Medicine, Washington, D.C., USA.	Therapeutic effects of oral NADH on the symptoms of patients with chronic fatigue syndrome.	Ann Allergy Asthma Immunol 1999 Feb;82(2):185-91Comment in: Ann Allergy Asthma Immunol. 2000 Jun;84(6):639-40	BACKGROUND: Chronic fatigue syndrome (CFS) is a disorder of unknown etiology, consisting of prolonged, debilitating fatigue, and a multitude of symptoms including neurocognitive dysfunction, flu-like symptoms, myalgia, weakness, arthralgia, low-grade fever, sore throat, headache, sleep disturbances, and swelling and tenderness of lymph nodes. No effective treatment for CFS is known. OBJECTIVE: The purpose of the study was to evaluate the efficacy of the reduced form of nicotinamide adenine dinucleotide (NADH) i.e., ENADA the stabilized oral absorbable form, in a randomized, double-blind, placebo-controlled crossover study in patients with CFS. Nicotinamide adenine dinucleotide is known to trigger energy production through ATP generation which may form the basis of its potential effects. METHODS: Twenty-

				six eligible patients who fulfilled the Center for Disease Control and Prevention criteria for CFS completed the study. Medical history, physical examination, laboratory studies, and questionnaire were obtained at baseline, 4, 8, and 12 weeks. Subjects were randomly assigned to receive either 10 mg of NADH or placebo for a 4-week period. Following a 4-week washout period, subjects were crossed to the alternate regimen for a final 4-week period. RESULTS: No severe adverse effects were observed related to the study drug. Within this cohort of 26 patients, 8 of 26 (31%) responded favorably to NADH in contrast to 2 of 26 (8%) to placebo. Based upon these encouraging results we have decided to conduct an open-label study in a larger cohort of patients. CONCLUSION: Collectively, the results of this pilot study indicate that NADH may be a valuable adjunctive therapy in the management of the chronic fatigue syndrome and suggest that further clinical trials be performed to establish its efficacy in this clinically perplexing disorder.
Frank E, Dingle AD.	Department of Family and Preventive Medicine, Emory University School of Medicine, Atlanta, GA 30303, USA. efrank@fpm.eushc.org	Self-reported depression and suicide attempts among U.S. women physicians.	Am J Psychiatry 1999 Dec;156(12):1887-94	OBJECTIVE: Studies examining suicide rates for U.S. women physicians and other U.S. women have found odds ratios as high as 4 to 1. Although such reports are controversial and are based on small groups (N = 17 to 49 suicides), they are often cited as evidence of a high prevalence of psychopathology among women physicians. METHOD: The authors used the results of the Women Physicians' Health Study (N = 4,501), a large, nationally distributed questionnaire, to assess the lifetime prevalence of self-identified depression and suicide attempts among U.S. women physicians. RESULTS: An estimated 1.5% (N = 61) of U.S. women physicians have attempted suicide, and 19.5% (N = 808) have a history of depression. Those who were born in the United States, were not Asian, had histories of cigarette smoking, alcohol abuse or dependence, sexual abuse, domestic violence, poor current mental health, more severe harassment, or a family history of psychiatric disorders were significantly more likely to report suicide attempts or depression. Depression was more common among those who were not partnered, were childless, had a household gun, had more stress at home, drank alcohol, had worse health, or had a history of obesity, chronic fatigue syndrome, substance abuse, an eating disorder, or another psychiatric disorder and among those who reported working too much, career dissatisfaction, less control at work, and high job stress. Strata reporting higher rates of depression tended to show higher (although usually nonsignificant) rates of suicide attempts. CONCLUSIONS: Depression is approximately as common among U.S. women physicians as among other U.S. women, but suicide attempts may be fewer. A number of conditions may help identify women physicians at high risk for suicide attempts and depression.

Garralda E, Rangel L, Levin M, Roberts H, Ukoumunne O.	Academic Unit of Child and Adolescent Psychiatry, Imperial College School of Medicine, St. Mary's Hospital, London, England. e.garralda@ic.ac.uk	Psychiatric adjustment in adolescents with a history of chronic fatigue syndrome.	J Am Acad Child Adolesc Psychiatry 1999 Dec;38(12):1515-21Comment in: J Am Acad Child Adolesc Psychiatry. 2000 Jul;39(7):808-9	OBJECTIVE: To ascertain psychiatric adjustment in youngsters with a history of childhood chronic fatigue syndrome (CFS). METHOD: Subjects were 25 children and adolescents with CFS who were seen in tertiary pediatric/psychiatric clinics (mean age 15.6 years, seen a mean of 45.5 months after illness onset; 17 subjects had recovered and 8 were still ill) and 15 healthy matched controls. Youngsters and their parents (usually mothers) were interviewed and completed questionnaires. Instruments used included the Schedule for Affective Disorders and Schizophrenia for School-Age Children (K-SADS), the Child Behavior Checklist (CBCL), and the Harter Self-Esteem Questionnaire. RESULTS: At assessment, psychiatric disorders (mainly anxiety and depressive disorders) were present in half the subjects with a history of CFS, a rate significantly higher than in healthy controls. On the CBCL youngsters with a history of CFS had an excess of psychological symptoms and decreased social competence. On the Harter Self-Esteem Questionnaire they reported reduced self-esteem, especially in social competence. Anxiety disorders were significantly more common in recovered subjects than in those with active CFS illness status. CONCLUSIONS: Psychiatric disorders were found to be increased in adolescents with a history of severe CFS; CFS may enhance the risk for or share common predisposing factors with anxiety disorders.
Gil'miiarova FN, Radomskaia VM, Kretova IG, Vinogradova LN, Samykina LN, Sheshunov IV, Babichev AV, Sharafutdinova IM, Ponomareva LA.		[Chronic fatigue syndrome:objective criteria of metabolic defects].[article in Russian]	Klin Lab Diagn 1999 Feb;(2):9-11	Multi-level system of defense mechanisms is studied in 206 normal subjects living in an ecologically unfavorable region and working at chemical plants. Control group consisted of 24 subjects living in en ecologically safe region. The content of total protein and albumin and its effective and binding capacity were decreased, while the content of medium molecular weight peptides increased in the blood of subjects exposed to technogenic environmental pollution. The detected shifts are regarded as a mechanism of development of chronic fatigue syndrome.
Godwin M, Delva D, Miller K, Molson J, Hobbs N, MacDonald S, MacLeod C.	Department of Family Medicine, Queen's University, Kingston, ON.	Investigating fatigue of less than 6 months' duration. Guidelines for family physicians.	Can Fam Physician 1999 Feb;45:373-9Comment in: Can Fam Physician. 1999 Apr;45:872-3 Can Fam Physician. 1999 May;45:1152	OBJECTIVE: To develop an evidence-based systematic approach to assessment of adult patients who present to family physicians complaining of fatigue of less than 6 months' duration. The guidelines present investigative options, making explicit what should be considered in all cases and what should be considered only in specific situations. They aim to provide physicians with an approach that, to the extent possible, is based on evidence so that time and cost are minimized and detection and management of the cause of the fatigue are optimized. QUALITY OF EVIDENCE: MEDLINE was searched from 1966 to 1997 using the key words "family practice" and "fatigue." Articles about chronic fatigue syndrome were excluded. Articles with level 3 evidence were found, but no randomized trials, cohort studies, or case-control studies were found. Articles looking specifically at the epidemiology, demographics, investigations, and diagnoses of patients with fatigue were chosen. Articles based on

				studies at referral and specialty centres were given less weight than those based on studies in family physicians' offices. MAIN MESSAGE: Adherence to these guidelines will decrease the cost of investigating the symptom of fatigue and optimize diagnosis and management. This needs to be proved in practice, however, and with research that produces level 1 and 2 evidence. CONCLUSIONS: Adults presenting with fatigue of less than 6 months' duration should be assessed for psychosocial causes and should have a focused history and physical examination to determine whether further investigations should be done. The guidelines outline investigations to be considered. The elderly require special consideration. These guidelines have group validation, but they need to be tested by more physicians in various locations and types of practices.

Gordon R, Michalewski HJ, Nguyen T, Gupta S, Starr A.	Department of Neurology, University of California, Irvine, Med. Surge I, Room 154, Irvine, CA 92697-4290, USA.	Cortical motor potential alterations in chronic fatigue syndrome.	Int J Mol Med 1999 Nov;4(5):493-9	Premovement, sensory, and cognitive brain potentials were recorded from patients with Chronic Fatigue Syndrome (CFS) in four tasks: i) target detection, ii) short-term memory, iii) self-paced movement, and iv) expectancy and reaction time (CNV). Accuracy and reaction times (RTs) were recorded for tasks i, ii, and iv. Results from CFS patients were compared to a group of healthy normals. Reaction times were slower for CFS patients in target detection and significantly slower in the short-term memory task compared to normals. In target detection, the amplitude of a premovement readiness potential beginning several hundred milliseconds prior to stimulus onset was reduced in CFS, whereas the poststimulus sensory (N100) and cognitive brain potentials (P300) did not differ in amplitude or latency. In the memory task, a negative potential related to memory load was smaller in CFS than normals. The potentials to self-paced movements and to expectancy and RT (CNV) were not different between groups. The findings in CFS of slowed RTs and reduced premovement-related potentials suggest that central motor mechanisms accompanying motor response preparation were impaired in CFS for some tasks. In contrast, measures of neural processes related to both sensory encoding (N100) and to stimulus classification (P300) were normal in CFS.
Granzow B.		[Mutual features of chronic fatigue syndrome, fibromyalgia and multiple chemical sensitivity].[article in German]	Dtsch Med Wochenschr 1999 Oct 15;124(41):1224	
Gray GC, Kaiser KS, Hawksworth AW, Hall	Emerging Illness Division, Naval Health	Increased postwar symptoms and	Am J Trop Med Hyg 1999 May;60(5):758-66	To investigate reports on war-related morbidity, 527 active-duty Gulf War veterans and 970 nondeployed veterans from 14 Seabee commands were studied in 1994 with

FW, Barrett-Connor E.	Research Center, San Diego, California 92186-5122, USA.	psychological morbidity among U.S. Navy Gulf War veterans.		a questionnaire, sera collection, handgrip strength, and pulmonary function testing. The questionnaire assessed postwar symptoms, war exposures, and screened for chronic fatigue syndrome, post-traumatic stress disorder, and psychological symptoms suggesting neurosis (Hopkins Symptom Checklist). Sera were tested with four nonspecific reactant assays: C-reactive protein, transferrin, ferritin, and haptoglobin. Gulf War veterans reported a higher prevalence for 35 of 41 symptoms, scored higher on psychological symptom scales, were more likely to screen for post-traumatic stress disorder, had lower handgrip strength, and had higher serum ferritin assay results. Numerous comparisons of these morbidity outcomes with 30 self-reported exposures demonstrated many associations, but no unique exposure or group of exposures were implicated. Morbidity data are consistent with other postwar observations, but the etiology for morbidity findings remains uncertain.
Green JL, Jennifer Romei, Benjamin Natelson		Stigma and Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1999: 5(2): 63 - 75	We predicted that the largely female population seeking relief from the incapacitating symptoms of chronic fatigue syndrome (CFS), an enigmatic illness, would feel stigmatized, and that attribution of CFS symptoms to psychological causes by physicians would contribute significantly to the CFS-related stigma. Most subjects scored high on measures of stigma: 95% had feelings of estrangement, 70% believed that others attributed their CFS symptoms to psychological causes, 77% coped by using an educational strategy (disclosure) and 39% saw a need to be secretive about their symptoms in some circumstances. Most subjects (77%) were labeled as 'psychological cases' by one or more of the physicians (mean = 8) consulted, but of the 4 stigma measures, only disclosure was related to physician labeling. Such factors as duration of illness and unemployment, dissatisfaction with spouse, and symptom severity correlated significantly with measures of stigma. That many physicians were reportedly ignorant or skeptical of CFS (male more so than female MD's) may influence attempts of CFS patients to legitimize their symptoms by disclosure and lead to high rates of health care system use
Gupta S, Aggarwal S, Starr A.	Department of Medicine, University of California, Irvine, CA 92697, USA.	Increased production of interleukin-6 by adherent and non-adherent mononuclear cells during 'natural fatigue' but not following 'experimental fatigue' in patients with chronic fatigue syndrome.	Int J Mol Med 1999 Feb;3(2):209-13	In an investigator-blinded study, adherent (monocytes) and non-adherent cells (lymphocytes) from patients with chronic fatigue syndrome (CFS) were examined on two separate occasions (when feeling 'fatigued' and when feeling 'rested') for in vitro spontaneous, phytohemagglutinin- (PHA, for lymphocytes), and lipopolysaccharide- (LPS, for monocytes) induced production of IL-6 by ELISA assay. A group of CFS patients and controls were also subjected to exercise-induced fatigue ('experimental fatigue') and IL-6 production was compared, in a double-blinded manner, prior to and following induction of fatigue. A significant increase in spontaneous, PHA- and LPS-induced IL-6 secretion by both lymphocytes and monocytes was observed in CFS patients during 'natural fatigue' as compared to during state. However, no such changes in IL-6 production were observed during 'experimental fatigue'. These data suggest a role of IL-6 in natural symptomatology and perhaps in the pathogenesis of CFS. In addition, the data demonstrate that laboratory-induced fatigue (experimental

				fatigue) may not be a good model to study immunological changes in CFS; immunological parameters should be studied in a longitudinal manner during the natural course of the disease.
Hartz AJ, Kuhn EM, Bentler SE, Levine PH, London R.	Department of Family Medicine, University of Iowa College of Medicine, Iowa City, USA.	Prognostic factors for persons with idiopathic chronic fatigue.	Arch Fam Med 1999 Nov-Dec;8(6):495-501	BACKGROUND: The simultaneous examination of a large number of patient characteristics in a prospective study of patients with chronic fatigue. OBJECTIVE: To compare the relative importance of these characteristics as prognostic factors. METHODS: The data analyzed were from 199 subjects in a registry of persons who were aged 18 years or older and had idiopathic fatigue for at least 6 months. All subjects completed an extensive baseline questionnaire that provided information about fatigue, demographic characteristics, medical conditions, lifestyle, sleeping habits, psychological characteristics, and the presence of criteria for chronic fatigue syndrome. Changes in fatigue severity from baseline to 2-year follow-up were tested for an association with risk factors at baseline and with changes in symptoms other than fatigue during the follow-up period. RESULTS: The following characteristics at baseline significantly and independently predicted greater fatigue improvement: less unclear thinking, fewer somatoform symptoms not used to define chronic fatigue syndrome, infrequent awakening, fewer hours sleeping, and being married. Of 29 subjects who at baseline reported no somatoform symptoms unrelated to chronic fatigue syndrome and who thought clearly most of the time, 8 substantially improved, compared with 1 of 29 subjects who had more than 2 somatoform symptoms and never thought clearly (P = .01). Improvements in the following symptoms were significantly and independently associated with improvements in fatigue: unclear thinking, depression, muscle aches, and trouble falling asleep. CONCLUSIONS: This study identified characteristics of subjects that seem to be of prognostic importance for idiopathic chronic fatigue. Symptoms that change concomitantly with changes in fatigue may be intrinsically linked to fatigue.
Heap LC, Peters TJ, Wessely S.	Department of Clinical Biochemistry, King's College School of Medicine, London, UK.	Vitamin B status in patients with chronic fatigue syndrome.	J R Soc Med 1999 Apr;92(4):183-5	Some patients with chronic fatigue syndrome say they benefit from taking vitamin supplements. We assessed functional status for the B vitamins pyridoxine, riboflavin and thiamine in 12 vitamin-untreated CFS patients and in 18 healthy controls matched for age and sex. Vitamin-dependent activities--aspartate aminotransferase (AST) for pyridoxine, glutathione reductase (GTR) for riboflavin, transketolase (TK) for thiamine--were measured in erythrocyte haemolysates before and after in-vitro addition of the relevant vitamin. For all three enzymes basal activity (U/g Hb) was lower in CFS patients than in controls: AST 2.84 (SD 0.62) vs 4.61 (1.43), $P < 0.001$; GTR 6.13 (1.89) vs 7.42 (1.25), $P < 0.04$; TK 0.50 (0.13) vs 0.60 (0.07), $P < 0.04$. This was also true of activated values: AST 4.91 (0.54) vs 7.89 (2.11), $P < 0.001$; GTR 8.29 (1.60) vs 10.0 (1.80), $P < 0.001$; TK 0.56 (0.19) vs 0.66 (0.08), $P < 0.07$. The activation ratios, however, did not differ between the groups. These data provide preliminary evidence of reduced functional B vitamin status, particularly of pyridoxine, in CFS patients.

Hickie I.	St George Hospital and Community Service, Kogarah, New South Wales, Australia. i.hickie@unsw.edu.au	Nefazodone for patients with chronic fatigue syndrome.	Aust N Z J Psychiatry 1999 Apr;33(2):278-80	OBJECTIVE: Patients with chronic fatigue syndrome (CFS) present with a variety of musculoskeletal, neurocognitive, sleep disturbance and mood symptoms. An open evaluation of the clinical utility of the novel antidepressant compound, nefazodone, was completed. METHOD: Ten patients with CFS presenting for assessment by a specialist psychiatrist were treated with nefazodone. Patients treated within this specialist service are also advised to engage in appropriate behavioural and sleep-wake cycle strategies to improve their level of functioning. RESULTS: Of the 10 patients, eight (80%) reported at least some improvement in the key symptom of fatigue, with four (40%) reporting moderate or marked symptom relief. Additionally, sleep disturbance and mood were both moderately or markedly improved in seven (70%) and eight (80%) of the patients, respectively. Five of the patients (50%) achieved at least a moderate improvement in overall functional outcome and were able to return to work or their previous level of role function. The mean dose of nefazodone was 370 mg/day (range = 200-800 mg), with a strong preference for nocturnal dosing. Seven of the patients had previously failed to respond to moclobemide, while seven had previously failed to respond to conventional antidepressant therapy. CONCLUSION: Nefazodone appears to be worthy of further systematic investigation in patients with CFS. Given its effects on sleep, mood and anxiety symptoms, it may have particular advantages in patients with this disorder.
Hill NF, Tiersky LA, Scavalla VR, Lavietes M, Natelson BH.	Chronic Fatigue Syndrome Center, Department of Neurosciences, University of Medicine and Dentistry-New Jersey Medical School, Newark, USA.	Natural history of severe chronic fatigue syndrome.	Arch Phys Med Rehabil 1999 Sep;80(9):1090-4	OBJECTIVE: To evaluate the natural history of chronic fatigue syndrome (CFS) in a severely ill group of patients at three points in time. DESIGN: Patients were enrolled from April 1992 to February 1994 and were evaluated three times. Time 1 (at enrollment): history, physical evaluation, and psychiatric evaluation; Time 2 (median = 1.6yrs after initial evaluation): postal questionnaire to assess current condition; Time 3 (median = 1.8 yrs after Time 2): medical and psychiatric evaluations. SETTING: The New Jersey CFS Cooperative Research Center, an ambulatory setting. PATIENTS: Twenty-three patients fulfilled the 1988 case definition for CFS and had symptom complaints that were substantial or worse in severity. All patients were ill less than 4.5 years; and none had a DSM-III-R psychiatric disorder in the 5 years before illness onset; none had substance abuse in the 10 years before enrollment. MAIN OUTCOME MEASURES: Severity of CFS symptoms was assessed by self-report questionnaires, laboratory tests, and medical examination. Psychological status was assessed using the Q-D15 and the Centers for Epidemiological Study-Depression Scale. At each time of evaluation, patients were categorized as severe, slightly improved, improved, and recovered. RESULTS: Over the 4 years of the study, 13 patients remained severely ill, 9 improved but still fulfilled the 1994 case definition for CFS, and 1 recovered. Illness duration, mode of onset, psychiatric status or depressed mood at intake, or chemical sensitivity did not predict illness outcome. One patient was diagnosed with an alternate illness, but it probably did not explain her CFS symptoms. Mood improved for those patients whose illness lessened. CONCLUSIONS: The prognosis for recovery

				was extremely poor for the severely ill subset of CFS patients. The majority showed no symptom improvement and only 4% of the patients recovered. Illness severity between Times 2 and 3 remained stable.
Hodgson MJ, Kipen HM.	Department of Medicine, University of Connecticut Health Center, Farmington, USA.	Gulf War illnesses: causation and treatment.	J Occup Environ Med 1999 Jun;41(6):443-52	Soldiers returning from the Gulf War in 1991 described a range of symptoms, including some consistent with the chronic fatigue syndrome, fibromyalgia, and multiple chemical sensitivity. Well-defined adverse health events attributable to service in the Gulf occurred. However, controlled epidemiological studies in Gulf War veterans and controls describe significant excesses of symptoms that were not clearly associated with pathologic disease. At least 12% of veterans currently receive some form of disability from the Department of Veterans Affairs. A number of reports outline theories proposed to explain the excess, but few are scientifically supported. Management guidelines for this spectrum of disorders resembles that of many of "emerging overlap syndromes," including multiple chemical sensitivity, chronic fatigue syndrome, and fibromyalgia. They include the establishment of a trusting doctor-patient relationship, negotiations around a common ground of scientific and etiologic beliefs, non-labeling of the disorder, and work toward recovery in the absence of clear etiologic answers.
Hotopf M, Wessely S.		Chronic fatigue syndrome--mapping the interior.	Psychol Med 1999 Mar;29(2):255-8	
Hudson M, Cleare AJ.	Department of Psychological Medicine, Guy's King's and St Thomas' School of Medicine and the Institute of Psychiatry, London, UK.	The 1microg short Synacthen test in chronic fatigue syndrome.	Clin Endocrinol (Oxf) 1999 Nov;51(5):625-30 Comment in: Clin Endocrinol (Oxf). 2000 Jun;52(6):797-9	OBJECTIVE: Many studies suggest mild hypocortisolism in chronic fatigue syndrome (CFS), usually assumed to be due to reduced suprahypothalamic drive to the hypothalamo-pituitary-adrenal (HPA) axis. We wished to explore further the state of the HPA axis in CFS using the 1 microg low dose short Synacthen test. DESIGN: Subjects received an intravenous bolus of 1 microg Synacthen; samples for cortisol estimation were taken at baseline and 2, 10, 20, 30, 40 and 60 minutes after injection. PATIENTS: We tested 20 subjects suffering from CFS according to the criteria of the Center for Diseases Control without psychiatric comorbidity and 20 matched healthy controls. All subjects were drug free for at least 1 month. MEASUREMENTS: We calculated the cortisol responses to the test as the maximum cortisol attained, the incremental rise in cortisol over baseline (Deltavalue) and as the integrated area under the curve. RESULTS: There were no significant differences in baseline cortisol or cortisol responses between patients and controls. However, responses generally were low, and many subjects' peak responses were prior to the standard 30 minute sampling time., CONCLUSIONS These results do not lend support to the theory that patients with chronic fatigue syndrome have a low adrenal reserve. However, results from studies assessing the HPA axis are proving to be inconsistent. We suggest that many other factors may be contributing to HPA axis alterations in chronic fatigue syndrome, including sleep disturbance, inactivity, altered circadian rhythmicity, illness chronicity, concomitant medication and comorbid psychiatric

				disturbance. These sources of heterogeneity need to be considered in future studies, and may explain the inconsistent findings to date.
Itoh Y, Igarashi T, Tatsuma N, Imai T, Yoshida J, Tsuchiya M, Murakami M, Fukunaga Y.	Department of Pediatrics, Nippon Medical School, Tokyo, Japan.	[Autoimmune fatigue syndrome and fibromyalgia syndrome].[article in Japanese]	Nippon Ika Daigaku Zasshi 1999 Aug;66(4):239-44	We have encounted two patients with fibromyalgia (FM) initially diagnosed as having autoimmune fatigue syndrome (AIFS). To investigate the relationship between AIFS and FM, the distribution of the tender points in patients with AIFS was assessed according to the ACR criteria for FM. It was revealed that AIFS patients had 5.6 tender points on averages. Patients with headaches, digestive problems, or difficulty going to school had more tender points than patients without. Patients with ANA titers < 1: 160 had more tender points than patients with ANA > or = 1: 160. Anti-Sa negative patients had more tender points than positive patients. These results suggest a relationship between AIFS and FM in terms of the pathophysiologic mechanisms of the numerous tender points. In other words, ANA-positive FM patients could be one form of AIFS, as well as ANA-positive chronic fatigue syndrome patients. Thus, autoimmunity could explain the controversial disease entities of FM and/or CFS.
Jackson EL.		The effects on siblings in families with a child with chronic fatigue syndrome.	J Child Health Care 1999 Summer;3(2):27-32	Paediatric CFS/ME is a stressor, which affects not only the sufferer but also the whole family. The sibling bond exerts a great influence on all the children in the family. Healthy siblings are often overlooked as attention is focused on the child with CFS/ME or other chronic illness. Individual children react in different ways to serious illness in another sibling by adopting a variety of coping mechanisms. There is a need for health and education professionals to consider the whole family when caring for and working with a child with CFS/ME.
Jahn K, Klenke T.	kj@multimedica.de	[Web sites on tinnitus, fibromyalgia, chronic fatigue syndrome, etc. Here your patients seek information].[article in German]	MMW Fortschr Med 1999 Dec 16;141(51-52):14	
Jason LA, King CP, Frankenberry EL, Jordan KM, Tryon WW, Rademaker F, Huang CF.	Department of Psychology, DePaul University, Chicago, IL 60613, USA.	Chronic fatigue syndrome: assessing symptoms and activity level.	J Clin Psychol 1999 Apr;55(4):411-24	Current approaches to the diagnosis and assessment of Chronic Fatigue Syndrome (CFS) rely primarily on scales that measure only the occurrence of various symptoms related to CFS. Such approaches do not provide information on either the severity of symptoms or on fluctuations in symptom severity and activity level that occur over time. As a result, these measures do not reflect the complexities and the interrelations among symptoms. By obscuring the fluctuating nature of CFS and its high variability, current assessment procedures may prevent health care professionals from understanding the complexities of this disease. The present study provides two CFS case studies to illustrate the advantages of using self-reporting rating scales in combination with a device used to measure the frequency and intensity of activity. The implications of this assessment system, which captures the symptom dynamics and variability involved in CFS, are discussed.

Jason LA, Melrose H, Lerman A, Burroughs V, Lewis K, King CP, Frankenberry EL.	DePaul University, Chicago, IL, USA.	Managing chronic fatigue syndrome: overview and case study.	AAOHN J 1999 Jan;47(1):17-21	1. The basic principles of envelope theory are explained. By not overexerting themselves, people with CFS can avoid the setbacks and relapses that commonly occur in response to overexertion while increasing their tolerance to activity. 2. By collecting time series data on fluctuations in energy levels, important clinical observations can be made in respect to a client's unique condition and experience with CFS.
Jason LA, Richman JA, Rademaker AW, Jordan KM, Plioplys AV, Taylor RR, McCready W, Huang CF, Plioplys S.	Department of Psychology, DePaul University, Chicago, IL 60614, USA. ljason@wppost.depaul.edu	A community-based study of chronic fatigue syndrome.	Arch Intern Med 1999 Oct 11;159(18):2129-37	BACKGROUND: Most previous estimates of the prevalence of chronic fatigue syndrome (CFS) have derived largely from treated populations, and have been biased by differential access to health care treatment linked with sex, ethnic identification, and socioeconomic status. OBJECTIVE: To assess the point prevalence of CFS in an ethnically diverse random community sample. DESIGN AND PARTICIPANTS: A sample of 28,673 adults in Chicago, Ill, was screened by telephone, and those with CFS-like symptoms were medically evaluated. MAIN OUTCOME MEASURES AND ANALYSES: Self-report questionnaires, psychiatric evaluations, and complete medical examinations with laboratory testing were used to diagnose patients with CFS. Univariate and multivariate statistical techniques were used to delineate the overall rate of CFS in this population, and its relative prevalence was subcategorized by sex, ethnic identification, age, and socioeconomic status. RESULTS: There was a 65.1% completion rate for the telephone interviews during the first phase of the study. Findings indicated that CFS occurs in about 0.42% (95% confidence interval, 0.29%-0.56%) of this random community-based sample. The highest levels of CFS were consistently found among women, minority groups, and persons with lower levels of education and occupational status. CONCLUSIONS: Chronic fatigue syndrome is a common chronic health condition, especially for women, occurring across ethnic groups. Earlier findings suggesting that CFS is a syndrome primarily affecting white, middle-class patients were not supported by our findings.
Jason LA, Tryon WW, Taylor RR, King C, Frankenberry EL, Jordan KM.	Department of Psychology, DePaul University, Chicago, IL 60614, USA.	Monitoring and assessing symptoms of chronic fatigue syndrome: use of time series regression.	Psychol Rep 1999 Aug;85(1):121-30	Chronic Fatigue Syndrome's principal symptoms are severe and include prolonged fatigue and a number of other minor symptoms. Behavioral data collection methods were used in a case study to show some of the benefits that can be derived from monitoring symptoms hourly and daily. Using time series regression, several statistically significant correlates of fatigue were found both within days and between days. Perceived energy, physical exertion, and mental exertion were significantly related to fatigue in both analyses. Collection of such data may help resolve a number of theoretical and methodological problems in research on the Chronic Fatigue Syndrome.

Johnson SK, DeLuca J, Natelson BH.	Department of Psychology, University of North Carolina, Charlotte 28223, USA.	Chronic fatigue syndrome: reviewing the research findings.	Ann Behav Med 1999 Summer;21(3):258-71	This article reviews the current state of research in chronic fatigue syndrome (CFS). The evolving definition, prevalence, and prognosis of this controversial illness are presented. We review studies examining psychiatric, personality, and psychosocial etiology for CFS. The evidence for pathophysiology in CFS is also presented, and studies investigating viral, immune, neuroimaging, neuroendocrine, and central and autonomic nervous system abnormalities in CFS are assessed. Current evidence indicates that CFS is multi-determined and heterogeneous and that subgrouping patients according to factors such as psychiatric state and symptom onset may be fruitful. The current state of treatment for CFS is reviewed, and the challenges for research aimed at resolving this prototypical mind/body problem are discussed.
Jones E, Wessely S.	Department of Psychological Medicine, Guy's, King's, and St Thomas's School of Medicine, London SE5 8AZ. E.Jones@hogarth7.demon.co.uk	Case of chronic fatigue syndrome after Crimean war and Indian mutiny.	BMJ 1999 Dec 18-25;319(7225):1645-7	
Kakumanu S, Yeager M, Craig TJ.	Pennsylvania State University, College of Medicine, Hershey, USA.	Chronic fatigue syndrome.	J Am Osteopath Assoc 1999 Oct;99(10 Su Pt 1):S1-5	The chronic fatigue syndrome is an illness of unknown etiology characterized by severe fatigue, myalgias, lymphadenopathy, arthralgias, chills, fevers, and postexertional malaise. Recognizing chronic fatigue syndrome is primarily a method of exclusion with no definitive diagnostic test or physical findings. As research continues to delve into the many possible etiologic agents for chronic fatigue syndrome--infectious, immunologic, neurologic, or psychiatric alone or in combination--the answer remains elusive. What is known is that chronic fatigue syndrome is a heterogeneous disorder very possibly involving an interaction of biological systems. Therefore, chronic fatigue syndrome may describe a large subset of patients, each exhibiting unique symptoms and serologic profiles dependent on the nature of the onset of illness and the genetic profile of individual patients.
Keenan PA. Editorial		Brain MRI abnormalities exist in chronic fatigue syndrome.	J Neurol Sci 1999 Dec 1;171(1):1-2 Comment on: J Neurol Sci. 1999 Dec 1;171(1):3-7	
Kenter EG, Okkes IM.	Academisch Medisch Centrum/Universiteit van Amsterdam, afd. Huisartsgeneeskunde.	[Patients with fatigue in family practice: prevalence and treatment].[article in Dutch]	Ned Tijdschr Geneeskd 1999 Apr 10;143(15):796-801	OBJECTIVE: To gain insight into the prevalence and treatment of severe fatigue in general practice. DESIGN: Secondary data analysis. METHOD: By means of an episode-oriented morbidity registration by 54 GPs throughout the Netherlands over the period 1985-1994 it was established how often in the course of one year 'fatigue' was listed as the reason for consultation, what diagnoses were then made, how long

				episodes of care because of 'fatigue' lasted and what interventions took place (n = 93,297). Of the patients with a care episode because of 'fatigue' lasting at least 6 months, age, sex, comorbidity and consumption of care were established; for this purpose use was also made of a file containing data on 4 years in succession (n = 9630). RESULTS: Per annum, 92 per 1000 listed patients consulted the GP because of fatigue. Somatic or psychic diagnoses were made in 27.7 per 1000 patients listed. The episode of care lasted 4 weeks at most in 86% and at least 6 months in approximately 4%. The GPs' management of patients with 'fatigue' included physical examination in 63% and blood testing in 34%, conversation in 35%, prescription of medication in 24% and referral to a specialist in 3%. Of the 97 patients with fatigue lasting longer than 6 months, 61% had a chronic disease or psychic problems. CONCLUSION: Fatigue is frequently encountered in general practice, but the estimate that one per 1000 listed patients meets the criteria of the chronic fatigue syndrome looks a little high. It appears that GPs, in accordance with recommendations, mostly adopt a policy of wait and see.
Kipen HM, Hallman W, Kang H, Fiedler N, Natelson BH.	New Jersey Center for Environmental Hazards Research, East Orange, USA.	Prevalence of chronic fatigue and chemical sensitivities in Gulf Registry Veterans.	Arch Environ Health 1999 Sep-Oct;54(5):313-8Comment in: Arch Environ Health. 1999 Sep-Oct;54(5):309-11	More than 68000 of the 700000 veterans of the Gulf War have become members of the Veteran Affairs' Gulf War Registry. In 1995, we undertook a questionnaire study of the symptoms and medical histories reported by a randomly selected subsample of 1935 of these veterans to characterize their complaints. All results reported were based on questionnaire responses without face-to-face evaluation or physical examinations. Inasmuch as initial registry symptoms overlapped those of Chronic Fatigue Syndrome and Multiple Chemical Sensitivities, we also included standard questions for these syndromes in the questionnaire. A total of 1161 (60%) individuals responded, and there were no major demographic biases; therefore, 15.7% of registry veterans qualified for Chronic Fatigue Syndrome in accordance with the 1994 Centers for Disease Control definition. In addition, 13.1% qualified for multiple chemical sensitivities in accordance with a widely used definition, and 3.3% of the respondents had both conditions. There were no effects of gender, race, branch, duty status (active or reserve), or rank, although Multiple Chemical Sensitivities was somewhat more prevalent in women and African Americans. The data gleaned in this study suggested that the unexplained symptom syndromes of Chronic Fatigue and Multiple Chemical Sensitivities may characterize an appreciable portion of the complaints of those who volunteered for the Veterans Affairs' Gulf War Registry, and further investigation is warranted.
Knobeloch L, Jackson R.	Bureau of Environmental Health, Wisconsin Division of Public Health, Madison 53703-3043, USA.	Recognition of chronic carbon monoxide poisoning.	WMJ 1999 Sep-Oct;98(6):26-9	Chronic exposure to low levels of carbon monoxide can cause vague symptoms that are easily mistaken for other common illnesses. During the past 5 years, three families have contacted the Wisconsin Division of Public Health to report illnesses that may have been caused by chronic exposure to carbon monoxide. Members of these families were diagnosed with a variety of conditions including chronic fatigue syndrome, depression and influenza. Carbon monoxide exposure was not suspected

				as a cause of these illnesses until heating contractors discovered that gas appliances in these families' homes were not properly vented. These cases serve as reminders that carbon monoxide exposure should be considered in the differential diagnosis of patients who present with chronic symptoms of headache, fatigue, dizziness, nausea and mental confusion--especially when these symptoms onset during the winter heating season.
Korszun A, Sackett-Lundeen L, Papadopoulos E, Brucksch C, Masterson L, Engelberg NC, Haus E, Demitrack MA, Crofford L.	Department of Psychiatry, University of Michigan Medical Center, Ann Arbor, USA. akorszun@umich.edu	Melatonin levels in women with fibromyalgia and chronic fatigue syndrome.	J Rheumatol 1999 Dec;26(12):2675-80	OBJECTIVE: Fibromyalgia (FM) and chronic fatigue syndrome (CFS) are stress associated disorders mainly affecting women. FM is characterized primarily by widespread musculoskeletal pain, and CFS by profound debilitating fatigue, but there is considerable overlap of clinical symptoms between these 2 syndromes. Neuroendocrine abnormalities have been noted in both FM and CFS and desynchronization of circadian systems has been postulated in their etiology. The pineal hormone melatonin is involved in synchronizing circadian systems and the use of exogenous melatonin has become widespread in patients with FM and CFS. METHODS: We examined the characteristics and relationship of melatonin and cortisol levels in premenopausal women with FM (n = 9) or CFS (n = 8), compared to age and menstrual cycle phase matched controls. Blood was collected from an indwelling intravenous catheter every 10 min over 24 h, and plasma melatonin and cortisol were determined by radioimmunoassay at 60 and 10 min intervals, respectively. RESULTS: Night time (23:00-06:50) plasma melatonin levels were significantly higher in FM patients compared to controls ($p<0.05$), but there was no significant difference in melatonin levels between CFS patients and controls. No differences in the timing of cortisol and melatonin secretory patterns and no internal desynchronization of the 2 rhythms were found in either patient group, compared to controls. CONCLUSION: Raised plasma melatonin concentrations have been documented in several other conditions that are associated with dysregulation of neuroendocrine axes. Increased melatonin levels may represent a marker of increased susceptibility to stress induced hypothalamic disruptions. These data indicate that there is no rationale for melatonin replacement therapy in patients with FM and CFS.

LaManca JJ, Peckerman A, Walker J, Kesil W, Cook S, Taylor A, Natelson BH.	CFS Cooperative Research Center, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark, USA.	Cardiovascular response during head-up tilt in chronic fatigue syndrome.	Clin Physiol 1999 Mar;19(2):111-20	This study examined the cardiovascular response to orthostatic challenge, and incidence and mechanisms of neurally mediated hypotension in chronic fatigue syndrome (CFS) during a head-up tilt test. Stoke volume was obtained by a thoracic impedance cardiograph, and continuous heart rate and blood pressure were recorded during a 45-min 70 degrees head-up tilt test. Thirty-nine CFS patients and 31 healthy physically inactive control subjects were studied. A positive tilt, i.e. a drop in systolic blood pressure of > 25 mmHg, no concurrent increase in heart rate and/or development of presyncopal symptoms, was seen in 11 CFS patients and 12 control subjects (P > 0.05). During baseline and the first 5 min of head-up tilt, CFS patients had higher heart rate and smaller pulsatile-systolic area than control subjects (P < 0.05). Among subjects who completed the test, those with CFS had higher heart rate and smaller stroke volume (P < 0.05) than corresponding control subjects. When comparing those who had a positive test outcome in each group, CFS patients had higher heart rates and lower pulse pressure and pulsatile-systolic areas during the last 4 min before being returned to supine (P < 0.05). These data show that there are baseline differences in the cardiovascular profiles of CFS patients when compared with control subjects and that this profile is maintained during head-up tilt. However, the frequency of positive tilts and the haemodynamic adjustments made to this orthostatic challenge are not different between groups.
LaManca JJ, Sisto SA, Zhou XD, Ottenweller JE, Cook S, Peckerman A, Zhang Q, Denny TN, Gause WC, Natelson BH.	NJ CFS Cooperative Research Center, UMDNJ-New Jersey Medical School, Newark 07103, USA.	Immunological response in chronic fatigue syndrome following a graded exercise test to exhaustion.	J Clin Immunol 1999 Mar;19(2):135-42	This study was conducted to evaluate the immunological response to an exhaustive treadmill exercise test in 20 female chronic fatigue syndrome patients compared to 14 matched sedentary controls. Venipuncture was performed at baseline and 4 min, 1 hr, and 24 hr postexercise. White blood cells were labeled for monoclonal antibody combinations and were quantified by FACsan. Cytokines were assayed utilizing quantitative RT/PCR. No group difference was seen in VO2peak (28.6 +/- 1.6 vs 30.9 +/- 1.2 ml.kg-1.min-1; P > 0.05). However, 24 hr after exercise the patients' fatigue levels were significantly increased (P < 0.05). The counts of WBC, CD3+ CD8+ cells, CD3+ CD4+ cells, T cells, B cells, natural killer cells, and IFN-gamma changed across time (P's < 0.01). No group differences were seen for any of the immune variables at baseline or after exercise (P's > 0.05). The immune response of chronic fatigue syndrome patients to exhaustive exercise is not significantly different from that of healthy nonphysically active controls.
Lange G, DeLuca J, Maldjian JA, Lee H, Tiersky LA, Natelson BH.	Department of Psychiatry, UMDNJ-New Jersey Medical School, MSB E-561, 185 S. Orange Avenue, Newark, NJ 07103-2714, USA.	Brain MRI abnormalities exist in a subset of patients with chronic fatigue syndrome.	J Neurol Sci 1999 Dec 1;171(1):3-7Comment in: J Neurol Sci. 1999 Dec 1;171(1):1-2	Presence of MRI brain abnormalities in patients with Chronic Fatigue Syndrome (CFS) was determined and the profile of MRI abnormalities was compared between 39 CFS patients, 18 with (CFS-Psych) and 21 without (CFS-No Psych) a DSM-III-R Axis I psychiatric diagnosis since illness onset, and 19 healthy, sedentary controls (HC). Two neuroradiologists, blind to group membership, separately read the MR films using a detailed protocol for rating and categorizing abnormal signal changes. When findings were incongruent, the two neuroradiologists met to try to reach consensus, otherwise a third neuroradiologist evaluated the MR images and served as a tie-

				breaker. The CFS-No Psych group showed a significantly larger number of brain abnormalities on T2 weighted images than the CFS-Psych and HC groups. Cerebral changes in the CFS-No Psych group consisted mostly of small, punctate, subcortical white matter hyperintensities, found predominantly in the frontal lobes. No significant difference was found when both CFS groups were combined and compared to the HC group. The use of stratification techniques is an important strategy in understanding the pathophysiology of CFS. This frontal lobe pathology could explain the more severe cognitive impairment previously reported in this subset of CFS patients.
Lange G, Tiersky L, DeLuca J, Peckerman A, Pollet C, Policastro T, Scharer J, Ottenweller JE, Fiedler N, Natelson BH.	Center for Environmental Hazards Research, VA Medical Center, East Orange, NJ, USA. langegu@umdnj.edu	Psychiatric diagnoses in Gulf War veterans with fatiguing illness.	Psychiatry Res 1999 Dec 13;89(1):39-48	The purpose of this study was to determine whether Gulf War Illness (GWI) can be explained by the presence of psychiatric disorders as assessed by DSM-III-R. To reduce the heterogeneity amongst Persian Gulf War veterans with GWI (PGV-F), only those were studied who presented with severe fatigue as a major complaint and also fulfilled clinical case definitions for Chronic Fatigue Syndrome, Idiopathic Chronic Fatigue, and/or Multiple Chemical Sensitivity. A total of 95 Registry PGVs were examined; 53 presented with GWI and 42 did not report any post-war health problems (PGV-H). All subjects were assessed for the presence of DSM-III-R Axis I psychiatric disorders. Compared to PGV-Hs, 49% of PGV-Fs had similar post-war psychiatric profiles: either no, or only one, psychiatric disorder was diagnosed. Psychiatric profiles of the remaining 51% of PGV-Fs were significantly different from PGV-Hs in that most of these veterans suffered from multiple post-war psychiatric diagnoses. The presence of psychiatric disorders as assessed by DSM-III-R criteria cannot explain symptoms of Gulf War Illness among all Persian Gulf veterans with severe fatiguing illness.

Lovell DM.	Oxford University Psychiatry Department, Warneford Hospital, Oxford, England.	Chronic fatigue syndrome among overseas development workers: A qualitative study.	J Travel Med 1999 Mar;6(1):16-23	BACKGROUND: A relatively high proportion of overseas development workers may develop chronic fatigue syndrome (CFS). A qualitative study was conducted in order to investigate how such people perceived their condition. METHODS: Twelve people who had developed CFS while working overseas with development organizations, or shortly after visiting development projects, were interviewed about their experiences. Their responses were analyzed using a grounded theory approach. RESULTS: Most of the participants considered themselves to have been extremely healthy before they developed CFS. The syndrome did not appear to have been caused by depression. The symptoms which were reported covered the range of symptoms typically found in studies of CFS. Respondents described difficulty in receiving, and accepting, a diagnosis. All of the participants attributed the CFS to

				multiple causes, the principal causes being overwork, stress and infections. Among the consequences of CFS reported to be the most difficult were having to leave the development project prematurely; pain; powerlessness; loss of independence, and the unpredictability of CFS. Factors which had helped respondents cope with these difficulties included religious beliefs; comparisons with people who were worse off than they were; thinking about positive consequences of the condition, and talking with supportive people. CONCLUSIONS: Some theories have suggested that CFS symptoms arise as a result of depression or other emotional difficulties, which the individual is not able to acknowledge. The results indicated that such theories may not apply to this subgroup of people with CFS. Further research on the etiology of CFS is warranted. Respondents described high levels of work-related stress as common to the experience of development work. It might be beneficial to train development workers in stress management techniques. Development organizations should be encouraged to ensure that their workers take sufficient time to rest, and attempts should be made to reduce work pressures.

Marcusson JA, Lindh G, Evengard B.	Department of Dermatology, Huddinge University Hospital, Sweden.	Chronic fatigue syndrome and nickel allergy.	Contact Dermatitis 1999 May;40(5):269-72Comment in: Contact Dermatitis. 2000 Jan;42(1):56-7	50 patients with chronic fatigue syndrome (CFS) and 73 controls were patch tested with 8 metal allergens. We found an overrepresentation of allergies among the CFS patients, which was not significant. However, allergy to nickel occurred in 36% of patients in the CFS group and in 19% of subjects in the control group ($p<0.05$). The high frequency of nickel allergy was more noteworthy in females in the CFS group than among female controls (52% and 24%, respectively, $p<0.05$). Similarly, in the males the figures were 14% and 9%. We suggest that in vivo immunoactivation by ions of nickel, or metal cross-reacting with nickel, could be an etiological factor in CFS.

Martin WJ.	Center for Complex Infectious Diseases, Rosemead, California 91770, USA.	Stealth adaptation of an African green monkey simian cytomegalovirus.	Exp Mol Pathol 1999 Apr;66(1):3-7	DNA extracted from cultures of a cytopathic virus isolated from a patient with chronic fatigue syndrome was cloned into pBluescript plasmid. The nucleotide sequences of the plasmid inserts were analyzed using the BlastN and BlastX programs of the National Center for Biotechnology Information. In confirmation of earlier studies, many of the sequences show partial homology to various regions within the genome of human cytomegalovirus (HCMV). The matching regions were unevenly distributed throughout the HCMV genome. No matches were seen with either the UL55 or the UL83 genes, which provide the major antigenic targets for anti-HCMV cytotoxic T-cell-mediated immunity. This finding is consistent with the notion that certain viruses can avoid immune elimination by deleting genes required for effective antigenic recognition by the cellular immune system. The term "stealth" has been applied to such viruses. Comparisons were also made between the sequences of the stealth virus and the limited sequence data available on cytomegaloviruses from rhesus monkeys and from African green monkeys. These comparisons unequivocally establish that the virus was derived from an African green monkey simian cytomegalovirus. Copyright 1999 Academic Press.

Matsumoto Y.	Center of Rheumatic Diseases, Toyokawa City Hospital.	[Fibromyalgia syndrome].[article in Japanese]	Nippon Rinsho 1999 Feb;57(2):364-9	Fibromyalgia syndrome (FMS) is recognizable syndrome characterized by chronic, diffuse pain, an absence of inflammatory or structural muscloskeletal abnormalities, and a range of symptoms that include fatigue, and sleep and mood disturbances. Physical examination and laboratory testing are unrevealing, except for the presence of pain on palpation of characteristic soft-tissue sites, the tender points. Despite the recognition of FMS by the World Health Organization, it remains a controversial condition and its existence as a distinct entity remains uncertain. However, the concept of FMS is a useful one, allowing many investigations to be avoided and

				appropriate advice on treatment to be given. FMS may overlap with symptoms of, and the patient further impaired by, anxiety and depression. The term FMS dose not imply causation and merely describes the most common symptoms. Many patients with chronic fatigue syndrome(CFS) fulfill the criteria of FMS and represent one end of a spectrum of presentation. Evidence for triggering viral infection and the lower level of serum acylcarnitine, observed in CFS patients, is lacking in the majority of patients with FMS. These findings are suggestive to be distinctively another disorders between FMS and CFS.

McCully KK, Natelson BH.	Department of Medicine, Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA 19129, USA. kmccully@coe.uga.edu	Impaired oxygen delivery to muscle in chronic fatigue syndrome.	Clin Sci (Colch) 1999 Nov;97(5):603-8; discussion 611-3Comment in: Clin Sci (Colch). 1999 Nov;97(5):611-3	The purpose of this study was to determine if chronic fatigue syndrome (CFS) is associated with reduced oxygen delivery to muscles. Patients with CFS according to CDC (Center for Disease Control) criteria (n=20) were compared with normal sedentary subjects (n=12). Muscle oxygen delivery was measured as the rate of post-exercise and post-ischaemia oxygen-haem resaturation. Oxygen-haem resaturation was measured in the medial gastrocnemius muscle using continuous-wavelength near-IR spectroscopy. Phosphocreatine resynthesis was measured simultaneously using (31)P magnetic resonance spectroscopy. The time constant of oxygen delivery was significantly reduced in CFS patients after exercise (46.5+/-16 s; mean+/-S.D.) compared with that in controls (29.4+/-6.9 s). The time constant of oxygen delivery was also reduced (20.0+/-12 s) compared with controls (12.0+/-2.8 s) after cuff ischaemia. Oxidative metabolism was also reduced by 20% in CFS patients, and a significant correlation was found between oxidative metabolism and recovery of oxygen delivery. In conclusion, oxygen delivery was reduced in CFS patients compared with that in sedentary controls. This result is consistent with previous studies showing abnormal autonomic control of blood flow. Reduced oxidative delivery in CFS patients could be specifically related to CFS, or could be a non-specific effect of reduced activity levels in these patients. While these results suggest that reduced oxygen delivery could result in reduced oxidative metabolism and muscle fatigue, further studies will be needed to address this issue.

Michiels V, de Gucht V, Cluydts R, Fischler B.	Free University of Brussels (VUB), Belgium.	Attention and information processing efficiency in patients with Chronic Fatigue Syndrome.	J Clin Exp Neuropsychol 1999 Oct;21(5):709-29	In this study a battery of attentional tests and a verbal memory task were administered to outpatients with Chronic Fatigue Syndrome (CFS) in order to evaluate aspects of attention that have not been explored in this group to date. In addition, this study was designed to further examine memory function and to extend the few reports investigating the rate of cognitive processing independent of motor speed and the possibility of a modality-specific impairment of information processing. Twenty-nine patients with CFS and 22 healthy controls matched for age, gender, intelligence, and education were included in this study. The results show that patients with CFS do not seem to be impaired for modification of phasic arousal level, nor for visual selective attention requiring shifting of attention in the visuospatial field. The results further support the presence of reduced information processing speed and efficiency, and strengthen the evidence of a global non-modality-specific attentional dysfunction in patients with CFS. In this study the poor performance of patients with CFS on recall of verbal information was due to poor initial storage rather than to a retrieval failure.
Mojarro Praxedes MD, Benjumea Pino P.	Servicio de Psiquiatria,Hospital Clinico Universitario, Sevilla, Sevilla, 41009,Espana.	[The chronic fatigue and neurasthenia in the student population].[article in Spanish]	Actas Esp Psiquiatr 1999 Jan-Feb;27(1):14-21	INTRODUCTION: Fatigue is one of the most common symptoms in community studies, primary care and other medical setting. In spite of a high frequency of fatigue, the incidence of chronic fatigue syndrome is very low. In this paper, we want to know the frequency of chronic fatigue syndrome and neurasthenia; we want to know the association between fatigue and depressive symptoms in students. METHODS: We studied 277 medical student, administering: 1. a center for disease control questionnaire to assess major criteria and minor criteria of chronic fatigue syndrome, 2. ICD 10 criteria for the diagnoses of neurasthenia and 3. Beck depression inventory. RESULTS AND CONCLUSIONS: We found that the 37,55% of the subjects suffer fatigue. 9 subjects (3,25% of the total) meet the criteria of neurasthenia. 2 subjects (0,72% of the total) meet the chronic fatigue syndrome criteria. The depressive symptoms are most frequent in the subjects with fatigue, but we don't know if they are the cause or the consequence of the fatigue. With the factorial analyses, we find that symtoms of physical fatigue, mental fatigue and cognitive difficulties are factor independent of each other.
Morriss RK, Ahmed M, Wearden AJ, Mullis R, Strickland P, Appleby L, Campbell IT,	Department of Community Psychiatry, Royal Preston Hospital, University of	The role of depression in pain, psychophysiological syndromes and	J Affect Disord 1999 Oct;55(2-3):143-8	BACKGROUND: The association between depression and pain, function, medically unexplained symptoms and psychophysiological syndromes such as irritable bowel syndrome has not been explored before in chronic fatigue syndrome. METHODS: Cross-sectional controlled study of the current prevalence of psychophysiological

Pearson D.	Manchester, UK.	medically unexplained symptoms associated with chronic fatigue syndrome.		syndromes, pain, function and lifetime prevalence of medically unexplained symptoms in 77 out-patients with chronic fatigue syndrome (CFS) without DSM-III-R depression, 42 CFS out-patients with DSM-III-R depression and 26 out-patient with primary DSM-III-R depression. RESULTS: Both CFS groups differed significantly from the primary depression group but not each other in the prevalence of tension headaches (P < 0.001), reporting of widespread bodily pain (P < 0.001) and the number of lifetime medically unexplained symptoms (P < 0.001). The three groups did not significantly differ in the prevalence of irritable bowel syndrome or fibromyalgia. CFS patients with depression were more impaired in social function than other CFS patients. CONCLUSION: Depression is not associated with the reporting of pain, psychophysiological syndromes and medically unexplained symptoms in CFS patients. Depression is associated with decreased social function in CFS patients. LIMITATIONS: Study depended on recall of symptoms, not confirmed by medical records and current investigations. Patients with depression were taking antidepressants. CLINICAL RELEVANCE: Treating depression in chronic fatigue syndrome is unlikely to diminish reporting of pain and medically unexplained symptoms but may improve social function.
Moss RB, Mercandetti A, Vojdani A.	The Immune Response Corporation, Carlsbad, California 92008, USA. shotdoc@imnr.com	TNF-alpha and chronic fatigue syndrome.	J Clin Immunol 1999 Sep;19(5):314-6	Based upon the clinical presentation of chronic fatigue syndrome (CFS), we hypothesized that proinflammatory cytokines may play a role in the pathogenesis of the disease. We therefore undertook a retrospective cross-sectional study to examine the role of TNF-alpha in patients with CFS. Our results suggest a significant increase serum TNF-alpha in patients with CFS (P<0.0001) compared to non-CFS controls. This study supports the further examination of the role of proinflammatory mediators in CFS. Furthermore, the clinical testing of TNF-alpha blockers and other antiinflammatory agents for the treatment of this disease is warranted.
Mullis R, Campbell IT, Wearden AJ, Morriss RK, Pearson DJ.	Department of Physiotherapy Studies, University of Keele, Staffordshire, United Kingdom.	Prediction of peak oxygen uptake in chronic fatigue syndrome.	Br J Sports Med 1999 Oct;33(5):352-6	OBJECTIVES: To establish a simple, valid, and acceptable method of predicting peak oxygen uptake (VO2peak) in patients with chronic fatigue syndrome (CFS), which could provide a basis for subsequent exercise prescription at an appropriate intensity as part of a clinical rehabilitation programme. METHODS: A total of 130 patients who met UK research criteria for CFS were taken from consecutive referrals for chronic fatigue to the University Department of Medicine at Withington Hospital, Manchester. VO2peak was determined using an incremental graded exercise test to exhaustion. Respiratory gas exchange, work rate, and heart rate were monitored throughout. RESULTS: In all patients, VO2peak was found to correlate strongly and significantly with peak work rate (WRpeak) during testing (r2 = 0.88, p<0.001). In patients who exercised for longer than two minutes (n = 119), regression analysis established the relation as Vo2peak = 13.1 x WRPpeak + 284, where VO2 is given in ml/min and WR in W. The mean error between the measured VO2peak and the predicted value was 10.7%. The relation between increase in work rate and oxygen uptake across the group was highly significant (r2 = 0.87, p<0.001), and given as

				VO2increase = 12.0 x WRincrease, this value being similar to that expected for healthy individuals. Almost all (97%) subjects reported no exacerbation of symptoms after maximal exercise testing. CONCLUSIONS: Using a simple to administer maximal exercise test on a cycle ergometer, it is possible to predict accurately the VO2peak of a patient with CFS from peak work rate alone. This value can then be used as an aid to setting appropriate exercise intensity for a rehabilitation programme. The increase in VO2 per unit increase in workload was consistent with that expected in healthy individuals, suggesting that the physiological response of the patients measured here was not abnormal. Contrary to the belief of many patients, maximal exercise testing to the point of subjective exhaustion proved to be harmless, with no subjects suffering any lasting deterioration in their condition after assessment.
Myers C, Wilks D.	Regional Infectious Diseases Unit, Western General Hospital, Edinburgh, UK.	Comparison of Euroqol EQ-5D and SF-36 in patients with chronic fatigue syndrome.	Qual Life Res 1999;8(1-2):9-16	The objective of the study was to compare the Euroqol EQ-5D (Euroqol) and short-form 36 (SF-36) health questionnaires in patients with chronic fatigue syndrome (CFS). One hundred and twenty-seven outpatients referred to a hospital-based infectious disease clinic with a diagnosis of CFS were contacted by post and asked to complete both questionnaires. Additional data were determined from hospital casenotes. Eighty-five patients returned correctly completed questionnaires. Euroqol health values and visual analogue scale (VAS) scores were strongly and significantly correlated with all dimensions of the SF-36, with the exception of physical limitation of role. SF-36 dimensions were in turn strongly and significantly correlated with each other, with the same exception. Patients reported a high degree of physical disability and a moderate degree of emotional or psychological ill-health. The Euroqol elements dealing with mobility and self-care referred to inappropriately severe degrees of disability for these patients with CFS. Similarly some dimensions in the SF-36 were oversensitive and did not discriminate between patients with moderate or severe disability. It was concluded that Euroqol scores correlated strongly with SF-36 scores and provided useful information about patients with CFS and that Euroqol would be a useful tool for the rapid assessment of health status in CFS. The current Euroqol instrument refers to inappropriately severe degrees of disability for patients with CFS and would need to be modified to be maximally useful in this situation.
Nakaya T, Takahashi H, Nakamur Y, Kuratsune H, Kitani T, Machii T, Yamanishi K, Ikuta K.	Section of Serology, Institute of Immunological Science, Hokkaido University, Sapporo, Japan.	Borna disease virus infection in two family clusters of patients with chronic fatigue syndrome.	Microbiol Immunol 1999;43(7):679-89	A high rate of Borna disease virus (BDV) infection has been demonstrated in patients with chronic fatigue syndrome (CFS). Herein, we focused on BDV infection in two family clusters of patients with CFS: a father, mother, two sons and one daughter (family #1); and a father, mother, two daughters and one son (family #2). All members, except for the elder son in family #1 and the father and son in family #2, were diagnosed with CFS. The results supported that all the family members with CFS were infected with BDV, as evidenced by the presence of antibodies to viral p40, p24 and/or gp18 and BDV p24 RNA in peripheral blood mononuclear cells. The healthy members, except for the father of family #2 who was positive for antibody to p24, were all negative by both assays. Follow-up studies in family #1 continued to reveal

				BDV antibodies and BDV RNA, except in the mother, who lost the RNA upon slight recovery from the disease.
Nasralla M, Haier J, Nicolson GL.	The Institute for Molecular Medicine, Huntington Beach, CA 92649-1041, USA.	Multiple mycoplasmal infections detected in blood of patients with chronic fatigue syndrome and/or fibromyalgia syndrome.	Eur J Clin Microbiol Infect Dis 1999 Dec;18(12):859-65	The aim of this study was to investigate the presence of different mycoplasmal species in blood samples from patients with chronic fatigue syndrome and/or fibromyalgia syndrome. Previously, more than 60% of patients with chronic fatigue syndrome/fibromyalgia syndrome were found to have mycoplasmal blood infections, such as Mycoplasma fermentans infection. In this study, patients with chronic fatigue syndrome/fibromyalgia syndrome were examined for multiple mycoplasmal infections in their blood. A total of 91 patients diagnosed with chronic fatigue syndrome/fibromyalgia syndrome and with a positive test for any mycoplasmal infection were investigated for the presence of Mycoplasma fermentans, Mycoplasma pneumoniae, Mycoplasma hominis and Mycoplasma penetrans in blood using forensic polymerase chain reaction. Among these mycoplasma-positive patients, infections were detected with Mycoplasma pneumoniae (54/91), Mycoplasma fermentans (44/91), Mycoplasma hominis (28/91) and Mycoplasma penetrans (18/91). Multiple mycoplasmal infections were found in 48 of 91 patients, with double infections being detected in 30.8% and triple infections in 22%, but only when one of the species was Mycoplasma pneumoniae or Mycoplasma fermentans. Patients infected with more than one mycoplasmal species generally had a longer history of illness, suggesting that they may have contracted additional mycoplasmal infections with time.
Natelson BH, Denny T, Zhou XD, LaManca JJ, Ottenweller JE, Tiersky L, DeLuca J, Gause WC.	Department of Neuroscience, UMDNJ-New Jersey Medical School, East Orange, Newark 07103, USA.	Is depression associated with immune activation?	J Affect Disord 1999 May;53(2):179-84	BACKGROUND: Some research immunologists have suggested that major depression amd chronic fatigue syndrome (CFS) are characterized by immune activation. To test this hypothesis, we compared immunological function in patients with major depression and in patients with CFS who developed major depression after the onset of CFS to that of sedentary healthy controls. METHODS: Subjects completed the Centers for Epidemiological Study-Depression (CES-D) questionnaire and allowed venisection. We performed flow cytometric analysis on 13 groups of white blood cells and used a reverse transcriptase PCR method to assay m-RNA of eight cytokines. RESULTS: CES-D scores were high in both patient groups and did not differ significantly. We found no evidence for immune activation in either patient group. Instead the data suggested immunological downregulation in depression. LIMITATIONS: Not all the subjects in the two patient groups were off antidepressants. CONCLUSIONS: The data indicate that immune activation is not necessary in depression--either alone or with CFS.
Nores JM		The Philosophy of Pain: New Concepts	Journal of Chronic Fatigue Syndrome 1999: 5(2): 99 - 105	This article examines the concept of physical pain and its relationship to philosophy within the context of ethics. The first question posing a problem is: should pain be added to or included in the list of the five senses? Whether sensation is present or not, pain does exist. Pain is part of the ''immediate data of consciousness'' dear to philosophers. Pain is at the heart of ontology, philosophy of the being and existential

				ontology, which places existence above essence. Pain is mine and teaches me that I exist. Pain conveys my existence more than thought. Why shouldn't we enrich Descartes's cogito? ''I suffer, therefore I exist'' rather than ''I think, therefore I exist'' or even ''I am something which suffers'' rather than ''I am a thing which thinks'' by Descartes. As pain is the witness of their existence, other beings resemble me. The use of physical pain to cause harm is the best transition towards the following question, that is, what is the relationship between pain and evil or harm? This is a question which is primordial and concerns philosophers, moralists and theologians. There is just pain which is harmful and is our enemy to be conquered. This would seem to be what philosophy has to teach those of us who are doctors fighting pain.
Onouchi H, Muro Y, Tomita Y.	Department of Dermatology, Nagoya University School of Medicine, Nagoya, Japan.	Clinical features and IgG subclass distribution of anti-p80 coilin antibodies.	J Autoimmun 1999 Sep;13(2):225-32	We examined the clinical features of patients presenting antinuclear autoantibodies against p80-coilin and the IgG subclass distribution of anti- p80-coilin antibodies. Sera from 365 Japanese patients were analysed. Immunoblotting and indirect immunofluorescence microscopy techniques were used with a polyclonal rabbit antiserum against p80-coilin. Eleven patients with anti-p80-coilin antibodies were found. All the patients were female and nine were in their twenties. None could be diagnosed with differentiated rheumatic disease except for one case of systemic scleroderma and another of Sjogren's syndrome. Most patients had general fatigue, arthralgia, headaches, dysmenorrhea, lymph node swelling and/or low grade fever such as chronic fatigue syndrome (CFS), and showed low complement. One patient fulfilled the criteria for CFS. All were younger females than those often diagnosed with rheumatic disease in previous reports. Patients' sera had a predominant distribution of subclass IgG(1)anti-p80-coilin antibodies and five sera had concomitant subclass IgG(2). Two rheumatic disease patients had a relatively high titer of IgG(2)anti-p80-coilin antibodies. The IgG(2)subclass of anti-p80-coilin antibodies may be a specific marker for systemic autoimmune disease. Copyright 1999 Academic Press.
Pagani M, Lucini D.	Centro Ricerca Terapia Neurovegetativa, Ospedale L. Sacco, University of Milan, Via G.B. Grassi, 74, 20157 Milan, Italy.	Chronic fatigue syndrome: a hypothesis focusing on the autonomic nervous system.	Clin Sci (Colch) 1999 Jan;96(1):117-25Comment in: Clin Sci (Colch). 1999 Sep;97(3):319-22	Chronic fatigue syndrome is a debilitating illness of unknown aetiology, with estimated levels of prevalence of up to about 8. 7/100 000 in the U.S.A. Like pain fatigue it is a personal, emotionally rich experience, which may originate from peripheral or central sites (or both). The nature of the symptoms is complex and reflects the interaction of the patient with the environment and cultural milieu. Accordingly the common use of the same terminology for different types of fatigue may be misleading. Autonomic activation is a key component of both real and simulated physical exercise. Alterations in autonomic nervous system activity are a key component of several physiopathological conditions. In chronic fatigue syndrome disturbances in autonomic activity, and in other homoeostatic mechanisms, such as the hormonal and immune systems, have been reported recently. In this review we followed the hypothesis that in chronic fatigue syndrome the paradoxical condition of disturbing somatic symptoms in the absence of organic evidence of disease might

				be addressed by focusing on attending functional correlates. In particular we addressed possible alterations in cardiovascular autonomic control, as can be assessed by spectral analysis of R-R interval and systolic arterial pressure variability. With this approach, in subjects complaining of unexplained fatigue, we obtained data suggesting a condition of prevailing sympathetic modulation of the sino-atrial node at rest, and reduced responsiveness to excitatory stimuli. Far from considering the issue resolved, we propose that in the context of the multiple physiological and psychological interactions involved in the perception and self-reporting of symptoms, attendant changes in physiological equivalents might furnish a convenient assessment independent from subjective components. Indices of sympathetic modulation could, accordingly, provide quantifiable signs of the interaction between subject's efforts and environmental demands, independently of self descriptions, which could provide convenient measurable outcomes, both for diagnosis and treatment titration in chronic fatigue syndrome.
Paul L, Wood L, Behan WM, Maclaren WM.	Department of Physiotherapy, Glasgow Caledonian University, Glasgow, Scotland.	Demonstration of delayed recovery from fatiguing exercise in chronic fatigue syndrome.	Eur J Neurol 1999 Jan;6(1):63-9	Patients with the chronic fatigue syndrome (CFS) complain consistently of delay in recovery of peripheral muscle function after exercise. The purpose of this study was to try to confirm this observation. A fatiguing exercise test was carried out on the quadriceps muscle group of ten patients and ten control subjects. The test consisted of 18 maximum voluntary contractions (MVCs) with a 50% duty cycle (10 s contraction, 10 s rest), and the force generated by each contraction was recorded using a KinCom dynamometer. This was followed by a recovery phase lasting 200 min in which quadriceps strength was evaluated at increasing intervals, and a follow-up session at 24 h post-exercise involving three 10 s MVCs. Throughout the exercise period, the MVCs obtained from the control group were significantly higher than those of the patient group ($P = 0.006$), but both groups showed a parallel decline in force over the 18 contractions, in keeping with a similar endurance capacity. Recovery was prolonged in the patient group, however, with a significant difference compared to initial MVCs being evident during the recovery phase after exercise ($P = 0.001$) and also at 24 h ($P < 0.001$). In contrast, the control group achieved MVCs which were not significantly different from initial values during the recovery phase, and maintained these at 24 h. These findings support the clinical complaint of delayed recovery after exercise in patients with CFS. Copyright 1999 Lippincott Williams & Wilkins

Pheley AM, Melby D, Schenck C, Mandel J, Peterson PK.	Ohio University College of Osteopathic Medicine, Athens, USA.	Can we predict recovery in chronic fatigue syndrome?	Minn Med 1999 Nov;82(11):52-6	PURPOSE: To determine if selected demographic or clinical features of chronic fatigue syndrome (CFS) are associated with recovery. PATIENTS AND METHODS: A follow-up questionnaire was mailed to 341 patients who had been ill on average for nine years to ascertain "recovery" rate (defined as self-reported recovery on a visual

				analog scale). Baseline demographic and clinical features (functional status and psychological status) recorded at the time of the initial (baseline) clinical visit were analyzed for their association with recovery at the time of follow-up. RESULTS: Of the 177 patients who responded to the follow-up questionnaire, only 21 (12%) reported "recovery." Patients with higher levels of physical and social functioning and lower levels of anxiety and obsessive-compulsiveness at baseline were more likely to report recovery at follow-up ($p < 0.05$). No specific demographic characteristics were associated with recovery. CONCLUSION: These findings support previous research that complete recovery from CFS is rare and that patients with less severe illness at the initial clinic visit are more likely to have a positive prognosis for recovery. However, considerable overlap in illness severity was observed between the recovered and nonrecovered groups, suggesting that accurate prediction of recovery in individual CFS patients is not currently feasible.

Prins JB, Bleijenberg G.	Department of Medical Psychology, Hospital Nijmegen, The Netherlands. j.prins@cksmps.az.nl	Cognitive behavior therapy for chronic fatigue syndrome: a case study.	J Behav Ther Exp Psychiatry 1999 Dec;30(4):325-39	The case of a 26-year old woman with Chronic Fatigue Syndrome (CFS) is presented. Multidimensional assessment showing severe debilitating fatigue and considerable psychological, social and occupational impairment confirmed the diagnosis. Cognitive behavior therapy (CBT) was based on a tested causal model of CFS and individual behavioral analyses. Key elements in CBT were process variables from the CFS model, like sense of control, causal attributions, physical activity and focusing on bodily functions. Goals were recovery from fatigue, returning to work and relapse prevention. The course of therapy is described in detail to illustrate difficulties in treating CFS. Assessments were made five times, at baseline and at 8, 14, 21 and 33 months. Comparison of the pretest, post-test and follow-up scores of the outcome variables, fatigue and functional impairment and of the process variables showed clinically significant improvement from the range of CFS patients to the range of healthy controls.
Propsner NM.	The classic profile of the chronic fatigue syndrome (CFS) patient is a white, middle-age female. Characterized by profound fatigue, CFS often starts with an acute viral infection. Orthostatic intolerance and chronic fatigue syndrome associated with Ehlers-Danlos syndrome.	J Pediatr 1999 Oct;135(4):494-9	OBJECTIVE: To report chronic fatigue syndrome (CFS) associated with both Ehlers-Danlos syndrome (EDS) and orthostatic intolerance. STUDY DESIGN: Case series of adolescents referred to a tertiary clinic for the evaluation of CFS. All subjects had 2-dimensional echocardiography, tests of orthostatic tolerance, and examinations by both a geneticist and an ophthalmologist. RESULTS: Twelve patients (11 female), median age 15.5 years, met diagnostic criteria for CFS and EDS, and all had either postural tachycardia or neurally mediated hypotension in response to orthostatic stress. Six had classical-type EDS and 6 had hypermobile-type EDS. CONCLUSIONS: Among patients with CFS and orthostatic intolerance, a subset also has EDS. We propose that the occurrence of these syndromes together can be attributed to the abnormal connective tissue in dependent blood vessels of those with EDS, which permits veins to distend excessively in response to ordinary hydrostatic pressures. This in turn leads to increased venous pooling and its hemodynamic and symptomatic consequences. These observations suggest that a careful search for hypermobility and connective tissue abnormalities should be part of the evaluation of patients with CFS and orthostatic intolerance syndromes.
Russell IJ, Vipraio GA, Michalek JE, Craig FE, Kang YK, Richards AB.	Department of Medicine, University Clinical Research Center, The University	Lymphocyte markers and natural killer cell activity in fibromyalgia syndrome: effects of	J Interferon Cytokine Res 1999 Aug;19(8):969-78	A clinical study was designed to utilize flow cytometric immunophenotyping and chromium release from cultured tumor target cells to characterize peripheral blood mononuclear leukocyte (PBML) subpopulations and natural killer activity in healthy normal controls (n = 18) and in patients with fibromyalgia syndrome (FMS) at

	of Texas Health Science Center, San Antonio 78284-7868, USA. russell@uthscsa.edu	low-dose, sublingual use of human interferon-alpha.		baseline (n = 124) and again after 6 weeks of treatment with low-doses of orally administered human interferon-alpha (IFN-alpha). Volunteer subjects discontinued all analgesic and sedative hypnotic medications for 2 weeks prior to the baseline phlebotomy. Laboratory measures included a complete blood count; a phenotypic analysis of PBML by flow cytometry; and in vitro natural killer (NK) cell activity. After baseline blood sample collection, the FMS patients were randomized to one of four parallel treatment groups (n = 28/group) to receive sublingual IFN-alpha (15 IU, 50 IU, 150 IU), or placebo every morning for 6 weeks. The tests were repeated at week 6 to evaluate treatment effects. At baseline, FMS patients exhibited fewer lymphocytes and more CD25+ T lymphocytes than did normal controls. By week 6, the main significant and consistent change was a decrease in the HLA-DR+ CD4+ subpopulation in the 15 IU and 150 IU treatment groups. These data do not support an immunologically dysfunctional PBML phenotype among patients with FMS as has been observed in the chronic fatigue syndrome.
Sacco P, Hope PA, Thickbroom GW, Byrnes ML, Mastaglia FL.	Australian Neuromuscular Research Institute, QE II Medical Centre, Nedlands, WA, Australia. psacco@cyllene.uwa.edu.au	Corticomotor excitability and perception of effort during sustained exercise in the chronic fatigue syndrome.	Clin Neurophysiol 1999 Nov;110(11):1883-91	OBJECTIVE: We have investigated the possibility of a central basis for the complaints of fatigue and poor exercise tolerance in subjects with chronic fatigue syndrome (CFS). METHODS: Transcranial magnetic stimulation of the motor cortex was used to measure sequential changes in motor evoked potential (MEP) amplitude, post-excitatory silent period (SP) duration and twitch force of the biceps brachii muscle during a 20% maximum isometric elbow flexor contraction maintained to the point of exhaustion. Ten patients with post-infectious CFS and 10 age- and sex-matched control subjects were studied. Results were analysed using non-parametric repeated measures analysis of variance (Friedman's test) and Mann-Whitney U-tests for intra- and inter-group comparisons respectively. RESULTS: Mean endurance time for the CFS group was lower (13.1+/-3.2 min, mean +/- SEM) than controls (18.6+/-2.6 min, P < 0.05) and CFS subjects reported higher ratings of perceived exertion. During the exercise period MEP amplitude and SP duration increased in both groups but to a lesser extent in CFS subjects. Interpolated twitch force amplitude also increased during exercise, being more pronounced in CFS subjects. CONCLUSION: The findings are in keeping with an exercise-related diminution in central motor drive in association with an increased perception of effort in CFS.
Saheki T.	Department of Biochemistry, Faculty of Medicine, Kagoshima University.	[Carnitine as a vitamin-like biofactor].[article in Japanese]	Nippon Rinsho 1999 Oct;57(10):2270-5	Carnitine is a well-known cofactor for the beta-oxidation of long-chain fatty acid. It also plays a role in transport of acetyl moity for fatty acid and cholesterol synthesis, excretion of organic acid and xenobiotic acid as carnitine ester, and control of ratio of acetylCoA to CoA. Therapeutic effect of acetylcarnitine on Alzheimer disease and HIV-infection, and aberrant incorporation acetylcarnitine into brain under chronic fatigue syndrome have been reported. Carnitine deficiency causes hyperammonemia through suppression of gene expression of urea cycle enzymes. On the other hand, a large amount of carnitine has a therapeutic effect on hyperammonemia by still unclear mechanism. These suggest carnitine as a multifunctional biofactor. Review

				Literature
Saul JP.	MUSC, Charleston 29425, USA.	Syncope: etiology, management, and when to refer.	J S C Med Assoc 1999 Oct;95(10):385-7	An abnormality of blood pressure control is by far the most likely cause of syncope in children; however, syncope in children may be due to primary cardiac dysrhythmias, particularly in the presence of structural heart disease. An appropriate work-up should include an ECG with a 60-second rhythm strip at first presentation. Tilt testing can usually wait until after a second occurrence on non-pharmacologic therapy. Patients who require more than a history and ECG by the algorithm in the Figure should probably be referred to a cardiologist familiar with the evaluation of syncope. The common form of neurally mediated syncope is also probably related to both breath-holding spells in toddlers, and to many of the cases of chronic fatigue syndrome.
Schondorf R, Benoit J, Wein T, Phaneuf D.	Department of Neurology, McGill University, Sir Mortimer B. Davis Jewish General Hospital, Montreal, Quebec, Canada. cxrs@musica.mcgill.ca	Orthostatic intolerance in the chronic fatigue syndrome.	J Auton Nerv Syst 1999 Feb 15;75(2-3):192-201	This study aims to investigate the prevalence and pathophysiology of orthostatic intolerance (OI) and its potential contribution to symptoms of a group of unselected patients with chronic fatigue syndrome (CFS). Seventy five patients (65 women, 10 men) with CFS were evaluated. During an initial visit, a clinical suspicion as to the likelihood of observing laboratory evidence of OI was assigned. Laboratory investigation consisted of beat-to-beat recordings of heart rate, blood pressure (Finapres), and stroke volume (impedance cardiograph) while supine and during 80 degrees head-up tilt (HUT), during rhythmic deep breathing (6 breaths/min) and during the Valsalva maneuver. The responses of 48 age-matched healthy controls who had no history of OI were used to define the range of normal responses to these three maneuvers. Forty percent of patients with CFS had OI during head-up tilt. Sixteen exhibited neurally-mediated syncope alone, seven tachycardia (> 35 bpm averaged over the whole of the head-up tilt) and six a mixture of tachycardia and syncope. Eight of 48 controls exhibited neurally-mediated syncope. The responses to the Valsalva maneuver and to deep breathing were similar in controls and patients. On average, the duration of disease and patient age were significantly less and the onset of symptoms was more often subacute in patients with OI than in those without OI. We conclude that there exists a clinically identifiable subgroup of patients with CFS and OI that differs from control subjects and from those with CFS without OI for whom treatment specifically aimed at improving orthostatic tolerance may be indicated.
Schondorf R, Freeman R.	Dept. of Neurology, McGill University, Sir Mortimer B. Davis Jewish General Hospital, Montreal, Quebec, Canada. cxrs@musica.mcgill.ca	The importance of orthostatic intolerance in the chronic fatigue syndrome.	Am J Med Sci 1999 Feb;317(2):117-23	Chronic fatigue syndrome (CFS) or myalgic encephalomyelitis is a clinically defined syndrome characterized by persistent or relapsing debilitating fatigue for longer than 6 months in the absence of any definable medical diagnosis. The cause of this syndrome is unknown. Symptoms of orthostatic intolerance, such as disabling fatigue, dizziness, diminished concentration, tremulousness, and nausea, are often found in patients with CFS. In this review, we critically evaluate the relationship between orthostatic intolerance and CFS. Particular emphasis is placed on clinical diagnosis, laboratory testing, pathophysiology, and therapeutic management. It is

				hoped that this review will provide a stimulus for further study of this complex and disabling condition.
Schutzer SE, Natelson BH.	Department of Medicine, University of Medicine and Dentistry, New Jersey Medical School, Newark 07103, USA. schutzer@umdnj.edu	Absence of Borrelia burgdorferi-specific immune complexes in chronic fatigue syndrome.	Neurology 1999 Oct 12;53(6):1340-1	Chronic fatigue syndrome (CFS) and Lyme disease often share clinical features, especially fatigue, contributing to concern that Borrelia burgdorferi (Bb), the cause of Lyme disease, may underlie CFS symptoms. We examined 39 CFS patients and 40 healthy controls with a Bb immune complex test. Patients and controls were nonreactive. Centers for Disease Control and Prevention-defined CFS patients lacking antecedent signs of Lyme disease--erythema migrans, Bell's palsy, or large joint arthritis--are not likely to have laboratory evidence of Bb infection.
Scott LV, Dinan TG.	Department of Psychiatry, Trinity College Medical School, St James' Hospital, Dublin, Ireland. Review, Academic	The neuroendocrinology of chronic fatigue syndrome: focus on the hypothalamic-pituitary-adrenal axis.	Funct Neurol 1999 Jan-Mar;14(1):3-11	
Scott LV, Medbak S, Dinan TG.	Department of Psychiatry, Trinity College Medical School, St. James' Hospital, Dublin, Ireland.	Desmopressin augments pituitary-adrenal responsivity to corticotropin-releasing hormone in subjects with chronic fatigue syndrome and in healthy volunteers.	Biol Psychiatry 1999 Jun 1;45(11):1447-54	BACKGROUND: Corticotropin-releasing hormone (CRH) and vasopressin (VP) are the two principal neuropeptide regulators of the hypothalamic-pituitary-adrenal axis in man, with VP serving to augment CRH-induced adrenocorticotropic hormone (ACTH) release. Unlike VP, desmopressin (DDAVP), which is a synthetic analogue of VP, when administered alone, has not been shown in healthy subjects to have consistent ACTH-releasing properties. It has been suggested that chronic fatigue syndrome (CFS), characterized by profound fatigue and a constellation of other symptoms, may be caused by a central deficiency of CRH. METHODS: We administered 100 micrograms ovine CRH (oCRH) and 10 micrograms DDAVP, both alone and in combination, to a group of subjects with CFS, and to a group of healthy volunteers. Our aim was to establish the effect of DDAVP on CRH-induced ACTH release in these two groups. RESULTS: The delta-ACTH responses to oCRH were attenuated in the CFS (21.0 +/- 4.5 ng/L) compared to the control subjects (57.8 +/- 11.0 ng/L; $t = 3.2$, $df = 21$, $p < .005$). The delta-cortisol responses were also reduced in the CFS (157.6 +/- 40.7 nmol/L) compared to the healthy subjects (303.5 +/- 20.9 nmol/L; $t = 3.1$, $df = 21$, $p < .01$). The delta-ACTH and delta-cortisol responses to DDAVP alone did not differ between the two groups. On administration of both CRH and DDAVP no response differences between the two groups for either ACTH ($p = .3$) or cortisol output ($p = .87$) were established. Comparing the ACTH and cortisol responses to CRH and CRH/DDAVP in only those individuals from each group who had both tests, the cortisol output to the combination was significantly greater in the CFS compared to the healthy group. The ACTH output was also increased in the former group, though this was not significant. CONCLUSIONS: DDAVP augments CRH-mediated pituitary-adrenal responsivity in healthy subjects and in patients with CFS. That DDAVP was capable of normalizing

				the pituitary-adrenal response to oCRH in the CFS group suggests there may be increased vasopressinergic responsivity of the anterior pituitary in CFS and/or that DDAVP may be exerting an effect at an adrenal level.
Scott LV, Salahuddin F, Cooney J, Svec F, Dinan TG.	Department of Psychiatry, Trinity College Medical School, Dublin, Ireland.	Differences in adrenal steroid profile in chronic fatigue syndrome, in depression and in health.	J Affect Disord 1999 Jul;54(1-2):129-37	BACKGROUND: Hyperactivity and hypoactivity of the HPA have been forwarded as of pathophysiological relevance in major depressive disorder and chronic fatigue syndrome (CFS), respectively. METHODS: This study examines cortisol levels in the two disorders, and also assesses levels of the adrenal androgens, dehydroepiandrosterone (DHEA) and its sulphate derivative (DHEA-S), and 17-alpha-hydroxyprogesterone; 15 subjects with CFS diagnosed according to CDC criteria, 15 subjects with DSM III-R major depression and 11 healthy subjects were compared. RESULTS: DHEA and DHEA-S levels were significantly lower in the CFS compared to the healthy group; DHEA-S levels, but not DHEA, were lower in the depressives; cortisol and 17-alpha-hydroxyprogesterone did not differ between the three groups. CONCLUSIONS: A potential role for DHEA, both therapeutically and as a diagnostic tool, in CFS, is suggested.
Scott LV, Teh J, Reznek R, Martin A, Sohaib A, Dinan TG.	Department of Psychiatry, Trinity College Dublin Medical School, St. James's, Hospital, Ireland.	Small adrenal glands in chronic fatigue syndrome: a preliminary computer tomography study.	Psychoneuroendocrinology 1999 Oct;24(7):759-68	No inclusive or satisfactory biomedical explanation for chronic fatigue syndrome (CFS) has as yet been forwarded. Recent research suggests that a dysregulated hypothalamic-pituitary-adrenal axis (HPA) may be contributory, and in particular that there may be diminished forward drive and adrenal under-stimulation. In this preliminary study we wished to examine a cohort of CFS patients in whom evidence for such hypofunctioning was found. Our aim was to establish whether these patients had altered adrenal gland size. Patients were recruited from a fatigue clinic. Those who fulfilled the Centre for Disease Control and Prevention (CDC) criteria underwent a 1 microgram adrenocorticotropin (ACTH) stimulation test, a test of adrenal gland functioning. Eight subjects (five females, three males) with a subnormal response to this test underwent a computer tomography (CT) adrenal gland assessment. Measurements were compared with those from a group of 55 healthy subjects. The right and left adrenal gland bodies were reduced by over 50% in the CFS subjects indicative of significant adrenal atrophy in a group of CFS patients with abnormal endocrine parameters. This is the first study to use imaging methods to measure adrenal gland size in CFS. It is a limitation of this study that a selected CFS sample was employed. A future larger study would optimally employ an unselected cohort of CFS patients. This study has implications not only for the elucidation of CFS pathophysiology, but also for possible therapeutic strategies.

Shlaes JL, Jason LA, Ferrari JR.	DePaul University, Department of Psychology, Chicago, IL 60614, USA.	The development of the Chronic Fatigue Syndrome Attitudes Test. A psychometric analysis.	Eval Health Prof 1999 Dec;22(4):442-65	Chronic Fatigue Syndrome (CFS) is characterized by debilitating symptoms including persistent or relapsing fatigue. As a result of CFS, some individuals experience significant stigma that is attached to this illness. Many medical professionals are skeptical of the validity of the illness, and employers often fail to appreciate the seriousness of the symptoms. Although negative attitudes greatly affect the lives of individuals with CFS, there is presently no measurement of attitudes toward this illness and people who have CFS. The purpose of the present studies was to create a scale that measures attitudes toward individuals with CFS--the Chronic Fatigue Attitudes Test (CAT)--and to assess the scale's reliability and validity. The 13-item scale was created using several constructs outlined in the literature regarding negative attitudes toward people with CFS, disabilities, and AIDS. Theoretical implications of the findings and the utility of the CAT are discussed.
Smith AP, Borysiewicz L, Pollock J, Thomas M, Perry K, Llewelyn M.	Department of Experimental Psychology, University of Bristol.	Acute fatigue in chronic fatigue syndrome patients.	Psychol Med 1999 Mar;29(2):283-90	BACKGROUND: Chronic fatigue syndrome (CFS) patients often complain that they are more susceptible to acute mental fatigue. It is important to determine whether this is observed using objective tests of sustained attention and responding. METHODS: Sixty-seven patients who fulfilled the criteria for CFS proposed by Sharpe et al. (1991) were compared with 126 matched healthy controls. Acute fatigue was assessed by comparing performance at the start and end of a lengthy test session and by examining changes over the course of individual tasks. RESULTS: CFS patients showed impaired performance compared to the controls and these differences increased as the volunteers developed acute fatigue. In addition, differences between the two groups were larger at the end of the test session. CONCLUSIONS: The present results show that CFS patients are more susceptible to acute fatigue than healthy controls. This could reflect motor fatigue or an inability to compensate for fatigue with increased effort. This profile is consistent with previous research on fatigue and suggests that interpretation of certain aspects of CFS may be helped by considering it as the end point of a continuum of fatigue rather than a distinct disease.
Social Security Administration.	Notice of Social Security ruling.	Social Security Ruling, SSR 99-2p.; titles II and XVI; evaluating cases involving chronic fatigue syndrome (CFS).	Fed Regist 1999 Apr 30;64(83):23380-4	In accordance with 20 CFR 402.35(b)(1), the Commissioner of Social Security gives notice of Social Security Ruling, SSR 99-2p. This Ruling clarifies disability policy for the evaluation and adjudication of disability claims involving Chronic Fatigue Syndrome (CFS). This Ruling explains that, when it is accompanied by appropriate medical signs or laboratory findings, CFS is a medically determinable impairment that can be the basis for a finding of "disability." This Ruling ensures that all adjudicators will use the same policies and procedures in evaluating disability claims involving CFS, and provides a consolidated statement of these policies and procedures.
Soetekouw PM, Lenders JW, Bleijenberg G, Thien T, van der Meer JW.	Department of Medicine, St. Radboud University Hospital, Nijmegen, The	Autonomic function in patients with chronic fatigue syndrome.	Clin Auton Res 1999 Dec;9(6):334-40	Subtle signs of autonomic dysfunction and orthostatic intolerance have been reported in patients with chronic fatigue syndrome (CFS). To assess cardiovascular autonomic function noninvasively in an unselected group of patients with CFS, we examined responsiveness to several cardiovascular reflex tests in 37 CFS patients and

	Netherlands.			38 healthy control subjects. Blood pressure and heart rate (HR) were recorded continuously by a Finapres device before and during forced breathing, standing up, Valsalva maneuver, and sustained handgrip exercise (HG). In addition, a mental arithmetic test was carried out and questionnaires to assess the severity of CFS symptoms were completed. At rest, there were no significant differences in blood pressure or in HR between the two groups. The in- and expiratory difference in HR tended to be lower in CFS patients (28.4 +/- 10.5 beats) than in healthy controls (32.2 +/- 9.5) ($p = 0.11$). The maximal increase in HR during standing up was not significantly different between the CFS group (37.6 +/-8.9 beats) and the control group (40.2 +/- 8.9 beats). There were no significant differences between both groups with regard to the Valsalva ratio, but the systolic and diastolic blood pressure responses were significantly larger in CFS patients, despite the fact that many CFS patients were not able to sustain the Valsalva maneuver. The HR response to MA was significantly less in the CFS group (22.6 +/- 9.9) than in the control group (29.5 +/- 16.7) ($p < 0.05$), suggesting impaired cardiac sympathetic responsiveness to mental stress. The lower HR responses could not be explained by the level of concentration in the CFS group. During HG exercise, the hemodynamic responses were lower in the CFS group than in the control group, but this might be attributed to the lower level of muscle exertion in CFS patients. There were no significant differences between CFS patients with and without symptoms of autonomic dysfunction regarding the hemodynamic responses to the cardiovascular reflex tests. The findings of the study suggest that there are no gross alterations in cardiovascular autonomic function in patients with CFS.
Sorenson WG.	Division of Respiratory Disease Studies, National Institute for Occupational Safety and Health, Morgantown, WV 26505, USA. wgs1@cdc.gov	Fungal spores: hazardous to health?	Environ Health Perspect 1999 Jun;107 Suppl 3:469-72	Fungi have long been known to affect human well being in various ways, including disease of essential crop plants, decay of stored foods with possible concomitant production of mycotoxins, superficial and systemic infection of human tissues, and disease associated with immune stimulation such as hypersensitivity pneumonitis and toxic pneumonitis. The spores of a large number of important fungi are less than 5 microm aerodynamic diameter, and therefore are able to enter the lungs. They also may contain significant amounts of mycotoxins. Diseases associated with inhalation of fungal spores include toxic pneumonitis, hypersensitivity pneumonitis, tremors, chronic fatigue syndrome, kidney failure, and cancer.
Starcevic V.	University of Belgrade School of Medicine, Yugoslavia.	Neurasthenia: cross-cultural and conceptual issues in relation to chronic fatigue syndrome.	Gen Hosp Psychiatry 1999 Jul-Aug;21(4):249-55	The purpose of this study was to examine several conceptual and cross-cultural issues in neurasthenia, particularly in terms of their relationship to chronic fatigue syndrome. A review of this relationship led to the conclusion that these conditions are much more alike in Western countries than in countries such as China, where neurasthenia could almost be regarded as a "culture-bound syndrome." This may be a consequence of factors such as the heterogeneous nature of neurasthenia and different diagnostic practices in different countries, despite the ICD-10 definition of neurasthenia, intended for worldwide use. Likewise, there is no consensus on what

				the "core" characteristics of neurasthenia are, because its clinical presentation and key features in different countries are very different. Despite the finding of relatively low comorbidity rates between neurasthenia and other mental disorders, clinical experience suggests that features of neurasthenia frequently overlap with those of depression, chronic anxiety, and somatoform disorders. There is no convincing evidence that in cases of overlap or comorbidity, other diagnoses should automatically have "primacy" over neurasthenia nor should the diagnosis of neurasthenia thereby be excluded. Although some aspects of its validity have improved recently, especially its descriptive validity, the overall validity of the diagnosis of neurasthenia is still not satisfactory. Suggestions for further research, aimed at improving the diagnostic validity of neurasthenia, are offered in this paper.
Stark FM, Sobetzko HM.	Klinik fur Psychiatrie und Psychotherapie, Universitatskrankenhaus Eppendorf, Hamburg, Germany.	Approaches to coping with chronic fatigue syndrome (CFS).	Zentralbl Hyg Umweltmed 1999 Aug;202(2-4):179-90	The 1994 approach to the definition of Chronic Fatigue Syndrome (CFS) describes a severe disorder with unknown etiology and pathophysiology. It results in substantial reduction in previous levels of occupational, educational, social, or personal activities. Most patients cannot continue their usual lifestyle. No causal treatments or other therapies suitable for all patients exist so far. Therefore it was intended to identify approaches to an effective disease management by the long time escort and observation of a CFS support group. CFS should be diagnosed according to the actual CDC guidelines. Conditions with similar symptoms explaining chronic fatigue have to be ruled out first. Then an individually shaped disease management comprising of different components plays a central role in the coping process. Medical long time care performed by a general practitioner and the membership in a suitable support group are integrated within this approach.
Stejskal VD, Danersund A, Lindvall A, Hudecek R, Nordman V, Yaqob A, Mayer W, Bieger W, Lindh U.	Dept Clinical Chemistry, Danderyd Hospital and Karolinska Institute, Stockholm, Sweden. vera.melisa@swipnet.se	Metal-specific lymphocytes: biomarkers of sensitivity in man.	Neuroendocrinol Lett 1999;20(5):289-298	Many patients attribute their health problems to amalgam and other dental metals. In genetically susceptible indviduals, mercury and gold may function as haptens and elicit allergic and autoimmune reactions. The frequency of metal-induced lymphocyte responses was examined in 3,162 patients in three European laboratories using MELISA(R), an optimized lymphocyte proliferation test. The patients suffered from local and systemic symptoms attributed to dental restorations. The effect of dental metal removal was studied in 111 patients with metal hypersensitivity and symptoms resembling Chronic Fatigue Syndrome (CFS). After consultation with a dentist the patients decided to replace their metal restorations with non-metallic materials. The changes in health and in vitro lymphocyte reactivity were studied by inquiries and follow-up MELISA(R). Lymphocyte reactivity was also analyzed in 116 healthy subjects with no complaints of metal allergy. A significant number of patients had metal-specific lymphocytes in the blood. Nickel was the most common sensitizer, followed by inorganic mercury, gold, phenylmercury, cadmium and palladium. As compared to lymphocyte responses in healthy subjects, the CFS group had significantly increased responses to several metals, especially to inorganic mercury, phenylmercury and gold. Following dental metal removal, 83 patients (76%) reported long-term health

				improvement. Twenty-four patients (22%) reported unchanged health and two (2%) reported worsening of symptoms. Following dental metal replacement, the lymphocyte reactivity to metals decreased as well. We propose that an inflammatory process induced by metals may modulate the hypothalamic-pituitary-adrenal axis (HPA axis) and trigger multiple non-specific symptoms characterizing CFS and other chronic conditions like myalgic encephalitis (ME) and multiple chemical sensitivity (MCS).
Sterzl I, Prochazkova J, Hrda P, Bartova J, Matucha P, Stejskal VD.	Institute of Endocrinology, Prague, Czech Republic.	Mercury and nickel allergy: risk factors in fatigue and autoimmunity.	Neuroendocrinol Lett 1999;20(3-4):221-228	This study examined the presence of hypersensitivity to dental and environmental metals in patients with clinical disorders complicated with chronic fatigue syndrome. Three groups of patients were examined through medical history, dental examination, and by using a modified test of blast transformation for metals-MELISA(R). The three groups consisted of the following: 22 patients with autoimmune thyroiditis with or without polyglandular autoimmune activation; 28 fatigued patients free from endocrinopathy; and 22 fatigued professionals without evidence of autoimmunity. As controls, a population sample or 13 healthy subjects without any evidence of metal sensitivity was included. Healthy controls did not complain of marked fatigue and their laboratory tests did not show signs of autoimmunity and endocrinopathy. We have found that fatigue, regardless of the underlying disease, is primarily associated with hypersensitivity to inorganic mercury and nickel. The lymphocyte stimulation by other metals was similar in fatigued and control groups. To evaluate clinical relevance of positive in vitro findings, the replacement of amalgam with metal-free restorations was performed in some of the patients. At a six-month follow-up, patients reported considerably alleviated fatigue and disappearance of many symptoms previously encountered; in parallel, lymphocyte responses to metals decreased as well. We suggest that metal-driven inflammation may affect the hypothalamic-pituitary-adrenal axis (HPA axis) and indirectly trigger psychosomatic multisymptoms characterizing chronic fatigue syndrome, fibromyalgia, and other diseases of unknown etiology.
Stewart JM, Gewitz MH, Weldon A, Arlievsky N, Li K, Munoz J.	Department of Pediatrics, New York Medical College, Valhalla, New York, USA.	Orthostatic intolerance in adolescent chronic fatigue syndrome.	Pediatrics 1999 Jan;103(1):116-21	OBJECTIVES: To demonstrate the association between orthostatic intolerance and the chronic fatigue syndrome (CFS) in adolescents and to delineate the form that orthostatic intolerance takes in these children. STUDY DESIGN: We investigated the heart rate and blood pressure (BP) responses to head-up tilt (HUT) in 26 adolescents aged 11 to 19 years with CFS compared with responses in adolescents referred for the evaluation of simple faint and to responses in 13 normal healthy control children of similar age. RESULTS: A total of 4/13 of the controls and 18/26 simple faint patients experienced typical faints with an abrupt decrease in BP and heart rate associated with loss of consciousness. One CFS patient had a normal HUT. A total of 25/26 CFS patients experienced severe orthostatic symptoms associated with syncope in 7/25, orthostatic tachycardia with hypotension in 15/25, and orthostatic tachycardia without significant hypotension in 3/25. Acrocyanosis, cool extremities,

				and edema indicated venous pooling in 18/25. None of the control or simple faint patients experienced comparable acral or tachycardic findings. CONCLUSIONS: We conclude that chronic fatigue syndrome is highly related to orthostatic intolerance in adolescents. The orthostatic intolerance of CFS often has heart rate and BP responses similar to responses in the syndrome of orthostatic tachycardia suggesting that a partial autonomic defect may contribute to symptomatology in these patients.
Stewart JM, Gewitz MH, Weldon A, Munoz J.	Department of Pediatrics, Division of Cardiology, New York Medical College, Valhalla 10595, USA.	Patterns of orthostatic intolerance: the orthostatic tachycardia syndrome and adolescent chronic fatigue.	J Pediatr 1999 Aug;135(2 Pt 1):218-25	OBJECTIVES: To describe the orthostatic tachycardia syndrome (OTS) in adolescents, similarities to and differences from chronic fatigue syndrome (CFS), and patterns of orthostatic intolerance during head-up tilt (HUT). STUDY DESIGN: Using electrocardiography and arterial tonometry, we investigated the heart rate and blood pressure responses during HUT in 20 adolescents with OTS compared with 25 adolescents with CFS, 13 healthy control subjects, and 20 patients with simple faint. RESULTS: Of the control subjects, 4 of 13 experienced typical vasovagal faints with an abrupt fall in blood pressure and heart rate, and 14 of 20 patients with simple faint experienced similar HUT responses. All patients with CFS (25/25) experienced severe orthostatic symptoms with syncope in 2 of 25, early orthostatic tachycardia during HUT in 16 of 23 (13/16 hypotensive), and delayed orthostatic tachycardia in 7 of 23 (6/7 hypotensive). Acrocyanosis and edema occurred in 18 of 25. Early orthostatic tachycardia occurred in 10 of 20 patients with OTS. Of these, 9 of 10 were hypotensive, but hypotension was delayed in 4 of 9. Delayed tachycardia occurred in 10 of 20 (all hypotensive). Acrocyanosis and edema occurred in most patients with CFS, fewer patients with OTS, and in one patient with simple faint. Orthostatic symptoms were similar but more severe in patients with CFS compared with patients with OTS. CONCLUSIONS: Symptoms and patterns of orthostatic heart rate and blood pressure change in OTS overlap strongly with those of CFS. Orthostatic intolerance in OTS may represent an attenuated form of chronic fatigue pathophysiology.

Terra JL.	Departement	[Symptomatic and	Rev Prat 1999 Apr	The symptomatic and concurrent depressions description need to resort to

	d'information et d'evaluation medicales, Centre hospitalier specialise Le Vinatier, Bron.	concurrent depressions].[article in French]	1;49(7):727-31	comorbidity and symptomatic co-occurrence concepts. Patients with depressive symptoms or in a major depressive episode may also be suffering from another nonmood psychiatric disorders as alcoholism, anxiety or eating disorders. Many general medical conditions which are link with depression are illustrated with the examples of cancer, coronary artery disease, endocrinologic diseases, dementia, stroke and chronic fatigue syndrome. When depression and another psychiatric or medical conditions occur together, it is important to provide to the practitioner guidelines for the decision to treat one of the two disorders. This paper contains an example of decisional algorithm.
Theorell T, Blomkvist V, Lindh G, Evengard B.	National Institute for Psychosocial Factors and Health, Stockholm, Sweden.	Critical life events, infections, and symptoms during the year preceding chronic fatigue syndrome (CFS): an examination of CFS patients and subjects with a nonspecific life crisis.	Psychosom Med 1999 May-Jun;61(3):304-10	OBJECTIVE: The purpose of this study was to describe the sequence of psychosocial events and infections preceding the onset of chronic fatigue syndrome (CFS). This information was related to the temporal development of crucial symptoms in relation to the onset of, namely, fatigue, sadness, irritability, pain, and feeling of fever. METHODS: A personal interview was conducted in 46 patients (mean age, 39.5 years; SD, 9 years) who fulfilled international CFS criteria. These patients were matched with regard to age and gender to 46 carefully matched control subjects. Twenty-three percent of the study subjects were men, and 77% were women. The patient at first identified the month that coincided with the onset of CFS. Similarly, each control subject was asked to identify a "very difficult period" within approximately the same period as the patient with whom the control subject was matched. A list of 14 different life events was perused. Participants were asked to identify for each month whether each of the listed events had occurred. Furthermore, they were asked to rate the importance of the events they had experienced. In addition, for each of the cardinal symptoms (fatigue, sadness, irritability, pain, and feeling of fever) and for each month, the subjects were asked to rate, on a visual analogue scale, the symptom intensity. Also, the number of infections was noted. RESULTS: A statistically significant group difference in fatigue intensity existed during the period 4 to 10 months before the onset of CFS. During the 3 months preceding the diagnosis for the CFS patients or the peak of the crisis for the control group, there was a dramatic rise in fatigue in both groups. The CFS group reached a much higher fatigue level, which leveled off somewhat during the first year of follow-up but still remained very high in comparison with the control group, which reached precrisis levels 4 months after the peak. Similar patterns were observed for fever and pain. With regard to sadness and irritability, no group difference was observed during the period preceding the crisis. In the patient group, the level stayed high throughout the whole first year of follow-up, whereas a slow return started in the control group; precrisis levels were reached after 1 year in this group. The prevalence ratio (CFS patients/control subjects) for negative events was around 1.0 for the periods 4 to 12 months preceding CFS but 1.9 during the quarter year preceding the onset. For infections, the prevalence ratio increased successively during the four quarters preceding CFS (from 1.4 to 2.3).

				CONCLUSIONS: According to the retrospective self-reports, there were differences between the groups in fatigue, pain, and feeling of fever during the months preceding the crisis. With regard to depressive and irritable feelings, no preillness differences were reported between the groups. There was a reported excess prevalence of both infections and negative life events during the quarter year preceding the onset of CFS or crisis. Potential sources of error are discussed. These findings must be replicated in longitudinal studies.
Vermel' AE.		[Chronic fatigue syndrome].[article in Russian]	Klin Med (Mosk) 1999;77(7):11-5	
Vojdani A, Lapp CW.	Immunosciences Laboratory Inc., Beverly Hills, California, USA. immunsci@ix.netcom.com	Interferon-induced proteins are elevated in blood samples of patients with chemically or virally induced chronic fatigue syndrome.	Immunopharmacol Immunotoxicol 1999 May;21(2):175-202	Overlapping symptomatologies between Chronic Fatigue Syndrome (CFS) and Chemical Sensitivity have been observed by different investigators. Therefore, it is of great importance to develop biomarker(s) for possible differentiation between viral induced CFS (without sensitivity to chemicals) versus chemically induced CFS. Since interferon induced proteins 2-5A Synthetase and Protein Kinase RNA (PKR) have been implicated in the viral induction of CFS, the objective of this study was to utilize 2-5A and PKR activity for differentiation between CFS induced by either viruses or chemicals. Based on the CDC definition and criteria, twenty CFS patients who were positive for viral genome(s) (mainly HHV6; HTLVII, EBV, and CMV) and did not have any history of exposure to toxic chemicals were included in this study. As a comparison, the second group of patients consisted of twenty individuals from the same geographical area who were negative for viral genomes but had been exposed to methyl tertiary-butyl ether concentration of up to 70 ppb and benzene concentration up to 14 ppb. All patients complained of fatigue and other symptoms overlapping between the two groups. From all 40 patients, blood was drawn, leukocyte extract was prepared and assayed for 2-5A Synthetase and PKR activity. Clinical specimens which were positive for viral genomes showed from 2.2-38.7 fold increase in 2-5A activity and 1.3-13.5 fold increase in PKR activities over the background of the healthy controls. Similarly, the second group (negative for viral genomes, but exposed to chemicals) showed a 1.1-29.2 fold increase for 2-5A Synthetase and a 1.3-11.6 fold increase for PKR when they were compared to healthy subjects. To elucidate mechanisms involved in viral versus chemical induction of 2-5A Synthetase and PKR, MDBK cell lines were cultured either in the presence or absence of HHV6, MTBE, or Benzene, heat shock proteins and interferon-beta. 2-5A and PKR activities were measured in all the above conditions. A clear induction of 2-5A and PKR was observed when MDBK cells were exposed to HHV6, MTBE, and Benzene. This induction was more significant with HSP90, HSP70, and IFN-beta indicating their involvement in the mechanism of action. However, when MDBK cells were incubated either with MTBE + Benzene or HHV6 in the presence or absence of anti IFN-beta or anti-HSP-70, the activities of both 2-5A and PKR in HHV6 infected cells were inhibited

				by more than 90% due to addition of anti IFN-beta, and only 20% by addition of anti-HSP70. While in MTBE + Benzene exposed cells anti IFN-beta reduced the activity of these enzymes by 40% and anti-HSP70 by more than 90%. This variation in the induction of 2-5A and PKR by anti-HSP70 or IFN-beta indicates involvement of IFN-beta in viral induction 2-5A and PKR, and HSP involvement in chemical induction of these enzymes. We conclude that 2-5A and PKR are not only biomarkers for viral induction of CFS, but biomarkers to other stressors that include MTBE and Benzene.

Chronic fatigue syndrome: the physiology of people on the low end of the spectrum of physical activity?	Clin Sci (Colch) 1999 Nov;97(5):611-3 Erratum in: Clin Sci (Colch) 1999 Dec;97(6):719 Comment on: Clin Sci (Colch). 1999 Nov;97(5):603-8; discussion 611-3	
Wagner-Raphael LI, Jason LA, Ferrari JR.	Department of Psychology, DePaul University, USA. lwagner@mcw.edu	Chronic fatigue syndrome, chronic fatigue, and psychiatric disorders: predictors of functional status in a national nursing sample.	J Occup Health Psychol 1999 Jan;4(1):63-71	Members of 2 nurses' associations (N = 71) were assessed using 2 mail questionnaires, a telephone questionnaire, the Diagnostic Interview Schedule, and medical records. Physicians reviewed participants to determine whether they met current criteria for chronic fatigue syndrome (CFS). Stepwise multivariate regression analyses were conducted to identify predictors of functional status scores. Impairments in physical, role, and social functioning increased as fatigue severity increased. Bodily pain increased as fatigue severity increased, and ratings of overall health increased as severity of fatigue decreased. Nurses with a current psychiatric diagnosis reported more impairments in emotional functioning than nurses with a lifetime diagnosis or no psychiatric diagnosis. Quality of life decreased as fatigue severity increased. Nurses with fatigue not meeting CFS criteria reported better quality of life than those with CFS or medical exclusions.

Wallace HL 2nd, Natelson B, Gause W, Hay J.	Department of Microbiology, State University of New York at Buffalo, Buffalo, New York 14214, USA.	Human herpesviruses in chronic fatigue syndrome.	Clin Diagn Lab Immunol 1999 Mar;6(2):216-23	We have conducted a double-blind study to assess the possible involvement of the human herpesviruses (HHVs) HHV6, HHV7, Epstein-Barr virus (EBV), and cytomegalovirus in chronic fatigue syndrome (CFS) patients compared to age-, race-, and gender-matched controls. The CFS patient population was composed of rigorously screened civilian and Persian Gulf War veterans meeting the Centers for Disease Control and Prevention's CFS case definition criteria. Healthy control civilian and veteran populations had no evidence of CFS or any other exclusionary medical or psychiatric condition. Patient peripheral blood mononuclear cells were analyzed by PCR for the presence of these HHVs. Using two-tailed Fisher's exact test analyses, we

				were unable to ascertain any statistically significant differences between the CFS patient and control populations in terms of the detection of one or more of these viruses. This observation was upheld when the CFS populations were further stratified with regard to the presence or absence of major axis I psychopathology and patient self-reported gradual versus acute onset of disease. In tandem, we performed serological analyses of serum anti-EBV and anti-HHV6 antibody titers and found no significant differences between the CFS and control patients.
Ware NC.	Department of Social Medicine, Harvard Medical School, Boston, MA 02115, USA.	Toward a model of social course in chronic illness: the example of chronic fatigue syndrome.	Cult Med Psychiatry 1999 Sep;23(3):303-31	Retrospective, narrative accounts of illness experience in chronic fatigue syndrome provide the empirical basis for a preliminary conceptual model of social course in chronic illness. Qualities of distress interact with culturally specific expectations for social life and personal conduct to trigger microsocial processes of marginalization: role constriction, delegitimation, impoverishment, and social isolation. Marginalizing processes are opposed by acts of resistance initiated by ill individuals and directed toward integration in social worlds. Social distance from the perceived centers of CFS sufferers' interpersonal worlds expands and contracts with the changing predominance of marginalizing and resisting influences over time. Social course thus consists of successive, bi-directional movements along a 'continuum of marginality' by persons living lives with chronic illness.
Warren G, McKendrick M, Peet M.	The University of Sheffield, Section of Psychiatry, Northern General Hospital, UK.	The role of essential fatty acids in chronic fatigue syndrome. A case-controlled study of red-cell membrane essential fatty acids (EFA) and a placebo-controlled treatment study with high dose of EFA.	Acta Neurol Scand 1999 Feb;99(2):112-6	OBJECTIVE: To replicate the treatment study by Behan et al. (1990) using current research criteria for Chronic Fatigue Syndrome (CFS). METHOD: Fifty patients who fulfilled the Oxford Criteria for CFS were randomly allocated to treatment with either Efamol Marine or placebo for 3 months. They were seen monthly and completed a physical symptoms checklist and the Beck Inventory for Depression and reported if they were the same, better or worse at the end of the study. RESULTS: Symptoms generally improved with time but not significantly and there were no significant differences between the treatment and placebo groups. Pretreatment red-cell membrane (RBC) lipids of patients compared with age-and sex-matched normal controls showed no significant differences. DISCUSSION: The results of this study contrast sharply with the previous study where 85% of patients had a clinically significant improvement of symptoms with Efamol Marine over a 3-month treatment period.
Wessely S, Hotopf M.	Academic Department of Psychological Medicine, Guy's, King's and St Thomas' School of Medicine, London, UK.	Is fibromyalgia a distinct clinical entity? Historical and epidemiological evidence.	Baillieres Best Pract Res Clin Rheumatol 1999 Sep;13(3):427-36	Most medical specialities have defined medically unexplained syndromes such as fibromyalgia, to categorize patients with prominent but unexplained symptoms. Other such syndromes include irritable bowel syndrome, chronic fatigue syndrome and atypical chest pain. In this chapter we present evidence to suggest that fibromyalgia is not a unique clinical entity, but shares much with these other syndromes. We use historical, clinical and epidemiological evidence to illustrate this idea. The historical data emphasize the essentially arbitrary way in which fibromyalgia developed. The clinical evidence shows the considerable overlap between patients with fibromyalgia and those with other unexplained syndromes.

				From an epidemiological perspective we emphasize the strong associations between symptoms such as myalgia and fatigue. We conclude by suggesting that fibromyalgia is one of many medically unexplained syndromes which have more similarities than differences between them.
Wessely S, Nimnuan C, Sharpe M.	Department of Psychological Medicine, Guy's, King's and St Thomas' School of Medicine, London, UK.	Functional somatic syndromes: one or many?	Lancet 1999 Sep 11;354(9182):936-9Comment in: Lancet. 1999 Dec 11;354(9195):2078; discussion 2078-9 Lancet. 1999 Dec 11;354(9195):2079 Lancet. 1999 Dec 11;354(9195):2079-80 Lancet. 1999 Dec 11;354(9195):2080	We review the concept and importance of functional somatic symptoms and syndromes such as irritable bowel syndrome and chronic fatigue syndrome. On the basis of a literature review, we conclude that a substantial overlap exists between the individual syndromes and that the similarities between them outweigh the differences. Similarities are apparent in case definition, reported symptoms, and in non-symptom association such as patients' sex, outlook, and response to treatment. We conclude that the existing definitions of these syndromes in terms of specific symptoms is of limited value; instead we believe a dimensional classification is likely to be more productive.
Wood B, Wessely S.	Maudsley Hospital and the Institute of Psychiatry, London, UK.	Personality and social attitudes in chronic fatigue syndrome.	J Psychosom Res 1999 Oct;47(4):385-97	One hundred one chronic fatigue syndrome (CFS) patients attending a specialist CFS clinic were compared with 45 rheumatoid arthritis (RA) patients on a range of standardized questionnaire measures, to investigate whether CFS patients are characterized by particular personality traits or social attitudes. No differences were found between CFS and RA patients in measures of perfectionism, attitudes toward mental illness, defensiveness, social desirability, or sensitivity to punishment (a concept related to neuroticism), on either crude or adjusted analyses. Alexithymia scores were greater in the RA patient group ($p<0.05$). Social adjustment, based on subjective assessment of overall restriction in activities and relationship difficulties, was substantially poorer in the CFS group ($p<0.001$). This was highly associated with depressive symptoms, but remained significant even after adjusting for depressive symptomatology. There was no evidence from this study of major differences between the personalities of CFS patients and RA patients. The stereotype of CFS sufferers as perfectionists with negative attitudes toward psychiatry was not supported.
Yamaguchi K, Sawada T, Naraki T, Igata-Yi R, Shiraki H, Horii Y, Ishii T, Ikeda K, Asou N, Okabe H, Mochizuki M, Takahashi K, Yamada S, Kubo K, Yashiki S, Waltrip RW 2nd, Carbone KM.	Blood Transfusion Service and Internal Medicine, Kumamoto University School of Medicine, Kumamoto, Japan. kyama@gpo.kumamoto-u.ac.jp	Detection of borna disease virus-reactive antibodies from patients with psychiatric disorders and from horses by electrochemiluminescence immunoassay.	Clin Diagn Lab Immunol 1999 Sep;6(5):696-700	The prevalence of Borna disease virus (BDV)-specific antibodies among patients with psychiatric disorders and healthy individuals has varied in several reports using several different serological assay methods. A reliable and specific method for anti-BDV antibodies needs to be developed to clarify the pathological significance of BDV infections in humans. We developed a new electrochemiluminescence immunoassay (ECLIA) for the antibody to BDV that uses two recombinant proteins of BDV, p40 and p24 (full length). Using this ECLIA, we examined 3,476 serum samples from humans with various diseases and 917 sera from blood donors in Japan for the presence of anti-BDV antibodies. By ECLIA, 26 (3.08%) of 845 schizophrenia patients and 9

				(3.59%) of 251 patients with mood disorders were seropositive for BDV. Among 323 patients with other psychiatric diseases, 114 with neurological diseases, 75 with chronic fatigue syndrome, 85 human immunodeficiency virus-infected patients, 50 with autoimmune diseases including rheumatoid arthritis and systemic lupus erythematosis and 17 with leprosy, there was no positive case except one case each with alcohol addiction, AIDS, and dementia. Although 19 (1.36%) of 1,393 patients with various ocular diseases, 10 (1.09%) of 917 blood donors, and 3 (4.55%) of 66 multitransfused patients were seropositive for BDV-specific antigen, high levels of seroprevalence in schizophrenia patients and young patients (16 to 59 years old) with mood disorders were statistically significant. The immunoreactivity of seropositive sera could be verified for specificity by blocking with soluble p40 and/or p24 recombinant protein. Anti-p24 antibody was more frequent than p40 antibody in most cases, and in some psychotic patients antibody profiles showed only p40 antibody. Although serum positive for both p40 and p24 antibodies was not found in this study, the p40 ECLIA count in schizophrenia patients was higher than that of blood donors. Furthermore, we examined 90 sera from Japanese feral horses. Antibody profiles of control human samples are similar to that of naturally BDV-infected feral horses. We concluded that BDV infection was associated in some way with psychiatric disorders.
Zhang Q, Zhou XD, Denny T, Ottenweller JE, Lange G, LaManca JJ, Lavietes MH, Pollet C, Gause WC, Natelson BH.	Center for Environmental Hazards Research, DVA Medical Center, E. Orange, New Jersey 07018, USA.	Changes in immune parameters seen in Gulf War veterans but not in civilians with chronic fatigue syndrome.	Clin Diagn Lab Immunol 1999 Jan;6(1):6-13	The purpose of this study was to evaluate immune function through the assessment of lymphocyte subpopulations (total T cells, major histocompatibility complex [MHC] I- and II-restricted T cells, B cells, NK cells, MHC II-restricted T-cell-derived naive and memory cells, and several MHC I-restricted T-cell activation markers) and the measurement of cytokine gene expression (interleukin 2 [IL-2], IL-4, IL-6, IL-10, IL-12, gamma interferon [IFN-gamma], and tumor necrosis factor alpha [TNF-alpha]) from peripheral blood lymphocytes. Subjects included two groups of patients meeting published case definitions for chronic fatigue syndrome (CFS)-a group of veterans who developed their illness following their return home from participating in the Gulf War and a group of nonveterans who developed the illness sporadically. Case control comparison groups were comprised of healthy Gulf War veterans and nonveterans, respectively. We found no significant difference for any of the immune variables in the nonveteran population. In contrast, veterans with CFS had significantly more total T cells and MHC II+ T cells and a significantly higher percentage of these lymphocyte subpopulations, as well as a significantly lower percentage of NK cells, than the respective controls. In addition, veterans with CFS had significantly higher levels of IL-2, IL-10, IFN-gamma, and TNF-alpha than the controls. These data do not support the hypothesis of immune dysfunction in the genesis of CFS for sporadic cases of CFS but do suggest that service in the Persian Gulf is associated with an altered immune status in veterans who returned with severe fatiguing illness.

Abu-Judeh HH, Levine S, Kumar M, el-Zeftawy H, Naddaf S, Lou JQ, Abdel-Dayem HM.	Department of Radiology, St. Vincent's Hospital, New York, NY 10011, USA.	Comparison of SPET brain perfusion and 18F-FDG brain metabolism in patients with chronic fatigue syndrome.	Nucl Med Commun 1998 Nov;19(11):1065-71	Chronic fatigue syndrome is a clinically defined condition of uncertain aetiology. We compared 99Tcm-HMPAO single photon emission tomography (SPET) brain perfusion with dual-head 18F-FDG brain metabolism in patients with chronic fatigue syndrome. Eighteen patients (14 females, 4 males), who fulfilled the diagnostic criteria of the Centers for Disease Control for chronic fatigue syndrome, were investigated. Thirteen patients had abnormal SPET brain perfusion scans and five had normal scans. Fifteen patients had normal glucose brain metabolism scans and three had abnormal scans. We conclude that, in chronic fatigue syndrome patients, there is discordance between SPET brain perfusion and 18F-FDG brain uptake. It is possible to have brain perfusion abnormalities without corresponding changes in glucose uptake.
Ambrogetti A, Leslie G. Olson, David C. Sutherland, John A. Malcolm, David Bliss, Stephen G. Gyulay		Daytime Sleepiness and REM Sleep Abnormalities in Chronic Fatigue A Case Series	Journal of Chronic Fatigue Syndrome 1998: 4(1): 23 - 35	Objective: To describe a subgroup of patients with chronic fatigue in whom there is increased physiological sleep tendency. Design: Prospective case series. Setting and Patients: Fifty-six consecutive patients with a working diagnosis of chronic fatigue syndrome underwent a sleep interview, overnight polysomnography and a Multiple Sleep Latency Test in a regional Sleep Disorders Center. Results: Of the 56 patients, 14 satisfied the current International Classification of Sleep Disorders criteria for the diagnosis of narcolepsy. Four of these patients had both excessive somnolence and clear-cut cataplexy and 10 pathological somnolence and polysomnographic criteria for narcolepsy. A further 35 had either increased daytime sleepiness, abnormal REM sleep regulation or both. Despite the objective evidence of daytime increased sleep tendency, the majority of the patients complained of fatigue and not of sleepiness. Twenty-nine patients were treated with either dexamphetamine or methylphenidate with good results in about half. Conclusion: We conclude that among patients investigated for chronic fatigue syndrome it is possible to identify a subgroup with significant daytime sleepiness and REM sleep abnormalities. Symptomatic treatment of these patients is often rewarding.
Andersson M, Bagby JR, Dyrehag L, Gottfries C.	Pain Unit, Kungalv Hospital, Sweden	Effects of staphylococcus toxoid vaccine on pain and fatigue in patients with fibromyalgia/chronic fatigue syndrome.	Eur J Pain 1998;2(2):133-142	Positive results of pilot studies of the effect of staphylococcus toxoid vaccine in patients with fibromyalgia and chronic fatigue syndrome were the incitement to the present, placebo-controlled study. It included 28 patients who fulfilled the criteria for both fibromyalgia and chronic fatigue syndrome. The effect of vaccination with a staphylococcus toxoid was compared with the effect of injections of sterile water. Psychometric assessment was made using 15 items from the comprehensive psychopathological rating scale (CPRS), Zung's self-rating depression scale and clinical global impressions (CGI). The visual analogue scale (VAS) was used to measure pain levels, and a hand-held electronic pressure algometer was used to measure pressure pain thresholds. Significant improvement was seen in seven of the 15 CPRS items in the vaccine group when pretreatment values were compared to post-treatment values. In CPRS <<fatiguability>>, there were significant intergroup differences, and in

				CPRS <<pain>> intergroup differences bordered on significance. There was no significant improvement in CPRS items in the placebo group. Clinical global impressions showed significant improvement in the vaccine-treated group, and VAS did so in both groups. In a follow-up study of 23 patients, the vaccine treatment was continued for 2-6 years. Fifty percent were rehabilitated successfully and resumed half-time or full-time work. The results of this study support the authors>> hypothesis that treatment with staphylococcus toxoid may be a fruitful strategy in patients with fibromyalgia and chronic fatigue syndrome. Copyright 1998 European Federation of Chapters of the International Association for the Study of Pain.
Arzomand ML		Chronic Fatigue Syndrome Among School Children and Their Special Educational Needs	Journal of Chronic Fatigue Syndrome 1998: 4(3): 59 - 69	Objectives: To determine the prevalence of Chronic Fatigue Syndrome (CFS) in school children. To explore their Special Educational Needs (SEN) arrangements. To evaluate the views of their parents, the educational and medical professionals involved in the process of special education needs assessment. Design: A postal questionnaire survey. Setting: The Merton and Sutton Junior and High Schools. Subjects: Pupils diagnosed with CFS. Main Outcome Measures: Responses to CFS about special educational needs and case details. Results: With a 53.8% return rate, 22 cases were identified giving an overall point prevalence of 0.07%. Of these 22 cases, 21 were in Sutton and one in Merton. There were equal numbers of boys and girls. Although the respondent groups generally agreed about Special Educational Needs arrangements, differences existed on home tuition and physical education (PE) at school. Parents were more against PE, 5 (71%) vs. 2 (14%) and 4 (11%) of doctors and educational staff, respectively (P = 0.001). Four out of seven parents (57%) said home tuition was necessary, while only one doctor (7%) and nine educational staffs (25.7%) agreed with this (P = 0.044). Conclusion: The estimated overall prevalence is consistent with previous paediatric studies. Two different findings, however, emerged. The equal prevalence in boys and girls (in contrast to previous studies) and the highly significant difference of case numbers between these two neighbouring boroughs (21 vs. 1). Further research is needed for possible explanation of these differences.
Ayres JG, Flint N, Smith EG, Tunnicliffe WS, Fletcher TJ, Hammond K, Ward D, Marmion BP.	Department of Respiratory Medicine, Heartlands Hospital, Birmingham, UK.	Post-infection fatigue syndrome following Q fever.	QJM 1998 Feb;91(2):105-23	In 1989, 147 individuals in the West Midlands, UK, were infected with Q fever. Five years later, following anecdotal reports of fatigue, we used a questionnaire-based case-control study to determine the prevalence of chronic fatigue syndrome symptoms in this group. Replies from 71 patients were compared with those from 142 age- and sex-matched controls. Increased sweating (52.9% vs. 31.6%, p = 0.006), breathlessness (50.7% vs. 30.6%, p = 0.006), blurred vision (34.3% vs. 17.8%, p = 0.016) and undue tiredness (68.7% vs. 51.5%, p = 0.03) were found in controls compared to cases. These findings were similar to those in Australian abbatoir workers occupationally exposed to Q fever. CDC criteria for chronic fatigue syndrome were fulfilled by 42.3% of cases and 26% of controls. Using visual analogue scores, symptoms were more severe in cases than in controls. Our findings support the existence of a chronic fatigue state following acute Q fever, in a group of patients

				exposed just once to the organism, and in circumstances free of such confounding factors as lawsuits over compensation.
Baraniuk JN, Clauw D, Yuta A, Ali M, Gaumond E, Upadhyayula N, Fujita K, Shimizu T.	Division of Rheumatology and Immunology and Allergy, Georgetown University, Washington, D.C. 20007-2197, USA.	Nasal secretion analysis in allergic rhinitis, cystic fibrosis, and nonallergic fibromyalgia/chronic fatigue syndrome subjects.	Am J Rhinol 1998 Nov-Dec;12(6):435-40	Rhinitis symptoms are present in approximately 70% of subjects with fibromyalgia and chronic fatigue syndrome (FM/CFS). Because only 35% to 50% have positive allergy skin tests, nonallergic mechanisms may also play a role. To better understand the mechanisms of nonallergic rhinitis in FM/CFS, nasal lavages were performed, and markers of vascular permeability, glandular secretion, and neutrophil and eosinophil infiltration measured in 27 nonallergic FM/CFS, 7 allergic rhinitis, 7 cystic fibrosis, and 9 normal subjects. Allergic rhinitis subjects had significantly increased vascular permeability (IgG) and ECP levels. Cystic fibrosis subjects had significantly higher elastase and total protein levels. There were no significant differences between FM/CFS and normal lavage fluids. Analysis of the constituents of nasal mucus provides information about ongoing secretory processes in rhinitis. There were no differences in the basal secretion of these markers of vascular permeability, submucosal gland serous cell secretion, eosinophil and neutrophil degranulation in nonallergic FM/CFS subjects. This suggests that constitutively active secretory processes that regulate continuous production of nasal secretions are not altered in FM/CFS. Future studies should examine alternative mechanisms such as inducible, irritant-activated, or reflex-mediated effects.
Baraniuk JN, Clauw DJ, Gaumond E.	Division of Rheumatology, Immunology and Allergy, Georgetown University, Washington, DC 20007-2197, USA.	Rhinitis symptoms in chronic fatigue syndrome.	Ann Allergy Asthma Immunol 1998 Oct;81(4):359-65	BACKGROUND: Atopy and allergic rhinitis are thought to be increased in prevalence in chronic fatigue syndrome (CFS). METHODS: To investigate this hypothesis, 51 CFS (CFS), 34 normal (N), 27 allergic rhinitis (AR), and 17 patients with other rheumatologic diseases filled out an Airway Symptom Severity self-report questionnaire to determine the frequencies of nasal, sinus, and chest symptoms, and a Systemic Complaints self-report questionnaire to determine the frequencies of complaints referable to neurologic, rheumatologic, gastrointestinal, and other systems. All subjects received a standard set of allergy skin tests, and were subdivided into those with positive and negative results. RESULTS: Allergy skin tests were positive in 35% of CFS and 44% of N subjects (difference not significant by Chi2). Significant rhinitis complaints were present in 83% of skin test positive CFS, 76% of skin test negative CFS, 74% of AR, and 23% of N subjects. Systemic Complaints scores were significantly elevated in skin test positive (94%) and negative (94%) CFS groups compared with AR (35%) and N (6%) groups. This score could significantly discriminate between CFS and N subjects. CONCLUSIONS: These data indicate that in this CFS population, 24% had no significant rhinitis complaints, 30% had positive skin tests suggesting the potential for allergic rhinitis complaints, and 46% had nonallergic rhinitis. The mechanism of the nonallergic component may offer insights into the pathogenesis of CFS.
Baraniuk JN, Daniel Clauw, Anna-Louisa		IgE Concentrations in Chronic Fatigue	Journal of Chronic Fatigue Syndrome	Hypothesis: Allergies have been proposed as a cause or contributing factor of chronic Fatigue syndrome (CFS). If this is so, then the stigmata of atopy, such as symptoms of

MacDowell-Carneiro, Joseph Bellanti, Pavani Pandiri, Sukmun Foong, Mushtaq Ali		Syndrome	1998: 4(1): 13 - 21	allergic rhinitis and high serum IgE, should be present in CFS subjects. Methods: Medical records from an allergy and immunology clinic were retrospectively reviewed. All subjects who had had a serum IgE measurement performed over a 4-year period were identified, and allergy history and skin test data reviewed. Patients were then classified as: (a) allergic rhinitis (n = 51), (b) CFS (n = 113, 1992 criteria), and (c) normal subjects without atopy, CFS or immunodeficiency (n = 76). IgE levels were compared between groups. Results: A clinical history of allergic rhinitis was present in 31% (35/113) of thc CFS subjects. The IgE levels of allergic rhinitis subjects and the subset of CPS subjects with allergic rhinitis were 392 ± 73 and 406 ± 123 IU/ml, respectively. In contrast, normal subjects and CFS subjccts who did not give a history of allergic rhinitis had normal IgE levels of 49 ± 9 and 33 ± 4 IU/ml, respectively. Conclusion: Atopy with clinically defined allergic rhinitis, high IgE, positive allergy skin tests and the presumed TH2 lymphocyte-IgE-mast cell-eosinophil axis overactivity and immediate hypersensitivity (Type I) immune response was present in a minority of CFS subjects. While atopy may coexist in some CFS subjects, it is unlikely that atopy plays a causal role in CFS pathogenesis.

Behan WMH, Ian J. Holt, David H. Kay, Pamela Moonie		In vitro Study of Muscle Aerobic Metabolism in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 5(1): 3 - 16	The purpose of this study was to establish if muscle aerobic metabolism is abnormal in chronic fatigue syndrome (CFS). Myoblast cultures from muscle biopsies of 16 patients with CFS and 10 healthy controls were established. Micromethods were used to determine the lactate/pyruvate (L/P) ratio, respiratory chain function and cytochrome oxidase and lactic dehydrogenase activities. Mitochondrial DNA (mtDNA) volume was measured and mtDNA rearrangements sought. The results showed that myoblasts from ten of 16 cases of CFS had defects in aerobic metabolism: two had increased L/P ratios, suggestive of a defect in oxidative phosphorylation while eight

				had decreased ratios, consistent with a deficiency in pyruvate dehydrogenase. There was a statistically significant broader range of L/P ratios in the patients' cultures, compared to controls (p = 0.011). No mtDNA rearrangements were present. This in vitro study confirms that there is convincing evidence of mild aerobic defects in skeletal muscle in some cases of CFS
Bell IR, Baldwin CM, Russek LG, Schwartz GE, Hardin EE.	Department of Psychiatry, University of Arizona, Tucson, USA.	Early life stress, negative paternal relationships, and chemical intolerance in middle-aged women: support for a neural sensitization model.	J Womens Health 1998 Nov;7(9):1135-47	This study (ntotal = 35) compared early life stress ratings, parental relationships, and health status, notably orthostatic blood pressures, of middle-aged women with low-level chemical intolerance (CI group) and depression, depressives without CI (DEP group), and normals. Environmental chemical intolerance is a symptom of several controversial conditions in which women are overrepresented, that is, sick building syndrome, multiple chemical sensitivity, chronic fatigue syndrome, and fibromyalgia. Previous investigators have postulated that people with CI have variants of somatization disorder, depression, posttraumatic stress disorder (PTSD) initiated by childhood abuse or a toxic exposure event. One neurobehavioral model for CI, somatization disorder, recurrent depression, and PTSD is neural sensitization, that is, the progressive amplification of host responses (e.g., behavioral, neurochemical) to repeated intermittent stimuli (e.g., drugs, chemicals, endogenous mediators, stressors). Females are more vulnerable to sensitization than are males. Limbic and mesolimbic pathways mediate central nervous system sensitization. Although both CI and DEP groups had high levels of life stress and past abuse, the CI group had the most distant and weak paternal relationships and highest limbic somatic dysfunction subscale scores. Only the CI group showed sensitization of sitting blood pressures over sessions. Together with prior evidence, these data are consistent with a neural sensitization model for CI in certain women. The findings may have implications for poorer long-term medical as well as neuropsychiatric health outcomes of a subset of women with CI. Subsequent research should test this model in specific clinical diagnostic groups with CI.
Bell IR, Baldwin CM, Schwartz GE.	Department of Psychiatry, University of Arizona, Tucson Veterans Affairs Medical Center, 85723, USA.	Illness from low levels of environmental chemicals: relevance to chronic fatigue syndrome and fibromyalgia.	Am J Med 1998 Sep 28;105(3A):74S-82S	This article summarizes (1) epidemiologic and clinical data on the symptoms of maladies in association with low-level chemicals in the environment, i.e., environmental chemical intolerance (CI), as it may relate to chronic fatigue syndrome (CFS) and fibromyalgia; and (2) the olfactory-limbic neural sensitization model for CI, a neurobehavioral synthesis of basic and clinical research. Severe CI is a characteristic of 20-47% of individuals with apparent CFS and/or fibromyalgia, all patients with multiple chemical sensitivity (MCS), and approximately 4-6% of the general population. In the general population, 15-30% report at least minor problems with CI. The levels of chemicals reported to trigger CI would normally be considered nontoxic or subtoxic. However, host factors--e.g., individual differences in susceptibility to neurohormonal sensitization (amplification) of endogenous responses--may contribute to generating a disabling intensity to the resultant multisystem dysfunctions in CI. One site for this amplification may be the limbic system of the

				brain, which receives input from the olfactory pathways and sends efferents to the hypothalamus and the mesolimbic dopaminergic [reward] pathway. Chemical, biologic, and psychological stimuli can initiate and elicit sensitization. In turn, subsequent activation of the sensitized limbic and mesolimbic pathways can then facilitate dysregulation of behavioral, autonomic, endocrine, and immune system functions. Research to date has demonstrated the initiation of neurobehavioral sensitization by volatile organic compounds and pesticides in animals, as well as sensitizability of cardiovascular parameters, beta-endorphin levels, resting EEG alpha-wave activity, and divided-attention task performance in persons with CI. The ability of multiple types of widely divergent stimuli to initiate and elicit sensitization offers a new perspective on the search for mechanisms of illness in CFS and fibromyalgia with CI.
Bell IR, Patarca R, Baldwin CM, Klimas NG, Schwartz GE, Hardin EE.	Department of Psychiatry, Psychology, Family and Community Medicine, University of Arizona Health Sciences Center, and the Department of Psychiatry, Tucson Veterans Affairs Medical Center, Tucson, Ariz., USA.	Serum neopterin and somatization in women with chemical intolerance, depressives, and normals.	Neuropsychobiology 1998;38(1):13-8	The symptom of intolerance to low levels of environmental chemicals (CI, chemical intolerance) is a feature of several controversial polysymptomatic conditions that overlap symptomatically with depression and somatization, i.e., chronic fatigue syndrome, fibromyalgia, multiple chemical sensitivity, and Persian Gulf syndrome. These syndromes can involve many somatic symptoms consistent with possible inflammation. Immunological or neurogenic triggering might account for such inflammation. Serum neopterin, which has an inverse relationship with l-tryptophan availability, may offer a marker of inflammation and macrophage/monocyte activation. This study compared middle-aged women with CI (who had high levels of affective distress; n = 14), depressives without CI (n = 10), and normals (n = 11). Groups did not differ in 4 p.m. resting levels of serum neopterin. However, the CI alone had strong positive correlations between neopterin and all of the scales measuring somatization. These preliminary findings suggest the need for additional research on biological correlates of 'unexplained' multiple somatic symptoms in subtypes of apparent somatizing disorders.
Bennett R.	Department of Medicine, Oregon Health Sciences Center, Portland 97201, USA.	Fibromyalgia, chronic fatigue syndrome, and myofascial pain.	Curr Opin Rheumatol 1998 Mar;10(2):95-103	Epidemiologic studies continue to provide evidence that fibromyalgia is part of a spectrum of chronic widespread pain. The prevalence of chronic widespread pain is several times higher than fibromyalgia as defined by the 1990 American College of Rheumatology guidelines. There is now compelling evidence of a familial clustering of fibromyalgia cases in female sufferers; whether this clustering results from nature or nature remains to be elucidated. A wide spectrum of fibromyalgia-associated symptomatology and syndromes continues to be described. During the past year the association with interstitial cystitis has been explored, and neurally mediated hypotension has been documented in both fibromyalgia and chronic fatigue syndrome. Abnormalities of the growth hormone-insulin-like growth factor-1 axis have been also documented in both fibromyalgia and chronic fatigue syndrome. The commonly reported but anecdotal association of fibromyalgia with whiplash-type neck trauma was validated in a report from Israel. However, unlike North America,

				100% of Israeli patients with posttraumatic fibromyalgia returned to work. Basic research in fibromyalgia continues to pinpoint abnormal sensory processing as being integral to understanding fibromyalgia pain. Drugs such as ketamine, which block N-methyl-D-aspartate receptors (which are often upregulated in central pain states) were shown to benefit fibromyalgia pain in an experimental setting. The combination of fluoxetine and amitriptyline was reported to be more beneficial than either drug alone in patients with fibromyalgia. A high prevalence of autoantibodies to cytoskeletal and nuclear envelope proteins was found in chronic fatigue syndrome, and an increased prevalence of antipolymer antibodies was found in symptomatic silicone breast implant recipients who often have fibromyalgia.
Berwaerts J, Greta Moorkens, Roger Abs		Review of Neuroendocrine Disturbances in the Chronic Fatigue Syndrome Indications for a Role of the Growth Hormone-IGF-1 Axis in the Pathogenesis	Journal of Chronic Fatigue Syndrome 1998: 4(4): 81 - 91	The investigation of the growth hormone (GH)-IGF-1 axis in patients with chronic fatigue syndrome (CFS) may be important for different reasons. Some of the disturbances of the hypothalamic-pituitaryadrenal axis and central serotoninergic (5-HT) function in CFS will be reviewed, before elaborating on three hypotheses that may explain thc role of a disturbed GH axis activity in CFS. Firstly, the disturbed central 5-HT receptor activity may be the cause of GH axis dysfunction. Secondly, CFS may be considered as a "stress-related illness," in which the disturbed central 5-HT function is a result rather than the cause of impaired neuroendocrine stress responses. Finally, by analogy with fibromyalgia, sleep abnormalities in CFS may impair nocturnal GH secretion. Whether the disturbed GH axis activity is a primary or secondary phenomenon in the pathogenesis of CFS, should be elucidated by future clinical investigations.
Berwaerts J, Moorkens G, Abs R.	Department of Endocrinology, Middelheim Hospital, Antwerp, Belgium.	Secretion of growth hormone in patients with chronic fatigue syndrome.	Growth Horm IGF Res 1998 Apr;8 Suppl B:127-9	Decreased serum levels of insulin-like growth factor I (IGF-I) are common in patients with fibromyalgia, which is frequently associated with chronic fatigue syndrome (CFS). Twenty patients with CFS (7 men, 13 women; age range, 30-60 years) and age- and sex-matched controls were tested for peak GH responses to insulin-induced hypoglycaemia and arginine administration. Nocturnal secretion of GH and serum levels of IGF-I were also measured. Serum IGF-I SDS (SD) was significantly lower in patients with CFS than in controls (SDS, -0.39 1.07 vs 0.33 0.84; P = 0.02). Patients with CFS also tended to have reduced nocturnal secretion of GH (area under the curve, 32.4 18.3 vs 62.7 43.7 microg/l/15 minutes; P= 0.06), but peak GH responses to insulin-induced hypoglycaemia and arginine administration did not differ significantly between the two groups. It is not clear whether the tendency for impaired spontaneous nocturnal GH secretion in patients with CFS is a cause or an effect of the condition.
Blackwood SK, MacHale SM, Power MJ, Goodwin GM, Lawrie SM.	Edinburgh University Department of Psychiatry, Royal Edinburgh Hospital, UK.	Effects of exercise on cognitive and motor function in chronic fatigue syndrome and depression.	J Neurol Neurosurg Psychiatry 1998 Oct;65(4):541-6	OBJECTIVES: Patients with chronic fatigue syndrome complain of physical and mental fatigue that is worsened by exertion. It was predicted that the cognitive and motor responses to vigorous exercise in patients with chronic fatigue syndrome would differ from those in depressed and healthy controls. METHODS: Ten patients with chronic fatigue syndrome, 10 with depressive illness, and 10 healthy controls completed

				cognitive and muscle strength testing before and after a treadmill exercise test. Measures of cardiovascular functioning and perceived effort, fatigue, and mood were taken during each stage of testing. RESULTS: Depressed patients performed worst on cognitive tests at baseline. During the treadmill test, patients with chronic fatigue syndrome had higher ratings of perceived effort and fatigue than both control groups, whereas patients with depression reported lower mood. After exertion, patients with chronic fatigue syndrome showed a greater decrease than healthy controls on everyday tests of focused (p=0.02) and sustained (p=0.001) attention, as well as greater deterioration than depressed patients on the focused attention task (p=0.03). No between group differences were found in cardiovascular or symptom measures taken during the cognitive testing. CONCLUSIONS: Patients with chronic fatigue syndrome show a specific sensitivity to the effects of exertion on effortful cognitive functioning. This occurs despite subjective and objective evidence of effort allocation in chronic fatigue syndrome, suggesting that patients have reduced working memory capacity, or a greater demand to monitor cognitive processes, or both. Further insight into the pathophysiology of the core complaints in chronic fatigue syndrome is likely to be realised by studying the effects of exercise on other aspects of everyday functioning.
Block W, Traber F, Kuhl CK, Keller E, Lamerichs R, Karitzky J, Rink H, Schild HH.	Radiologische Klinik der Universitat Bonn. block@uni-bonn.de	[31P-mr spectroscopy of peripheral skeletal musculature under load: demonstration of normal energy metabolites compared with metabolic muscle diseases].[article in German]	Rofo Fortschr Geb Rontgenstr Neuen Bildgeb Verfahr 1998 Mar;168(3):250-7	PURPOSE: 31P-MR spectroscopy of skeletal muscle under exercise was used to obtain the range of normal variation and comparison was made for different neuromuscular diseases. METHODS: 41 examinations of 24 volunteers and 41 investigations in 35 patients were performed on 1.5 T MR systems (Gyroscan 515 und S15/ACSII, Philips). Localised 31P-MR spectra of the calf muscle were obtained in time series with a resolution of 12 s. RESULTS: Two types of muscle energy metabolism were identified from the pattern of spectroscopic time course in volunteers: While the first group was characterised by a remarkable decline to lower pH values during exercise, the second group showed only small pH shifts (minimum pH: 6.48 0.13 vs 6.87 0.07, p < 10(-6)) although comparable workload conditions were maintained. The pH-values correlated well with blood lactate analysis. Patients with metabolic disorders and chronic fatigue syndrome (CFS) showed decreased resting values of PCr/(PCr Pi) and increased pH levels during exercise. PCr recovery was significantly delayed (0.31 vs 0.65 min-1, p < 0.00005) in metabolic muscle disorders but was normal in CFS patients. CONCLUSION: Findings in volunteers indicate utilisation of different metabolic pathways which seems to be related to the fibre type composition of muscle. Reduced resting levels for PCr/(PCr Pi), altered pH time courses, and decreased PCr recovery seem to be helpful indicators for diagnosis of metabolic muscle disorders.
Borish L, Schmaling K, DiClementi JD, Streib J, Negri J, Jones JF.	Department of Medicine, National Jewish Medical and	Chronic fatigue syndrome: identification of	J Allergy Clin Immunol 1998 Aug;102(2):222-30	BACKGROUND: We investigated a role for allergic inflammation and psychologic parameters in the development of chronic fatigue syndrome (CFS). METHODS: The design was a comparison between subjects with CFS and age- and sex-matched

	Research Center, University of Colorado Health Sciences Center, Denver 80206, USA.	distinct subgroups on the basis of allergy and psychologic variables.		control cohorts. Studies were performed on CFS subjects (n = 18) and control cohorts consisting of normal subjects (n = 11), allergic subjects (n = 14), and individuals with primary depression (n = 12). We quantified cytokines at baseline as cell-associated immunoreactive peptides and as transcripts evaluated by means of semiquantitative RNA-based polymerase chain reactions. Psychologic evaluations included administration of the Diagnostic Interview Schedule, the Structured Clinical Interview, and the Symptom Checklist 90-Revised. RESULTS: Increases in tumor necrosis factor (TNF)-alpha were identified in individual subjects with CFS (50.1 14.4 pg TNF-alpha per 10(7) peripheral blood mononuclear cells [PBMCs]; mean SEM) and allergic subjects (41.6 7.6) in comparison with normal subjects (13.1 8.8) (P < .01 and P < .05, respectively). Similar trends were observed for interferon (IFN)-alpha in allergic subjects (3.0 1.7 pg/10(7) PBMCs) and subjects with CFS (6.4 3.4) compared with normal subjects (1.9 1.4). A significant increase (P < .05) in TNF-alpha transcripts was demonstrated between subjects with CFS and depressed subjects. In contrast to these proinflammatory cytokines, both subjects with CFS (2.6 1.8 pg/10(7) PBMCs) and allergic subjects (3.4 2.8) were associated with a statistically significant (P < .01) decrease in IL-10 concentrations compared with normal subjects (60.2 18.2). As shown in other studies, most of our subjects with CFS were allergic (15 of 18) and therefore presumably demonstrated cytokine gene activation on that basis. The seasonal exacerbation of allergy was associated with a further increase in cellular IFN-alpha (from 2.1 1.2 to 14.2 4.5 pg/107 PBMCs; P < .05) but no further modulation of TNF-alpha or IL-10. Similarly, self-reported exacerbations of CFS were associated with a further increase in IFN-alpha (from 2.5 1.0 to 21.9 7.8; P < .05) and occurred at times of seasonal exposures to allergens. This linkage does not permit making any definitive conclusions regarding a causative influence of either seasonal allergies or the increase in cellular IFN-alpha with the increase in CFS symptoms. The close association between atopy and CFS led us to speculate that CFS may arise from an abnormal psychologic response to the disordered expression of these proinflammatory and antiinflammatory cytokines. Psychologic variables were predictive of immune status within the CFS sample (65.9% of the variance in immune status; F (3,10) = 6.44, P < .05). Specifically, the absence of a personality disorder but greater endorsement of global psychiatric symptoms was predictive of immune activation. CONCLUSIONS: Most of our subjects with CFS were allergic, and the CFS and allergy cohorts were similar in terms of their immune status. However, the CFS subjects could be discriminated by the distinct psychologic profiles among subjects with and without immune activation. We propose that in at least a large subgroup of subjects with CFS who had allergies, the concomitant influences of immune activation brought on by allergic inflammation in an individual with the appropriate psychologic profile may interact to produce the symptoms of CFS. In a psychologically predisposed individual, symptoms associated with allergic inflammation are

				recognized as illness.
Borok G		Chronic Fatigue Syndrome An Atopic State	Journal of Chronic Fatigue Syndrome 1998: 4(3): 39 - 57	The cause of the tiredness and depression, may be due to a virus in the acute or recuperative phase, but in the long-term fatigue must be due to other mechanisms. As varied as are our size, shape, skin and eye colour so are the more subtle nuances of antibodies and enzymes which each cell produces. It is postulated that it is mostly atopic patients who will also react abnormally to certain foods, inhalants and skin applications. Sugars (refined foods) play a major role in leading to fatigue by their chemical, physiological, pharmacological and glycosylogical properties. Bread plays a major role in provoking the symptoms of depression in the chronic fatigue syndrome. What is suggested is that in a genetically predisposed group of people food intolerance causes symptoms akin to both the major and minor criteria of CFS.
Brown SL, Langone JJ, Brinton LA.		Silicone breast implants and autoimmune disease.	J Am Med Womens Assoc 1998 Winter;53(1):21-4, 40	In 1992, the Food and Drug Administration requested a voluntary moratorium on the scale and implantation of silicone-gel-filled breast implants because of growing concern over the lack of scientific and clinical data supporting their safety and effectiveness. Breast implants had been reported to cause serious local complications, and new questions about breast implants and increased risk for autoimmune disease, including the rare but sometimes fatal connective tissue disease scleroderma, were also raised. Since that time, clinical studies have focused on the adjuvant effect of silicone and of potential autoantibody production. Epidemiologic studies have ruled out a large increased risk for connective tissue disease overall in women with breast implants, but samples were too small to rule out an increase in rare connective tissue diseases. Nor were studies properly designed to address whether an atypical syndrome might develop in women with breast implants. Meta-analyses of these studies cannot remedy their underlying methodologic weaknesses. While the question of whether rare connective tissue disease is associated with breast implants may never be answered definitively, recent progress in identifying new syndromes such as fibromyalgia and chronic fatigue syndrome may provide an insight into methodology for evaluating the existence of a silicone-related syndrome in women with breast implants.
Bruno RL, Creange SJ, Frick NM.	Kids' Fatigue Management Program and The Post-Polio Institute, Englewood Hospital and Medical Center, New Jersey 07631, USA.	Parallels between post-polio fatigue and chronic fatigue syndrome: a common pathophysiology?	Am J Med 1998 Sep 28;105(3A):66S-73S	Fatigue is the most commonly reported and most debilitating of post-polio sequelae affecting the >1.8 million North American polio survivors. Post-polio fatigue is characterized by subjective reports of difficulty with attention, cognition, and maintaining wakefulness. These symptoms resemble those reported in nearly 2 dozen outbreaks of post-viral fatigue syndromes (PVFS) that have recurred during this century and that are related clinically, historically, anatomically, or physiologically to poliovirus infections. This article reviews recent studies that relate the symptoms of post-polio fatigue and chronic fatigue syndrome (CFS) to clinically significant deficits on neuropsychologic tests of attention, histopathologic and neuroradiologic evidence of brain lesions, impaired activation of the hypothalamic-pituitary-adrenal axis, increased prolactin secretion, and electroencephalogram (EEG)

				slow-wave activity. A possible common pathophysiology for post-polio fatigue and CFS, based on the Brain Fatigue Generator Model of PVFS, and a possible pharmacotherapy for PVFS based on replacement of depleted brain dopamine, will be described.
Bruno RL, Susan Creange, Jerald R. Zirnmerman Nancy M. Frick		Elevated Plasma Prolactin and EEG Slow Wave Power in Post-Polio Fatigue Implications for a Dopamine Deficiency Underlying Post-Viral Fatigue Syndromes	Journal of Chronic Fatigue Syndrome 1998: 4(2): 61 - 75	To test the hypothesis that plasma prolactin and electroencephalographic (EEG) slow wave activity are correlated with fatigue, 33 polio survivors without medical or psychologic comorbidities were studied. Subjects were administered the Post-Polio Fatigue Questionnaire (PFQ) and had resting measurement of both plasma prolactin and bilateral temporal-occipital power across the EEG frequency spectrum. Typical daily fatigue severity on the PFQ was significantly correlated with daily difficulty with attention, staying awake and motivation, but not with measures of acute polio severity or the number of limbs affected by late-onset Post-Polio Sequelae symptoms. Prolactin was significantly correlated with daily fatigue severity on the PFQ ($r = .39$; $p < .05$). EEG power was equal between the two hemispheres across all frequency bands. However, EEG slow wave power in the right hemisphere was significantly correlated with daily fatigue severity and prolactin level ($r = .37$; $p < .05$). Using multiple linear regression, age at acute polio, frequency of difficulty with attention on the PFQ, prolactin and right hemisphere slow wave power predicted 72% of the variance of the daily fatigue severity rating ($r = 85$; $p < .0001$). These data suggest that increased prolactin secretion and EEG slowing are related to the severity of post-polio fatigue, findings similar to those in patients with acute paralytic and non-paralytic poliomyelitis and with chronic fatigue syndrome. A primary role is suggested for a dopamine deficiency (versus serotonergic receptor supersensitivity) underlying impaired cortical activation and the symptoms associated with putative post-viral fatigue syndromes.
Calkins H, Rowe PC.	The Johns Hopkins University School of Medicine, Baltimore, Maryland.	Relationship Between Chronic Fatigue Syndrome and Neurally Mediated Hypotension.	Cardiol Rev 1998 May;6(3):125-134	Chronic fatigue syndrome is a chronic debilitating disease that afflicts 4/1000 of the general population. The pathophysiologic basis for this condition is unknown, and no known consistently effective therapy has been identified. Recent studies have reported a link between the chronic fatigue syndrome and neurally mediated hypotension, a common abnormality of blood pressure regulation. In nonrandomized studies, treatment directed at neurally mediated hypotension has been effective in treating the symptoms of the chronic fatigue syndrome in two-thirds of patients. Prospective randomized trials are now in progress.
Cannon JG, Angel JB, Abad LW, O'Grady J, Lundgren N, Fagioli L, Komaroff AL.	Department of Medicine, New England Medical Center, Boston, Massachusetts, USA. jgc2@psu.edu	Hormonal influences on stress-induced neutrophil mobilization in health and chronic fatigue syndrome.	J Clin Immunol 1998 Jul;18(4):291-8	This investigation tested the hypotheses that women diagnosed with chronic fatigue syndrome (CFS) would exhibit significantly greater systemic indices of exercise-induced leukocyte mobilization and inflammation (neutrophilia, lactoferrin release, complement activation) than controls matched for age, weight, and habitual activity and that responses in the luteal phase of the menstrual cycle would be greater than in the follicular phase. Subjects stepped up and down on a platform adjusted to the height of the patella for 15 min, paced by metronome. Blood samples were collected

				under basal conditions (the day before exercise) and following exercise for determination of circulating neutrophils and plasma concentrations of lactoferrin, C3a des arg, and creatine kinase. Complete, 24-hr urine collections were made for determination of cortisol excretion. For all subjects, circulating neutrophil counts increased 33% (P < 0.0001) and lactoferrin increased 27% (P = 0.0006) after exercise, whereas plasma C3a des arg and creatine kinase did not increase. No indication of an exaggerated or excessive response was observed in the CFS patients compared to the controls. In healthy women, circulating neutrophil numbers exhibited previously described relationships with physiological variables: basal neutrophil counts correlated with plasma progesterone concentrations (R = 0.726, P = 0.003) and the exercise-induced neutrophilia correlated with both urinary cortisol (R = 0.660, P = 0.007) and plasma creatine kinase (R = 0.523, P = 0.038) concentrations. These relationships were not observed in the CFS patients (R = 0.240, P = 0.370; R = 0.042, P = 0.892; and R = 0.293, P = 0.270; respectively). These results suggest that normal endocrine influences on the circulating neutrophil pool may be disrupted in patients with CFS.
Capen K.		Chronic fatigue syndrome get court's nod of approval as legitimate disorder.	CMAJ 1998 Sep 8;159(5):533-4Comment in: CMAJ. 1999 Mar 9;160(5):636, 638 CMAJ. 1999 Mar 9;160(5):638	Lawyer Karen Capen looks at the implications of a recent Alberta court case involving chronic fatigue syndrome. She thinks Canada's physicians should pay close attention to this precedent-setting case.

Cathebras P, Lauwers A, Rousset H.	Service de Medecine Interne, Hopital Nord, Saint-Etienne.	[Fibromyalgia. A critical review].[article in French]	Ann Med Interne (Paris) 1998 Nov;149(7):406-14	Fibromyalgia is a chronic pain syndrome, more common in women. Its prevalence is estimated around 2% in the general population, and up to 20% among rheumatology outpatients. Besides musculoskeletal pain, symptoms as fatigue and sleep disturbance are considered characteristic. Research criteria have been set up, but their seemingly preciseness is unable to distinguish clearly between fibromyalgia and other functional somatic syndromes (chronic fatigue syndrome, irritable bowel syndrome) and psychiatric disorders (depression, anxiety), with which a striking comorbidity is documented. The diagnosis of fibromyalgia does not theoretically require the exclusion of muscle, joint, or metabolic diseases, but in clinical practice this problem proves to be of crucial importance. There are numbers of

				pathophysiological hypothesis for fibromyalgia, but none of them is fully satisfying: muscle is probably innocent; sleep disturbance, although sometimes considered a landmark of the syndrome, is unspecific; stress response studies show subtle anomaly; psychiatric disorders may represent factors of vulnerability and perpetuation rather than causes. We propose to include some of these etiological contributors in vicious circles leading to a "final common pathway" characterized by generalized hyperalgesia. Treatments of fibromyalgia, whether pharmacological (antidepressants) or psychological (cognitive-behavioral therapies) are of little efficacy, and the global prognosis of fibromyalgia is poor. However, the outcome might prove better outside the specialized clinics in which studies of chronic sufferers with severe abnormal illness behaviors are done. The social consequences of the popularization of the diagnosis of fibromyalgia should not be neglected.
Chester AC.		Chronic fatigue syndrome.	JAMA 1998 Feb 11;279(6):432; discussion 432-3 Comment on: JAMA. 1997 Oct 8;278(14):1179-85	
Choppa PC, Vojdani A, Tagle C, Andrin R, Magtoto L.	Immunosciences Lab Incorporated Beverly Hills, CA, USA.	Multiplex PCR for the detection of Mycoplasma fermentans, M. hominis and M. penetrans in cell cultures and blood samples of patients with chronic fatigue syndrome.	Mol Cell Probes 1998 Oct;12(5):301-8	A multiplex polymerase chain reaction (PCR) was initially developed to detect the presence of mycoplasma genus DNA sequences in cell cultures and to differentiate between three human pathogenic mycoplasma species simultaneously. The assay in turn, proved to be a useful tool for the detection of mycoplasma infection in human DNA samples. One set of oligonucleotide primers which are specific for a highly conserved region among all members of the genus mycoplasma along with three other primer sets which are specific for Mycoplasma fermentans, Mycoplasma hominis andMycoplasma penetrans species were used in this assay. The sensitivity of detection was determined by infecting peripheral blood mononuclear cells (PBMC) of healthy individuals with known bacterial copy numbers from each species, extracting the DNA, and subjecting 1 microgram of DNA from each sample to 40 cycles of amplification. By using agarose gel electrophoresis the detection level was determined to be 7, 7, 9 and 15 mycoplasma cells per microgram of human genomic DNA for M. genus,M. fermentans, M. hominis and M. penetrans, respectively. The assay was applied to DNA extracted from the PBMCs of individuals suffering from chronic fatigue syndrome (CFS) (n=100) as determined by the Center for Disease Control (CDC) criteria, and compared to healthy individuals (n=100). The percentage of M. genus infection was found to be 52% in CFS patients and only 15% in healthy individuals.Mycoplasma fermentans, M. hominis andM. penetrans were detected in 32, 9 and 6% of the CFS patients while they were detected in 8, 3 and 2% of the healthy control subjects, respectively. This assay provides a rapid and cost efficient procedure to screen either cell cultures or clinical samples for the presence of three

				potentially pathogenic species of mycoplasma with a high level of sensitivity and specificity. Copyright 1998 Academic Press.
Christodoulou C, DeLuca J, Lange G, Johnson SK, Sisto SA, Korn L, Natelson BH.	University of Medicine and Dentistry of New Jersey, New Jersey Medical School, Newark, USA.	Relation between neuropsychological impairment and functional disability in patients with chronic fatigue syndrome.	J Neurol Neurosurg Psychiatry 1998 Apr;64(4):431-4Comment in: J Neurol Neurosurg Psychiatry. 1998 Apr;64(4):430	OBJECTIVES: To examine the relation between neuropsychological impairment and functional disability in patients with chronic fatigue syndrome, and determine whether the relation is independent of psychiatric factors. METHODS: The subjects were 53 patients with chronic fatigue syndrome and 32 healthy controls who did not exercise regularly. Subjects were administered a structured psychiatric interview and completed questionnaires focusing on depression and functional disability. They also completed a battery of standardised neuropsychological tasks focusing on the cognitive domains that patients with chronic fatigue syndrome experience as particularly difficult: memory (verbal and visual), and attention/concentration. A test score was defined as failing when it was > or =2 SD below the mean of the healthy controls after controlling for demographic factors. RESULTS: Those patients with chronic fatigue syndrome with higher numbers of failing neuropsychological test scores reported significantly more days of general inactivity in the past month than those with fewer failing scores. This result remained significant even after partialling out the contribution of the presence of a comorbid axis I psychiatric episode and the overall level of depressive symptomology. Patients with failing verbal memory scores were particularly functionally disabled compared with those with passing scores. CONCLUSION: A relation was found between cognitive impairment and functional disability which could not be explained entirely on the basis of psychiatric factors.

Conti F, Pittoni V, Sacerdote P, Priori R, Meroni PL, Valesini G.	Istituto di Clinica Medica I, Universita degli Studi di Roma La Sapienza, Rome, Italy.	Decreased immunoreactive beta-endorphin in mononuclear leucocytes from patients with chronic fatigue syndrome.	Clin Exp Rheumatol 1998 Nov-Dec;16(6):729-32	OBJECTIVE: To investigate beta-endorphin concentrations in the peripheral blood mononuclear cells (PBMC) of patients with chronic fatigue syndrome (CFS). METHODS: Sixteen patients with CFS were enrolled in this study. Ten healthy subjects were studied as controls. Beta-endorphin concentrations were measured in PBMC by radioimmunoassay performed with antibodies specific for the C-terminal portion of human beta-endorphin. RESULTS: Beta-endorphin concentrations in the PBMC of chronic fatigue patients were significantly lower ($p < 0.001$) than in healthy subjects (mean SD: 8.5 7.0 vs. 42.6 22.6). CONCLUSION: Patients with CFS were found to have low levels of PBMC beta-endorphin. This finding may reflect the condition of chronic immune activation in CFS that has been reported in previous investigations. Beta-endorphin concentrations in PBMC seem to mirror the central nervous system

				homeostasis of the opioid. Therefore, we would postulate that the fatigue and weakness typical of CFS could be related to low beta-endorphin concentrations at the central nervous system level.

Crofford LJ.	Division of Rheumatology, University of Michigan, Ann Arbor 48109-0680, USA. crofford@umich.edu	The hypothalamic-pituitary-adrenal stress axis in fibromyalgia and chronic fatigue syndrome.	Z Rheumatol 1998;57 Suppl 2:67-71	HPA axis abnormalities in FM, CFS, and other stress-related disorders must be placed in a broad clinical context. We know that interventions providing symptomatic improvement in patients with FM and CFS can directly or indirectly affect the HPA axis. These interventions include exercise, tricyclic anti-depressants, and serotonin reuptake inhibitors. There is little direct information as to how the specific HPA axis perturbations seen in FM can be related to the major symptomatic manifestations of pain, fatigue, sleep disturbance, and psychological distress. Since many of these somatic and psychological symptoms are present in other syndromes that exhibit HPA axis disturbances, it seems reasonable to suggest that there may be some relationship between basal and dynamic function of the HPA axis and clinical manifestations of FM and CFS.
Csef H.	Med. Poliklinik der Univ. Wurzburg.	[The non-specific environmental syndromes MCS (Multiple Chemical Sensitivity), IEI (Idiopathic Environmental Intolerance) and SBS (Sick Building Syndrome)].[article in German]	Fortschr Med 1998 Nov 30;116(33):18-20, 22, 24	This review starts with a clinical description of the most common unspecific environmental diseases, such as Multiple Chemical Sensitivities (MCS), Idiopathic Environmental Intolerances (IEI) and Sick Building Syndrome (SBS). These syndromes are very controversial discussed between scientific medicine and "clinical ecology". In addition, they have fundamental similarities to Chronic Fatigue Syndrome (CFS) and Fibromyalgia. Finally the spectrum of therapeutic approaches is discussed.

De Becker P, Dendale P, De Meirleir K, Campine I, Vandenborne K,	Department of Human Physiology, University Hospital, Free University, Brussels,	Autonomic testing in patients with chronic fatigue syndrome.	Am J Med 1998 Sep 28;105(3A):22S-26S	The purpose of this study was to determine whether chronic fatigue syndrome (CFS) patients show autonomic dysfunction at the cardiac level and if so, to discover whether these abnormalities explain the fatiguability and/or other symptoms in CFS. The study population consisted of 21 CFS patients (Centers for Disease Control and

Hagers Y.	Belgium.			Prevention [CDC] criteria, 1988) and 13 age- and sex-matched healthy controls. The autonomic testing consisted of: (1) postural challenge: registration of heart rate and blood pressure (BP) and heart rate variability in supine and in upright position (tilted to 70 degrees); (2) Valsalva maneuver; (3) handgrip test; (4) cold pressor test; and (5) heart rate response to deep breathing. Statistical analysis was performed using the Mann Whitney rank sum test; results of the test were considered significant at the 0.05 level. After tilting heart rate was significantly higher in CFS patients compared with healthy controls (mean CFS = 88.9 beats/min vs control = 77.9 beats/min; P <0.01). Low frequency power after tilting was significantly higher in CFS patients compared with controls (mean CFS = 0.603 vs control = 0.428; P = 0.02). There was a trend toward an increased heart rate during the cold pressor test. Other parameters did not differ between the CFS and control populations. The observed changes point toward a sympathetic overactivity in CFS patients when they are exposed to stress. Parasympathetic abnormalities could not be observed. Therefore, our findings provide no real explanation for the fatigue and intolerance to physical exertion in these patients.
De Lorenzo F, Hargreaves J, Kakkar VV.	Beatrice Research Centre, London, UK.	Phosphate diabetes in patients with chronic fatigue syndrome.	Postgrad Med J 1998 Apr;74(870):229-32Comment in: Postgrad Med J. 1998 Nov;74(877):701	Phosphate depletion is associated with neuromuscular dysfunction due to changes in mitochondrial respiration that result in a defect of intracellular oxidative metabolism. Phosphate diabetes causes phosphate depletion due to abnormal renal re-absorption of phosphate be the proximal renal tubule. Most of the symptoms presented by patients with phosphate diabetes such as myalgia, fatigue and mild depression, are also common in patients with chronic fatigue syndrome, but this differential diagnosis has not been considered. We investigated the possible association between chronic fatigue syndrome and phosphate diabetes in 87 patients who fulfilled the criteria for chronic fatigue syndrome. Control subjects were 37 volunteers, who explicitly denied fatigue and chronic illness on a screening questionnaire. Re-absorption of phosphate by the proximal renal tubule, phosphate clearance and renal threshold phosphate concentration were the main outcome measures in both groups. Of the 87 patients with chronic fatigue syndrome, nine also fulfilled the diagnostic criteria for phosphate diabetes. In conclusion, we report a previously undefined relationship between chronic fatigue syndrome and phosphate diabetes. Phosphate diabetes should be considered in differential diagnosis with chronic fatigue syndrome; further studies are needed to investigate the incidence of phosphate diabetes in patients with chronic fatigue syndrome and the possible beneficial effect of vitamin D and oral phosphate supplements.
De Lorenzo F, Xiao H, Mukherjee M, Harcup J, Suleiman S, Kadziola Z, Kakkar VV.	Thrombosis Research Institute, London, UK.	Chronic fatigue syndrome: physical and cardiovascular deconditioning.	QJM 1998 Jul;91(7):475-81	We investigated whether chronic fatigue syndrome (CFS) patients have physical and/or cardiovascular de-conditioning, in 273 CFS patients and 72 healthy controls. We used laboratory tests to assess haematological, biochemical, endocrinological and immunological systems. The cardiovascular system was assessed by echocardiography and carotid echography. Body composition was determined by

				dual energy X-ray absorptiometry (DEXA). CFS patients had smaller left ventricular end systolic ($p < 0.001$) and diastolic ($p = 0.008$) dimensions but thinner posterior walls ($p = 0.02$) than corresponding values in healthy controls. Left ventricular mass was also reduced in CFS patients ($p = 0.006$). Both maximum ($p < 0.001$) and minimum ($p < 0.008$) diameter of the carotid artery were smaller in CFS patients. The laboratory screening tests showed significant differences in serum albumin ($p = 0.05$), phosphate ($p = 0.02$), HDL-cholesterol ($p = 0.03$), HDL:total cholesterol ratio ($p = 0.01$), triglycerides ($p = 0.02$), neutrophils ($p = 0.01$) and thyroid-stimulating hormone ($p = 0.04$) between CFS patients and controls. Male CFS patients had an increased percentage of fat mass compared with healthy male subjects ($p = 0.02$). This large group of CFS patients had evidence of physical and cardiovascular de-conditioning, suggesting that in these patients a graded exercise programme could lead to physical reconditioning and could increase their ability to perform physical activities.
Deale A, Chalder T, Wessely S.	Department of Psychological Medicine, Kings College Hospital, and Institute of Psychiatry, London, UK.	Illness beliefs and treatment outcome in chronic fatigue syndrome.	J Psychosom Res 1998 Jul;45(1 Spec No):77-83	Longitudinal studies have shown that physical illness attributions are associated with poor prognosis in chronic fatigue syndrome (CFS). Speculation exists over whether such attributions influence treatment outcome. This study reports the effect of illness beliefs on outcome in a randomized controlled trial of cognitive-behavior therapy versus relaxation. Causal attributions and beliefs about exercise, activity, and rest were recorded before and after treatment in 60 CFS patients recruited to the trial. Physical illness attributions were widespread, did not change with treatment, and were not associated with poor outcome in either the cognitive-behavior therapy group or the control group. Beliefs about avoidance of exercise and activity changed in the cognitive behavior therapy group, but not in the control group. This change was associated with improved outcome. These findings suggest that physical illness attributions are less important in determining outcome (at least in treatment studies) than has been previously thought. In this study, good outcome is associated with change in avoidance behavior, and related beliefs, rather than causal attributions.

May 1;840:684-97	diffuse somatic symptoms. Our group has established that impaired activation of the hypothalamic-pituitary-adrenal (HPA) axis is an essential neuroendocrine feature of this condition. The relevance of this finding to the pathophysiology of CFS is supported by the observation that the onset and course of this illness is excerbated by physical and emotional stressors. It is also notable that this HPA dysregulation differs from that seen in melancholic depression, but shares features with other clinical syndromes (e.g., fibromyalgia). How the HPA axis dysfunction develops is unclear, though recent work suggests disturbances in serotonergic neurotransmission and alterations in the activity of AVP, an important co-secretagogue that, along with CRH, influences HPA axis function. In order to provide a more refined view of the nature of the HPA dusturbance in patients with CFS, we have studied the detailed, pulsatile characteristics of the HPA axis in a group of patients meeting the 1994 CDC case criteria for CFS. Results of that work are consistent with the view that patients with CFS have a reduction of HPA axis activity due, in part, to impaired central nervous system drive. These observations provide an important clue to the development of more effective treatment to this disabling condition.
Demitrack MA.	Lilly Research Laboratories, Indianapolis, Indiana, USA.	Chronic fatigue syndrome and fibromyalgia. Dilemmas in diagnosis and clinical management.	Psychiatr Clin North Am 1998 Sep;21(3):671-92, viii	There has been a resurgence of interest in recent years in both chronic fatigue syndrome and fibromyalgia. These perplexing and common clinical conditions are a source of significant patient morbidity and frame one of the more enduring dilemmas of contemporary Western medical thought, namely the ambiguous interface between mind and body. In this article, the current definitions are reviewed, and a framework for an emerging psychobiological model of these syndromes is presented. These issues are synthesized into a pragmatic approach to clinical management. Review, Academic

Duprez DA, De Buyzere ML, Drieghe B, Vanhaverbeke F, Taes Y, Michielsen W,	Department of Cardiology and Angiology, University Hospital, Gent,	Long- and short-term blood pressure and RR-interval variability and psychosomatic distress	Clin Sci (Colch) 1998 Jan;94(1):57-63Comment in: Clin Sci (Colch). 1999	1. Chronic low blood pressure has been associated with fatigue and low mood. However, in the chronic fatigue syndrome (CFS) the blood pressure (BP) and heart rate profile and their variabilities have not been characterized as yet. 2. We performed office and 24 h ambulatory BP recordings in 38 subjects (age, 34.8 8.0

Clement DL.	Belgium.	in chronic fatigue syndrome.	Sep;97(3):319-22	years) who fulfilled the Holmes criteria for CFS and in 38 healthy control subjects (age 35.6 10.5 years), as well as short-term beat-to-beat BP and RR-interval recordings for 10 min in supine and standing position, and calculated spectral indices. 3. In CFS office (123 19/70 12 mmHg) as well as 24-h, day- and night-time blood pressure values (116 11.1/71 11.1, 121 9.2/77 8.0 and 110 10.5/65 9.2 mmHg respectively) were within reference limits. 4. Heart rate was consistently higher ($P < 0.01$) in CFS patients, based on both office (77 12 compared with 68 12 beats min-1) and 24 h ambulatory recordings (77 12 compared with 67 15 beats min-1). 5. In supine position, spectral indices of BP variability (total, low-frequency and high-frequency variances) were all significantly ($P < 0.01$) lower in CFS. In standing position the differences disappeared. Analysis of RR-interval variability could not detect major alterations in autonomic function in CFS.
Dykman KD, Tone C, Ford C, Dykman RA.	Mannatech Inc., Coppell Texas 75019, USA.	The effects of nutritional supplements on the symptoms of fibromyalgia and chronic fatigue syndrome.	Integr Physiol Behav Sci 1998 Jan-Mar;33(1):61-71	This article reports the results of a within-subject design. Fifty subjects with a physician diagnosis of fibromyalgia (FM) and/or chronic fatigue syndrome (CFS) were interviewed using a structured interview from. Each subject was interviewed initially, and again nine months later (follow-up). Subjects had, on their own, consumed nutritional supplements including freeze-dried aloe vera gel extract; a combination of freeze-dried aloe vera gel extract and additional plant-derived saccharides; freeze-dried fruits and vegetables in combination with the saccharides; and a formulation of dioscorea complex containing the saccharides and a vitamin/mineral complex. With medical treatments, approximately 25 percent of FM patients improve, but the beneficial effects of medical treatment rarely persist more than a few months. All subjects in this study had received some form of medical treatment prior to taking the nutritional supplements, but none with enduring success. Nutritional supplements resulted in a remarkable reduction in initial symptom severity, with continued improvement in the period between initial assessment and the follow-up. Further research is needed to verify these results, specifically crossover designs in well-defined populations.
Empson M.		Celiac disease or chronic fatigue syndrome--can the current CDC working case definition discriminate?	Am J Med 1998 Jul;105(1):79-80	
Endicott NA		Chronic Fatigue Syndrome in Psychiatric Patients: Evidence of Premorbid Anomalous Patterns of Brain Organization	Journal of Chronic Fatigue Syndrome 1998: 5(1): 29 - 45	Forty-six patients with chronic fatigue syndrome (CFS) were matched with two control groups: one chosen on the basis of relatively good physical health (N = 92) and the other without regard to physical health (N = 46). All patients were from the same psychiatric practice. The groups were compared on 20 anomalous brain conditions or phenomena (ABCP) used as markers of patterns of brain organization. The results suggest that psychiatric patients who subsequently develop CFS have a

				higher number of pre-CFS ABCP, of both childhood and adult onset, than psychiatric patients who have not developed this condition
Endicott NA.	Department of Research Assessment and Training, New York State Psychiatric Institute, New York, USA.	Chronic fatigue syndrome in psychiatric patients: lifetime and premorbid personal history of physical health.	Psychosom Med 1998 Nov-Dec;60(6):744-51	OBJECTIVE: This preliminary report compares a group of chronic fatigue syndrome (CFS) patients and controls on several variables of potential significance in the etiology of CFS. METHOD: The lifetime prevalence of reported physical disorders was compared among 46 CFS psychiatric patients, 92 relatively physically healthy psychiatric patients (C-I), and 46 psychiatric patients selected without regard to physical health (C-II). All patients were matched on age, sex, and psychiatric diagnosis and were drawn from the same psychiatric practice. The same groups were compared on a 7-point scale of lifetime physical health by three raters independently evaluating physical health narratives of the CFS patients up to the time of onset of CFS and that of the controls up to the corresponding age. RESULTS: The CFS patients had a significantly higher reported lifetime prevalence of irritable bowel syndrome (IBS), infectious mononucleosis-like syndromes (IM), infectious mononucleosis-like syndromes two or more times (IM x 2), and herpes (other than genital or perioral herpes) than one or both control groups. The CFS group also had a higher incidence of allergic rhinitis or asthma, IBS, IM, and IM x 2 than the combined controls. On the independent ratings, the CFS patients had significantly more impaired physical health up to the time of onset of the CFS than C-I at a comparable age. CONCLUSIONS: The findings suggest that a general health factor may be involved in the pathogenesis of some cases of CFS.
Essame CS, Sue Phelan, Percy Aggett Peter D. White		Pilot Study of a Multidisciplinary Inpatient Rehabilitation of Severely Incapacitated Patients with the Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 4(2): 51 - 60	The outcome of severely incapacitated patients with the chronic fatigue syndrome is poor. We examined the outcome of the first 19 such patients admitted to a psychiatric ward in a general hospital for a multidisciplinary rehabilitation programme. Seventeen (89%) patients had functionally improved by discharge, the median Karnofsky score improvement being 15 points in all 19 patients. All fourteen patients who were followed up had maintained or exceeded their improvement by one year, with a median Karnofsky score improvement of 25 in all 16 followed up patients, compared to admission. Only two patients had not improved by discharge and they were the same or worse at one year. A randomised controlled trial is necessary to confirm the efficacy and acceptability of this form of rehabilitation.
Evengard B, Nilsson CG, Lindh G, Lindquist L, Eneroth P, Fredrikson S, Terenius L, Henriksson KG.	Department of Infectious Diseases, Karolinska Institute at Huddinge Hospital, Stockholm, Sweden.	Chronic fatigue syndrome differs from fibromyalgia. No evidence for elevated substance P levels in cerebrospinal fluid of patients with chronic fatigue syndrome.	Pain 1998 Nov;78(2):153-5	Levels of substance P were determined in the cerebrospinal fluid (CSF) in 15 patients with chronic fatigue syndrome (CFS). All values were within normal range. This is in contrast to fibromyalgia (FM). The majority of patients with FM have increased substance P values in the CSF. The results support the notion that FM and CFS are different disorders in spite of overlapping symptomatology.
Findley JC, Kerns R,	V.A. Connecticut	Self-efficacy as a	J Behav Med 1998	Chronic fatigue syndrome (CFS) is characterized by debilitating fatigue and a variety

Weinberg LD, Rosenberg R.	Healthcare System, West Haven 06516, USA.	psychological moderator of chronic fatigue syndrome.	Aug;21(4):351-62	of somatic symptoms. Few studies have examined psychological aspects of CFS. In the present study, self-efficacy is shown to be a significant predictor of CFS symptoms beyond the variance accounted for by demographic variables and distress. Further psychological CFS research is encouraged by (1) identifying dimensions that are salient in the experience and study of CFS, (2) providing preliminary psychometric data for measures of those dimensions, and (3) identifying psychological variables that serve as moderators of the experience of CFS.
Fischler B, Patrick Flamen Hendrik Everaert Axel Bossuyt Kenny De Meirleir		Physiopathological Significance of 99mTc HMPAO SPECT Scan Anomalies in Chronic Fatigue Syndrome A Replication Study	Journal of Chronic Fatigue Syndrome 1998: 4(4): 15 - 30	Regional cerebral blood flow as measured by 99mTc HMPAO SPECT imaging was compared between chronic fatigue syndrome (CFS) and healthy controls (HC). Larger right(R) > left(L) asymmetry at the parietotemporal level in CFS as compared to HC was observed in accordance with several previous studies. On the contrary, in most regions of interest, hypoperfusion was not confirmed in CFS, and hyperperfusion was demonstrated in several frontal and temporal regions. No significant correlations were found between frontal tracer uptake and R-L parietotemporal asymmetry, on the one hand, and clinically relevant CFS dimensions, on the other.

Fuller NS, Morrison RE.	Division of General Internal Medicine, University of Tennessee, College of Medicine, Memphis 38103, USA.	Chronic fatigue syndrome. Helping patients cope with this enigmatic illness.	Postgrad Med 1998 Jan;103(1):175-6, 179-84	Chronic fatigue syndrome is a recurring, debilitating illness complicated by the fact that its diagnosis is largely based on subjective complaints and the absence of reproducibly reliable tests. There is no known "cure" for this illness; however, in general, the prognosis for patients is good. Some physicians accept the existence of chronic fatigue syndrome, while others are convinced that it exists only in the minds of its "victims." The majority of physicians, however, are skeptical but open-minded and wish to help their chronically fatigued patients. As more information comes to light, it is likely that modern medicine will have to rethink its views on this elusive illness. In the interim, patients with chronic fatigue syndrome need the support and reassurance of their physicians to help them cope with their symptoms and resume normal, productive lives.
Garcia-Borreguero D, Dale JK, Rosenthal NE, Chiara A, O'Fallon A, Bartko JJ, Straus SE.	Clinical Psychobiology Branch, National Institute of Mental Health, Bethesda, MD 20892, USA.	Lack of seasonal variation of symptoms in patients with chronic fatigue syndrome.	Psychiatry Res 1998 Feb 9;77(2):71-7	Several of the symptoms involved in chronic fatigue syndrome (CFS) such as fatigue, hypersomnia, hyperphagia, weight gain, and mood show seasonal variations in the general population. The aim of this study was to investigate whether patients with CFS experience seasonal fluctuations in these symptoms as well. Seasonal variation of symptoms was assessed in a group of 41 patients with CFS and 41 controls closely matched for age, gender, and city of residence. Participants were recruited across the US and were asked to complete the Seasonal Pattern Assessment Questionnaire (SPAQ) and the Profile of Mood States (POMS). CFS patients showed significantly lower scores on multiple SPAQ-derived measures as compared with controls. These included seasonal variation in energy, mood, appetite, weight, and sleep length. Patients also reported a significantly reduced sensitivity toward sunny, dry, and long days than controls. No association was noted between intensity of seasonal changes

				and severity of depressive symptoms. Patients with CFS exhibit an abnormally reduced seasonal variation in mood and behavior and would not be expected to benefit from light therapy.
Gibbons, Pheby , C. Richards , F. I. Bray		Severe CFS/ME of Juvenile Onset- A Report from the CHROME Database	Journal of Chronic Fatigue Syndrome 1998: 4(4): 67 - 80	CHROME has been collecting data since 1995 on very severely disabled patients in the UK with ME, in order to assess aspects of physical and cognitive levels of disability at the onset of the illness and to monitor progress. Results of the first two years data (225 cases) collection are reported. The modal age of onset for this severe group of patients was 11-15, and the proportion increased with more recent years of onset. Patients tended to deteriorate between onset and recruitment in cognitive and functional ability, and in sensory and sleep disturbance. Statistical significance was assessed using McNemar's Test for comparing correlated proportions.
Gimenez HB, P. Cash, R. B. S. Laing, J. G. Douglas		Cytokine Expression and Morphology of in vitro Grown Monocytes from Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 5(1): 47 - 60	Although the underlying metabolic cause of chronic fatigue syndrome (CFS) is unknown, specific defects have been proposed to exist in the skeletal muscle, the immune system and the neuroendocrine system. Peripheral blood mononuclear cells from CFS patients and healthy controls were fractionated as adherent cells (monocyte-enriched fraction) and non-adherent cells. We have investigated some activities of the former during in vitro culture. It was observed that the morphology (shape and size) of adherent cells from CFS patients, cocultivated with homologous non-adherent cells, differed between CFS patients and healthy controls for 21 out of 25 (84%) paired samples (i.e., CFS patient and healthy control). Cytokine expression was examined for the adherent cell population collected from 14 CFS patients and 12 healthy controls. Unstimulated and LPS stimulated tumour necrosis factor-α (TNFα) expression was higher for monocytes from 7 out of 14 CFS patients. Unstimulated interleukin-1β (IL-1β) expression was higher for monocytes from 10 out of 14 CFS patients, whereas LPS-stimulated IL-1β expression was higher for 8 out of 14 CFS patients. The proportional increase of IL-1β and TNFα following LPS stimulation was lower for the majority of the CFS patients studied, suggesting that the monocytes from CFS patients were less responsive to LPS than the respective healthy controls. The basis for the abnormal in vitro monocyte maturation, the elevated unstimulated levels of IL-1β expression and the abnormal response of the monocytes to LPS is unknown. The relevance of these findings to CFS pathogenesis is discussed
Glaser R, Kiecolt-Glaser JK.	Department of Medical Microbiology and Immunology, Comprehensive Cancer Center, The Ohio State University College of Medicine, Columbus 43210, USA.	Stress-associated immune modulation: relevance to viral infections and chronic fatigue syndrome.	Am J Med 1998 Sep 28;105(3A):35S-42S	The frequent association of an active viral infection with the symptoms of CFS led researchers to hypothesize that chronic fatigue syndrome (CFS) is induced by a virus. Results of these studies indicated that despite clinical support for this hypothesis, there were no clear data linking viruses to CFS. In this overview, we will explore the interrelation of the immune, endocrine, and central nervous systems, and the possibility that stress and/or the reactivation/replication of a latent virus (such as Epstein Barr virus) could modulate the immune system to induce CFS. Relevant research conducted in the developing field of psychoneuroimmunology will be reviewed, with a particular focus on cytokine synthesis, natural killer (NK) cell

				activity, and T-lymphocyte function, as they relate to CFS.
Goshorn RK.	Department of Internal Medicine, Indiana University Hospital, Indianapolis, USA.	Chronic fatigue syndrome: a review for clinicians.	Semin Neurol 1998;18(2):237-42	Syndromes characterized by persistent fatigue, musculoskeletal pain, sleep disturbance, and subjective cognitive impairment have been common problems in clinical practice for decades. The chronic fatigue syndrome case definition was created to standardize the patient population in research studies and to foster a systematic and comprehensive approach to the attempt to define the etiology and pathophysiology of these syndromes. The pathogenesis of chronic fatigue syndrome remains unknown, though it does appear to be associated with subtle neuroendocrine and immunologic abnormalities. Treatment of chronic fatigue syndrome is empirical. Significant palliation is often possible, though treatment success requires skillful practice of the art of medicine.
Hall GH, Hamilton WT, Round AP.		Increased illness experience preceding chronic fatigue syndrome.	J R Coll Physicians Lond 1998 Jul-Aug;32(4):389 Comment on: J R Coll Physicians Lond. 1998 May-Jun;32(3):274	
Hall GH, Hamilton WT, Round AP.		Increased illness experience preceding chronic fatigue syndrome: a case control study.	J R Coll Physicians Lond 1998 Jan-Feb;32(1):44-8Comment in: J R Coll Physicians Lond. 1998 May-Jun;32(3):274	BACKGROUND: Almost all published work on chronic fatigue syndrome (CFS) has involved retrospective surveys of cases, which may introduce recall bias. Only medical records collected before diagnosis of CFS can eliminate this. METHODS: Using data collected several years prior to the development of the illness, we performed a case control study, comparing the reported illness records of all people who subsequently made an insurance claim as a result of CFS, with those of future multiple sclerosis (MS) claimants, and those of non-claimant controls (NC). RESULTS: The study encompassed 133 CFS, 75 MS and 162 NC cases. CFS cases had recorded significantly more illnesses at time of proposal for insurance than the two control groups, and had significantly more claims between proposal and diagnosis of their disorder. Almost all disease categories were reported higher in future CFS sufferers, lethargy having the highest odds ratio after adjustment in a multivariate model. INTERPRETATION: The results of this paper on CFS patients who claim permanent health insurance do not support a specific viral or immunological explanation for CFS. We conclude that abnormal illness behaviour is of greater importance than previously recognised.
Hamilos DL, Nutter D, Gershtenson J, Redmond DP, Clementi JD, Schmaling KB, Make BJ, Jones JF.	National Jewish Center for Immunology and Respiratory Medicine, Denver, Colorado, USA.	Core body temperature is normal in chronic fatigue syndrome.	Biol Psychiatry 1998 Feb 15;43(4):293-302	BACKGROUND: Subjects with chronic fatigue syndrome (CFS) frequently report symptoms of subnormal body temperature and low-grade fever. We conducted a study to determine whether CFS subjects manifest any abnormality of core body temperature (CBT) that might help explain their fatigue. METHODS: Continuous 24-hour recordings of CBT measured every 5 min were performed in 7 subjects meeting the Centers for Disease Control definition of CFS. Three additional groups were studied: normal controls, subjects with seasonal allergy, and subjects with major depression. Subjects (n = 7) in each group were age-, sex-, and weight-matched to

				the CFS group and had normal basal metabolic rates, thyroid function, and 24-hour urinary free cortisol excretions. CBT was measured with an ingestible radio frequency transmitter pill and a belt-worn receiver-logger. Each pill was factory-calibrated to 0.1 degree C and field-calibrated with a water bath calibration prior to use. RESULTS: The 24-hour mean calibration-adjusted CBTs of each group were not significantly different (control: 37.00 0.17 degrees C; CFS: 37.04 0.31 degrees C; allergy: 37.15 0.18 degrees C; depression: 37.16 0.18 degrees C). Similarly, the mean peak and trough circadian temperatures were not statistically different. The mean 24-hour profile of CBT for each group showed a similar circadian rhythm. In simultaneously collected blood samples, each group showed a similar circadian profile of serum cortisol with a peak occurring at 08:00. CONCLUSIONS: Subjects with CFS have normal CBT despite frequent self-reports of subnormal body temperature and low-grade fever.
Harlow BL, Signorello LB, Hall JE, Dailey C, Komaroff AL.	Obstetrics and Gynecology Epidemiology Center, Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts 02115, USA.	Reproductive correlates of chronic fatigue syndrome.	Am J Med 1998 Sep 28;105(3A):94S-99S	A case-control study was conducted to determine whether menstrual and gynecologic abnormalities precede the onset of chronic fatigue syndrome (CFS) in women with this disorder to a greater extent than that observed among healthy controls. We identified 150 women who met the 1988 Centers for Disease Control criteria for CFS from the Brigham and Women's Hospital Cooperative CFS Research Center. A comparison group of 149 women being seen for nongynecologic conditions were selected from the waiting area of the Brigham and Women's Hospital Internal Medicine outpatient department. Women with and without CFS completed self-administered questionnaires on menstrual, reproductive, and medical history. Women with CFS reported increased gynecologic complications and a lower incidence of premenstrual symptomatology. After adjustment for age, a somewhat greater number of cases compared with controls self-reported irregular cycles, periods of amenorrhea, and sporadic bleeding between menstrual periods. Factors suggestive of abnormal ovarian function--such as a history of polycystic ovarian syndrome, hirsutism, and ovarian cysts--were reported more often in CFS cases compared with controls. Frequent anovulatory cycles due to ovarian hyperandrogenism (PCOS) or hyperprolactinemia may increase risk for CFS through loss of the potential immunomodulatory effects of progesterone in the presence of continued estrogen production. We hypothesize that frequent anovulatory cycles due to PCOS and/or hyperprolactinemia may explain the increased reporting of gynecologic complications and the lower reported premenstrual symptomatology observed in women with CFS.
Harrigan P.		Controversy continues over chronic fatigue syndrome.	Lancet 1998 Feb 21;351(9102):574Comment in: Lancet. 1998 Apr 25;351(9111):1292	
Hartz AJ, Evelyn M.		Characteristics of	Journal of Chronic	Background: Characteristics of persons with chronic fatigue syndrome (CFS) have

Kuhn , Paul H. Levine		Fatigued Persons Associated with Features of Chronic Fatigue Syndrome	Fatigue Syndrome 1998: 4(3): 71 - 97	previously been studied by comparing subjects with CFS to subjects with other conditions or no symptoms of fatigue. In the present study of subjects with idiopathic chronic fatigue we examined the association between the number and severity of the features of CFS with other characteristics of the subjects. Methods: Data were obtained from a registry of persons over the age of 17 with fatigue for at least six months. All subjects in the registry completed an extensive questionnaire that provided information about fatigue, demographic characteristics, medical conditions, life style, sleeping habits, and psychological characteristics. The characteristics of the subjects were tested for an association with the number of CFS symptoms and the severity of individual CPS symptoms that are considered to be of fundamental importance and may identify more homogeneous subjects with chronic fatigue. Results: The number of CFS symptoms had a bell shaped distribution. This number was strongly associated with the severity of fatigue, the response of fatigue to mental and physical activity, and the following subject characteristics: a greater frequency of sinus and respiratory infections, a higher frequency of migraine headaches, a greater number of somatoform symptoms that were not included as criteria for CFS, and not drinking alcohol. These same subject characteristics were generally associated with at least one of the individual CFS symptoms but more weakly. Psychological complaints only had a statistically significant positive association with one feature of CFS, neurocognitive complaints. Conclusions: Persons with fatigue can be usefully characterized by the extent to which they meet the CFS criteria.
Hassan IS, Bannister BA, Akbar A, Weir W, Bofill M.	Department of Infectious & Tropical Diseases, Royal Free Hospital, London, England.	A study of the immunology of the chronic fatigue syndrome: correlation of immunologic parameters to health dysfunction.	Clin Immunol Immunopathol 1998 Apr;87(1):60-7	Surface and intracellular immunologic and apoptotic markers and functional lymphocyte assays after stimulation with anti-CD3/anti-CD28 antibodies or phytohemagglutinin (PHA) were studied in 44 patients fulfilling the Oxford criteria for chronic fatigue syndrome (CFS). Results were then correlated to scores for the Short Form-36 health questionnaire (SF-36), which assesses eight aspects of patient's well-being, and for the general health questionnaire (GHQ), which detects current psychiatric disorder. Patients had significantly increased mean fluorescence intensity readings of HLA-DR in CD4 and CD8 cells ($P < 0.05$). Expression of the costimulatory receptor CD28 in CD8 cells was significantly reduced, and the apoptosis repressor ratio of bcl-2/bax in both CD4 and CD8 was increased in patients ($P < 0.05$). Patients with increased HLA-DR expression had significantly lower SF-36 total scores, worse body pains, and poorer general health perception and physical functioning scores. Increased spontaneous lymphocyte proliferation was associated with poor general health perception. PHA proliferative responses were lower in patients with poor emotional and mental health scores, and the anti-CD3/anti-CD28 response was low in those with low general health perception scores. Higher spontaneous proliferation and reduced PHA responses correlated with higher GHQ scores. Similarly, GHQ scores were significantly higher, indicating worse mental health, in those with lower total

				SF-36 scores and worse general and mental health scores in the SF-36 questionnaire. Finally, higher expression of the costimulatory molecule CD28 correlated with higher total SF-36 scores, general health perception and social functioning scores, and with lower role limitation due to physical health. The increased expression of class II antigens and the reduced expression of the costimulatory receptor CD28, which is a marker of terminally differentiated cells, lend further support to the concept of immunoactivation of T-lymphocytes in CFS and may be consistent with the notion of a viral etiopathogenesis in the illness. We report, for the first time, increased expression of the apoptosis repressor protein bcl-2, which may contribute to enhanced survival of activated lymphocytes. Using the SF-36 health assessment questionnaire and the GHQ, we demonstrated changes in different immunological parameters, each of which correlated with particular aspects of disease symptomatology.
Heijmans M, de Ridder D.	Department of Health Psychology, Utrecht University, The Netherlands.	Assessing illness representations of chronic illness: explorations of their disease-specific nature.	J Behav Med 1998 Oct;21(5):485-503	Elaborating on the five-dimensional structure of illness representation, as described in the self-regulation model of Leventhal (1980), the present study is aimed at identifying the relevance of this generic structure for two chronic illnesses: chronic fatigue syndrome (CFS) and Addison's disease (AD). Factor analyses showed the importance of the five dimensions identity, time-line, control/cure, cause, and consequences to differ according to the type of disease. That is, the items representing the five dimensions merged together for CFS patients and AD patients in a different manner and thereby produced different factor solutions for the two patient groups. In CFS patients, a four-factor solution was identified with manageability, seriousness, personal responsibility, and external cause as the factors. In AD patients a four-factor solution was also identified but with seriousness, cause, chronicity, and controllability as the factors. The value of these findings for our understanding of the disease-specific nature of illness representation is discussed.
Heijmans MJ.	Department of Clinical and Health Psychology, Utrecht University, The Netherlands. M.Heijmans@fsw.ruu.nl	Coping and adaptive outcome in chronic fatigue syndrome: importance of illness cognitions.	J Psychosom Res 1998 Jul;45(1 Spec No):39-51	In this study, the relations between illness representations, coping behavior, and adaptive outcomes in chronic fatigue syndrome (CFS) patients (N=98) were examined. Following Leventhal's self-regulation model, it was hypothesized that illness representations would be directly related to coping and, via coping, to adaptive outcome. The results showed patients who considered their illness to be a serious condition, who believed that they had no control over their illness, who saw little possibility for cure, and who believed their illness to have serious consequences to cope with their illness in a passive way, report higher levels of impairment in physical and social functioning and report greater problems in mental health and vitality. A series of regression analyses showed illness representations to be stronger predictors of adaptive outcome than coping scores. The implications of these findings for the treatment of CFS patients are discussed.
Heller U, Becker EW, Zenner HP, Berg PA.	HNO-Klinik, Universitat Tubingen.	[Incidence and clinical relevance of antibodies	HNO 1998 Jun;46(6):583-	Immunoserological assays of patients with sudden deafness and progressive hearing losses have revealed the presence of different antibodies, leading to the assumption

		to phospholipids, serotonin and ganglioside in patients with sudden deafness and progressive inner ear hearing loss].[article in German]	6Comment in: HNO. 1998 Jun;46(6):565-6	that immunological processes may be involved. Recent investigations have demonstrated that these patients have phospholipid antibodies that can cause venous or arterial vasculopathies. In the present study we analyzed the incidence of these antibodies in patients with inner ear disorders. Sera of 55 patients with sudden deafness and 80 patients with progressive hearing loss were tested. Phospholipid antibodies were demonstrable in 49% of the patients with sudden hearing loss and 50% of the patients with progressive hearing loss. Serotonin and ganglioside antibodies were found in 53% of the patients with sudden hearing loss and 63% of the patients with progressive hearing loss. Since these three antibodies are also frequently found in patients with fibromyalgia syndrome (FMS) and chronic fatigue syndrome (CFS), 28 of the patients studied displayed symptoms typical for these disorders, including fatigue, myalgia, arthralgia, depressions, sicca symptoms and diarrhea. We now recommend questioning patients suffering from inner ear disorders for symptoms typical for FMS or CFS, since these diseases are often closely related to inner ear disorders. If symptoms are present, antibodies should be tested against phospholipids, serotonin and gangliosides. If present, the antibodies are diagnostic for each syndrome. Additionally these immunologic and serologic findings show that these antibodies may play a role in the etiology of hearing loss disorders.
Hicks MH, Kleinman A, Yang L.	Department of Social Medicine, Harvard Medical School, Boston, USA.	The social course of schizophrenia: local and societal factors.	Kaohsiung J Med Sci 1998 Jul;14(7):432-47	In this paper, we propose a model of social course of schizophrenia based on cross-cultural research on the influence of family, wider social network, work, political economy, and legal and mental health care institutions on the experience of illness. We posit the way these ordinary arrangements of daily living organize the course of schizophrenia in part through cultural processes that affect the body-self in suffering and in part through social processes that establish an intersubjective matrix for the experience of illness. We believe this model can be generalized to other chronic illness such as depression, diabetes, asthma, osteoarthritis, chronic pain syndrome, chronic fatigue syndrome, and even heart disease and cancer. We develop the implications of this anthropological approach for research and practice.
Hilgers A, Johannes Frank, Petra Bolte		Prolongation of Central Motor Conduction Time in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 4(2): 23 - 32	We compared the central motor conduction time (CMCT) obtained by magnetic stimulation of the central nervous system (CNS) of 181 patients who filfilled the criteria (see Fukuda 1994) for CFS with those of 27 healthy control subjects. A cortical and a cervical stimulation was performed on each person under standardised conditions, and the motor evoked potentials (MEP) either from Musculus Abductor Pollicis Brevis (M. APB) or from Musculus Abductor Digiti Minimi (M. ADM) was recorded. For the CFS patients a significant prolongation of the central motor conduction time (M. APB right: $p < 0.0001$; M. ADP left: $p < 0.00005$; M. ADM right: $p < 0.00005$; M. ADM left: $p < 0.005$) was observed compared to controls. The results presented in this study suggest a central nervous system dysfunction in CFS.
Hyman H, Thomas E. Wasser		Gastrointestinal Manifestations of	Journal of Chronic Fatigue Syndrome	Objectives: This study examines the differences in symptoms and Quality of Life (QOL) among patients presenting to a gastrointestinal (GI) service with combinations

		Chronic Fatigue Syndrome (CFS) Symptom Perceptions and Quality of Life	1998: 4(1): 43 - 52	of chronic fatigue syndrome (CFS) and GI complaints. Methods: We conducted a clinical examination of patients from a private GI practice and divided them into three groups: A combination group consisting of patients diagnosed with both CFS and functional bowel disease (FBD) (Group 1, n = 5); those positively diagnosed with CFS, who also reported GI symptoms, but without a prior GI diagnosis (Group 2, n = 6); and those with FBD, but without a diagnosis of CFS (Group 3, n = 11). These groups were prospectively surveyed, using the Medical Outcomes Study Short Form-36 (SF-36) and the Symptom Index Survey (SIS). Results: Data indicate CFS patients report more symptoms than non-CFS patients, as measured by the SIS, in these areas: Allergies, Digestive Tract, Ears, Eyes, Head, Immune, Joints/Muscles and Metabolism/Endocrine. SF-36 data indicated lower QOL for CFS patients compared to FBD alone (Group 3) patients in the General Health and Energy/Fatigue subscales. Conclusions: CFS patients with GI complaints demonstrate a significant relationship between both diagnoses. Since the observed differences occur between Groups 1 and 3, both with GI diagnoses, this indicates that these differences are a result of the presence or absence of CFS. Also, since these differences occur between CFS/ FBD and FBD-only, the classification of irritable bowel syndrome (IBS) should be modified to include a subset of patients who have a combination of CFS and IBS.
Jain SS, DeLisa JA.	Department of Physical Medicine and Rehabilitation, UMDNJ-New Jersey Medical School, Newark, USA.	Chronic fatigue syndrome: a literature review from a physiatric perspective.	Am J Phys Med Rehabil 1998 Mar-Apr;77(2):160-7	To examine the literature on chronic fatigue syndrome (CFS), especially as it relates to cognitive deficits and exercise, more than 200 articles related to CFS were selected from computer-based research as well as pertinent articles noted in the references of individual articles. All were relevant articles on CFS, although articles in a foreign language were excluded. CFS is a controversial diagnosis of exclusion, but certain subgroups do appear to exist. It may represent multiple diseases or multiple stages of the same disease. Although cognitive deficits are commonly reported, the measured impairments are relatively subtle and are in the area of complex information processing speed, or efficiency. Magnetic resonance imaging, single-photon emission computer tomography, and neuroendocrine studies present preliminary evidence suggestive of the cerebral involvement primarily in the white matter. The weakness and fatigue may be the result of alterations in the central nervous system, not in the peripheral muscles. However, it is hard to separate the documented weakness and endurance deficits from deconditioning. Autonomic symptoms such as orthostatic intolerance and a predisposition to neurally mediated syncope may be explained by cardiovascular deconditioning, a postviral idiopathic autonomic neuropathy, or both. The review points out the need for more carefully designed studies of CFS that focus on the relationship between neuropathology, psychopathology and neuropsychologic functioning. The role of exercise as a stimulus for exacerbation or in treatment needs to be further studied using clear diagnostic criteria as well as control groups that carefully match the activity level.
Jason LA, Wagner L,	Department of	Estimating the	Am J Med 1998 Sep	The present study assessed the prevalence of chronic fatigue syndrome (CFS) in a

Rosenthal S, Goodlatte J, Lipkin D, Papernik M, Plioplys S, Plioplys AV.	Psychology, DePaul University, Northwestern Medical School, Rush Presbyterian--St. Luke's Medical Center, Chicago, Illinois 60614, USA.	prevalence of chronic fatigue syndrome among nurses.	28;105(3A):91S-93S	sample of nurses. There is a paucity of studies on the prevalence of CFS in healthcare professionals. Two samples of nurses were recruited through mailed questionnaires. Data were collected on demographic characteristics and symptoms. In addition from the sample, those nurses with CFS-like symptoms were more comprehensively evaluated using a structured clinical interview and reviewing their medical records. A physician review team estimated the prevalence of CFS to be 1,088 per 100,000. These findings suggest that nurses might represent a high-risk group for this illness, possibly due to occupational stressors such as exposure to viruses in the work setting, stressful shift work that is disruptive to biologic rhythms, or to other possible stressors in the work settings (e.g., accidents).
Jiaxu C, Yang Weiyi		Treatment of Chronic Fatigue Syndrome with Chinese Medicine	Journal of Chronic Fatigue Syndrome 1998: 5(1): 61 - 65	Chronic fatigue syndrome (CFS) is a severe, debilitating disorder, which prominently features self-reported impairments in concentration and short-term memory, and disturbances in sleep and emotions, all of which can affect any one and seriously affect quality of life. In 1987, the Centers for Disease Control and Prevention (CDC) defined CFS as persistent or relapsing fatigue, with at least 50% reduction of baseline activity level lasting for at least 6 months, as one of the main symptoms. Since its cause is still unknown, treatment of CFS has been palliative and has included usually orally administered products, such as vitamin B12, vitamin C, folic acid, iron, magnesium, essential fatty acids, coenzyme Q10 and nicotinamide adenine dinucleotide (NADH), among others. The latter therapeutic modalities can only relieve some symptoms to some extent, but cannot fundamentally eliminate fatigue. It is, therefore, urgent to seek safe and effective drugs for the treatment of fatigue. We propose here that regulating homeostasis and enhancing immunity are important for the treatment of fatigue. In China, many Chinese herbs with such functions have been proven effective, an observation which opens the possibility of a new therapeutic method of eliminating fatigue with traditional Chinese medicine (TCM).

Joyce J, Rabe-Hesketh S, Wessely S.	Institute of Psychiatry, King's College School of	Reviewing the reviews: the example of chronic	JAMA 1998 Jul 15;280(3):264-6	OBJECTIVE: To test the hypothesis that the selection of literature in review articles is unsystematic and is influenced by the authors' discipline and country of residence.

	Medicine, London, England.	fatigue syndrome.		DATA SOURCES: Reviews in English published between 1980 and March 1996 in MEDLINE, EMBASE (BIDS), PSYCHLIT, and Current Contents were searched. STUDY SELECTION: Reviews of chronic fatigue syndrome (CFS) were selected. Articles explicitly concerned with a specialty aspect of CFS and unattributed, unreferenced, or insufficiently referenced articles were discarded. DATA EXTRACTION: Record of data sources in each review was noted as was the departmental specialty of the first author and his or her country of residence. The references cited in each index paper were tabulated by assigning them to 6 specialty categories, by article title, and by assigning them to 8 categories, by country of journal publication. DATA SYNTHESIS: Of 89 reviews, 3 (3.4%) reported on literature search and described search method. Authors from laboratory-based disciplines preferentially cited laboratory references, while psychiatry-based disciplines preferentially cited psychiatric literature (P = .01). A total of 71.6% of references cited by US authors were from US journals, while 54.9% of references cited by United Kingdom authors were published in United Kingdom journals (P = .001). CONCLUSION: Citation of the literature is influenced by review authors' discipline and nationality.
Kawakami N, Iwata N, Fujihara S, Kitamura T.	The Department of Public Health, Gifu University School of Medicine, Japan. norito@cc.gifu-u.ac.jp	Prevalence of chronic fatigue syndrome in a community population in Japan.	Tohoku J Exp Med 1998 Sep;186(1):33-41	In order to know the prevalence of chronic fatigue syndrome (CFS) in a community population in Japan, we analyzed data from a population-based interview survey. Two cases out of 137 respondents experienced chronic fatigue during a period of nine months, suffered from 50% or more reduction of daily activity due to fatigue and had no other physical or psychiatric diagnosis. Both of the two cases fulfilled the 1994 Centers for Disease Control (CDC) criteria and the British criteria. The point and nine-month prevalence rates of CFS were both 1.5% (95% confidence intervals, 0.4-5.2%). None fulfilled the 1989 CDC criteria for CFS. The prevalence rate of CFS was higher than those in previous studies in the Western countries, suggesting a need for future research on cross-cultural differences in the definition, prevalence and symptomatology of CFS.
Kenner C.	Department of Parent-Child Health Nursing, College of Nursing and Health University of Cincinnati, Ohio, USA.	Fibromyalgia and chronic fatigue: the holistic perspective.	Holist Nurs Pract 1998 Apr;12(3):55-63	Fibromyalgia syndrome (FMS) and chronic fatigue syndrome (CFS) are not new conditions, but they are receiving more attention as more research is conducted. These two conditions are primarily women's health problems. In some instances, there may be a genetic predisposition for these conditions. The impact of FMS and CFS can be devastating both physically and emotionally. The treatment plan must be interdisciplinary and holistic and include alternative therapies if the client and family are to be truly supported and helped in coping with these chronic conditions.

Klineberg I, McGregor N, Butt H, Dunstan H,	Faculty of Dentistry, University of Sydney.	Chronic orofacial muscle pain: a new	Alpha Omegan 1998 Jul;91(2):25-8	The initial data from this study indicate that there are clearly identifiable chronic muscle pain conditions in the form of localized pain; myofascial pain or regional pain

Roberts T, Zerbes M.		approach to diagnosis and management.		conditions; and fibromyalgia or generalized pain conditions. A clear difference exists between the prevalence of these conditions in male and female patients, with a higher percentage of female patients suffering generalized pain problems and temporomandibular problems. Generalized or localized pain appears to be an individual variant of a similar problem and pain patients may have a genetically determined vulnerability associated with bacterial toxins, particularly within the genitourinary tract. It appears that in fibromyalgia there is an underlying genetic factor that causes abnormalities in the muscle metabolic cycle, and preliminary data suggest that lipid anomalies predispose to fibromyalgia and possibly chronic fatigue syndrome. Patients report infectious events at/or around onset in more than 60 percent of cases. Seventy percent of fibromyalgic cases report orofacial pain.
Komaroff AL, Buchwald DS.	Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts 02115, USA.	Chronic fatigue syndrome: an update.	Annu Rev Med 1998;49:1-13	Among the many patients who seek medical care for the complaint of fatigue, a small number suffer from chronic fatigue syndrome (CFS). CFS is a poorly understood condition characterized by debilitating fatigue and associated symptoms lasting at least six months. Studies indicate that the illness is not simply a manifestation of an underlying psychiatric disorder, but rather is an illness characterized by activation of the immune system, various abnormalities of several hypothalamic-pituitary axes, and reactivation of certain infectious agents.
Korszun A, Papadopoulos E, Demitrack M, Engleberg C, Crofford L.	Department of Psychiatry and School of Dentistry, University of Michigan, Ann Arbor 48109-0840, USA.	The relationship between temporomandibular disorders and stress-associated syndromes.	Oral Surg Oral Med Oral Pathol Oral Radiol Endod 1998 Oct;86(4):416-20	OBJECTIVES: The purpose of this study was to determine the comorbidity of temporomandibular disorders and other stress-associated conditions in patients with chronic fatigue syndrome and fibromyalgia. STUDY DESIGN: Of 92 patients who fulfilled the criteria for chronic fatigue syndrome or fibromyalgia (or both), 39 (42%) reported a prior diagnosis of temporomandibular disorder. Further questionnaires were sent to the members of this group, and 30 patients responded. RESULTS: Of the original 92 patients, of whom 42% reported temporomandibular disorders, 46% had histories of irritable bowel syndrome, 42% of premenstrual syndrome, and 19% of interstitial cystitis. Of the patients with temporomandibular disorders, the great majority reported an onset of generalized symptoms before the onset of facial pain. Despite this, 75% had been treated exclusively for temporomandibular disorders, usually with bite splints. CONCLUSIONS: Patients appearing for treatment with chronic facial pain show a high comorbidity with other stress-associated syndromes. The clinical overlap between these conditions may reflect a shared underlying pathophysiologic basis involving dysregulation of the hypothalamic-pituitary-adrenal stress hormone axis in predisposed individuals. A multidisciplinary clinical approach to temporomandibular disorders would improve diagnosis and treatment outcomes for this group of patients.
Kuratsune H, Yamaguti K, Lindh G, Evengard B, Takahashi M, Machii T, Matsumura K, Takaishi	Hematology and Oncology, Osaka University Medical School, Suita, Osaka	Low levels of serum acylcarnitine in chronic fatigue syndrome and chronic hepatitis type	Int J Mol Med 1998 Jul;2(1):51-6	Recently, we found a serum acylcarnitine (ACR) deficiency in Japanese patients with chronic fatigue syndrome (CFS). To clarify whether this ACR abnormality is a characteristic of CFS or not, we also studied the levels of serum carnitine in Swedish subjects. Both serum ACR and free carnitine (FCR) levels in normal healthy subjects

J, Kawata S, Langstrom B, Kanakura Y, Kitani T, Watanabe Y.	565, Japan.	C, but not seen in other diseases.		were quite different between Japanese (n=131) and Swedish people (n=46) (p<0.001). However, it is confirmed that Swedish patients with CFS (n=57) also had serum ACR deficiency (p<0.001). When we studied the levels of serum ACR and FCR in Japanese patients with various kinds of diseases (CFS, hematological malignancies, chronic pancreatitis, hypertension, diabetes mellitus, chronic hepatitis type C, psychiatric diseases), a significant decrease in the levels of serum ACR was only found in patients with CFS and chronic hepatitis type C (p<0.001). Therefore, we concluded that ACR deficiency in serum might be a characteristic abnormality in only certain types of diseases.
Kuratsune H, Yamaguti K, Sawada M, Kodate S, Machii T, Kanakura Y, Kitani T.	Department of Hematology and Oncology, Osaka University Medical School, Suita city, Osaka 565, Japan.	Dehydroepiandrosterone sulfate deficiency in chronic fatigue syndrome.	Int J Mol Med 1998 Jan;1(1):143-6	The chronic fatigue syndrome (CFS) is a condition of unknown etiology, characterized by a persistent debilitating fatigue, the muscle-related symptoms and the neuropsychiatric symptoms. Recently, it has been reported that the patients with CFS might have impaired activation of the hypothalamic-pituitary-adrenal axis, and suggested that a part of the patho-genesis of CFS might be associated with abnormalities of the endocrine system. Herein, we show that the majority of Japanese patients with CFS had a serum dehydroepiandrosterone sulfate (DHEA-S) deficiency. Serum DHEA-S is one of the most abundantly produced hormones which is secreted from the adrenal glands, and its physiological function is thought to be a precursor of sex steroids. DHEA-S has recently been shown to have physiological properties, such as neurosteroids, which are associated with such psychophysiological phenomena as memory, stress, anxiety, sleep and depression. Therefore, the deficiency of DHEA-S might be related to the neuropsychiatric symptoms in patients with CFS.
LaManca JJ, Sisto SA, DeLuca J, Johnson SK, Lange G, Pareja J, Cook S, Natelson BH.	Chronic Fatigue Syndrome Cooperative Research Center, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark, USA.	Influence of exhaustive treadmill exercise on cognitive functioning in chronic fatigue syndrome.	Am J Med 1998 Sep 28;105(3A):59S-65S	The purpose of this study was to determine the effect of exhaustive exercise on cognitive performance of patients with chronic fatigue syndrome (CFS) and sedentary healthy controls (CON). Subjects were 19 women with CFS and 20 CON. A test battery consisting of 4 cognitive tests (CTB) was given pre-, immediately post-, and 24 hours post-treadmill exercise to exhaustion. No differences were seen on the CTB pre-exercise. CFS patients improved at a slower rate than CON on the Symbol Digit Modalities Test (SDMT), Stroop Word Test (SWT), and Stroop Color Test (SCT). When compared with CON, a lower number of correct responses was seen for the CFS immediately postexercise on the SDMT (61 3 vs 66 2), SWT (137 6 vs 146 6), and SCT (99 4 vs 107 3), and 24 hours postexercise on the SDMT (64 3 vs 69 2), SWT (134 7 vs 148 5), and SCT (101 4 vs 106 3). We conclude that after physically demanding exercise, CFS subjects demonstrated impaired cognitive processing compared with healthy individuals.
Lane RJ, Barrett MC, Taylor DJ, Kemp GJ, Lodi R.	Division of Clinical Neuroscience and Psychological Medicine, Imperial	Heterogeneity in chronic fatigue syndrome: evidence from magnetic	Neuromuscul Disord 1998 May;8(3-4):204-9	It has been shown previously that some patients with chronic fatigue syndrome show an abnormal increase in plasma lactate following a short period of moderate exercise, in the sub-anaerobic threshold exercise test (SATET). This cannot be explained satisfactorily by the effects of 'inactivity' or 'deconditioning', and patients

	College School of Medicine, Charing Cross Hospital, London, UK. r.lane@cxwms.ac.uk	resonance spectroscopy of muscle.		with abnormal lactate responses to exercise (SATET) have been found to have significantly fewer Type 1 muscle fibres in quadriceps biopsies than SATET -ve patients. We performed phosphorus magnetic resonance spectroscopy on forearm muscles of 10 SATET patients, 9 SATET -ve patients and 13 sedentary volunteers. There were no differences in resting spectra between these groups but at the end of exercise, intracellular pH in the SATET patients was significantly lower than in both the SATET -ve cases and controls ($P < 0.03$), and the SATET patients also showed a significantly lower ATP synthesis rate during recovery ($P < 0.01$), indicating impaired mitochondrial oxidative phosphorylation. These observations support other evidence which indicates that chronic fatigue syndrome is a heterogeneous disorder, and confirms the view that some chronic fatigue syndrome patients have a peripheral component to their fatigue.
Lane RJ, Barrett MC, Woodrow D, Moss J, Fletcher R, Archard LC.	Division of Neuroscience and Psychological Medicine, Imperial College School of Medicine, Charing Cross Hospital, London, UK. r.lane@cxwms.ac.uk	Muscle fibre characteristics and lactate responses to exercise in chronic fatigue syndrome.	J Neurol Neurosurg Psychiatry 1998 Mar;64(3):362-7	OBJECTIVES: To examine the proportions of type 1 and type 2 muscle fibres and the degree of muscle fibre atrophy and hypertrophy in patients with chronic fatigue syndrome in relation to lactate responses to exercise, and to determine to what extent any abnormalities found might be due to inactivity. METHODS: Quadriceps needle muscle biopsies were obtained from 105 patients with chronic fatigue syndrome and the proportions of type 1 and 2 fibres and fibre atrophy and hypertrophy factors were determined from histochemical preparations, using a semiautomated image analysis system. Forty one randomly selected biopsies were also examined by electron microscopy. Lactate responses to exercise were measured in the subanaerobic threshold exercise test (SATET). RESULTS: Inactivity would be expected to result in a shift to type 2 fibre predominance and fibre atrophy, but type 1 predominance (23%) was more common than type 2 predominance (3%), and fibre atrophy was found in only 10.4% of cases. Patients with increased lactate responses to exercise did have significantly fewer type 1 muscle fibres ($p<0.043$ males, $p<0.0003$ females), but there was no evidence that this group was less active than the patients with normal lactate responses. No significant ultrastructural abnormalities were found. CONCLUSION: Muscle histometry in patients with chronic fatigue syndrome generally did not show the changes expected as a result of inactivity. However, patients with abnormal lactate responses to exercise had a significantly lower proportion of mitochondria rich type 1 muscle fibres.
Lange G, Wang S, DeLuca J, Natelson BH.	Department of Psychiatry, Chronic Fatigue Syndrome Center, University of Medicine and Dentistry-New Jersey Medical School, Newark, USA.	Neuroimaging in chronic fatigue syndrome.	Am J Med 1998 Sep 28;105(3A):50S-53S	The diagnosis of chronic fatigue syndrome (CFS) is made difficult by the absence of specific biomedical markers, and depends primarily on determining whether subjective information provided by the patient meets the clinical case definition of this syndrome. Reported cognitive difficulties and/or complaints of headache may instigate referral for brain imaging. This article will discuss the value of neuroimaging in evaluating CFS, specifically reviewing studies that (1) used static magnetic resonance imaging (MRI) to assess structural abnormalities; and (2) assessed regional cerebral blood flow (rCBF) via detection of Tc-99m hexamethylpropyl-eneamine

				oxime distribution by single-photon emission computed tomography (SPECT). Future research design considerations are explored including (1) the utilization of positron emission tomography (PET) and other emerging neuroimaging technologies; and (2) methodological concerns, i.e., the influence of psychopathology (such as depression) and neurologic disease (such as multiple sclerosis) as possible confounding factors.
Lavietes MH, Michael T. Bergen, Benjamin H. Natelson		Measurement of C02 in Chronic Fatigue Syndrome Patients	Journal of Chronic Fatigue Syndrome 1998: 4(3): 3 - 11	This study has two goals: one, to compare the resting end-tidal pCO2 (PetCO2) and heart rate (HR) of chronic fatigue syndrome patients (CFS) with controls; two, to examine the effects of a mouthpiece and noseclips upon measurements of PetC02 and HR. Patients from the CFS Center came to the University Hospital pulmonary function laboratory for one testing session. Arterial (PaCO2), PetCO2, end-nasal (PenC02) and HR were measured twice; both with and again without the subject breathing through the mouthpiece. We found that PenCO2 was greater and HR lower for both CFS and non-CFS groups when subjects were not confined by the mouthpiece. We conclude that there is no abnormality in the regulation of respiration in CFS patients. Changes in HR accompany changes in PetCO2 in this study. Most likely, both result from anxiety associated with mouthpiece breathing
Laylander JA		A Nutrient/Toxin Interaction Theory of the Etiology and Pathogenesis of Chronic Pain-Fatigue Syndromes: Part II	Journal of Chronic Fatigue Syndrome 1998: 5(1): 93 - 126	This second part of the review paper covers the evidence in favor of the theory which proposes that Chronic Fatigue Syndrome, Fibromyalgia Syndrome, and Persian Gulf Syndrome represent finitely variable combinations of multiple systemic dysfunctions which share a common underlying etiology at the subcellular level: magnesium deficiency plus concomitant fluoride excess (MDFE). Treatment suggestions are listed at the end of the manuscript through a call for clinical trials to test the theory presented
Laylander JA		A Nutrient/Toxin Interaction Theory of the Etiology and Pathogenesis of Chronic Pain-Fatigue Syndromes: Part I	Journal of Chronic Fatigue Syndrome 1998: 5(1): 67 - 91	Recent research suggests that Chronic Fatigue Syndrome (CFS), Fibromyalgia Syndrome (FMS), and Persian Gulf Syndrome (PGS) may represent the effects of dysfunctions involving the central and/or peripheral nervous system, neuroendocrine system, neuromuscular system, immune system, metabolism, or sleep patterns. Each systemic dysfunction is accepted here as being central to these syndromes but not causal. This two-part review introduces the theory that the syndromes listed above represent finitely variable combinations of multiple systemic dysfunctions which all share a common underlying etiology at the subcellular level: magnesium deficiency plus concomitant fluoride excess (MDFE). The theory is introduced in Part I; detailed evidence which supports the theory is presented in Part II. Treatment suggestions are listed at the end of Part II through a call for clinical trials to test this theory.

Levine PH, Fears TR, Cummings P, Hoover RN.	Division of Cancer Epidemiology and Genetics, NIH, Bethesda, Maryland 20892, USA.	Cancer and a fatiguing illness in Northern Nevada--a causal hypothesis.	Ann Epidemiol 1998 May;8(4):245-9	PURPOSE: We investigated the possibility that chronic fatigue syndrome (CFS) predisposes to cancer by comparing the cancer pattern in an area in northern Nevada, where an outbreak of a fatiguing illness, which included cases of CFS, was reported, to an area in southern Nevada, where no such illness was reported. METHODS: Data from the computerized Nevada Cancer Registry were utilized to compare incidence rates of four malignancies--brain cancer, non-Hodgkin lymphoma (NHL), lung cancer, and breast cancer--in Washoe and Lyon Counties, where an unexplained fatiguing illness was reported during 1984-86, with comparably sized Clark County, where no such illness was reported. RESULTS: Higher incidences of NHL and primary brain tumors were noted in the two northern Nevada counties (Washoe and Lyon) in 1986 and 1987 respectively, compared to the southern Nevada (Clark) county. Similar patterns were not seen for breast or lung cancer. CONCLUSIONS: This study provides a model for investigating the possible predisposition of CFS patients to develop cancer using other cohorts, but it is currently premature to accept such a link at this time.
Levine PH, Whiteside TL, Friberg D, Bryant J, Colclough G, Herberman RB.	National Cancer Institute, Bethesda, Maryland, 20892, USA.	Dysfunction of natural killer activity in a family with chronic fatigue syndrome.	Clin Immunol Immunopathol 1998 Jul;88(1):96-104	A family was identified with 5 of 6 siblings and 3 other immediate family members who had developed chronic fatigue syndrome (CFS) as adults. All 8 met criteria for the CFS case definition as recommended by the Centers for Disease Control and Prevention. Sixty-eight blood samples were obtained over a period of 2 years from 20 family members (8 affected, 12 unaffected) and 8 normal controls. All blood samples were tested for NK activity in 4-h 51Cr-release assays and for the number of circulating CD3-CD56() and CD3-CD16() by flow cytometry. NK activity of the affected immediate family members (cases, n = 8) was significantly lower (P = 0.006, two-sided) than that of the concurrently tested normal controls. The results for unaffected family members were intermediate between these two groups, and the pairwise comparison of unaffected family members to either cases or controls showed no statistically significant difference (P = 0.29, two-sided). No differences were seen between the groups in the absolute number of CD3-CD56() or CD3-CD16() lymphocytes in the peripheral blood. Familial CFS was associated with persistently low NK activity, which was documented in 6/8 cases and in 4/12 unaffected family members. In the family with 5 of 6 siblings who had documented CFS, 2 of their offspring had pediatric malignancies. Low NK activity in this family may be a result of a genetically determined immunologic abnormality predisposing to CFS and cancer.

Levine PH.	George Washington University Medical Center, Washington, DC, USA.	What we know about chronic fatigue syndrome and its relevance to the practicing physician.	Am J Med 1998 Sep 28;105(3A):100S-103S	A number of recent reports have emphasized laboratory abnormalities, clinical tests, and therapeutic approaches that appear to have great promise in the evaluation and management of chronic fatigue syndrome (CFS). Because of the heterogeneity of CFS, the cost of many of these assays and procedures, and the frequent lack of skilled consultants able to apply relevant sophisticated procedures, the solo healthcare provider is often left with uncertain options in patient management. This article summarizes current approaches to patient management, utilizing available information relevant to CFS.
Litzman J, Lokaj J, Fucikova T.	Ustav klinicke imunologie a alergologie, FN u svate Anny, Brno, Praha.	[Chronic fatigue syndrome].[article in Czech]	Cas Lek Cesk 1998 May 18;137(10):295-8	A great concern is recently given to the chronic fatigue syndrome in the Czech Republic. Unfortunately, published data allow us to state neither the etiologic agent nor the pathophysiology of the disease. Although many authors published various laboratory abnormalities, these changes are inconstant and do not allow to state a diagnosis of the chronic fatigue syndrome by a single laboratory test, and effective therapy is not known either. Psychotherapy, and in some cases antidepressants, are recommended by some authors to alleviate patient's symptoms. Neither immunological nor antiviral therapy showed positive results in controlled trials and are not generally used in most centers.
Lloyd AR.	The Inflammation Research Unit, School of Pathology, University of New South Wales, Sydney, Australia.	Chronic fatigue and chronic fatigue syndrome: shifting boundaries and attributions.	Am J Med 1998 Sep 28;105(3A):7S-10S	The subjective symptom of "fatigue" is one of the most widespread in the general population and is a major source of healthcare utilization. Prolonged fatigue is often associated with neuropsychological and musculoskeletal symptoms that form the basis of several syndromal diagnoses including chronic fatigue syndrome, fibromyalgia, and neurasthenia, and is clearly not simply the result of a lack of force generation from the muscle. Current epidemiologic research in this area relies predominantly on self-report data to document the prevalence and associations of chronic fatigue. Of necessity, this subjective data source gives rise to uncertain diagnostic boundaries and consequent divergent epidemiologic, clinical, and pathophysiologic research findings. This review will highlight the impact of the case definition and ascertainment methods on the varying prevalence estimates of chronic fatigue syndrome and patterns of reported psychological comorbidty. It will also evaluate the evidence for a true postinfective fatigue syndrome.
Loblay RH.		Chronic fatigue syndrome.	Lancet 1998 Apr 25;351(9111):1292 Comment on: Lancet. 1998 Feb 21;351(9102):574	
Low PA.	Mayo Medical School, Department of Neurology, Mayo Clinic, Rochester, MN 55905, USA.	Autonomic neuropathies.	Curr Opin Neurol 1998 Oct;11(5):531-7	A limited autonomic neuropathy may underlie some unusual clinical syndromes, including the postural tachycardia syndrome, pseudo-obstruction syndrome, heat intolerance, and perhaps chronic fatigue syndrome. Antibodies to autonomic structures are common in diabetes, but their specificity is unknown. The presence of autonomic failure worsens prognosis in the diabetic state. Some autonomic

				neuropathies are treatable. Familial amyloid polyneuropathy may respond to liver transplantation. There are anecdotal reports of acute panautonomic neuropathy responding to intravenous gamma globulin. Orthostatic hypotension may respond to erythropoietin or midodrine.

MacHale SM, Cavanagh JT, Bennie J, Carroll S, Goodwin GM, Lawrie SM.	Department of Psychiatry, University of Edinburgh, Edinburgh, UK.	Diurnal variation of adrenocortical activity in chronic fatigue syndrome.	Neuropsychobiology 1998 Nov;38(4):213-7	Baseline morning and evening serum cortisol and ACTH concentrations, and diurnal changes in hormone levels, were measured in 30 patients with chronic fatigue syndrome (CFS) but without concurrent depressive disorder and a control group of 15 weight-, age- and sex-matched healthy volunteers. Morning cortisol levels were non-significantly lower in CFS patients, while evening levels were non-significantly higher. ACTH concentrations were non-significantly higher in both the morning and evening. The diurnal change in cortisol levels was significantly less in CFS than in controls ($p < 0.05$). In CFS subjects, evening levels of cortisol correlated significantly with measures of general health and physical functioning, while diurnal change in cortisol was positively correlated with measures of functional improvement over the past year and current social functioning. These results suggest that there is a relationship between adrenocortical function and disability in CFS, but do not reveal the causal connection.
Mackinnon LT.	Department of Human Movement Studies, The University of Queensland, Australia.	Future directions in exercise and immunology: regulation and integration.	Int J Sports Med 1998 Jul;19 Suppl 3:S205-9; discussion S209-11	Although it is difficult to predict future directions in a rapidly expanding field such as exercise immunology, recently published research along with that presented at this Symposium allow us to ask some key questions which may point to new directions: 1) Are athletes immunocompromised? Athletes are not clinically immunodeficient, yet endurance athletes are at increased risk of illness. Long-term prospective studies are needed to understand the relationship between infection, training variables and immune parameters. 2) Is downregulation of nonspecific immunity beneficial or harmful? In athletes, neutrophils appear to be downregulated, and this may alter resistance to illness. Alternatively, neutrophils are mediators of tissue damage during inflammation. Downregulation of neutrophil function may be protective by limiting chronic inflammation. In athletes, mild immunosuppression may reflect a compromise between the body's attempts to limit inflammation while maintaining immune function. 3) What mediates communication between events in skeletal muscle and the immune system? Leukocyte mobility is affected by metabolic and mechanical factors during exercise. Exercise increases cytokine levels in damaged skeletal muscle and expression of adhesion molecules. Future work is likely to focus on the role of cytokines and adhesion molecules in mediating exercise-induced changes in leukocyte mobility. 4) Can exercise training provide a "countermeasure" against immunosuppressive events? Moderate exercise training may have a role in

				stimulating the immune system during certain diseases (e.g., HIV-infection), immune dysfunction (e.g., chronic fatigue syndrome) or reduced responsiveness (e.g. aging, spaceflight). It is also likely that future study will apply molecular biology techniques to further identify mechanisms by which exercise influences immune function.
Marlin RG, Anchel H, Gibson JC, Goldberg WM, Swinton M.	MRS Health Services, St. Joseph's Hospital, and McMaster University, Hamilton, Ontario, Canada.	An evaluation of multidisciplinary intervention for chronic fatigue syndrome with long-term follow-up, and a comparison with untreated controls.	Am J Med 1998 Sep 28;105(3A):110S-114S	Individuals meeting the Fukuda et al definition for chronic fatigue syndrome completed a multidisciplinary assessment that included medical, psychiatric, behavioral, and psychological evaluations. Patients were then offered a comprehensive multidisciplinary intervention that included (1) bringing the patient under optimal medical management; (2) treating any ongoing affective or anxiety disorder pharmacologically; and (3) implementing a comprehensive cognitive-behavioral treatment program. Fifty-one patients proceeded to treatment. The cognitive-behavioral component was carried out through the use of a therapist working with the patients in their own environments. The program was individually tailored to patients, but included (1) structured physical exercise and activation; (2) sleep management strategies; (3) careful activity management; (4) regulation of stimulant intake and reductions in use of symptomatic medications; (5) cognitive intervention designed to deal with patients' beliefs concerning the nature of their disorder; (6) participation of patients' family; and (7) efforts to establish specific vocational and avocational goals. Third parties were encouraged to collaborate cooperatively. Employers were urged to provide employment opportunities and facilitate a graduated but time-targeted return to work. Disability carriers were encouraged to provide interim financial support in the form of disability benefits, support therapeutic intervention, but also to establish a clear time-frame to access to benefits. Of 51 treated patients, 31 returned to gainful employment, 14 were functioning at a level equivalent to employment, and 6 remained significantly disabled. Twenty of the original 71 patients were contacted an average of 33 months later. Patients who had been treated showed good maintenance of gains. Untreated patients showed improvement in only a minority of cases.
Martin WJ.	Center for Complex Infectious Diseases, Rosemead, Calif 91770, USA.	Cellular sequences in stealth viruses.	Pathobiology 1998;66(2):53-8	Cloned DNA obtained from the culture of an African green monkey simian cytomegalovirus-derived stealth virus contains multiple discrete regions of significant sequence homology (p values ranging from 4 x 10(-3) to 1 x 10(-20)) to portions of known human cellular genes. The stealth virus was cultured from a patient with chronic fatigue syndrome (CFS). Earlier studies had revealed considerable sequence heterogeneity within DNA fragments isolated from virus-infected cells. A set of polymerase chain reaction (PCR) primers generated different PCR products when tested on stealth virus cultures from 4 patients with CFS. Several of the PCR products also contain regions of significant partial homology to distinct cellular sequences, including sequences repetitively expressed throughout the cellular genome. Stealth viruses may play an important role in the origins and in the genetic diversity of both viral and cellular sequences.

McCluskey DR.	Queens University of Belfast, Ireland.	Chronic fatigue syndrome: Its cause and a strategy for management.	Compr Ther 1998 Aug;24(8):357-63	This article describes the features of chronic fatigue syndrome and, by analysis of the many clinical paradoxes which it manifests, attempts to give a unifying explanation of the cause of the disorder and a strategy for management.

Laboratory of Clinical Investigation, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD 20892-1888, USA.	Low-dose hydrocortisone for treatment of chronic fatigue syndrome: a randomized controlled trial.	JAMA 1998 Sep 23-30;280(12):1061-6Comment in: JAMA. 1999 May 26;281(20):1887-8; discussion 1888-9 JAMA. 1999 May 26;281(20):1887; discussion 1888-9 JAMA. 1999 May 26;281(20):1888-9	CONTEXT: Chronic fatigue syndrome (CFS) is associated with a dysregulated hypothalamic-pituitary adrenal axis and hypocortisolemia. OBJECTIVE: To evaluate the efficacy and safety of low-dose oral hydrocortisone as a treatment for CFS. DESIGN: A randomized, placebo-controlled, double-blind therapeutic trial, conducted between 1992 and 1996. SETTING: A single-center study in a tertiary care research institution. PATIENTS: A total of 56 women and 14 men aged 18 to 55 years who met the 1988 Centers for Disease Control and Prevention case criteria for CFS and who withheld concomitant treatment with other medications. INTERVENTION: Oral hydrocortisone, 13 mg/m2 of body surface area every morning and 3 mg/m2 every afternoon, or placebo, for approximately 12 weeks. MAIN OUTCOME MEASURES: A global Wellness scale and other self-rating instruments were completed repeatedly before and during treatment. Resting and cosyntropin-stimulated cortisol levels were obtained before and at the end of treatment. Patients recorded adverse effects on a checklist. RESULTS: The number of patients showing improvement on the Wellness scale was 19 (54.3%) of 35 placebo recipients vs 20 (66.7%) of 30 hydrocortisone recipients (P =.31). Hydrocortisone recipients had a greater improvement in mean Wellness score (6.3 vs 1.7 points; P=.06), a greater percentage (53% vs 29%; P=.04) recording an improvement of 5 or more points in Wellness score, and a higher average improvement in Wellness score on more days than did placebo recipients (P<.001). Statistical evidence of improvement was not seen with other self-rating scales. Although adverse symptoms reported by patients taking hydrocortisone were mild, suppression of adrenal glucocorticoid responsiveness was documented in 12 patients who received it vs none in the placebo group (P<.001). CONCLUSIONS: Although hydrocortisone treatment was associated with some improvement in symptoms of CFS, the degree of adrenal suppression precludes its practical use for CFS.
Meyer FP.		ber die laquo;Omnipotenz>> der Chelattherapie.	Forsch Komplementarmed 1998;5(6):266-271	About the 'Omnipotence' of the Chelation Therapy In the eighties the 'method of treatment proven in many thousands of cases over 20 years' was transferred from the USA to Germany (enjoys a priori considerable faith) using very dubious promises. It was Clarke et al. who introduced this 'therapy' in 1955. The dubious promise was to maintain that the chelation therapy eliminates or alleviates symptoms in the case of the following illnesses: Alzheimer's disease, senility, schizophrenia, rheumatoid arthritis, osteoarthritis, gout, renal calculus, apoplectic coma, gallstones, multiple sclerosis, osteoporosis, chronic fatigue syndrome, varicose veins, hypertension, failure of memory, scleroderma, Raynaud's disease, digitalis intoxication, intermittent claudication, diabetic ulcer, disturbance of the blood supply, ulcer on the legs, snake

				poison, impotence, emotional difficulties, defective hearing, vision disorder. There is not the slightest proof of effectiveness for any of the listed indications. The burden of proof lies with the supplier. Even in the case of the relatively often examined peripheral atherosclerotic changes (claudicatio intermittens) there is no proof that EDTA has a greater effect than placebo. For coronary heart disease too there is no evidence for any usefulness of the chelation therapy beyond that of a placebo effect. Only controlled studies can help to improve the therapy in the sense of 'Evidence-based medicine'. Retrospective investigations on thousands of patients cannot 'prove' anything, although this is maintained again andagain.
Michiels V, Cluydts R, Fischler B.	Department of Psychology, Free University of Brussels, Belgium. vmichiel@vub.ac.be	Attention and verbal learning in patients with chronic fatigue syndrome.	J Int Neuropsychol Soc 1998 Sep;4(5):456-66	Former neuropsychological studies with Chronic Fatigue Syndrome (CFS) patients evaluated a broad range of cognitive functions. Several, but not all, reported subtle attentional and memory impairments suggesting possible mild cerebral involvement. In this study, a battery of attentional tests and a verbal memory task were administered to 20 CFS patients and 22 healthy controls (HC) in order to clarify the specific nature of attention and memory impairment in these patients. The results provide evidence for attentional dysfunction in patients with CFS as compared to HC. CFS patients performed more poorly on a span test measuring attentional capacity and working memory. Speeded attentional tasks with a more complex element of memory scanning and divided attention seem to be a sensitive measure of reduced attentional capacity in these patients. Focused attention, defined as the ability to attend to a single stimulus while ignoring irrelevant stimuli, appears not to be impaired. CFS patients were poorer on recall of verbal information across learning trials, and poor performance on delayed recall may be due to poor initial learning and not only to a retrieval failure.
Miller BJ, John L. Whiting, Andrew D. Clouston		Coincidental Splenectomy in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 4(1): 37 - 42	A unique case of coincidental splenectomy for trauma during chronic fatigue syndrome (CFS) is presented. The patient had a two-year history of CFS prior to her involvement in a road crash. Delayed rupture of the spleen ten days later necessitated urgent laparotomy. At operation, the splenic parenchyma was spongy and friable. Splenorrhaphy was considered inadvisable and a splenectomy was performed. Histological examination of the spleen revealed chronic inflammatory changes of uncertain etiology. One year post-operatively, the patient recovered from her CFS symptoms and returned to work. These histopathological changes in the spleen of a patient with CFS have not been described before.
Moorkens G, Wynants H, Abs R.	Department of Internal Medicine, University Hospital Antwerp, Belgium.	Effect of growth hormone treatment in patients with chronic fatigue syndrome: a preliminary study.	Growth Horm IGF Res 1998 Apr;8 Suppl B:131-3	The efficacy of growth hormone (GH) therapy was evaluated in patients with chronic fatigue syndrome (CFS) who had peak serum GH levels below 10 microg/l during stage-controlled sleep. Twenty patients (7 men, 13 women; age range, 30-60 years) with CFS were randomized to receive placebo or GH therapy, 6.7 microg/kg/day (0.02 IU/kg/day), for 12 weeks. Following this double-blind treatment period, the 17 patients remaining in the study were given GH therapy at the above dose for an open period of 9 months. Mean (SD) serum levels of insulin-like growth factor I (IGF-I)

				increased during GH treatment, from 173 46 microg/l to 296 89 microg/l (P < 0.001); IGF-I SDS values increased from -0.45 1.14 to .43 1.09 (P < 0.001). Fat-free mass and total body water were significantly increased after 12 months of treatment. Although quality of life, as assessed using two different questionnaires, did not improve significantly during GH treatment, four patients were able to resume work after a long period of sick leave.
Morehouse RL, Flanigan M, MacDonald DD, Braha D, Shapiro C.	Department of Psychiatry, Dalhousie University, QEII Health Sciences Centre, Halifax, Nova Scotia.	Depression and short REM latency in subjects with chronic fatigue syndrome.	Psychosom Med 1998 May-Jun;60(3):347-51	OBJECTIVE: The hypothesized polysomnographic marker for depression, Rapid Eye Movement Latency (REML), was used to investigate two groups of subjects; Chronic Fatigue Syndrome (CFS)-not depressed and CFS-depressed. METHOD: CFS subjects were classified into depressed and not depressed groups, using the Diagnostic Interview Schedule (DIS), and subsequently were studied in a sleep laboratory to ascertain REML. RESULTS: Short REML showed a statistically significant correlation with the depressed state in CFS subjects. CONCLUSION: Short REM latency is associated with depression in the CFS population.
Morriss RK, Wearden AJ, Mullis R.	Department of Community Psychiatry, University of Manchester, UK.	Exploring the validity of the Chalder Fatigue scale in chronic fatigue syndrome.	J Psychosom Res 1998 Nov;45(5):411-7	The Chalder fatigue scale is widely used to measure physical and mental fatigue in chronic fatigue syndrome patients, but the constructs of the scale have not been examined in this patient sample. We examined the constructs of the 14-item fatigue scale in a sample of 136 chronic fatigue syndrome patients through principal components analysis, followed by correlations with measures of subjective and objective cognitive performance, physiological measures of strength and functional work capacity, depression, anxiety, and subjective sleep difficulties. There were four factors of fatigue explaining 67% of the total variance. Factor 1 was correlated with subjective everyday cognitive difficulties, concentration difficulties, and a deficit in paired associate learning. Factor 2 was correlated with difficulties in maintaining sleep. Factor 3 was inversely correlated with grip strength, peak VO2, peak heart rate, and peak functional work capacity. Factor 4 was correlated with interview and self-rated measures of depression. The results support the validity of mental and physical fatigue subscales and the dropping of the "loss of interest" item in the 11-item version of the fatigue scale.
Morriss RK, Wearden AJ.	Department of Psychiatry, University of Manchester, UK.	Screening instruments for psychiatric morbidity in chronic fatigue syndrome.	J R Soc Med 1998 Jul;91(7):365-8	Physicians require a screening instrument to detect psychiatric disorders in patients with chronic fatigue syndrome (CFS). Different threshold scores on the Hospital Anxiety and Depression scale (HAD) and the mental health scale of the Medical Outcome Survey (MOS) were compared with two gold standards for the presence or absence of psychiatric disorder, standard diagnostic criteria (DSM-III-R) and a threshold score for the number of psychiatric symptoms at a standardized psychiatric interview (Revised Clinical Interview Schedule total cut-off score of 11/12). They were compared by use of validating coefficients and receiver operating characteristics in 136 consecutive CFS medical outpatients. The HAD scale at cut-off of 9/10 was a valid and efficient screening instrument for anxiety and depression by comparison with both gold standards. The MOS mental health scale at its recommended cut-off score

				of 67/68 yielded too many false-positives to be recommended as a psychiatric screening instrument in CFS patients.
Natelson BH, Cheu J, Hill N, Bergen M, Korn L, Denny T, Dahl K.	Department of Neurosciences, University of Medicine and Dentistry of New Jersey, Newark, USA. bhn@nbunj.jvnc.net	Single-blind, placebo phase-in trial of two escalating doses of selegiline in the chronic fatigue syndrome.	Neuropsychobiology 1998;37(3):150-4	AIM: To perform a clinical trial of selegiline in 25 patients with chronic fatigue syndrome (CFS) where patients were told they would receive placebo or active agent at different times during the 6-week trial. We chose selegiline, a specific monoamine oxidase (MAO) B receptor inhibitor, because a prior trial of lowdose phenelzine, a nonspecific MAO inhibitor, showed a small but significant therapeutic effect. METHODS: Questionnaires comprised of 19 tests of mood, fatigue, functional status and symptom severity were collected at the start and end of the trial as well as 2 weeks after its start. The trial was done in three 2-week blocks: in the first, 2 placebo pills were given per day; in the next, one 5-mg tablet of agent and one placebo were given per day, and in the last, a 5-mg tablet of agent was given twice a day. The plan was to compare the changes in the 19 tests during the placebo phase to those found in the active treatment phase in 19 patients completing the trial. FINDINGS: Significant improvement in 3 variables-tension/anxiety, vigor and sexual relations-was found. A significant pattern of improvement compared to worsening was found for the 19 self-report vehicles during active treatment as compared with placebo treatment. Evidence for an antidepressant effect of the drug was not found. CONCLUSIONS: Selegiline has a small but significant therapeutic effect in CFS which appears independent of an antidepressant effect.
Natelson BH, LaManca JJ, Denny TN, Vladutiu A, Oleske J, Hill N, Bergen MT, Korn L, Hay J.	Department of Neurosciences, Chronic Fatigue Syndrome Cooperative Research Center, University of Medicine and Dentistry of New Jersey--New Jersey Medical School, Newark 07018, USA.	Immunologic parameters in chronic fatigue syndrome, major depression, and multiple sclerosis.	Am J Med 1998 Sep 28;105(3A):43S-49S	The purpose of this study was to evaluate the immune dysfunction hypothesis of chronic fatigue syndrome (CFS) by comparing immunologic data from patients with CFS with data from patients with other fatiguing illnesses--major depression and multiple sclerosis (MS)--and with data from healthy sedentary controls. The subjects were 65 healthy sedentary controls, 71 CFS patients (41 with no axis-I diagnosis), 23 patients with mild MS, and 21 patients with major depression. Blood was sampled and assayed for the following: (1) immunologic serologic variables--circulating immune complexes (i.e., Raji cell and C1q binding), immunoglobulins A, E, G, and M, and IgG subclasses; (2) cell surface activation markers--the proportion of CD4 cells expressing CD45RA and CD45RO and the proportion of CD8 cells expressing CD38, CD11b-, HLA-DR and CD28; and (3) natural killer (NK) total cell count as well as the proportion of lymphocytes expressing NK cell surface markers (i.e., CD3-/CD16 and CD56. Of the 18 variables studied, differences between CFS patients and controls were found only for IgG1 and IgG3. When CFS patients were stratified by the presence or absence of concurrent axis-I disease, it was the group with axis-I disorder that had the lowest IgG1 values-contrary to expectation. When data from patients with MS and major depression were also evaluated, the subclass deficiency was no longer significant. The one group to show evidence for immune activation (i.e., an elevated proportion of CD4 cells expressing the CD45RA activation marker) was the group with mild MS. These data support neither immune dysfunction nor immune

				activation in CFS or in major depression, for the variables studied. The reductions in IgG subclasses may be an epiphenomenon of patient or control subject composition. In contrast, MS, even in the mild and early stages, as in the patients studied here, is associated with immune activation.
Newman ME, Shapira B, Lerer B.	Biological Psychiatry Laboratory, Dept. of Psychiatry, Hadassah - Hebrew University Medical Center.	Evaluation of central serotonergic function in affective and related disorders by the fenfluramine challenge test: a critical review.	Int J Neuropsychopharmcol 1998 Jul;1(1):49-69	Plasma prolactin levels following oral administration of the serotonin (5-HT) releasing agent, fenfluramine hydrochloride, have been extensively used to evaluate central serotonergic function in affective and related disorders. Cortisol responses to fenfluramine have generally been a less informative measure. In healthy subjects, prolactin release by fenfluramine is dose-dependent, blocked by antagonists of serotonin receptors of the 5-HT-2a/2c type, negatively correlated with age and increased in young females. In major depression, a preponderance of studies have found blunted prolactin responses compared to matched normal controls. Although a significant minority of studies have not found blunting, increased prolactin release has not been observed. The blunted prolactin release is not due to a deficient secretory capacity of pituitary lactotrophs and is congruent with other evidence for reduced central serotonergic function in major depression. Blunting of the prolactin response may be associated with severity of depression and with elevated baseline cortisol levels. Treatment with antidepressant drugs and electroconvulsive therapy has been reported to increase the prolactin response but this has not been replicated in all studies. Blunted prolactin responses to fenfluramine have been fairly consistently associated with impulsive aggression in different personality disorders and with severity of suicide attempts in depressed patients. A number of studies employing the fenfluramine challenge test (FCT) have been conducted in obsessive compulsive disorder but their results have been variable. Prolactin responses to fenfluramine may be enhanced in panic disorder and chronic fatigue syndrome but the number of studies in these conditions is small as is the case for seasonal affective disorder. Since the therapeutic administration of fenfluramine as an appetite suppressant has been suspended because of reports of cardiac complications, further use of this compound as a challenge agent is not anticipated. Future studies are likely to employ agents acting on specific serotonin receptors and should apply methodological insights from the use of the FCT, which are considered in this review. Use of concomitant brain imaging to evaluate the central effects of challenge agents directly is likely to become more prevalent and may supplant neuroendocrine challenge paradigms such as the FCT which have been remarkably heuristic but are limited in scope and methodologically complex.
Nicolson GL, Nicolson NL.	Institute for Molecular Medicine, Huntington Beach, CA 92649-1041, USA. gnicimm@ix.netcom.co	Gulf War illnesses: complex medical, scientific and political paradox.	Med Confl Surviv 1998 Apr-Jun;14(2):156-65	Gulf War illnesses are a collection of disorders that for the most part can be diagnosed and treated, if effective programmes exist to assist veterans, and in some cases their immediate family members. Although these illnesses are complex and have multi-organ signs and symptoms, a proportion of these patients can be identified as having Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME)

	m			and/or Fibromyalgia Syndrome (FMS). Although there are many possible causes of CSF/ME/FMS, chronic infections can explain, at least in a subset of patients, the apparent transmission of these illnesses to family members and the appearance of chronic, multi-organ and auto-immune signs and symptoms. Unfortunately, many veterans who have been diagnosed with chronic infections, such as mycoplasmal infections, cannot obtain adequate treatment for their condition, resulting in their reliance on private physicians and clinics for assistance. This lack of response may ultimately be responsible for the transmission of the illness to non-veterans.
Nisenbaum R, Reyes M, Mawle AC, Reeves WC.	Klemm Analysis Group, Atlanta, GA, USA.	Factor analysis of unexplained severe fatigue and interrelated symptoms: overlap with criteria for chronic fatigue syndrome.	Am J Epidemiol 1998 Jul 1;148(1):72-7	The objective of this study was to identify factors explaining the correlations among unexplained severe fatigue of different durations (1-5 months or > or =6 months) and symptoms reported as being significant health problems during a preceding 4-week period. Between June and December of 1994, a cross-sectional, random digit dialing telephone survey was conducted among residents of San Francisco, California. All subjects who reported having severe fatigue lasting for > or =1 month and a random sample of nonfatigued subjects were asked to participate in a detailed telephone interview. Data from 1,510 individuals aged 18-60 years who did not have medical or psychiatric conditions that could explain their severe fatigue were analyzed. Common factor analyses identified three correlated factors (defined as "fatigue-mood-cognition" symptoms, "flu-type" symptoms, and "visual impairment") that explained the correlations among fatigue lasting for > or =6 months and 14 interrelated symptoms. No factor explained the correlations among fatigue lasting for 1-5 months and other symptoms. The combination of fatigue of > or =6 months' duration and selected symptoms overlaps with published criteria used to define cases of chronic fatigue syndrome (CFS). Although symptoms described in this study were reported as appearing within the preceding month, and CFS symptoms must have been present for the previous 6 months, these results provide empirical support for the interrelations among unexplained fatigue of > or =6 months' duration and symptoms included in the CFS case definition.
Ogawa M, Nishiura T, Yoshimura M, Horikawa Y, Yoshida H, Okajima Y, Matsumura I, Ishikawa J, Nakao H, Tomiyama Y, Kanayama Y, Kanakura Y, Matsuzawa Y.	Osaka University Medical School, Osaka, Japan.	Decreased nitric oxide-mediated natural killer cell activation in chronic fatigue syndrome.	Eur J Clin Invest 1998 Nov;28(11):937-43	BACKGROUND: L-Arginine (L-Arg), one of the essential amino acids, has been reported to have an immunomodulatory effect. The precise mechanism of the L-Arg-induced natural killer (NK) cell activation remains unresolved,and the effect of L-Arg on NK cells in chronic fatigue syndrome (CFS) patients has not been estimated. METHODS: NK cell function was evaluated in 20 subjects with CFS and compared with that in 21 healthy individuals. RESULTS: In healthy control subjects, NK activity was significantly increased after treatment with L-Arg, an NK function enhancer, for 24 h, whereas the same treatment failed to enhance NK activity in the CFS patients. We thus focused on L-Arg metabolism, which involves nitric oxide (NO) production through NO synthase (NOS). The expression of inducible NO synthase (iNOS) transcripts in peripheral blood mononuclear cells was not significantly different between healthy control subjects and CFS patients. The L-Arg-mediated NK cell

				activation was abolished by addition of NG-monomethyl-L-arginine, an inhibitor for iNOS. Furthermore, incubation with S-nitroso-N-acetyl-penicillamine, an NO donor, stimulated NK activity in healthy control subjects but not in CFS patients. CONCLUSION: These results demonstrate that the L-Arg-induced activation of NK activity is mediated by NO and that a possible dysfunction exists in the NO-mediated NK cell activation in CFS patients.
Olson LG, Cole MF, Ambrogetti A.	Sleep Disorders Centre, Royal Newcastle Hospital, NSW, Australia. lolson@mail.newcastle.edu.au	Correlations among Epworth Sleepiness Scale scores, multiple sleep latency tests and psychological symptoms.	J Sleep Res 1998 Dec;7(4):248-53	The aim of this study was to identify factors other than objective sleep tendency associated with scores on the Epworth Sleepiness Scale (ESS). There were 225 subjects, of whom 40% had obstructive sleep apnoea (OSA), 16% had simple snoring, and 4.9% had snoring with sleep disruption (upper airway resistance syndrome); 9.3% had narcolepsy and 7.5% had hypersomnolence without REM sleep abnormalities; 12% had chronic fatigue syndrome; 7.5% had periodic limb movement disorder and 3% had diurnal rhythm disorders. ESS, the results of overnight polysomnography and multiple sleep latency test (MSLT) and SCL-90 as a measure of psychological symptoms were recorded. The ESS score and the mean sleep latency (MSL) were correlated (Spearman rho = -0.30, P < 0.0001). The MSL was correlated with total sleep time (TST) and with sleep efficiency but not with apnoea/hypopnoea index. There was no association between the MSL and any aspect of SCL-90 scores, except a borderline significant association with the somatisation subscale. The ESS was correlated with TST but not with sleep efficiency or apnoea/hypopnoea index. The ESS was correlated with all subscales of the SCL-90 except psychoticism. An ESS > or = 10 had poor sensitivity and specificity as a predictor of MSL < 10 min or MSL < 5 min. We conclude that the MSLT and the ESS are not interchangeable. The ESS was influenced by psychological factors by which the MSL was not affected. The ESS cannot be used to demonstrate or exclude sleepiness as it is measured by MSLT.
Ottenweller JE, Natelson BH, Gause WC, Carroll KK, Beldowicz D, Zhou XD, LaManca JJ.	Neurobehavioral Unit, VA Medical Center, East Orange, NJ 07018-1095, USA. jeo@nbunj.jvnc.net	Mouse running activity is lowered by Brucella abortus treatment: a potential model to study chronic fatigue.	Physiol Behav 1998 Mar;63(5):795-801	Chronic fatigue syndrome, which can occur after acute infection and last for years, is characterized by severe and persistent fatigue. Others have reported decreases in mouse running activity following infection and have suggested this may provide an animal model for studying chronic fatigue. Voluntary running is a highly motivated activity in mice, which will often run 5-7 mi/day in our laboratory. Following 2 weeks of acclimation to running wheels with food and water available ad lib, female BALB/c mice received 0.2-mL tail vein injections of killed Brucella abortus (BA) or saline vehicle. Subsequently the effects on voluntary running and grooming behavior were determined. Injection of BA caused an immediate large decrease in running and a lack of grooming. Vehicle injections produced no changes in behavior. After the first several days of reduced running behavior, levels of running and grooming slowly returned back to normal over the next 2-4 weeks, with substantial individual differences in the rate of recovery. The pattern of running during recovery was intriguing in that BA mice first ran at normal levels just after the lights went out, but they stopped after only 1-2 h. As recovery proceeded, they gradually increased the

				duration of the running bout during the night. Because this model uses voluntary exertion and the ability to run for longer periods of time characterizes recovery, the model may be a good one for studying the biologic underpinnings of chronic fatigue.
Panay N, Studd JW.	Academic Department of Obstetrics and Gynaecology, Chelsea and Westminster Hospital, London, UK.	The psychotherapeutic effects of estrogens.	Gynecol Endocrinol 1998 Oct;12(5):353-65	The effect of estrogens on the central nervous system, particularly mood and behavior, remains a controversial area which needs clarification, not just for understanding of depression in women but to ensure that such commonplace problems in women have efficient and appropriate therapy. There is now good evidence that estrogens are rapidly effective in the treatment of depression in many women but this information has not found its way through to those health care personnel, psychiatrists and psychologists who are principally involved in the treatment of depression. There is also strong evidence for the benefits of estrogens on cognitive functioning, not only in preventing the onset of dementia but also in improving the symptoms in the established condition. Recent work has also suggested a benefit for estrogens on mood in women diagnosed as suffering from chronic fatigue syndrome. This article reviews the effect of endogenous estrogen on the female central nervous system and the ever increasing evidence for the diverse psychotherapeutic effects of exogenous estrogens.
Patarca R, Mary Ann Fletcher		Interleukin-6 and Disease Two Case Reports that Point to the Usefulness of Measuring Cytokine Levels in Clinical Settings	Journal of Chronic Fatigue Syndrome 1998: 4(1): 53 - 69	Chronic fatigue syndrome has been associated with patterns of cytokine imbalances whose relevance to disease status remains to be documented. We present here two case reports that illustrate thc relevance of measuring interleukin-6 levels in biological fluids in two clinical entities: hypothermia and Sjögren's syndrome. Further studies of this nature in extended patient populations will allow to discern the relevant contribution among the pleiotropy of roles of each particular cytokine in different clinical settings. It becomes apparent from the cases presented that the clinical manifestation of the imbalance in the expression of a particular cytokine is contingent upon the compartment where it occurs and upon levels of other cytokines. Similar studies will allow to define signature cytokine imbalances for each disease condition and may also shed light on thus far uncharacterized etiological agents.
Peterson PK, Pheley A, Schroeppel J, Schenck C, Marshall P, Kind A, Haugland JM, Lambrecht LJ, Swan S, Goldsmith S.	Department of Medicine, Hennepin County Medical Center, Minneapolis, Minn 55415, USA. peter137@maroon.tc.umn.edu	A preliminary placebo-controlled crossover trial of fludrocortisone for chronic fatigue syndrome.	Arch Intern Med 1998 Apr 27;158(8):908-14Comment in: Arch Intern Med. 1998 Nov 9;158(20):2266-7	OBJECTIVE: To provide a preliminary assessment of the efficacy and safety of fludrocortisone acetate treatment of chronic fatigue syndrome. DESIGN: A placebo-controlled, double-blind, random-allocation crossover trial of 6 weeks of fludrocortisone. SETTING: An outpatient clinical trials unit. PATIENTS: Twenty-five participants with chronic fatigue syndrome (mean age, 40 years; 19 [76%] women; mean duration of illness, 7.0 years) were recruited from a research and clinic registry. Five patients withdrew from the trial. INTERVENTIONS: All participants were scheduled to receive fludrocortisone acetate (0.1-0.2 mg) or a placebo for 6 weeks in each treatment. MAIN OUTCOME MEASURES: Self-administered questionnaires were completed at the beginning and end of each treatment arm that asked patients to rate the severity of their symptoms on a visual analogue scale. The Medical

				Outcomes Study 36-Item Short-Form Health Survey, a reaction time test, and a treadmill exercise test were used to assess functional status. Blood pressure, heart rate, and plasma norepinephrine levels were obtained at baseline. Blood pressure and heart rate were recorded at the end of the exercise test and monitored at all subsequent visits. RESULTS: At baseline, the study participants reported symptom severity greater than 5 for most symptoms, and all had evidence of marked functional impairments. No improvement was observed in the severity of any symptom or in any test of function for the 20 participants who completed both arms of the trial. Blood pressure and heart rate readings were unaffected by treatment, and plasma norepinephrine levels did not differ from those of a healthy control group. The incidence of adverse experiences was similar in the fludrocortisone and placebo arms of the trial. CONCLUSION: Low-dose fludrocortisone does not provide sufficient benefit to be evident in a preliminary blinded trial of unselected patients with chronic fatigue syndrome. Publication Types: Clinical Trial Randomized Controlled Trial
Pollet C, Natelson BH, Lange G, Tiersky L, DeLuca J, Policastro T, Desai P, Ottenweller JE, Korn L, Fiedler N, Kipen H.	Center for Environmental Hazards Research, VA Medical Center, East Orange, NJ 07018, USA.	Medical evaluation of Persian Gulf veterans with fatigue and/or chemical sensitivity.	J Med 1998;29(3-4):101-13	The purpose of this study was to determine if Gulf War veterans with complaints of severe fatigue and/or chemical sensitivity (n = 72) fulfill case definitions for chronic fatigue syndrome (CFS) and/or multiple chemical sensitivity (MCS) and to compare the characteristics of those veterans who received a diagnosis of CFS (n = 24) to a group of non-veterans diagnosed with CFS (n = 95). Thirty-three veterans received a diagnosis of CFS with 14 having MCS concurrently; an additional six had MCS but did not fulfill a case definition for CFS. The group of fatigued veterans receiving a diagnosis of CFS was comprised of significantly fewer women and fewer Caucasians than the civilian group, and significantly fewer veterans reported a sudden onset to their illness. Veterans with CFS had a milder form of the illness than their civilian counterparts based on medical examiner assessment of the severity of the symptoms, reported days of reduced activity, and ability to work. Since CFS in veterans seems less severe than that seen in civilians, the prognosis for recovery of veterans with this disorder may be better.
Poteliakhoff A		Fatigue Syndromes and the Aetiology of Autoimmune Disease	Journal of Chronic Fatigue Syndrome 1998: 4(4): 31 - 49	In the last decade or so, an impairment of HypothalamicPituitary-Adrenal (HPA) axis activity has been observed in fatigue syndromes. Elevated levels of glucocorticoids help to prevent the immune system From over-reacting and generating a damaging autoimmune proccss. The corollary should be that reduced activity of the HPA axis and diminished levels of plasma cortisol could be associated with autoimmune (AI) disease. Experimental work in mice and rats supports this view. Furthermore, plasma levels of cortisol have been found to be low in the early stages of rheumatoid arthritis. There is some clinical evidence that connective tissue disorders (many of which are regarded as autoimmune diseases) occur approximately one year after the onset of prolonged or chronic fatigue, with the implication that fatigue is not merely a symptom of these disorders but precedes them. Many workers have found changes

				in the immune system of subjects suffering from CFS (mainly immune activation) which could be conducive to the development of AI disease. It has recently been found that there is, in the CFS, some deficiency of another adrenal steroid, namely that of dehydroepiandrosterone. This steroid exerts a regulatory activity on the immune system and a deficiency may well be an additional factor in the genesis of AI disease. If an association can be established between fatigue syndromes and autoimmune disease then these syndromes will need to be addressed in a more concerned manner and prophylactic measures undertaken to to forestall AI disease.
Richardson J, Durval Campos Costa		Relationship Between SPECT Scans and Buspirone Tests in Patients with ME/CFS	Journal of Chronic Fatigue Syndrome 1998: 4(3): 23 - 38	The purpose of this exercise was to study the relationship between the detail shown on the SPECT brain scans with those seen in the buspirone tests. Thirty-nine patients are included in this study. These patients were selected from a large number who had been referred to Dr. Richardson from various parts of the country by their doctors because of a tentative diagnosis of ME/CFS. All the selected patients were confirmed by Dr. Richardson as suffering from ME/CFS taking into account the subjective scoring methods, clinical examination, virology and buspirone tests. This study is an attempt to link together the results of the previously described techniques to investigate possible areas of impaired cellular function in brain which may have purely neuroncural effects or possibly neurohormonal effects. All patients within this study displayed hypoperfusion in some brain area as shown by their SPECT scans (see Appendix, Table 1.1). Thirty-five (90%) showed hypoperfusion in the regions comprising: Twenty-four (62%) in the Brain Stem Twenty (51%) in tlic Caudate Nuclei Nine (23%) showed hypoperfusion in both Brain Stem and Caudate Nuclei regions Thirty (77%) cased demonstrated hypoperfusion in the regions comprising: Tweny-four (62%) in the Temporal Lobes Twelve (31%) in the Parietal Lobes Nine (23%) in the Frontal Lobes. The significance of these results is to confirm that there is actual evidence of neurological dysfunction which results in the continuing morbidity in these ME/CFS patients. The completion of this buspirone test and SPECT scan can be deemed to be basic complementary evidence for the positive diagnosis of ME/CFS.
Rowbottom D, David Keast, , Zhukov Pervan, Carmel Goodman, Chotoo Bhagat Byron Kakulas Alan Morton		The Role of Glutamine in the Aetiology of the Chronic Fatigue Syndrome A Prospective Study	Journal of Chronic Fatigue Syndrome 1998: 4(2): 3 - 22	Background: Recent studies have observed low plasma glutamine concentrations in chronic fatigue syndrome (CFS) subjects. Glutamine has been shown to be essential for immune function and a key substrate in brain neurochemistry. A dysfunctional immune response to infection and/or neurotransmitter dysfunction may be associated with CFS. Objective: To compare the glutamine status of CFS subjects to matched controls and to test the effect of L-glutamine supplementation on the symptoms associated with CFS. Design: A 26-week, randomised, double-blind, placebo-controlled trial. Patients: Sixteen subjects diagnosed with CFS and 16 ageand sex-matched, healthy controls. Intervention: L-glutamine or placebo (2000 mg/day for 26 weeks). Measurements: Plasma and muscle glutamine concentrations, complete haematology counts, lymphocyte surface marker analysis, serum cortisol and testosterone concentrations, and self-reported symptomatic status. Results:

				Plasma and muscle glutamine concentrations were lower in CFS subjects than controls (P < 0.001 and P = 0.027, respectively). Significant increases in plasma (P = 0.020) and muscle (P = 0.037) glutamine concentration were observed following L-glutamine, but not placebo (P > 0.05), supplementation. However, improvements in symptomatic status were not observed in the L-glutamine group. Although six subjects showed clinical improvements during the trial, there was no change in their plasma or muscle glutamine concentrations. Conclusions: These data suggest that while low plasma glutamine concentrations may occur coincident with CFS, they may not be directly causative of fatigue or other symptoms.
Rowbottom D, David Keast, Zhukov Pervan, Alan Morton		The Physiological Response to Exercise in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 4(2): 33 - 49	Background: The chronic fatigue syndrome (CFS) is characterised by a limited exercise capacity. Studies have reported reduced muscle oxidative capacity in CFS, evidenced by abnormal acidosis during exercise and reduced aerobic capacity and exercise endurance. Objective: To compare physiological responses to walking exercise in CFS subjects, sedentary controls, and clinically improved CFS subjects. Design: Ageand sex-matched pairs, with repeated measures. Subjects: Sixteen subjects diagnosed with CFS and 16 ageand sex-matched sedentary controls. Measurements: Heart rate (HR), oxygen uptake (VO2), ventilation (VE) and relative perceived exertion (RPE) responses to incremental walking exercise to volitional exhaustion. Results: CFS subjects reached significantly lower HRpeak (P = 0.023) and achieved nonsignificantly (P > 0.05) lower VO2peak than control subjects. Despite no differences in submaximal exercise responses, CFS subjects reported higher RPE scores than controls (P = 0.003) at submaximal workloads. RPE scores correlated with symptomatic scores for emotionality (r = 0.642) and general fatigue (r = 0.568). Symptomatic recovery in six CFS subjects was associated with nonsignificant increases in HRpeak, VO2peak and VEpeak, and nonsignificant decreases in RPE scores at submaximal workloads. Conclusions: These data suggested that the limited exercise capacity in CFS subjects may be explained by deconditioning due to the sedentary lifestyle necessitated bv the condition. coupled with an increased perception of exertion, potentially linked to psychological symptoms associated with CFS.
Rowbottom DG, Keast D, Green S, Kakulas B, Morton AR.	Department of Human Movement, University of Western Australia, Nedlands, Australia.	The case history of an elite ultra-endurance cyclist who developed chronic fatigue syndrome.	Med Sci Sports Exerc 1998 Sep;30(9):1345-8	An elite ultra-endurance athlete, who had previously undergone physiological and performance testing, developed chronic fatigue syndrome (CFS). An incremental cycling exercise test conducted while he was suffering from CFS indicated decreases in maximum workload achieved (Wmax; -11.3%), the maximum oxygen uptake (VO2max; -12.5%), and the anaerobic threshold (AT; -14.3%) compared to pre-CFS data. A third test conducted after the athlete had shown indications of significant improvement in his clinical condition revealed further decreases in Wmax (-7.9%), VO2max (-10.2%) and AT (-8.3%). These data, along with submaximal exercise data and muscle biopsy electron microscopic analyses, suggest that the performance decrements were the result of detraining, rather than an impairment of aerobic metabolism due to CFS per se. These data may be indicative of central, possibly

				neurological, factors influencing fatigue perception in CFS sufferers.
Rowe PC, Calkins H.	Department of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, Maryland, USA.	Neurally mediated hypotension and chronic fatigue syndrome.	Am J Med 1998 Sep 28;105(3A):15S-21S	A substantial body of clinical evidence now supports an association between various forms of hypotension and both idiopathic chronic fatigue and the chronic fatigue syndrome (CFS). Patients with CFS have a high prevalence of neurally mediated hypotension, and open treatment of this autonomic dysfunction has been associated with improvements in CFS symptoms. Randomized trials are now in progress to evaluate the efficacy of treatments directed at neurally mediated hypotension in those with CFS patients, and the results of these trials should help guide more basic inquiries into the mechanisms of orthostatic intolerance in affected individuals.
Russo J, Katon W, Clark M, Kith P, Sintay M, Buchwald D.	Department of Psychiatry & Behavioral Sciences, Harborview Medical Center, University of Washington, Seattle 98104, USA. jerusso@u.washington.edu	Longitudinal changes associated with improvement in chronic fatigue patients.	J Psychosom Res 1998 Jul;45(1 Spec No):67-76	Tertiary care patients with chronic fatigue were followed for 2.5 years to determine if changes in physical and psychological status were associated with improvements in chronic fatigue, physical functioning, and return to work. Results indicated that improvement in psychological symptoms, DSM-III-R disorders, physical examination signs, and changes in whether the patient continued to meet criteria for chronic fatigue syndrome (CFS) were associated with recovery from fatigue, improved functioning, and return to work. Patients who never met CFS criteria or only met criteria at the initial assessment, reported improved physical functioning. Patients whose psychiatric disorders and physical examination signs were still present at a mean follow-up time of 2.5 years were more likely to have persistent fatigue and work disability. Loss of physical examination signs was a significant independent predictor of improved functioning and return to work. These results suggest that psychiatric status, as well as physical status, are associated with recovery from chronic fatigue.
Saggini R, Pizzigallo E, Vecchiet J, Macellari V, Giacomozzi C.	Institute of Medical Pathophysiology, University G. D'Annunzio, Chieti, Italy.	Alteration of spatial-temporal parameters of gait in Chronic Fatigue Syndrome patients.	J Neurol Sci 1998 Jan 21;154(1):18-25	Chronic Fatigue Syndrome (CFS) has been widely studied and a lot of information is available in the literature regarding the immunological, virological, neuroendocrinal and psychiatric aspects of the disease, but its aetiology is still poorly understood. Great attention has also been paid to the alteration of the muscular function caused by CFS. The aim of the present work was to study CFS patients' gait in order to find out objective measures which can better characterize the pathology. Spatial and temporal parameters of gait were collected from a group of 12 CFS informed volunteers by using the typical instrumentation of movement analysis, and raw data were statistically elaborated. Comparisons with reference data from a population of healthy subjects revealed significant abnormalities in the symmetry indices of the bilateral parameters and in the linear relationships among parameters, and between these parameters and the physical characteristics of the patients. Interestingly, the abnormalities were present as from the beginning of the gait, which indicates that they are unlikely to be caused by the rapid increasing fatigue. This strengthens the hypothesis of a direct involvement of the central nervous system (CNS) in the onset of the disease.
Saltzstein BJ, Wyshak	Harvard Medical	A naturalistic study of	Gen Hosp Psychiatry	Chronic fatigue syndrome (CFS), a controversial illness without clear etiology, causes

G, Hubbuch JT, Perry JC.	School, Boston, MA, USA.	the chronic fatigue syndrome among women in primary care.	1998 Sep;20(5):307-16	profound debilitation in its sufferers. This study explored subjects' perceptions of the variables that mediated the course of their illness and identified coping strategies in 15 women with CFS referred from the practice of a primary care physician. Exploratory semistructured interviews were adapted from Kleinman's Illness Narratives. Four instruments were used: the Beck Depression Inventory, the Sickness Impact Profile, a modified Karnofsky scale, and the Defense Mechanism Rating Scale. Of the 15 women, 60% reported improvement and/or recovery at the time of the interview. Improvement was associated with social support and lower levels of depressive symptoms. Health status was influenced by how subjects perceived their illness, their future, and the doctor's prognosis; and by the physician's early diagnosis, validation of the CFS, and intensive medical follow-up. Obsessional and healthy neurotic defense levels predominated, which differs from historical comparison groups with dysthymia and panic disorder. Psychological adaptation to CFS is similar to adaptive coping in other chronic illnesses: subjective perceptions of health status can predict functional status. Physician validation is particularly important given the controversial status of CFS. Maintaining relationships with others--doctor, work, family, and group/spiritual activities reflected healthy coping strategies that promoted hope and attitudinal shifts. The finding of a mixture of neurotic and healthy defenses and a low proportion of defenses associated with personality disorders has not been previously reported in the CFS literature and warrants further investigation.
Schmaling KB, Daniel L. Hamilos Jeannie D. DiClementi, James F. Jones		Pain Perception in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 4(3): 13 - 22	Pain complaints (myalgia, arthralgia, headache, sore throat) are commonly associated with chronic fatigue syndrome (CFS), yet to date, these patients' responses to standardized measures of pain perception have not been investigated. Pain perception was measured by pressure dolorimeter and ice water cold pressor tests, and the McGill Pain Questionnaire among 15 female subjects with CFS, 11 suhjects with Major Depression and 11 healthy controls. No differences were found between the groups for pain threshold or intolerance levels on the pressure dolorimeter and cold pressor tests. CFS and depressed subjects endorsed significantly more self-reported pain complaints than did control subjects. Although more pain complaints were predicted by greater somatization and lower health perceptions, pain threshold and intolerance were not associated with psychiatric symptoms or functional status. The study yielded some interesting preliminary observations related to variability in pain tolerance among CFS patients. These preliminary observations are discussed in terms of the need for future research and their potential implications for treatment and coping with the illness.
Scott LV, Burnett F, Medbak S, Dinan TG.	Department of Psychological Medicine, St Bartholomew's and the	Naloxone-mediated activation of the hypothalamic-pituitary-adrenal axis in chronic	Psychol Med 1998 Mar;28(2):285-93	BACKGROUND: Opioidergic pathways have an inhibitory regulatory influence on the hypothalamic-pituitary-adrenal axis (HPA) in man. Previous studies have suggested impairment of pituitary-adrenal activation in chronic fatigue syndrome (CFS). We, therefore, decided to investigate the extent of opioid inhibition of HPA activity in CFS

	Royal London School of Medicine.	fatigue syndrome.		as a possible explanation for the reputed HPA hypofunctioning in patients with CFS. METHOD: Thirteen patients with CFS, diagnosed according to CDC criteria, were compared with thirteen healthy subjects. Adrenocorticotropin (ACTH) and cortisol (CORT) responses were measured following the administration of the opiate antagonist naloxone. RESULTS: Baseline ACTH and cortisol levels did not differ between the two groups. The release of ACTH (but not cortisol) was significantly blunted in the CFS subjects compared with controls. CONCLUSIONS: Naloxone mediated activation of the HPA is attenuated in CFS. Excessive opioid inhibition of the HPA is thus an unlikely explanation for the HPA dysregulation in this disorder.
Scott LV, Dinan TG.	Department of Psychological Medicine, St. Bartholomew's Hospital and the Royal London School of Medicine, West Smithfield, UK.	Urinary free cortisol excretion in chronic fatigue syndrome, major depression and in healthy volunteers.	J Affect Disord 1998 Jan;47(1-3):49-54	Urinary free cortisol excretion (UFC) was compared in 21 patients with chronic fatigue syndrome (CFS), in 10 melancholic depressives and in 15 healthy controls. Patients with depression had UFC values which were significantly higher than healthy comparison subjects, whereas UFC excretion of CFS patients was significantly lower than the comparison group. These findings are in keeping with currently held hypotheses of hyperactivity and hypoactivity of the hypothalamic-pituitary-adrenal (HPA) axis in depression and chronic fatigue syndrome respectively. Five of the 21 CFS patients had a co-morbid depressive illness. This sub-group retained the profile of UFC excretion of those with CFS alone, suggesting a different pathophysiological basis for depressive symptoms in CFS.
Scott LV, Medbak S, Dinan TG.	Department of Psychological Medicine, St Bartholomew's and the Royal London School of Medicine, West Smithfield, UK.	Blunted adrenocorticotropin and cortisol responses to corticotropin-releasing hormone stimulation in chronic fatigue syndrome.	Acta Psychiatr Scand 1998 Jun;97(6):450-7	Hypofunctioning of the pituitary-adrenal axis has been suggested as the pathophysiological basis for chronic fatigue syndrome (CFS). Blunted adrenocorticotropin (ACTH) responses but normal cortisol responses to exogenous corticotropin-releasing hormone (CRH), the main regulator of this axis, have been previously demonstrated in CFS patients, some of whom had a comorbid psychiatric disorder. We wished to re-examine CRH activation of this axis in CFS patients free from concurrent psychiatric illness. A sample of 14 patients with CDC-diagnosed CFS were compared with 14 healthy volunteers. ACTH and cortisol responses were measured following the administration of 100 microg ovine CRH. Basal ACTH and cortisol values did not differ between the two groups. The release of ACTH was significantly attenuated in the CFS group ($P < 0.005$), as was the release of cortisol ($P < 0.05$). The blunted response of ACTH to exogenous CRH stimulation may be due to an abnormality in CRH levels with a resultant alteration in pituitary CRH receptor sensitivity, or it may reflect a dysregulation of vasopressin or other factors involved in HPA regulation. A diminished output of neurotrophic ACTH, causing a reduced adrenocortical secretory reserve, inadequately compensated for by adrenoceptor upregulation, may explain the reduced cortisol production demonstrated in this study.
Scott LV, Medbak S, Dinan TG.	Department of Psychiatry, Trinity College Medical	The low dose ACTH test in chronic fatigue syndrome and in	525: Clin Endocrinol (Oxf) 1998 Jun;48(6):733-	OBJECTIVE: A number of dynamic tests of the hypothalamic-pituitary-adrenal axis provide evidence for a mild central adrenal insufficiency in chronic fatigue syndrome (CFS). The 1 microgram adrenocorticotropin (ACTH) test has been proposed to be

	School, Dublin, Eire.	health.	7Comment in: Clin Endocrinol (Oxf). 2000 Jun;52(6):797-9	more sensitive than the standard 250 micrograms ACTH test in the detection of subtle pituitary-adrenal hypofunctioning. We aimed to establish whether the 1 microgram ACTH test would support such a dysregulation in CFS, and also, given the relative novelty of this test in clinical practice and the uncertainty with regard to appropriate cut-off values for normality, to compare our healthy volunteer data with those of previous studies. PATIENTS AND DESIGN: Twenty subjects with CFS, diagnosed according to Centres for Disease Control and Prevention criteria, were compared with 20 healthy volunteer subjects. All participants underwent a 1 microgram ACTH test beginning at 1400 h. Plasma samples for cortisol estimation were drawn at 0, and min. RESULTS: Baseline cortisol values did not differ between CFS patients and healthy subjects. The delta cortisol (maximum increment from baseline) value was significantly lower in the CFS than the volunteer group ($P < 0.05$). Comparison of the min cortisol values revealed no significant differences. Using an incremental cortisol of > 250 nmol/l as an arbitrary cutoff point, two (10%) of the healthy subjects and nine (45%) of the CFS subjects failed the test on this basis ($chi 2 = 4.3$, $df = 38$, $P < 0.05$). CONCLUSIONS: This study provides further evidence for a subtle pituitary-adrenal insufficiency in subjects with chronic fatigue syndrome compared to healthy volunteers. Disparities between our healthy volunteer data and those of other groups using the 1 microgram ACTH test suggest that the test may not be as reliable as previously indicated.
See DM, Cimoch P, Chou S, Chang J, Tilles J.	University of California, Irvine, Department of Medicine, Orange 92668, USA.	The in vitro immunomodulatory effects of glyconutrients on peripheral blood mononuclear cells of patients with chronic fatigue syndrome.	Integr Physiol Behav Sci 1998 Jul-Sep;33(3):280-7	In humans, eight monosaccharides are required for the synthesis of glycoproteins. Dietary supplements that supply these crucial sugars are known as glyconutrients. A glyconutrient compound was added to Peripheral Blood Mononuclear Cells (PBMC) isolated from normal controls and patients with the Chronic Fatigue Syndrome (CFS), a disease associated with immune dysregulation. The in vitro immunomodulatory effects were investigated. Cell surface expression of the glycoproteins CD5, CD8, and CD11a were significantly lower in patients with CFS compared to normal controls. Addition of glyconutrient homogenate to PBMC from patients with CFS stimulated with phytohemagglutinin significantly increased the expression of each glycoprotein. Furthermore, natural killer (NK) cell function was reduced in CFS patients. The glyconutrient preparation significantly enhanced NK cell activity versus human herpes virus 6 (HHV-6)-infected H9 cells in an 8 h 51Cr release assay compared to placebo for PBMC from patients with CFS ($p< .01$). Finally, apoptosis was significantly higher in patients with CFS. The percentage of apoptotic cells was significantly decreased in PBMC from patients with CFS that had been incubated for 48 h with glyconutrients. Thus, glyconutrients improved abnormal immune parameters in vitro in patients with CFS.
Seelig M		Review and Hypothesis Might Patients with the Chronic Fatigue	Journal of Chronic Fatigue Syndrome 1998: 4(2): 77 - 108	The latent tetany syndrome (LTS) parallels CFS in its neuromuscular and psychiatric manifestations, as well as in inner ear disturbances: vestibular in CFS and FM, as well as in LTS, and increased vulnerability to noise-induced deafness in LTS. Microvascular

		Syndrome Have Latent Tetany of Magnesium Deficiency		damage to the cochlea is seen in Mg deficiency, noise-induced deafness, and might be a factor in migraine and other severe headaches in both LTS and in CFS and FM. Abnormal sleep patterns occur in both LTS and CFS; impaired cognition more in CFS than in LTS. However, some brain and neurotransmitter dysfunctions seen with Mg deficiency might be contributory to cognitive disorders of CFS. Mg loss caused by enhanced catecholamine release produced by stress may well be contributory to stress-induced acute episodes of CFS. Malfunctions of the cellular and humoral immunological systems are caused by experimental Mg deficiency. Whether allergies in CFS patients and abnormal response to antigenic challenge are results of low Mg remains to be proven. Mitral valve prolapse is seen in many LTS and CFS patients; whether a putative Mg deficiency predisposes to this abnormality is not known. Clinical improvement with Mg treatment has been proven in LTS, and seemed helpful in the rare cases of CFS and FM in whom it has been tried. The Mg status should be determined in patient with CFS and FM, but methodology is a handicap. Serum Mg is an inaccurate index. Three methods show promise. Percentage retention of a Mg load is accurate but requires patient's cooperation. Free ionic Mg measurement requires ion-selective electrodes. Blood cell Mg is reliable in a little more than half the patients; sublingual cell Mg seems more accurate. More intensive, and controlled studies of the Mg status of CFS and FM patients, and of their response to Mg therapy is desirable.
Servatius RJ, Tapp WN, Bergen MT, Pollet CA, Drastal SD, Tiersky LA, Desai P, Natelson BH.	New Jersey Medical School, Department of Neuroscience, East Orange 07019, USA.	Impaired associative learning in chronic fatigue syndrome.	Neuroreport 1998 Apr 20;9(6):1153-7	Patients with chronic fatigue syndrome (CFS) report cognitive difficulties (impaired attention, memory and reasoning). Neuropsychological tests have failed to consistently find cognitive impairments to the degree reported by CFS patients. We tested patients with CFS and sedentary controls in protocols designed to measure sensory reactivity and acquisition of the classically conditioned eyeblink response. Patients with CFS exhibited normal sensitivity and responsivity to acoustic stimuli. However, CFS patients displayed impaired acquisition of the eyeblink response using a delayed-type conditioning paradigm. Sensitivity and responsivity to the airpuff stimulus were normal. In the absence of sensory/motor abnormalities, impaired acquisition of the classically conditioned eyeblink response indicates an associative deficit. These data suggest organic brain dysfunction within a defined neural substrate in CFS patients.

Sharpe M.	University of Edinburgh Department of Psychiatry, Royal Edinburgh Hospital, United Kingdom.	Cognitive behavior therapy for chronic fatigue syndrome: efficacy and implications.	Am J Med 1998 Sep 28;105(3A):104S-109S	Cognitive behavior therapy (CBT) is a form of non-pharmacologic treatment. It is based on a model of chronic fatigue syndrome (CFS) that hypothesizes that certain cognitions and behavior may perpetuate symptoms and disability--that is, act as obstacles to recovery. Treatment emphasizes self-help and aims to help the patient to recover by changing these unhelpful cognitions and behavior. There is now good evidence from 2 independent randomized clinical trials to support the efficacy of CBT in patients with CFS. The treatment effect is substantial, although few patients are cured. The urgent clinical need is to make this form of treatment available to patients with CFS. One approach is to incorporate the principles of CBT into routine clinical practice. The preliminary evaluation of these simpler forms of CBT are promising, although the results of controlled trials are awaited. At present, intensive individual CBT administered by a skilled therapist remains the treatment of choice for patients with CFS.
Sibbald B.		Chronic fatigue syndrome comes out of the closet.	CMAJ 1998 Sep 8;159(5):537-41Comment in: CMAJ. 1999 Mar 9;160(5):636, 638 CMAJ. 1999 Mar 9;160(5):638	An Alberta court ruling and new guidelines for physicians issued by the Quebec medical college are giving chronic fatigue syndrome a legitimacy it never before enjoyed. What will this mean for physicians?
Sisto SA, Tapp WN, LaManca JJ, Ling W, Korn LR, Nelson AJ, Natelson BH.	NJCFS Center, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark, USA. sueann@nbunj.jvnc.net	Physical activity before and after exercise in women with chronic fatigue syndrome.	QJM 1998 Jul;91(7):465-73	We measured physical activity after strenuous exercise in 20 women with chronic fatigue syndrome (CFS), compared to 20 sedentary healthy volunteers who exercised no more than once per week. Activity was measured for 2 weeks using a portable waist-worn vertical accelerometer. After the first week of activity monitoring, all participants returned for a maximal treadmill test, followed by continued activity monitoring for the second week. Five activity measures were derived from the data: (i) average activity; (ii) total activity; (iii) duration of waking day; (iv) duration; and (v) number of daily rests. A repeated measures ANCOVA was used to determine post-treadmill group differences accounting for pre-treadmill differences. There was a significant reduction in overall average activity after the treadmill test, with the greatest decrease on days 12 through 14. This reduction was accompanied by a significant increase in the duration of the waking day and number of daily rests. Thus, marked exertion does produce changes in activity, but later than self-report would suggest, and are apparently not so severe that CFS patients cannot compensate.
Smit AA, Bolweg NM, Lenders JW, Wieling W.	Academisch Medisch Centrum, afd. Interne Genceskunde, Amsterdam.	[No strong evidence of disturbed regulation of blood pressure in chronic fatigue syndrome].[article in	Ned Tijdschr Geneeskd 1998 Mar 21;142(12):625-8	Recent medical publications postulate a connection between the Chronic Fatigue Syndrome (CFS) and disturbed regulation of the circulation, manifesting itself during orthostatic stress testing. Four studies were published on the circulatory response on prolonged head up tilt testing. Numerous CFS patients displayed postural tachycardia or syncope during the test. However, many CFS patients examined had had

		Dutch]		orthostatic symptoms prior to the examination. It is not certain that cardiovascular dysregulation is present in CFS patients without orthostatic symptoms. It is also not clear whether such a dysregulation would be the effect of physical inactivity or a manifestation of a subtle form of autonomic neuropathy.

Steele L, Dobbins JG, Fukuda K, Reyes M, Randall B, Koppelman M, Reeves WC.	Viral Exanthems and Herpesvirus Branch, Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, US Centers for Disease Control and Prevention, Atlanta, Georgia 30333, USA.	The epidemiology of chronic fatigue in San Francisco.	Am J Med 1998 Sep 28;105(3A):83S-90S	Despite considerable research on chronic fatigue syndrome (CFS) and conditions associated with unexplained chronic fatigue (CF), little is known about their prevalence and demographic distribution in the population. The present study describes the epidemiology and characteristics of self-reported CF and related conditions in a diverse urban community. The study used a cross-sectional telephone screening survey of households in San Francisco, followed by interviews with fatigued and nonfatigued residents. Respondents who appeared to meet case definition criteria for CFS, based on self-reported fatigue characteristics, symptoms, and medical history, were classified as CFS-like cases. Subjects who reported idiopathic chronic fatigue (ICF) that did not meet CFS criteria were classified as ICF-like cases. Screening interviews were completed for 8,004 households, providing fatigue and demographic information for 16,970 residents. Unexplained CF was extremely rare among household residents <18 years of age, but was reported by 2% of adult respondents. A total of 33 adults (0.2% of the study population) were classified as CFS-like cases and 259 (1.8%) as ICF-like cases. Neither condition clustered within households. CFS- and ICF-like illnesses were most prevalent among women and persons with annual household incomes below $40,000, and least prevalent among Asians. The prevalence of CFS-like illness was elevated among African Americans, Native Americans, and persons engaged in clerical occupations. Although CFS-like cases were more severely ill than those with ICF-like illness, a similar symptom pattern was observed in both groups. In conclusion, conditions associated with unexplained CF occur in all sociodemographic groups but appear to be most prevalent among women, persons with lower income, and some racial minorities.
Stewart J, Weldon A, Arlievsky N, Li K, Munoz J.	Department of Pediatrics, New York Medical College, Valhalla 10595, USA. stewart@nymc.edu	Neurally mediated hypotension and autonomic dysfunction measured by heart rate variability during head-	Clin Auton Res 1998 Aug;8(4):221-30	Recent investigations suggest a role for neurally mediated hypotension (NMH) in the symptomatology of chronic fatigue syndrome (CFS) in adults. Our previous observations in children with NMH and syncope (S) unrelated to CFS indicate that the modulation of sympathetic and parasympathetic tone measured by indices of heart rate variability (HRV) is abnormal in children who faint during head-up tilt (HUT). In

		up tilt testing in children with chronic fatigue syndrome.		order to determine the effects of autonomic tone on HUT in children with CFS we performed measurements of HRV during HUT in 16 patients aged 11-19 with CFS. Data were compared to 26 patients evaluated for syncope and with 13 normal control subjects. After 30 minutes supine, patients were tilted to 80 degrees for 40 minutes or until syncope occurred. Time domain indices included RR interval, SDNN, RMSSD, and pNN50. An autoregressive model was used to calculate power spectra. LFP (.04-.15 Hz), HFP (.15-.40Hz), and TP (.01-.40Hz). Data were obtained supine (baseline) and after HUT. Thirteen CFS patients fainted (CFS, 5/13 pure vasodepressor syncope) and three patients did not (CFS-). Sixteen syncope patients fainted (S, all mixed vasodepressor-cardioinhibitory) and 10 did not (S-). Four control patients fainted (Control, all mixed vasodepressor-cardioinhibitory) and nine did not (Control-). Baseline indices of HRV were not different between Control and S, and between Control- and S-, but were depressed in S compared to S-. HRV indices were strikingly decreased in CFS patients compared to all other groups. With tilt, SDNN, RMSSD, and pNN50 and spectral indices decreased in all groups, remaining much depressed in CFS compared to S or control subjects. With HUT, sympathovagal indices (LFP/HFP, nLFP, and nHFP) were relatively unchanged in CFS, which contrasts with the increase in nLFP with HUT in all other groups. With syncope RMSSD, SDNN, LFP, TP, and HFP increased in S (and Control), suggesting enhanced vagal heart rate regulation. These increases were not observed in CFS patients. CFS is associated with NMH during HUT in children. All indices of HRV are markedly depressed in CFS patients, even when compared with already low HRV in S or Control patients. Sympathovagal balance does not shift toward enhanced sympathetic modulation of heart rate with HUT and there is blunting in the overall HRV response with syncope during HUT. Taken together these data may indicate autonomic impairment in patients with CFS.
Stores G, Fry A, Crawford C.	University Section, Park Hospital for Children, Oxford, UK.	Sleep abnormalities demonstrated by home polysomnography in teenagers with chronic fatigue syndrome.	J Psychosom Res 1998 Jul;45(1 Spec No):85-91	To provide objective information about sleep physiology in young people with chronic fatigue syndrome (CFS), home polysomnography (PSG) was performed on 18 teenagers, aged 11-17 years, in whom CFS had been diagnosed according to internationally accepted criteria. The results were compared with those for healthy controls matched individually for gender and age. Compared with controls, CFS subjects showed significantly higher levels of sleep disruption by both brief and longer awakenings. Disruption of sleep in this way could at least contribute to the daytime symptoms of young people with CFS. The underlying cause of the disruption needs to be considered in each individual case. Further research is required to clarify the relative contribution of this neurobiological aspect of CFS in young people.
Streeten DH, Anderson GH Jr.	Department of Medicine, SUNY Health Science Center, Syracuse, NY 13210, USA.	The role of delayed orthostatic hypotension in the pathogenesis of chronic fatigue.	Clin Auton Res 1998 Apr;8(2):119-24	Past studies have shown that severe fatigue was the presenting symptom in six of seven patients with delayed orthostatic hypotension and that tilt table-induced hypotension was found in 22 of 23 patients with the chronic fatigue syndrome. We have determined the prevalence of fatigue, volunteered in response to a nonspecific pre-examination questionnaire used in 431 patients, each subsequently diagnosed as

				having one of eight neurological or endocrine disorders. The results show that fatigue is a very common symptom in patients with delayed orthostatic hypotension (n = 21), as well as both primary (n = 30) and secondary (n = 106) hypocortisolism: 70-83% in all groups. In contrast, fatigue was an uncommon complaint in patients with multiple system atrophy (MSA) (n = 30), pituitary disorders without hypocortisolism (n = 106) or idiopathic hirsutism (n = 96): 7-33% in all groups, and was intermediate in prevalence in patients with acute hyperadrenergic orthostatic hypotension (n = 32): 41%. It is concluded that fatigue commonly results from delayed orthostatic hypotension and all forms of hypocortisolism but is less common in patients with acute orthostatic hypotension, both idiopathic and due to MSA, which more commonly present with lightheadedness or syncope.
Streeten DH, David S. Bell		Original ResearchCirculating Blood Volume in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 4(1): 3 - 11	Chronic fatigue syndrome (CFS) is an illness associated with severe activity limitation and a characteristic pattern of symptoms despite a relatively normal physical examination and routine laboratory evaluation. The recent description of delayed orthostatic hypotension in patients with CFS, and previous findings of reduced red blood cell (RBC) mass in other patients with orthostatic hypotension not known to have CFS, led us to measure RBC mass and plasma volume in 19 individuals (15 female, four male) with well characterized, severe CFS. RBC mass was found to be significantly reduced ($p < 0.001$) below the published normal range in the 16 women, being subnormal in 15 (93.8%) of them as well as in two of the four men. Plasma volume was subnormal in 10 (52.6%) patients and total blood volume was below normal in 12 (63.2%). The high prevalence and frequent severity of the low RBC mass suggest that this abnormality might contribute to the symptoms of CFS by reducing the oxygen-carrying power of the blood reaching the brain in many of these patients.
Strickland P, Morriss R, Wearden A, Deakin B.	University of Manchester and (Guild NHS Trust), Department of Community Psychiatry, Royal Preston Hospital, Fulwood, UK.	A comparison of salivary cortisol in chronic fatigue syndrome, community depression and healthy controls.	J Affect Disord 1998 Jan;47(1-3):191-4	BACKGROUND: Previous studies reporting cortisol hyposecretion in chronic fatigue syndrome may have been confounded by venepuncture, fasting and hospitalisation. METHODS: Morning and evening salivary cortisol were obtained on consecutive days in the first 3 days of the menstrual cycle and compared in three samples of women taking no medication and matched for age: 14 patients with chronic fatigue syndrome, 26 community cases of ICD-10 current depressive episodes and 131 healthy community controls. RESULTS: The mean evening cortisol was significantly lower in the chronic fatigue syndrome patients compared to controls with depression ($P = 0.02$) and healthy controls ($P = 0.005$). Chronic fatigue syndrome patients without psychiatric disorder had significantly lower morning salivary cortisols compared to controls ($P = 0.009$). CONCLUSION: Chronic fatigue syndrome patients display cortisol hyposecretion in saliva as well as plasma compared to patients with depression and healthy controls. LIMITATIONS: Small samples of female patients with cortisol estimated at only two time points in the day. Cortisol secretion may be secondary to other neurotransmitter abnormalities or other physiological or lifestyle factors in chronic fatigue syndrome patients. CLINICAL RELEVANCE: Chronic fatigue

				syndrome is biochemically distinct from community depression.
Swanink CM, Stolk-Engelaar VM, van der Meer JW, Vercoulen JH, Bleijenberg G, Fennis JF, Galama JM, Hoogkamp-Korstanje JA.	Department of Medical Microbiology, University Hospital Nijmegen, The Netherlands.	Yersinia enterocolitica and the chronic fatigue syndrome.	J Infect 1998 May;36(3):269-72	OBJECTIVES: To investigate the potential role of Yersinia enterocolitica in patients with chronic fatigue syndrome (CFS). METHODS: An immunoblot technique was used to detect antibodies to various Yersinia outer membrane proteins (YOPs) in serum samples from 88 patients with CFS and 77 healthy neighbourhood controls, matched for gender and age. RESULTS: The prevalence of IgG and IgA antibodies to various Yersinia outer membrane proteins (YOPs) did not differ between patients with CFS and healthy controls. Twenty-four patients (27%) and nineteen controls (25%) had IgG antibodies to one or more YOPs. Four patients and two controls had both serum IgG and IgA antibodies to at least two different YOPs, compatible with a recent or persistent infection. Although all patients with positive IgG and IgA reactions to two or more YOPs had symptoms that could point to persistent Yersinia infection, these symptoms were also found frequently in patients without antibodies to YOPs. CONCLUSIONS: We conclude that Y. enterocolitica is unlikely to play a major role in the aetiology of CFS.
Terman M, Levine SM, Terman JS, Doherty S.	Department of Psychiatry, College of Physicians and Surgeons, Columbia University, New York State Psychiatric Institute, New York 10032, USA.	Chronic fatigue syndrome and seasonal affective disorder: comorbidity, diagnostic overlap, and implications for treatment.	Am J Med 1998 Sep 28;105(3A):115S-124S	This study aimed to determine symptom patterns in patients with chronic fatigue syndrome (CFS), in summer and winter. Comparison data for patients with seasonal affective disorder (SAD) were used to evaluate seasonal variation in mood and behavior, atypical neurovegetative symptoms characteristic of SAD, and somatic symptoms characteristic of CFS. Rating scale questionnaires were mailed to patients previously diagnosed with CFS. Instruments included the Personal Inventory for Depression and SAD (PIDS) and the Systematic Assessment for Treatment Emergent Effects (SAFTEE), which catalogs the current severity of a wide range of somatic, behavioral, and affective symptoms. Data sets from 110 CFS patients matched across seasons were entered into the analysis. Symptoms that conform with the Centers for Disease Control and Prevention (CDC) case definition of CFS were rated as moderate to very severe during the winter months by varying proportions of patients (from 43% for lymph node pain or enlargement, to 79% for muscle, joint, or bone pain). Fatigue was reported by 92%. Prominent affective symptoms included irritability (55%), depressed mood (52%), and anxiety (51%). Retrospective monthly ratings of mood, social activity, energy, sleep duration, amount eaten, and weight change showed a coherent pattern of winter worsening. Of patients with consistent summer and winter ratings (n = 73), 37% showed high global seasonality scores (GSS) > or = 10. About half this group reported symptoms indicative of major depressive disorder, which was strongly associated with high seasonality. Hierarchical cluster analysis of wintertime symptoms revealed 2 distinct clinical profiles among CFS patients: (a) those with high seasonality, for whom depressed mood clustered with atypical neurovegetative symptoms of hypersomnia and hyperphagia, as is seen in SAD; and (b) those with low seasonality, who showed a primary clustering of classic CFS symptoms (fatigue, aches, cognitive disturbance), with depressed mood most closely

				associated with irritability, insomnia, and anxiety. It appears that a subgroup of patients with CFS shows seasonal variation in symptoms resembling those of SAD, with winter exacerbation. Light therapy may provide patients with CFS an effective treatment alternative or adjunct to antidepressant drugs.
Thompson D, Hylan TR, McMullen W, Romeis ME, Buesching D, Oster G.	Policy Analysis, Inc., Indianapolis, USA. dthompson@pai2.com	Predictors of a medical-offset effect among patients receiving antidepressant therapy.	Am J Psychiatry 1998 Jun;155(6):824-7	OBJECTIVE: Characteristics of patients receiving antidepressant therapy were examined to identify factors that may be associated with a medical-offset effect. METHOD: In a retrospective study, the authors analyzed claims data from a large health insurer in New England. The study subjects included 1,661 persons initiating treatment for depression with selective serotonin reuptake inhibitors or tricyclic antidepressants between July 1991 and June 1993. RESULTS: Patients with anxiety disorders, coronary heart disease, cancer, and chronic fatigue syndrome and those remaining on their initial regimens of antidepressant therapy for at least 6 months were more likely to experience significant reductions in the costs of medical care services. The number of visits to mental health providers had no effect on the costs of medical services. CONCLUSIONS: Specific comorbid conditions and sustained use of antidepressant drugs may be associated with a medical-offset effect for patients receiving treatment for depression.
Timothy K. Roberts , Neil R. McGregor, R. Hugh Dunstan, Mark Donohoe, Raymond N. Murdoch , D. Hope , DipEd, S. Zhang BMed, Henry L. Butt , Jennifer A. Watkins , Warren G. Taylor		Immunological and Haematological Parameters in Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 4(4): 51 - 65	Red and white blood cell parameter profiles and pokeweed mitogen responses were investigated in 57 CDC-defined CFS patients and 34 age-and sex-matched controls. CFS patients had significantly different red and white blood cell profiles compared with controls. Red cell distribution width (RDW) was the primary regression factor differentiating the groups. RDW was positively associated with mean platelet volume (MPV) in control subjects, but negatively correlated with MPV in CFS patients, indicating a reversal of the functional relationship between these parameters in CFS patients. Hematological parameters, and not the immunological parameters studied, were more important in differentiating CFS patients from healthy control subjects. Female CFS patients had significant increases in RDW and mean platelet volume, and decreases in the numbers of T-helper cells, T-cells and lymphocytes compared with control females. These alterations were not observed in corresponding male comparisons. There were no differences in the pokeweed mitogen (PWM) response between the CFS and control groups. However, in control subjects, a significant association was observed between pokeweed mitogen responses and Rh(D) antigen status, whereas no similar association was measured in CFS patients. Rh(D)-negative control subjects had a significantly increased mitogen response compared with Rh(D)-positive subjects, whereas in CFS patients, no difference was found. It was concluded that future blood parameter and lymphocyte mitogen response studies in CFS patients should bc controlled for sex and Rh status, respectively.
Tirelli U, Chierichetti F, Tavio M, Simonelli C, Bianchin G, Zanco P,	Division of Medical Oncology and Acquired Immunodeficiency	Brain positron emission tomography (PET) in chronic fatigue	Am J Med 1998 Sep 28;105(3A):54S-58S	Chronic fatigue syndrome (CFS) has been widely studied by neuroimaging techniques in recent years with conflicting results. In particular, using single-photon emission computed tomography (SPECT) and perfusion tracers, hypoperfusion has been found

Ferlin G.	Syndrome, Centro di Riferimento Oncologico, Aviano, Italy.	syndrome: preliminary data.		in several brain regions, although the findings vary across research centers. The objective of this study was to investigate brain metabolism of patients affected by CFS, using [18F]fluorine-deoxyglucose (18FDG) positron emission tomography (PET). We performed 18FDG PET in 18 patients who fulfilled the criteria of the working case definition of CFS. Twelve of the 18 patients were females; the mean age was 34 15 years (range, 15-68) and the median time from CFS diagnosis was 16 months (range, 9-138). Psychiatric diseases and anxiety/neurosis were excluded in all CFS patients. CFS patients were compared with a group of 6 patients affected by depression (according to DSM IV-R) and 6 age-matched healthy controls. The CFS patients were not taking any medication at the time of PET, and depressed patients were drug-free for at least 1 week before the PET examination. The PET images examined 22 cortical and subcortical areas. CFS patients showed a significant hypometabolism in right mediofrontal cortex (P = 0.010) and brainstem (P = 0.013) in comparison with the healthy controls. Moreover, comparing patients affected by CFS and depression, the latter group showed a significant and severe hypometabolism of the medial and upper frontal regions bilaterally (P = 0.037-0.001), whereas the metabolism of brain stem was normal. Brain 18FDG PET showed specific metabolism abnormalities in patients with CFS in comparison with both healthy controls and depressed patients. The most relevant result of our study is the brain stem hypometabolism which, as reported in a perfusion SPECT study, seems to be a marker for the in vivo diagnosis of CFS.
Treib J, Fernandez A, Haass A, Grauer MT, Holzer G, Woessner R.	Department of Neurology, University of the Saarland, Homburg, Germany.	Clinical and serologic follow-up in patients with neuroborreliosis.	Neurology 1998 Nov;51(5):1489-91Comment in: Neurology. 1999 Sep 11;53(4):895-6	The authors performed a clinical and serologic follow-up study after 4.2 1.2 years in 44 patients with clinical signs of neuroborreliosis and specific intrathecal antibody production. All patients had been treated with ceftriaxone 2 g/day for 10 days. Although neurologic deficits decreased significantly, more than half the patients had unspecific complaints resembling a chronic fatigue syndrome and showed persisting positive immunoglobulin M serum titers for Borrelia in the Western blot analysis.
Tuck I, Human N.	Department of Nursing Systems, Community and Psychiatric Mental Health Nursing, School of Nursing, Virginia Commonwealth University, Richmond 23298-0567, USA.	The experience of living with chronic fatigue syndrome.	J Psychosoc Nurs Ment Health Serv 1998 Feb;36(2):15-9	1. Chronic fatigue syndrome (CFS) is a condition that affects the total person, body, mind, and spirit. 2. CFS sufferers describe the experience as being in the illness, remembering life before the illness, and living with the symptoms. 3. Empathy and compassion are essential components of providing nursing care for clients with CFS.
van de Luit L, van der Meulen J, Cleophas TJ, Zwinderman AH.	Department of Medicine, Merwede Hospital Dordrecht, The Netherlands.	Amplified amplitudes of circadian rhythms and nighttime hypotension in patients with chronic fatigue	Angiology 1998 Nov;49(11):903-8	Fatigue is an important symptom of a disturbed circadian rhythm. To date, no studies of circadian rhythms in patients with chronic fatigue syndrome (CFS) have been published. The objectives of the study were to study rhythms of heart rate and systolic and diastolic blood pressure in patients with chronic fatigue syndrome compared with age-matched normotensive controls and to study the effects of

		syndrome: improvement by inopamil but not by melatonin.		melatonin and inopamil on such rhythms. Ambulatory blood pressure (ABP) measurements (Space Lab, Inc, validated) of 18 patients with CFS were made according to the 1987 U.S. Center for Disease Control Criteria, and measurements of 12 age-matched normotensive controls were used in a cosinor analysis of the two groups. The effects of melatonin and inopamil on ABP were studied subsequently in four patients in an 8-week open-label evaluation. One patient was hypertensive (diastolic blood pressure > 90 mm Hg at least once every 4 hours), and was, therefore, excluded. The data of the remaining 17 patients (15 women, 2 men) revealed a significant 12-hour rhythm in heart rate and 24-hour rhythm in systolic and diastolic blood pressure with 95% confidence intervals not significantly different from sinusoidal patterns. Although these rhythms were synchronous with the control group rhythms, their amplitudes were not and showed, respectively, 2.8, 2.8, and 9.0 times the size of the control group rhythms ($p < 0.001$, $p < 0.001$, and $p < 0.0001$, respectively). Systolic blood pressures in the patients with CFS were consistently below 100 mm Hg during the nighttime. In a subsequent pilot study of four patients from the study population treated with melatonin 4 mg daily and inopamil 200 mg daily for 4 weeks, inopamil reduced nighttime hypotension ($p < 0.05$), whereas melatonin increased nighttime hypotension ($p < 0.02$). Patients with CFS have increased amplitudes of circadian rhythms and systolic blood pressures consistently below 100 mm Hg during the nighttime. Positive inotropic compounds may be beneficial in such patients, but melatonin may not be.
Vercoulen JH, Bazelmans E, Swanink CM, Galama JM, Fennis JF, van der Meer JW, Bleijenberg G.	Department of Medical Psychology, University Hospital Nijmegen, The Netherlands. j.vercoulen@cksmps.kun.nl	Evaluating neuropsychological impairment in chronic fatigue syndrome.	J Clin Exp Neuropsychol 1998 Apr;20(2):144-56	This study was designed to provide an estimate of the prevalence of neuropsychological impairment in chronic fatigue syndrome (CFS), to evaluate the concordance between impairment found on standardized tests and self-reported neuropsychological problems, and to study the relationship between neuropsychological functioning and fatigue severity and psychological processes. We adopted an individual approach to determine neuropsychological impairment as contrasted with the group-comparisons approach used in previous studies. Also, correction for premorbid functioning and confounders was done on an individual basis. The results show that a minority of participants were impaired in neuropsychological functioning. There was no relationship between neuropsychological impairment on standardized tests and self-reported memory and concentration problems. Neuropsychological functioning was not related to fatigue or depression. Slowed speed of information processing and motor speed were related to low levels of physical activity.
Vercoulen JH, Swanink CM, Galama JM, Fennis JF, Jongen PJ, Hommes OR, van der Meer JW, Bleijenberg	Department of Medical Psychology, University Hospital Nijmegen, The Netherlands.	The persistence of fatigue in chronic fatigue syndrome and multiple sclerosis: development of a	J Psychosom Res 1998 Dec;45(6):507-17	The cause of chronic fatigue syndrome (CFS) is unknown. With respect to factors perpetuating fatigue, on the other hand, a model has been postulated in the literature in which behavioral, cognitive, and affective factors play a role in perpetuating fatigue. In the present study, this hypothesized model was tested on patients with CFS and on fatigued patients with multiple sclerosis (MS). The model

G.		model.		was formulated in terms of cause-and-effect relationships and an integral test of this model was performed by the statistical technique, "structural equation modeling," in 51 patients with chronic fatigue syndrome and 50 patients with multiple sclerosis matched for age, gender, and education. Attributing complaints to a somatic cause produced low levels of physical activity, which in turn had a causal effect on fatigue severity. Depression had to be deleted from the model. Sense of control over symptoms and focusing on bodily symptoms each had a direct causal effect on fatigue. The model showed an excellent fit for CFS patients, but was rejected for MS patients. Therefore, a new model for MS patients had to be developed in which sense of control had a causal effect on fatigue. In the MS model, no causal relationship was found between the physical state as measured by the Expanded Disability Status Score (EDSS) and fatigue or functional impairment. The present study shows that cognitive and behavioral factors are involved in the persistence of fatigue. Treatment should be directed at these factors. The processes involved in the subjective experience of fatigue in CFS were different from the processes related to fatigue in MS.
Vilikus Z, Mareckova H, Janatkova I, Krystufkova O, Barackova M, Boudova L, Brandejsky P, Fucikova T.	Ustav telovychovneho lekarstvi a Ustav klinicke imunologie 1. lekarske fakulty Univerzity Karlovy, Praha, Czech Republic. zdenek vilikus@medicom.cz	[Risk factors for ischemic heart disease in patients with chronic fatigue syndrome].[article in Czech]	Sb Lek 1998;99(1):53-61	Risk factors of coronary artery disease (CAD) between a group of patients suffering of chronic fatigue syndrome (CFS) and a control group of healthy persons (whose exercise activity was not health-limited) were compared. Thirty three patients (27 women, 6 men, average age 39.9 11.7 years) and the same number of controls matched in age (39.8 10.3 years), gender and body weight. The Minnesota Questionnaire (by Taylor) and the Compendium of Physical Activities (by Ainsworth) were used to estimate total energetic expenditure in exercise activity as well as in job. The risk factors of CAD in the patients with CFS were not higher than in the control group. Aerobic physical fitness, basic anthropometric data, blood pressure, spectrum of blood lipoproteins, blood uric acid and smoking habits were not different between the compared groups. Patients suffering from CFS had lower total energetic expenditure in exercise activity. Nevertheless, this significant difference in sports activity was not large enough to cause any difference in risk factors of CAD between the CFS patients and the control group.
Visser J, Blauw B, Hinloopen B, Brommer E, de Kloet ER, Kluft C, Nagelkerken L.	Division of Immunological and Infectious Diseases, TNO Prevention and Health, Leiden Amsterdam Center for Drug Research, The Netherlands.	CD4 T lymphocytes from patients with chronic fatigue syndrome have decreased interferon-gamma production and increased sensitivity to dexamethasone.	607: J Infect Dis 1998 Feb;177(2):451-4	A disturbed hypothalamus-pituitary-adrenal gland axis and alterations at the immune system level have been observed in patients with chronic fatigue syndrome (CFS). Glucocorticoids are known to modulate T cell responses; therefore, purified CD4 T cells from CFS patients were studied to determine whether they have an altered sensitivity to dexamethasone (DEX). CD4 T cells from CFS patients produced less interferon-gamma than did cells from controls; by contrast, interleukin-4 production and cell proliferation were comparable. With CD4 T cells from CFS patients (compared with cells from controls), a 10- to 20-fold lower DEX concentration was needed to achieve 50% inhibition of interleukin-4 production and proliferation, indicating an increased sensitivity to DEX in CFS patients. Surprisingly, interferon-

				gamma production in patients and controls was equally sensitive to DEX. A differential sensitivity of cytokines or CD4 T cell subsets to glucocorticoids might explain an altered immunologic function in CFS patients.
Vojdani A, Choppa PC, Tagle C, Andrin R, Samimi B, Lapp CW.	Immunosciences Laboratory, Beverly Hills, CA 90211, USA. immunsi@ix.netcom.com	Detection of Mycoplasma genus and Mycoplasma fermentans by PCR in patients with Chronic Fatigue Syndrome.	FEMS Immunol Med Microbiol 1998 Dec;22(4):355-65	Mycoplasma fermentans and other Mycoplasma species are colonizers of human mucosal surfaces and may be associated with human immunodeficiency virus infection. While many infectious agents have been described in different percentages of patients with Chronic Fatigue Syndrome (CFS), little is known about the prevalence of mycoplasmas and especially M. fermentans in CFS patients. A polymerase chain reaction (PCR)-based assay was used to detect Mycoplasma genus and M. fermentans genomes in peripheral blood mononuclear cells (PBMC) of CFS patients. Blood was collected from 100 patients with CFS and 50 control subjects. The amplified products of 717 bp of Mycoplasma genus, and 206 bp of M. fermentans were detected in DNA purified from blood samples in 52% and 34% of CFS samples, respectively. In contrast, these genomes were found in only 14% and 8% of healthy control subjects respectively ($P < 0.0001$). All samples were confirmed by Southern blot with a specific probe based on internal sequences of the expected amplification product. Several samples, which were positive for Mycoplasma genus, were negative for M. fermentans indicating that other Mycoplasma species are involved. A quantitative PCR was developed to determine the number of M. fermentans genome copies present in 1 microg of DNA for controls and CFS patients. Mycoplasma copy numbers ranging from 130 to 880 and from 264 to 2400 were detected in controls and CFS positive subjects, respectively. An enzyme immunoassay was applied for the detection of antibodies against p29 surface lipoprotein of M. fermentans to determine the relationship between M. fermentans genome copy numbers and antibody levels. Individuals with high genome copy numbers exhibited higher IgG and IgM antibodies against M. fermentans specific peptides. Isolation of this organism by culture from clinical specimens is needed in order to demonstrate specificity of signal detected by PCR in this study.
Vollmer-Conna U, Lloyd A, Hickie I, Wakefield D.	Inflammation Research Unit, School of Pathology, University of New South Wales, Sydney, Australia.	Chronic fatigue syndrome: an immunological perspective.	Aust N Z J Psychiatry 1998 Aug;32(4):523-7	OBJECTIVE: The aim of this study is to review research examining an immunological basis for chronic fatigue syndrome (CFS) and to discuss how a disturbance in immunity could produce central nervous system (CNS)-mediated symptoms. METHOD: Data relevant to the hypothesis that abnormal cytokine release plays a role in the pathogenesis of CFS are reviewed as well as recent evidence relating to potential mechanisms by which immune products may enter the brain and produce a disturbance in CNS processes. RESULTS: Examinations of cytokine levels in patients with CFS have produced inconclusive results. Recent evidence suggests that abnormal release of cytokines within the CNS may cause neural dysfunction by a variety of complex mechanisms. CONCLUSION: Neuropsychiatric symptoms in patients with CFS may be more closely related to disordered cytokine production by glial cells within the CNS than to circulating cytokines. This possibility is discussed in

				the context of unresolved issues in the pathogenesis of CFS. Review Literature
Ware NC.	Department of Social Medicine, Harvard Medical School, Boston, Massachusetts 02115, USA. nware@warren.med.harvard.edu	Sociosomatics and illness in chronic fatigue syndrome.	Psychosom Med 1998 Jul-Aug;60(4):394-401Comment in: Psychosom Med. 1999 Mar-Apr;61(2):256	OBJECTIVE: This study examines social processes that construct the course of chronic illness. Specifically, it identifies and describes mechanisms that constitute the process of role constriction in employment for individuals with chronic illness. METHOD: Sixty-six persons meeting the Centers for Disease Control case definition of chronic fatigue syndrome (CFS) participated in a longitudinal study involving three waves of data collection over 3 years. Qualitative and quantitative methods were combined in the research, which included face-to-face semistructured interviews, telephone interviews, and self-report questionnaires. Materials presented in this study are drawn principally from the Year 1 face-to-face and telephone interviews. RESULTS: When patterns of symptoms and of the illness course in CFS intersect with work requirements, they impede performance and place ill individuals at risk for job loss. Persons with CFS devise and implement specific strategies to resist role constriction and remain in the work force. CONCLUSIONS: Role constriction is a social process of marginalization in chronic illness. Opposing forces of marginalization and resistance define the social course in chronic illness and suggest that chronicity can be thought of as a marginalized position in social space.
Watson WS, Donald C. McMillan, Abhijit Chaudhuri, Peter O. Behan		Increased Resting Energy Expenditure in the Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1998: 4(4): 3 - 14	It has been suggested that resting energy expenditure may be raised in chronic fatigue syndrome due to an upregulation of transmembrane ion transport. We measured resting energy expenditure by indirect calorimetry in 11 women with chronic fatigue and in 11 healthy women. Total body potassium, by whole body counting, and total body water, extracellular water and intracellular water, by a bioelectrical impedance method, were also measured. When individual resting energy expenditure was predicted on the basis of total body potassium values for the chronic fatigue group, 5 out of 11 of these subjects had resting energy expenditure above the upper limit of normal as defined by the control group data. This is consistent with the hypothesis that there is upregulation of the sodium-potassium pump in chronic fatigue syndrome.
Wearden AJ, Morriss RK, Mullis R, Strickland PL, Pearson DJ, Appleby L, Campbell IT, Morris JA.	University of Manchester, Department of Psychiatry, Withington Hospital.	Randomised, double-blind, placebo-controlled treatment trial of fluoxetine and graded exercise for chronic fatigue syndrome. Erratum in: Br J Psychiatry 1998 Jul;173:89Comment in: Br J Psychiatry. 1998 Jun;172:491-2 Br J Psychiatry. 1998	Br J Psychiatry 1998 Jun;172:485-90	BACKGROUND: The Joint Working Group of the Royal Colleges of Physicians, Psychiatrists and General Practitioners (1996) recommended graded exercise and antidepressants for patients with chronic fatigue syndrome. We assessed efficacy and acceptability of these treatments. METHOD: Six-month prospective randomised placebo and therapist contact time controlled trial with allocation to one of four treatment cells: exercise and 20 mg fluoxetine, exercise and placebo drug, appointments only and 20 mg fluoxetine, appointments and placebo drug. Drug treatment was double blind and patients were blind to assignment to exercise or appointments. RESULTS: Ninety-six (71%) of 136 patients completed the trial. Patients were more likely to drop out of exercise than non-exercise treatment (P = 0.05). In an intention to treat analysis, exercise resulted in fewer patients with case level fatigue than appointments only at 26 weeks (12 (18%) v. 4 (6%) respectively P =

		Oct;173:353 Br J		0.025) and improvement in functional work capacity at 12 (P = 0.005) and 26 weeks (P = 0.03). Fluoxetine had a significant effect on depression at week 12 only (P = 0.04). Exercise significantly improved health perception (P = 0.012) and fatigue (P = 0.028) at 28 weeks. CONCLUSIONS: Graded exercise produced improvements in functional work capacity and fatigue, while fluoxetine improved depression only.
Weiss B.	Department of Environmental Medicine, University of Rochester Medical Center, NY 14642, USA.	Neurobehavioral properties of chemical sensitivity syndromes.	Neurotoxicology 1998 Apr;19(2):259-68	Chemical sensitivity Syndromes refers to aggregations of symptoms marked by largely subjective neurobehavioral complaints and hypothesized links to immune system dysfunction. The entities reviewed here consist of the Multiple Chemical Sensitivity Syndrome, the Sick Building Syndrome, the Chronic Fatigue Syndrome, and the Gulf War Syndrome. Except for the Chronic Fatigue Syndrome, toxic chemical exposures are accorded a significant role in their etiology. The connections are ambiguous because of the variety of chemical agents cited and, for the most part, the relatively low levels at which exposures occur. Conventional clinical signs are also typically lacking. Explanatory mechanisms include psychiatric diagnoses such as somatization, behavioral mechanisms such as conditioning and generalization, neuropharmacological mechanisms such as sensitization, and psychoneuroimmunological mechanisms such as those involving the hypothalamic-pituitary-adrenal axis. Laboratory animal experimentation and controlled clinical trials, especially with inhaled material, provide the means for exploring the proffered explanations.

White PD, Thomas JM, Amess J, Crawford DH, Grover SA, Kangro HO, Clare AW.	St Bartholomew's, London.	Incidence, risk and prognosis of acute and chronic fatigue syndromes and psychiatric disorders after glandular fever.	Br J Psychiatry 1998 Dec;173:475-81	BACKGROUND: The role of viruses in the aetiology of both chronic fatigue syndrome (CFS) and depressive illness is uncertain. METHOD: A prospective cohort study of 250 primary care patients, presenting with glandular fever or an ordinary upper respiratory tract infection (URTI). RESULTS: The incidence of an acute fatigue syndrome was 47% at onset, after glandular fever, compared with 20% with an ordinary URTI (relative risk 2.3, 95% CI 1.3-4.1). The acute fatigue syndrome lasted a median (interquartile range) of eight weeks (4-16) after glandular fever, but only three weeks (2-4) after an URTI. The prevalence of CFS was 9-22% six months after glandular fever, compared with 0-6% following an ordinary URTI, with relative risks of 2.7-5.1. The most conservative measure of the incidence of CFS was 9% after glandular fever, compared with no cases after an URTI. A conservative estimate is that glandular fever accounts for 3113 (95% CI 1698-4528) new cases of CFS per annum in England and Wales. New episodes of major depressive disorder were triggered by infection, especially the Epstein-Barr virus, but lasted a median of only three weeks. No psychiatric disorder was significantly more prevalent six months after onset than before. CONCLUSIONS: Glandular fever is a significant risk factor for both acute and chronic fatigue syndromes. Transient new major depressive disorders

				occur close to onset, but are not related to any particular infection if they last more than a month.
Whiteside TL, Friberg D.	University of Pittsburgh Cancer Institute, Pennsylvania 15213-2582, USA.	Natural killer cells and natural killer cell activity in chronic fatigue syndrome.	Am J Med 1998 Sep 28;105(3A):27S-34S	Chronic fatigue syndrome (CFS) is associated with insidious and persistent immunologic abnormalities that have proved difficult to reproduce. The heterogeneity of CFS, the variable quality of immunologic assays and their performance, along with an almost complete absence of longitudinal studies of cellular immune abnormalities in CFS may explain this difficulty. However, in a significant proportion of cases, low levels of natural killer (NK) cell activity have been reported. This article will explore the mechanisms responsible for low NK cell activity, discuss the relation between levels of NK cell activity and health/disease, describe new findings on NK cell-brain interactions, and put forth a specific hypothesis for the role of NK cells in the pathogenesis of CFS.
Wilke WS, Fouad-Tarazi FM, Cash JM, Calabrese LH.	Department of Rheumatic and Immunologic Disease, Cleveland Clinic Foundation, OH 44195, USA.	The connection between chronic fatigue syndrome and neurally mediated hypotension.	Cleve Clin J Med 1998 May;65(5):261-6	Research from several groups of investigators indicates that some patients with chronic fatigue syndrome have abnormal vasovagal or vasodepressor responses to upright posture. If confirmed, these findings may explain some of the symptoms of chronic fatigue syndrome. There is also speculation that neurally mediated hypotension may be present in fibromyalgia. This article discusses the original research in this area, the results of follow-up studies, and the current approach to treating patients with chronic fatigue syndrome in whom neurally mediated hypotension is suspected.
Wood B, Wessely S, Papadopoulos A, Poon L, Checkley S.	Institute of Psychiatry, London, UK.	Salivary cortisol profiles in chronic fatigue syndrome.	Neuropsychobiology 1998;37(1):1-4	Salivary cortisol profiles (hourly sampling over a 16-hour period) of 10 patients with chronic fatigue syndrome (CFS) but without concurrent depressive disorder were compared with those of 10 healthy volunteers matched for age, sex and menstrual cycle. The mean saliva cortisol concentration over the 16-hour period was slightly but significantly greater in the patients than the controls ($p < 0.05$). These findings are at variance with earlier reports that CFS is a hypocortisolaemic state and suggest that in CFS the symptom of fatigue is not caused by hypocortisolaemia.

Young AH, Sharpe M, Clements A, Dowling B, Hawton KE, Cowen PJ.	University Department of Psychiatry, Warneford Hospital, Oxford, United Kingdom.	Basal activity of the hypothalamic-pituitary-adrenal axis in patients with the chronic fatigue syndrome (neurasthenia).	Biol Psychiatry 1998 Feb 1;43(3):236-7	BACKGROUND: Impairments in both basal activity and activation of the hypothalamic-pituitary-adrenal axis (HPA) have been reported in chronic fatigue syndrome (CFS; neurasthenia). We sought to replicate these findings and examined basal activity of the HPA in a carefully selected sample of patients with CFS. METHODS: Basal activity of the HPA was assessed using salivary and urinary cortisol collection over a 24-hour period in 22 (12 male; 10 female) patients meeting criteria for CFS and appropriate controls. RESULTS: Salivary and urinary cortisol measures did not differ between CFS patients and controls. CONCLUSIONS: Basal activity of the HPA was not reduced in CFS patients. Reasons for the failure to replicate previous findings are discussed.

Albus C.	Institut und Poliklinik fur Psychosomatik und Psychotherapie, Universitat zu Koln.	[Chronic fatigue syndrome--a disease entity or an unspecified psychosomatic disorder]?[article in German]	Z Arztl Fortbild Qualitatssich 1997 Dec;91(8):717-21	In spite of its nature as an often severe and disabeling disease, it is still unclear, whether the Chronic Fatigue Syndrome (CFS) is an entire disease of its own right or not. Moreover, there is a growing evidence that patients with CFS belong to an inhomogeneous group with different etiologic constellations. Specific somatic factors, e.g. viruses, seem to be less important for onset than certain personality-traits like depressiveness and workaholism. These traits lead to an increased vulnerability to unspecific psychological or biological stressors that may cause chronic fatigue by complex psychosomatic interferences. Concerning diagnosis, there are no specific methods or results available, the same is true for pharmacological treatment. As a consequence, practitioners should be aware not to miss a somatic disease causing fatigue, and, parallel to this, start right from the beginning talking about the psychosomatic background of CFS. Furthermore, psychotherapy has shown to be effective in CFS.
Allain TJ, Bearn JA, Coskeran P, Jones J, Checkley A, Butler J, Wessely S, Miell JP.	Department of Medicine, Kings College School of Medicine and Dentistry, London, United Kingdom.	Changes in growth hormone, insulin, insulinlike growth factors (IGFs), and IGF-binding protein-1 in chronic fatigue syndrome.	Biol Psychiatry 1997 Mar 1;41(5):567-73	Chronic fatigue syndrome (CFS) is characterized by severe physical and mental fatigue of central origin. Similar clinical features may occur in disorders of the hypothalamopituitary axis. The aim of the study was to determine whether patients with CFS have abnormalities of the growth hormone/insulinlike growth factor (GH-IGF) axis basally or following hypothalamic stimulation with insulin-induced hypoglycemia. We compared levels of GH, IGF-I, IGF-II, IGF-binding protein-1 (IGFBP-1), insulin, and C-peptide in nondepressed CFS patients and normal controls. We found attenuated basal levels of IGF-I (214 +/- 17 vs. 263.4 +/- 13.4 micrograms/L, p = .036) and IGF-II (420 +/- 19.8 vs. 536 +/- 24.3 micrograms/L, p = .02) in CFS patients and a reduced GH response to hypoglycemia (peak GH; 41.9 +/- 11.5 vs. 106.0 +/- 25.6 mU/L, p = .017). Insulin levels were higher (7.6 +/- 1.0 vs. 4.3 +/- 0.8 mU/L, p = .02) and IGFBP-1 levels were lower (19.7 +/- 4.6 vs. 43.2 +/- 2.7 mg/L, p = .004) in CFS patients compared with controls. This study provides preliminary data abnormalities of the GH-IGF axis in CFS. It is not apparent whether these changes are components of a primary pathological process or are acquired secondary to behavioral aspects of CFS such as reduced physical activity.
Anderson JS, Ferrans CE.	University of Illinois at Chicago Medical Center, Department of Psychiatry 60612, USA.	The quality of life of persons with chronic fatigue syndrome.	J Nerv Ment Dis 1997 Jun;185(6):359-67	This descriptive study used a between-methods triangulation design to analyze the multiple dimensions of quality of life in persons with chronic fatigue syndrome (CFS). This method, which refers to the combination of both quantitative and qualitative methods in the same study, allowed the authors to obtain more comprehensive and robust data than could be obtained by either method alone. A convenience sample of 110 persons with CFS completed the quality of life index and CFS questionnaire, and a subset of 22 persons were interviewed regarding their lived experience with CFS. Overall scores on the

				quality of life index were significantly lower in CFS than for other chronic illness groups. Subjects reported the lowest quality of life scores in health and functioning domain. Indepth interviews provided a more complete understanding of the quality of life in CFS and further explained the low ratings that were found on the quality of life index. The findings suggest that quality of life is particularly and uniquely disrupted in CFS.
Ax S, Gregg VH, Jones D.	Birkback College, University of London, England.	Chronic fatigue syndrome: sufferers' evaluation of medical support.	J R Soc Med 1997 May;90(5):250-4	In response to reports of negative cooperation between sufferers of chronic fatigue syndrome (CFS) and their doctors, semi-structured interviews were conducted with sufferers from two different patient samples. Satisfaction with support received and with medical professionals in general was low. Sufferers complained about insufficient informational as well as emotional support from their doctors, and as a consequence most opted for alternative or complementary forms of treatment. In addition, disagreements over illness aetiology and treatment precluded effective cooperation. If satisfaction and compliance are to improve, sufferers will need more information about CFS and more support.

Bazelmans E, Vercoulen JH, Galama JM, van Weel C, van der Meer JW, Bleijenberg G.	Afd. Medische Psychologie, Academisch Ziekenhuis, Nijmegen.	[Prevalence of chronic fatigue syndrome and primary fibromyalgia syndrome in The Netherlands].[article in Dutch] Erratum in: Ned	Ned Tijdschr Geneeskd 1997 Aug 2;141(31):1520-3	OBJECTIVE: To determine the prevalence of chronic fatigue syndrome (CFS) and of primary fibromyalgia syndrome (PFS) in the Netherlands. DESIGN: Questionnaire. SETTING: Department of Medical Psychology, University Hospital Nijmegen, the Netherlands. METHOD: A questionnaire was mailed to all the 6657 general practitioners in the Netherlands in order to inform them of the existence of CFS and to ask them if they had any CFS or PFS patients in their practices.

		Tijdschr Geneeskd 1997 Sep 13;141(37):2686		RESULTS: Sixty percent (n = 4027) of the general practitioners returned the questionnaire. Of all the general practitioners, 27% said they had no CFS patients, 23% said they had 1 CFS patient, while 21% had 2 CFS patients, and 29% said they had 3 or more CFS patients in their practice. Concerning PFS the results were 17% (no PFS patients), 18%, 18% and 47%, respectively. With a mean practice of 2486 patients per general practice, the estimated prevalence of CFS was 112 per 100,000 and that of PFS 157 per 100,000 persons. Of the CFS patients 81% were women and 55% were 25-44 years old; for PFS these figures were 87% and 48% respectively. CONCLUSION: Extrapolation of the study results indicates that there are at least 17,000 CFS patients and 24,000 PFS patients in the Netherlands. The found prevalence is probably an under-estimation.
Beh HC.	Department of Psychology, University of Sydney, New South Wales, Australia.	Effect of noise stress on chronic fatigue syndrome patients.	J Nerv Ment Dis 1997 Jan;185(1):55-8	
Bell DS		Illness Onset Characteristics in Children with Chronic Fatigue Syndrome and Idiopathic Chronic Fatigue	Journal of Chronic Fatigue Syndrome 1997: 3(2): 43 - 51	Twenty-three children and adolescents with unexplained chronic fatigue were evaluated with emphasis upon illness-onset characteristics. Ten subjects had an acute, "flu-like" onset, and four of these subjects had episodes of mild fatigue in the year prior to onset. The thirteen remaining subjects had a gradual onset of chronic fatigue, the majority describing increasing episodes of apparent infectious illnesses associated with fatigue. In these subjects, the fatigue eventually became constant, causing reduction in overall activity levels. In a comparison of subjects who did and did not meet diagnostic criteria for chronic fatigue syndrome, there were no differences in onset characteristics, but differences were noted in illness severity. The majority of children and adolescents with unexplained chronic fatigue had a gradual onset of debilitating symptoms
Bell IR, Michele E. Walsh, Anita Gross, Jane Gersmeyer, Gary E. Schwartz, Philip Kanof		Cognitive Dysfunction and Disability in Geriatric Veterans with Self-Reported Intolerance to Environmental Chemicals	Journal of Chronic Fatigue Syndrome 1997: 3(3): 15 - 42	The symptom of sensitivity or intolerance to low levels of environmental chemicals (CI) is a characteristic of several clinical conditions, such as multiple chemical sensitivity (MCS), chronic fatigue syndrome (CFS), fibromyalgia (FM), and the "Persian Gulf Syndrome." Lesser degrees of CI also occur in 15-30% of non-clinical populations. The present study examined the prevalence and concomitant health patterns of CI in elderly veterans in a VA primary care medical clinic (N = 160, primarily men). Thirty-seven percent of the sample endorsed the screening question asking whether or not they considered themselves "especially sensitive to certain chemicals." The group with CI reported a significantly higher rate of physical disability and increased susceptibility to becoming sick. The CI group reported significantly decreased rates of current cigarette smoking and alcohol use. Those with and those without CI did not differ in level of depression or in past occupational chemical exposures.

				However, the CI group scored significantly lower on a screening test for cognitive dysfunction, including a verbal memory performance pattern consistent with early dementia. When the groups were subdivided into individuals high and low in depression, the depressives without CI reported the highest rate of prior occupational exposure to pesticides. The subgroup who had both CI and depression performed most poorly on the attention/concentration screening test. Taken together, the data suggest that CI as a symptom is extremely common in older male veterans and may be a marker for increased risk of further cognitive decline and/or loss of functional independence. However, the role of occupational chemical exposures in initiating CI in these non-MCS patients is unclear and requires additional study.
Bennett A.		A view of the violence contained in chronic fatigue syndrome.	J Anal Psychol 1997 Apr;42(2):237-51	In this paper I ask whether there might be any one particular psychopathology likely to be linked specifically with the physical illness known as chronic fatigue syndrome (CFS) or myalgic encephalomyelitis (ME), and whether CFS/ME aids and abets and "fits' an original mental state. I think the question cannot yet be answered. However it is my hypothesis that in some personality structures the onset of CFS/ ME following a physical illness exacerbates negativity and is an aspect of ordinary depression where there is a lowering of energy levels and a loss of zest for life, or it may reveal the pathological aspect of unresolved rage. Depending on the degree of pathological disturbance, working with and through the rage may or may not result in a resolution of the symptoms of ME. In this paper I consider some of the problems in the transference and countertransference relationship, which make it extremely difficult to separate out reality from phantasy. There is then the further problem of the denial of the psyche by the patient as part of the violence inherent in the illness. One case is presented, an example of ME in a borderline male patient in whom resolution could not be achieved.
Bennett AL, Chao CC, Hu S, Buchwald D, Fagioli LR, Schur PH, Peterson PK, Komaroff AL.	Chronic Fatigue Syndrome Cooperative Research Center, Brigham and Women's Hospital, Boston, Massachusetts, USA.	Elevation of bioactive transforming growth factor-beta in serum from patients with chronic fatigue syndrome.	J Clin Immunol 1997 Mar;17(2):160-6	The level of bioactive transforming growth factor-beta (TGF-beta) was measured in serum from patients with chronic fatigue syndrome (CFS), healthy control subjects, and patients with major depression, systemic lupus erythematosis (SLE), and multiple sclerosis (MS) of both the relapsing/remitting (R/R) and the chronic progressive (CP) types. Patients with CFS had significantly higher levels of bioactive TGF-beta levels compared to the healthy control major depression, SLE, R/R MS, and CP MS groups ($P < 0.01$). Additionally, no significant differences were found between the healthy control subjects and any of the disease comparison groups. The current finding that TGF-beta is significantly elevated among patients with CFS supports the findings of two previous studies examining smaller numbers of CFS patients. In conclusion, TGF-beta levels were significantly higher in CFS patients compared to patients with various diseases known to be associated with immunologic abnormalities and/or pathologic fatigue. These

				findings raise interesting questions about the possible role of TGF-beta in the pathogenesis of CFS.
Bennett AL, Mayes DM, Fagioli LR, Guerriero R, Komaroff AL.	Department of Medicine, Brigham and Women's Hospital, Boston, MA 02115, USA.	Somatomedin C (insulin-like growth factor I) levels in patients with chronic fatigue syndrome.	J Psychiatr Res 1997 Jan-Feb;31(1):91-6	Chronic fatigue syndrome is a disorder clinically quite similar to fibromyalgia syndrome, and it is of interest to examine if these two syndromes have pathogenetic as well as clinical features in common. Somatomedin C levels have been found to be lower in patients with fibromyalgia syndrome than in healthy controls. An attractive hypothesis relating sleep disturbance, altered somatotropic neuroendocrine function and fibromyalgia symptoms has been put forward as a plausible pathogenic mechanism for fibromyalgia syndrome. We therefore sought to investigate the level of somatomedin C in patients with chronic fatigue syndrome. Somatomedin C levels were determined by radioimmunoassay in frozen serum specimens from 49 patients with CFS and 30 healthy blood donor control subjects of similar age and gender. Somatomedin C levels were higher in patients with CFS than in healthy control subjects (255.3 +/- 68.5 vs 211.9 +/- 76.2, P = 0.01). There was no effect of gender, use of nonsteroidal anti-inflammatory drugs or tricyclic drugs on levels of somatomedin C. There was a tendency for somatomedin C levels to fall with age. In contrast to patients with fibromyalgia, in whom levels of somatomedin C have been found to be reduced, levels in patients with CFS were found to be elevated. Thus, despite the clinical similarities between these two conditions, they may be associated with different abnormalities of sleep and/or of the somatotropic neuroendocrine axis.
Berlin B.		Confronting AIDS in older adults.	N J Med 1997 Nov;94(11):39-41	A 57-year-old corporate executive, married with three grown children, began suffering from severe flu-like symptoms and weight loss. Hospitalized for a week, he was tested for chronic fatigue syndrome and mononucleosis. Finally, with no change in his symptoms, his physician recommended an HIV test. The results were positive.

Bleijenberg G.	Academisch Ziekenhuis, afd. Medische Psychologie, Nijmegen.	[Attributions and chronic fatigue].[article in Dutch]	Ned Tijdschr Geneeskd 1997 Aug 2;141(31):1510-2Comment in: Ned Tijdschr Geneeskd. 1997 Nov 29;141(48):2360 Ned Tijdschr Geneeskd. 1997 Nov	It was recently suggested that chronic fatigue is merely a question of attribution. Attribution clearly contributes to the course of chronic fatigue syndrome (CFS) but is not its sole determinant. The presence of strong somatic attributions appears to be one of the perpetuating factors in CFS but not the only one. Many CFS patients present a self-diagnosis, e.g. myalgic encephalomyelitis. Communication problems between patient and doctor easily arise because of different attributions of the complaints. At the start of fatigue somatic attributions are of less importance than later on in the course of the complaints.

			29;141(48):2360-1	In this process an iatrogenic factor might be involved. On the other hand doctors are able to influence these attributions actively in a favourable direction.
Bowman MA, Kirk JK, Michielutte R, Preisser JS. Controlled Clinical Trial Letter		Use of amantadine for chronic fatigue syndrome.	Arch Intern Med 1997 Jun 9;157(11):1264-5	
Bruno RL		Chronic Fatigue, Fainting and Autonomic Dysfunction: Further Similarities Between Post-Polio Fatigue and Chronic Fatigue Syndrome?	Journal of Chronic Fatigue Syndrome 1997: 3(3): 109 - 116	To test the hypothesis that fatigue and fainting occur together, 1,047 polio survivors and 419 non-disabled control subjects were asked about the frequency and cause of fainting and asked to rate their typical daily fatigue severity. Fatigue severity was significantly higher in polio survivors as compared to controls, and in both polio survivors and controls who had fainted, as compared to those who had not. Daily fatigue severity also increased in both groups as the number of lifetime faints increased. Fatigue was significantly higher in controls who fainted one time and three times as compared to controls who had never fainted. Daily fatigue severity was significantly higher in polio survivors who had fainted three, four and five times as compared to those who had never fainted. These findings suggest a physiological relationship between fatigue and fainting, possibly attributable to the close proximity of cardiovascular regulation and brain activation centers within the brain stem. Fatigue and hypotension in patients with chronic fatigue syndrome and in polio
Buchwald D, Pearlman T, Kith P, Katon W, Schmaling K.	Department of Medicine, University of Washington, Seattle, USA.	Screening for psychiatric disorders in chronic fatigue and chronic fatigue syndrome.	J Psychosom Res 1997 Jan;42(1):87-94	Psychiatric disorders are common in chronic fatigue (CF) and chronic fatigue syndrome (CFS). To determine the usefulness of the General Health Questionnaire (GHQ), a self-report measure of psychological distress, in identifying those with psychiatric illnesses, a structured psychiatric interview and the GHQ were administered to 120 CF and 161 CFS patients seen in a referral clinic. Overall, 87 (35%) patients had a current and 210 (82%) a lifetime psychiatric disorder. Compared to patients without psychiatric disorders, GHQ scores above the threshold (> or = 12) were more frequent among patients with current ($p < 0.001$) and lifetime ($p < 0.05$) diagnoses; scores among patients with CF and CFS were similar. Longer illness duration, greater fatigue severity, and current psychiatric disorders were significant predictors of the GHQ score. In CF and CFS, the best sensitivity (0.69-0.76) and specificity (0.51-0.62) were achieved for current psychiatric diagnoses using a threshold score of > or = 12. Thus, patients scoring < 12 on the GHQ are significantly less likely to have a psychiatric disorder.
Buchwald D, Wener MH, Pearlman T, Kith P.	Department of Medicine, University of Washington, Seattle, USA.	Markers of inflammation and immune activation in chronic fatigue and chronic fatigue	J Rheumatol 1997 Feb;24(2):372-6	OBJECTIVE: Chronic fatigue syndrome (CFS) has been hypothesized to result from immune activation. We examined the role of serum markers of inflammation and immune activation among patients with CFS and in those with chronic fatigue (CF) not meeting the case definition. METHODS: Assays for soluble interleukin 2 (IL-2) receptor, IL-6, C-reactive protein, beta 2-microglobulin, and neopterin were

		syndrome.		performed in 153 fatigued patients in a referral clinic. Patients were classified according to whether they met criteria for CFS, reported onset of illness with a viral syndrome or had a temperature > 37.5 degrees C on examination. RESULTS: Compared to control subjects, mean concentrations of C-reactive protein, beta 2-microglobulin, and neopterin were higher in patients with CFS (p < or = 0.01) and CF (p < or = 0.01). Results did not distinguish CFS from CF. IL-6 was elevated among febrile patients compared to those without this finding (p < or = 0.001), but other consistent differences between patient subgroups were not observed. The presence of several markers was highly correlated (p < 0.01). CONCLUSION: Our findings that levels of several markers were significantly correlated points to a subset of patients with immune system activation. Whether this phenomenon reflects an intercurrent, transient, common condition, such as an upper respiratory infection, or is the result of an ongoing illness associated process is unknown. Overall, serum markers of inflammation and immune activation are of limited diagnostic usefulness in the evaluation of patients with CSF and CF.
Cannon JG, Angel JB, Abad LW, Vannier E, Mileno MD, Fagioli L, Wolff SM, Komaroff AL.	Department of Medicine, Tufts University-New England Medical Center, Boston, Massachusetts 02111, USA.	Interleukin-1 beta, interleukin-1 receptor antagonist, and soluble interleukin-1 receptor type II secretion in chronic fatigue syndrome.	J Clin Immunol 1997 May;17(3):253-61	Chronic fatigue syndrome is a condition that affects women in disproportionate numbers, and that is often exacerbated in the premenstrual period and following physical exertion. The signs and symptoms, which include fatigue, myalgia, and low-grade fever, are similar to those experienced by patients infused with cytokines such as interleukin-1. The present study was carried out to test the hypotheses that (1) cellular secretion of interleukin-1 beta (IL-1 beta), interleukin-1 receptor antagonist (IL-1Ra), and soluble interleukin-1 receptor type II (IL-1sRII) is abnormal in female CFS patients compared to age- and activity-matched controls; (2) that these abnormalities may be evident only at certain times in the menstrual cycle; and (3) that physical exertion (stepping up and down on a platform for 15 min) may accentuate differences between these groups. Isolated peripheral blood mononuclear cells from healthy women, but not CFS patients, exhibited significant menstrual cycle-related differences in IL-1 beta secretion that were related to estradiol and progesterone levels (R2 = 0.65, P < 0.01). IL-1Ra secretion for CFS patients was twofold higher than controls during the follicular phase (P = 0.023), but luteal-phase levels were similar between groups. In both phases of the menstrual cycle, IL-1sRII release was significantly higher for CFS patients compared to controls (P = 0.002). The only changes that might be attributable to exertion occurred in the control subjects during the follicular phase, who exhibited an increase in IL-1 beta secretion 48 hr after the stress (P = 0.020). These results suggest that an abnormality exists in IL-1 beta secretion in CFS patients that may be related to altered sensitivity to estradiol and progesterone. Furthermore, the increased release of IL-1Ra and sIL-1RII by cells from CFS patients is consistent with the hypothesis that CFS is associated with chronic, low-level activation of the immune system.

Cannon JG, St Pierre BA.	Intercollege Physiology Program, Pennsylvania State University, University Park 16802-6900, USA.	Gender differences in host defense mechanisms.	J Psychiatr Res 1997 Jan-Feb;31(1):99-113	Extensive studies in both humans and animals have shown that females express enhanced levels of immunoreactivity compared to males. Whereas this provides females with increased resistance to many types of infection, it also makes them more susceptible to autoimmune diseases. This review will focus on gender-related differences in non-specific host defense mechanisms with a particular emphasis on monocyte/macrophage function and a primary product of monocytes: interleukin-1 (IL-1). Immunomodulatory cytokines such as IL-1 are influenced by gender-sensitive hormones, and reciprocally, these cytokines influence gender-specific hormones and tissues. Patients with chronic fatigue syndrome (CFS) are predominantly women, therefore it may be useful to look toward gender-specific differences in immune function to find a key for this poorly understood syndrome.

Chester AC, Levine PH.	Georgetown University Medical Center, Washington DC, USA.	The natural history of concurrent sick building syndrome and chronic fatigue syndrome.	J Psychiatr Res 1997 Jan-Feb;31(1):51-7	An outbreak of chronic fatigue syndrome linked with sick building syndrome was recently described as a new association. Whether chronic fatigue syndrome acquired in this setting tends to remit or, as sporadic cases often do, persist, is unknown. To clarify the natural history of chronic fatigue syndrome in association with sick building syndrome the 23 individuals involved in the outbreak were interviewed four years after the onset. In the previous interview one year after the onset of symptoms, 15 (including 5 with chronic fatigue syndrome and 10 with idiopathic chronic fatigue) of the 23 noted fatigue. Three years later 10 of the 15 were "fatigue free" or "much improved". Five were only "some better", "the same", or "worse". Three of the five people previously diagnosed with chronic fatigue syndrome were "much improved" (two) or "fatigue free" (one). The remaining two were seriously impaired, homebound and unable to work. The 10 individuals with substantially improved fatigue (three of the five with chronic fatigue syndrome and seven of the 10 with idiopathic chronic fatigue) were more likely to have noted improvement in nasal and sinus symptoms, sore throats, headaches, and tender cervical lymph nodes when compared to those with a lingering significant fatigue ($p < 0.001$). Upper respiratory symptoms and headaches improved in those with reduced fatigue but remained problematic in those with persisting significant fatigue. We conclude that the fatigue related to sick building syndrome, including chronic fatigue syndrome, is significantly more likely to improve than fatigue identified in sporadic cases of chronic fatigue syndrome.
Chester AC.	Georgetown University Medical Center,	Chronic fatigue syndrome criteria in	J Psychiatr Res 1997 Jan-Feb;31(1):45-50	To determine the prevalence of chronic fatigue syndrome (CFS) criteria in other forms of unexplained chronic fatigue, 297 consecutive outpatients under the age

	Washington D.C., USA.	patients with other forms of unexplained chronic fatigue.		of 40 from a general medicine practice were studied. After excluding the three with chronic fatigue syndrome, the remaining 294 individuals were divided into those with unexplained chronic fatigue (64 patients) those without (the remaining 230 patients). Chronic fatigue syndrome criteria noted to be significantly more common in those with unexplained fatigue compared to those without include: fever, painful adenopathy, muscle weakness, myalgia, headache, migratory arthralgia, neuropsychologic symptoms, and sleep disorder. Like chronic fatigue syndrome, unexplained chronic fatigue often started suddenly. I conclude that the CFS criteria are noted more commonly than expected in other forms of unexplained chronic fatigue.

Clauw DJ, Chrousos GP.	Department of Medicine, Georgetown University Medical Center, Washington, D.C. 20007, USA.	Chronic pain and fatigue syndromes: overlapping clinical and neuroendocrine features and potential pathogenic mechanisms.	Neuroimmunomodulation 1997 May-Jun;4(3):134-53	Patients with unexplained chronic pain and/or fatigue have been described for centuries in the medical literature, although the terms used to describe these symptom complexes have changed frequently. The currently preferred terms for these syndromes are fibromyalgia and chronic fatigue syndrome, names which describe the prominent clinical features of the illness without any attempt to identify the cause. This review delineates the definitions of these syndromes, and the overlapping clinical features. A hypothesis is presented to demonstrate how genetic and environmental factors may interact to cause the development of these syndromes, which we postulate are caused by central nervous system dysfunction. Various components of the central nervous system appear to be involved, including the hypothalamic pituitary axes, pain-processing pathways, and autonomic nervous system. These central nervous system changes lead to corresponding changes in immune function, which we postulate are epiphenomena rather than the cause of the illnesses. Review, Academic
Clauw DJ, Schmidt M, Radulovic D, Singer A, Katz P, Bresette J.	Division of Rheumatology, Immunology and Allergy, Georgetown University Medical Center, Washington, D.C., USA.	The relationship between fibromyalgia and interstitial cystitis.	J Psychiatr Res 1997 Jan-Feb;31(1):125-31	Interstitial cystitis (IC) is a relatively uncommon and enigmatic disorder characterized by pain in the bladder and pelvic region, typically accompanied by urinary urgency and frequency. Fibromyalgia is a more common disorder, with the prominent symptoms being diffuse musculoskeletal pain and fatigue, and it has been well established that there is substantial clinical overlap between fibromyalgia and chronic fatigue syndrome (CFS). Although genitourinary and musculoskeletal symptoms predominate in IC and fibromyalgia respectively, both disorders share a number of features, including similar demographics, "allied conditions" (e.g. irritable bowel syndrome, headaches, etc.), natural history, aggravating factors, and efficacious therapy. We hypothesized that there was substantial clinical overlap between fibromyalgia and IC, and examined cohorts of

				individuals with these two disorders in parallel, to compare the spectrum of symptomatology. Sixty fibromyalgia patients, 30 IC patients, and 30 age-matched healthy controls were questioned regarding current symptomatology. A dolorimeter examination was also performed in the three groups to assess peripheral nociception. We found that the frequency of current symptoms was very similar for the fibromyalgia and IC groups. Both the fibromyalgia and IC patients displayed increased pain sensitivity when compared to healthy individuals, at both tender and control points. These data suggest that IC and fibromyalgia have significant overlap in symptomatology, and that IC patients display diffusely increased peripheral nociception, as is seen in fibromyalgia. Although central mechanisms have been suspected to contribute to the pathogenesis of fibromyalgia for some time, we speculate that these same types of mechanisms may be operative in IC, which has traditionally been felt to be a bladder disorder.
Clements A, Sharpe M, Simkin S, Borrill J, Hawton K.	Department of Psychiatry, University of Oxford, Warneford Hospital, UK. alison.clements@psychiatry.ox.ac.uk	Chronic fatigue syndrome: a qualitative investigation of patients' beliefs about the illness.	J Psychosom Res 1997 Jun;42(6):615-24	The chronic fatigue syndrome is a disabling chronic condition of uncertain cause. Previous studies have found that patients seen in hospital clinics with the syndrome often strongly believe that their illness is physical in nature and minimize the role of psychological and social factors. There is also evidence that patients cope by avoiding activity. However, almost all of these studies have assessed illness beliefs only by questionnaire. The aim of this study was to explore the nature and origin of illness beliefs in more detail using in-depth interviews and a qualitative analysis of patient responses. Sixty-six consecutive referrals meeting Oxford criteria for chronic fatigue syndrome were recruited. Analysis of responses indicated that, whereas the most commonly described explanation for the illness was a physical one, more than half the patients also believed "stress" had played a role. Patients believed that they could partially control the symptoms by reducing activity but felt helpless to influence the physical disease process and hence the course of the illness. Patients reported that they had arrived at these beliefs about the illness after prolonged reflection on their own experience combined with the reading of media reports, self help books, and patient group literature. The views of health professionals played a relatively small role. There is potentially a considerable opportunity to help patients arrive at a wider and more enabling explanation of their illness when they first present to primary care.
Cuende JI, Civeira P, Diez N, Prieto J.	Laboratorio de Biologia Molecular, Hospital Provincial San Telmo, Palencia.	[High prevalence without reactivation of herpes virus 6 in subjects with chronic fatigue syndrome].[article in	An Med Interna 1997 Sep;14(9):441-4	INTRODUCTION: Chronic fatigue syndrome (CFS) is a disorder of unknown etiology. Some viruses have been associated with CFS etiology, specially herpesviruses, enteroviruses and retroviruses. Some studies suggest an association between human herpesvirus-6 (HHV-6) and CFS. In order to know if there is an active HHV-6 infection in CFS patients we studied the immunologic and virologic status of HHV-6. MATERIALS AND METHODS: Twenty patients with

		Spanish]		CFS were studied. IgG and IgM anti HHV-6 were determined by indirect immunofluorescence assay. DNA from serum and peripheral blood mononuclear cells (PBMC) were studied by dot- and Southern-blotting and nested-PCR to detect HHV-6 DNA. HHV-6 RNA from PBMC were amplified by RT(retrotranscription)-PCR. RESULTS: Ten patients (50%) had IgG anti-HHV-6 in serum but none had IgM anti-HHV-6. Dot-blotting of DNA from 200 microliters of serum and Southern-blotting of 10 micrograms of PBMC DNA were negative. Nested-PCR from sera were negative. Nested-PCR with 1 microgram PBMC DNA were positive in 8 out 20 (40%) and with 5 micrograms PBMC DNA were positive in 16 out of 20 (80%). No viral RNA were detected in PBMC. CONCLUSIONS: There is a high proportion of CFS patients infected with HHV-6 but with low viral load. Results do not support HHV-6 reactivation in CFS patients.
de Jong LW, Prins JB, Fiselier TJ, Weemaes CM, Meijer-van den Bergh EM, Bleijenberg G.	Afd. Medische Psychologie, Academisch Ziekenhuis, Nijmegen.	[Chronic fatigue syndrome in young persons].[article in Dutch]	Ned Tijdschr Geneeskd 1997 Aug 2;141(31):1513-6	The prevalence of chronic fatigue syndrome (CFS) in teenagers is 10-20 per 100,000 inhabitants in the Netherlands. The natural course of the disorder is not favourable according to the literature. Proposed criteria for the diagnosis 'CFS' in adolescence are: absence of a physical explanation for the complaints, a disabling fatigue for at least six months and prolonged school absenteeism or severe motor and social disabilities. Exclusion criterion should be a psychiatric disorder. Factors that attribute to the persistence of fatigue are somatic attributions, illness enhancing cognitions and behaviour of parents as well as physical inactivity. The role of the physician and the role of parents can enhance the problems. The treatment should focus on decreasing the somatic attributions, on reinforcement by the parents of healthy adolescent behaviour, on the gradual increase of physical activity and on decreasing attention (including medical attention) for the somatic complaints.

De Lorenzo F, Hargreaves J, Kakkar VV.	Thrombosis Research Institute, London, UK.	Pathogenesis and management of delayed orthostatic hypotension in patients with chronic fatigue syndrome.	Clin Auton Res 1997 Aug;7(4):185-90	The relationship between orthostatic hypotension and chronic fatigue syndrome (CFS) has been reported previously. To study the pathogenesis and management of delayed orthostatic hypotension in patients with CFS, a case comparison study with follow-up of 8 weeks has been designed. A group of 78 patients with CFS (mean age 40 years; 49% men and 51% women), who fulfilled the Centre for Disease Control and Prevention criteria were studied. There were 38 healthy controls (mean age 43 years; 47% men and 53% women). At entry to the study each subject underwent an upright tilt-table test, and clinical and laboratory evaluation. Patients with orthostatic hypotension were offered therapy with sodium chloride (1200 mg) in a sustained-release formulation for 3 weeks, prior to resubmission to the tilt-table testing, and clinical and laboratory evaluation. An

				abnormal response to upright tilt was observed in 22 of 78 patients with CFS. After sodium chloride therapy for 8 weeks, tilt-table testing was repeated on the 22 patients with an abnormal response at baseline. Of these 22 patients, 10 redeveloped orthostatic hypotension, while 11 did not show an abnormal response to the test and reported an improvement of CFS symptoms. However, those CFS patients who again developed an abnormal response to tilt-test had a significantly reduced plasma renin activity (0.79 pmol/ml per h) compared both with healthy controls (1.29 pmol/ml per h) and with those 11 chronic fatigue patients (1.0 pmol/ml per h) who improved after sodium chloride therapy (p = 0.04). In conclusion, in our study CFS patients who did not respond to sodium chloride therapy were found to have low plasma renin activity. In these patients an abnormal renin-angiotensin-aldosterone system could explain the pathogenesis of orthostatic hypotension and the abnormal response to treatment.
Deale A, Chalder T, Marks I, Wessely S.	Academic Department of Psychological Medicine, King's College Hospital, London, United Kingdom.	Cognitive behavior therapy for chronic fatigue syndrome: a randomized controlled trial.	Am J Psychiatry 1997 Mar;154(3):408-14 comment in: Am J Psychiatry. 1998 Oct;155(10):1461-2	OBJECTIVE: Cognitive behavior therapy for chronic fatigue syndrome was compared with relaxation in a randomized controlled trial. METHODS: Sixty patients with chronic fatigue syndrome were randomly assigned to 13 sessions of either cognitive behavior therapy (graded activity and cognitive restructuring) or relaxation. Outcome was evaluated by using measures of functional impairment, fatigue, mood, and global improvement. RESULTS: Treatment was completed by 53 patients. Functional impairment and fatigue improved more in the group that received cognitive behavior therapy. At final follow-up, 70% of the completers in the cognitive behavior therapy group achieved good outcomes (substantial improvement in physical functioning) compared with 19% of those in the relaxation group who completed treatment. CONCLUSIONS: Cognitive behavior therapy was more effective than a relaxation control in the management of patients with chronic fatigue syndrome. Improvements were sustained over 6 months of follow-up. Randomized Controlled Trial
DeLuca J, Johnson SK, Ellis SP, Natelson BH.	UMDNJ-New Jersey Medical School, Newark, USA.	Sudden vs gradual onset of chronic fatigue syndrome differentiates individuals on cognitive and psychiatric measures.	J Psychiatr Res 1997 Jan-Feb;31(1):83-90	To examine the influence of mode of illness onset on psychiatric status and neuropsychological performance, 36 patients with CFS were divided into two groups: sudden vs gradual onset of symptoms. These two CFS subgroups were compared to each other and to sedentary healthy controls on standardized neuropsychological tests of attention/concentration, information processing efficiency, memory, and higher cortical functions. In addition, the distribution of comorbid Axis I psychiatric disease between the two CFS groups was examined. The rate of concurrent psychiatric disease was significantly greater in the CFS-gradual group relative to the CFS-sudden group. While both CFS groups showed a significant reduction in information processing ability relative to controls, impairment in memory was more severe in the CFS-sudden group. Because of the significant heterogeneity of the CFS population, the need for subgroup analysis is

				discussed.
DeLuca J, Johnson SK, Ellis SP, Natelson BH.	University of Medicine and Dentistry of New Jersey, New Jersey Medical School, Newark, USA.	Cognitive functioning is impaired in patients with chronic fatigue syndrome devoid of psychiatric disease.	J Neurol Neurosurg Psychiatry 1997 Feb;62(2):151-5	OBJECTIVE: To examine the effect of the presence or absence of psychiatric disease on cognitive functioning in chronic fatigue syndrome. METHODS: Thirty six patients with chronic fatigue syndrome and 31 healthy controls who did not exercise regularly were studied. Subgroups within the chronic fatigue syndrome sample were formed based on the presence or absence of comorbid axis I psychiatric disorders. Patients with psychiatric disorders preceding the onset chronic fatigue syndrome were excluded. Subjects were administered a battery of standardised neuropsychological tests as well as a structured psychiatric interview. RESULTS: Patients with chronic fatigue syndrome without psychiatric comorbidity were impaired relative to controls and patients with chronic fatigue syndrome with concurrent psychiatric disease on tests of memory, attention, and information processing. CONCLUSION: Impaired cognition in chronic fatigue syndrome cannot be explained solely by the presence of a psychiatric condition. Controlled Clinical Trial

Demitrack MA.	Lilly Research Laboratories, Lilly Corporate Center, Indianapolis, IN 46285, USA.	Neuroendocrine correlates of chronic fatigue syndrome: a brief review.	J Psychiatr Res 1997 Jan-Feb;31(1):69-82	Chronic fatigue syndrome remains one of the more perplexing syndromes in contemporary clinical medicine. One approach to understanding this condition has been to acknowledge its similarities to other disorders of clearer pathophysiology. In this review, a rationale for the study of neuroendocrine correlates of chronic fatigue syndrome is presented, based in part on the clinical observation that asthenic or fatigue states share many of the somatic symptom characteristics seen in recognized endocrine disorders. Of additional interest is the observation that psychological symptoms, particularly disturbances in mood and anxiety, are equally prominent in this condition. At this time, several reports have provided replicated evidence of disruptions in the integrity of the hypothalamic-pituitary-adrenal axis in patients with chronic fatigue syndrome. It is notable that the pattern of the alteration in the stress response apparatus is not reminiscent of the well-understood hypercortisolism of melancholic depression but, rather, suggests a sustained inactivation od central nervous system components of this system. Recent work also implicates alterations in central serotonergic tone in the overall pathophysiology of this finding. The implications of these observations are far from clear, but they highlight the fact that, though chronic fatigue syndrome overlaps with the well-described illness category of major depression, these are not identical clinical conditions.
Derman W, Schwellnus MP, Lambert MI, Emms M, Sinclair-Smith C,	MRC/UCT Bioenergetics of Exercise Research Unit, University of Cape	The 'worn-out athlete': a clinical approach to chronic fatigue in	J Sports Sci 1997 Jun;15(3):341-51	Chronic fatigue in the athletic population is a common but difficult diagnostic challenge for the sports physician. While a degree of fatigue may be normal for any athlete during periods of high-volume training, the clinician must be able to

Kirby P, Noakes TD.	Town Medical School, Sports Science Institute of South Africa, Newlands, South Africa.	athletes.		differentiate between this physiological fatigue and more prolonged, severe fatigue which may be due to a pathological condition. As chronic fatigue can be the presenting symptom of many curable and harmful diseases, medical conditions which cause chronic fatigue have to be excluded. The clinician must then be able to differentiate between chronic fatigue associated with training or chronic fatigue from other medical causes, and also between the chronic fatigue syndrome and the overtraining syndrome. Once the clinician has excluded all of the above medical conditions which cause chronic fatigue in athletes, a significant proportion of fatigued athletes remain without a diagnosis. Novel data indicate that skeletal muscle disorders may play a role in the development of symptoms experienced by the athlete with chronic fatigue. The histological findings from muscle biopsies of athletes suffering from the 'fatigued athlete myopathic syndrome' are presented. We have designed a clinical approach to the diagnosis and work-up of the athlete presenting with chronic fatigue. The strength of this approach is that it hinges on the participation of a multidisciplinary team in the diagnosis and management of the athlete with chronic fatigue. The athlete, coach, dietician, exercise physiologist and sport psychologist all play an important role in enabling the physician to make the correct diagnosis.
Dickinson CJ.	Wolfson Institute of Preventive Medicine, St. Bartholomew's & Royal London School of Medicine & Dentistry, London, UK.	Chronic fatigue syndrome--aetiological aspects.	Eur J Clin Invest 1997 Apr;27(4):257-67Comment in: Eur J Clin Invest. 1997 Apr;27(4):255-6 Eur J Clin Invest. 1997 Dec;27(12):1061-2	The chronic fatigue syndrome (CFS) has been intensively studied over the last 40 years, but no conclusions have yet been agreed as to its cause. Most cases nowadays are sporadic. In the established chronic condition there are no consistently abnormal physical signs or abnormalities on laboratory investigation. Many physicians remain convinced that the symptoms are psychological rather than physical in origin. This view is reinforced by the emotional way in which many patients present themselves. The overlap of symptoms between CFS and depression remains a source of confusion and difficulty. But even if all CFS patients were rediagnosed as depressives, this would not negate the possibility of an underlying organic cause for the condition, in view of the growing evidence that depression itself has a physical cause and responds best to physical treatments. There is some evidence both for active viral infection and for an immunological disorder in the CFS. Many observations suggest that the syndrome could derive from residual damage to the reticular activating system (RAS) of the upper brain stem and/or to its cortical projections. Such damage could be produced by a previous viral infection, leaving functional defects unaccompanied by any gross histological changes. In animal experiments activation of the RAS can change sleep state and activate or stimulate cortical functions. RAS lesions can produce somnolence and apathy. Studies by modern imaging techniques have not been entirely consistent, but many magnetic resonance imaging (MRI) studies already suggest that small discrete patchy brain stem and subcortical

				lesions can often be seen in CFS. Regional blood flow studies by single photon-emission computerized tomography (SPECT) have been more consistent. They have revealed blood flow reductions in many regions, especially in the hind brain. Similar lesions have been reported after poliomyelitis and in multiple sclerosis--in both of which conditions chronic fatigue is characteristically present. In the well-known post-polio fatigue syndrome, lesions predominate in the RAS of the brain stem. If similar underlying lesions in the RAS can eventually be identified in CFS, the therapeutic target for CFS would be better defined than it is at present. A number of logical approaches to treatment can already be envisaged.

Dinan TG, Majeed T, Lavelle E, Scott LV, Berti C, Behan P.	Department of Psychological Medicine, St Bartholomew's Hospital, London, UK. T.G.Dinan@mds.qmw.ac.uk	Blunted serotonin-mediated activation of the hypothalamic-pituitary-adrenal axis in chronic fatigue syndrome.	Psychoneuroendocrinology 1997 May;22(4):261-7	We examined 5HT1a-mediated ACTH release in patients with chronic fatigue syndrome (CFS) using a between-subjects design. Patients attending a specialist outpatient clinic for CFS, who fulfilled CDC criteria, together with age- and sex-matched healthy comparison subjects, were recruited. Subjects had a cannula inserted in a forearm vein at 0830 h and were allowed to relax until 0900 h, when baseline bloods for ACTH and cortisol were drawn. They were then given ipsapirone 20 mg PO and further blood for hormone estimation was taken at +30, +60, +90, +120 and +180 min. Baseline ACTH and cortisol levels did not differ between the two groups. Release of ACTH (but not cortisol) in response to ipsapirone challenge was significantly blunted in patients with CFS. We conclude that serotonergic activation of the hypothalamic-pituitary-adrenal axis is defective in CFS. This defect may be of pathophysiological significance.
Dobbins JG, Bonnie Randall, Michele Reyes , Lea Steele, Elizabeth A. Livens BA, William C. Reeves		The Prevalence of Chronic Fatiguing Illnesses Among Adolescents in the United States	Journal of Chronic Fatigue Syndrome 1997: 3(2): 15 - 27	Objective. To compare the prevalence of unexplained chronic fatigue (CF) and chronic fatigue syndrome (CFS) among adolescents in three studies conducted by the Centers for Disease Control and Prevention and to compare these estimates with those for adults in two of the studies. Design. Thc studies used the following three designs: (i) a physicianbased CFS surveillance system, (ii) a random, cross-sectional community telephone survey and (iii) a cross-sectional survey of school nurses. Setting. Surveillance included all patients with unexplained fatigue seen by participating physicians in four communities over a 2-year period; the community survey was conducted in a defined, urban population; and the survey of nurses included all middle, junior, and high school nurses in two communities. Patients or other participants. Twenty-three adolescent cases of unexplained chronic fatiguing illness were reported to the surveillance system, 7 of whom were classified with CFS. The community survey screened 2,249 persons between the ages of 2 and 17 years and identified 5 with unexplained chronic fatiguing illness, only one of whom might have had CFS. The school nurses identified 22 students with unexplained fatiguing illness, 10 of whom had received a diagnosis

				of CFS. Main outcome measures. The prevalence of unexplained chronic fatiguing illness was estimated in all three studies. The prevalence of CFS was estimated in one study, the prevalence of CFS-like illness was estimated in another, and the prevalence of a reported diagnosis of CFS was estimated in the third. Results. In general, the prevalence estimates of CF, CFS-like illness, and CFS for adolescents were lower than those for adults. One study also included children ages 2 to 11 years and found very little CF and no CFS. Cases of CFS among adolescents were evenly distributed across individual years of age. Conclusions. CFS was clearly present among adolescents, although the prevalence for this group was lower than for most adult age groups: Differences in prevalence estimates among the three studies were consistent with differences in study designs. The validity of adolescent/adult comparisons within each study should not be affected by the study design. Further study of the applicability of the current CFS case definition to adolescents is warranted.
Dowsett EG, Colby J.		Chronic fatigue syndrome in children. Journal was wrong to critizise study in schoolchildren.	BMJ 1997 Oct 11;315(7113):949 Comment on: BMJ. 1997 Jun 7;314(7095):1635-6	
Dowsett EG, Jane Colby		Long-Term Sickness Absence Due to ME/CFS in UK Schools An Epidemiological Study with Medical and Educational Implications	Journal of Chronic Fatigue Syndrome 1997: 3(2): 29 - 42	A study was made to determine whether the recognition of multiple cases of myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) in one school is a unique experience. A five-year retrospective period prevalence survey (1991-1995) was collated from sequential reports made in six English Local Education Authority (LEA) areas. By means of a confidential questionnaire circulated to 2,942 school principals via internal mail, 1,098 schools, comprising 27,327 staff and 333,024 pupils, were investigated. Details were obtained on age, gender, location in school sector, work pattern and morbidity. Forty-two percent of all medically certified long-term sickness absence was ascribed to ME/CFS, this figure being well in excess of all other causes. This diagnosis was significantly associated with case clustering, variable geographical prevalence, a marked increase in the female:male case ratio at puberty and prolonged disturbance of educational potential. We conclude that ME/CFS in schools leads to serious economic and career problems. Redirection of research to special educational needs and to early diagnosis of infectious agents which can trigger ME/CFS in schools might prevent, at low cost, much chronic illness and education deficit.
Droge W, Holm E.	Division of Immunochemistry, Deutsches Krebsforschungszentrum, Heidelberg,	Role of cysteine and glutathione in HIV infection and other diseases associated with muscle wasting and	FASEB J 1997 Nov;11(13):1077-89	The combination of abnormally low plasma cystine and glutamine levels, low natural killer (NK) cell activity, skeletal muscle wasting or muscle fatigue, and increased rates of urea production defines a complex of abnormalities that is tentatively called "low CG syndrome." These symptoms are found in patients with HIV infection, cancer, major injuries, sepsis, Crohn's disease, ulcerative

	Germany.	immunological dysfunction.		colitis, chronic fatigue syndrome, and to some extent in overtrained athletes. The coincidence of these symptoms in diseases of different etiological origin suggests a causal relationship. The low NK cell activity in most cases is not life-threatening, but may be disastrous in HIV infection because it may compromise the initially stable balance between the immune system and virus, and trigger disease progression. This hypothesis is supported by the coincidence observed between the decrease of CD4+ T cells and a decrease in the plasma cystine level. In addition, recent studies revealed important clues about the role of cysteine and glutathione in the development of skeletal muscle wasting. Evidence suggests that 1) the cystine level is regulated primarily by the normal postabsorptive skeletal muscle protein catabolism, 2) the cystine level itself is a physiological regulator of nitrogen balance and body cell mass, 3) the cyst(e)ine-mediated regulatory circuit is compromised in various catabolic conditions, including old age, and 4) cysteine supplementation may be a useful therapy if combined with disease-specific treatments such as antiviral therapy in HIV infection. Review, Academic
Durlach J, Bac P, Durlach V, Bara M, Guiet-Bara A.	SDRM, Hopital Saint-Vincent-de-Paul, Paris.	Neurotic, neuromuscular and autonomic nervous form of magnesium imbalance.	Magnes Res 1997 Jun;10(2):169-95	The nervous form of magnesium imbalance represents the best documented experimental and clinical aspects of magnesium disorders. The nervous form of primary magnesium deficit (MD) in the adult appears as the best descriptive model for analysis of the symptomatology, aetiology, physiopathology, diagnosis and therapy of the most frequent form of MD. Nervous hyperexcitability due to chronic MD in the adult results in a non-specific clinical pattern with associated central and peripheral neuromuscular symptoms, analogous to the symptomatology previously described in medical literature as latent tetany, hyperventilation syndrome, spasmophilia, chronic fatigue syndrome, neurocirculatory asthenia and idiopathic Barlow's disease. On encountering this non-specific pattern, the signs of neuromuscular hyperexcitability are of much greater importance. Trousseau's sign is less sensitive than Chvostek's sign, but their sensitivities are increased by hyperventilation (Von Bondsdorff's test). Examination of the precordial area will be conducted in order to search clinical stigmata of mitral valve prolapse (MVP) which is a frequent dyskinesia due to chronic MD (about a quarter to one-third of cases). The electromyogram (EMG) shows one (or several) trains of autorhythmic activities beating for more than 2 min of one of the three tetanic activities (uniplets, multiplets or 'complex tonicoclonic tracings') during one of the three facilitation procedures: tourniquet-induced ischaemia lasting 10 min. post-ischaemia lasting 10 min after the removal of the tourniquet and hyperventilation over 5 min. A repetitive EMG constitutes the principal mark of nervous hyperexcitability (NHE) due to MD. The echocardiogram (ECC) is the best tool for detecting MVP, the 2-dimensional ECC with pulsed Doppler being more accurate than time-motion ECC. The routine

				ionic investigations comprise five static tests: plasma and erythrocyte magnesium, plasma calcium and daily magnesiuria and calciuria. An evaluation of magnesium intake is desirable. Normal concentrations of magnesium in blood do not rule out the diagnosis of the nervous form of primary chronic MD. The histograms of MD group reveal Gaussian type magnesaemias with significantly lower means and the constituent elements can be individually hypo- (one-third of cases), normo- (about two-thirds of cases) and even, exceptionally, hyper-magnesaemic. The diagnosis of MD requires an oral magnesium load test. At physiological dose (5 mg of Mg/kg/day), oral magnesium is totally devoid of the pharmacological effects of parenteral magnesium. Corrections of symptomatology by this oral physiological magnesium load is the best proof that it was due to magnesium deficiency. In particular clinical forms, more sophisticated studies may be useful: standard and quantitative electroencephalograms, electropolygraphic studies of afternoon sleep, electronystagmography, optokinetic test, skin conductance reflex, psychometric inventories, standard or monitoring electrocardiogram, treadmill test, other static and dynamic investigations: e.g. ionized free Mg2+, lymphocyte Mg, brain Mg, cerebrospinal Mg, Mg balance, Mg parenteral load test, glucose load, and even radio-isotope study, the only one able to reveal intestinal magnesium hypersecretion. Nervous primary chronic MD progresses by phases of decompensation against a background of latency. Marginal magnesium deficiency, that is to say an insufficient magnesium intake which merely requires simple oral physiological supplementation, is fundamental in the aetiology of primary magnesium deficit. However a constitutional homeostatic lability of the nervous system or of magnesium metabolism such as belonging to the B35 type of HLA group must be involved. Part of the aetiology of this magnesium deficit is a magnesium depletion, where the disorder which induces magnesium deficit is related to a dysregulation of the control mechanisms of magnesium status which requires a more or less difficult Review, Academic

	och immunologi, Huddinge sjukhus.	virus has been detected in human neuropathy].[article in Swedish]		or results in manifest disturbances of movement behaviour. Although BDV has not been unequivocally implicated in any human disease, several reports have suggested relationship to exist between BDV infection and certain neuropsychiatric syndromes including affective disorders, chronic fatigue syndrome, and schizophrenia. Moreover, at least one centre has initiated a trial of antiviral therapy in patients with affective disorders attributable to BDV. The article consists in a review of recent advances in the molecular biology, pathogenesis and epidemiology of BDV, and an outline of anticipated directions for future research.
Fairhurst D, Waterman M, Lynch S.		Cognitive slowing in chronic fatigue syndrome (CFS)	Psychosom Med 1997 Nov-Dec;59(6):638 Comment on: Psychosom Med. 1997 Jan-Feb;59(1):58-66	
Field TM, William Sunshine , Maria Hernandez-Reif , Olga Quintino BS, Saul Schanberg , Cynthia Kuhn , Iris Burman		Massage Therapy Effects on Depression and Somatic Symptoms in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1997: 3(3): 43 - 51	Subsequent to recent reports of psychomotor retardation in chronic fatigue syndrome (CFS), the present study investigated the relative contributions of cognitive and motor components to psychomotor functioning in CFS. These components were differentiated by means of a reaction time paradigm proposed by Cornell, Suarez and Berent (1). The relationship between the cognitive and motor components of psychomotor performance and subjective cognitive and motor complaints was also investigated. Three groups of subjects participated in the study: an experimental group comprised of ten patients with CFS, and two comparison groups comprised of ten depressed and ten healthy individuals. Although the results of this study are suggestive of minimal functional impairment in CFS, they implicate motor factors in psychomotor slowing in unmedicated CFS patients
Fiore G, Giacovazzo F, Giacovazzo M.	VI Cattedra di Medicina Interna, Universita La Sapienza, Roma, Italy.	Three cases of dermatomyositis erroneously diagnosed as "chronic fatigue syndrome".	Eur Rev Med Pharmacol Sci 1997 Nov-Dec;1(6):193-5	The authors report three cases of dermatomyositis, which ha been erroneously diagnosed as "chronic fatigue syndrome" due to the presence of elevated titers of serum anti-Epstein Barr antibodies.
Fischler B, Cluydts R, De Gucht Y, Kaufman L, De Meirleir K.	Department of Psychiatry, Academic Hospital, Brussels, Balgium.	Generalized anxiety disorder in chronic fatigue syndrome.	Acta Psychiatr Scand 1997 May;95(5):405-13	A structured psychiatric interview, forming part of a global psychopathological approach, revealed higher prevalence rates of current and lifetime psychiatric disorders and a higher degree of psychiatric comorbidity in patients with chronic fatigue syndrome (CFS) than in a medical control group. In contrast to previous studies, a very high prevalence of generalized anxiety disorder (GAD) was found in CFS, characterized by an early onset and a high rate of psychiatric comorbidity. It is postulated that GAD represents a susceptibility factor for the development of CFS. A significantly higher prevalence was also observed for the somatization disorder (SD) in the CFS group. Apart from a higher female-to-male ratio in

				fibromyalgia, no marked differences were observed in sociodemographic or illness-related features, or in psychiatric morbidity, between CFS patients with and without fibromyalgia. CFS patients with SD have a longer illness duration and a higher rate of psychiatric comorbidity. These findings are consistent with the suggestion of Hickie et al. (1) that chronic fatigued subjects with SD should be distinguished from subjects with CFS.
Fischler B, Dendale P, Michiels V, Cluydts R, Kaufman L, De Meirleir K.	Department of Psychiatry, Academic Hospital, Free University of Brussels, Belgium.	Physical fatigability and exercise capacity in chronic fatigue syndrome: association with disability, somatization and psychopathology.	J Psychosom Res 1997 Apr;42(4):369-78	Physical fatigability and avoidance of physically demanding tasks in chronic fatigue syndrome (CFS) were assessed by the achievement or nonachievement of 85% of age-predicted maximal heart rate (target heart rate, THR) during incremental exercise. The association with functional status impairment, somatization, and psychopathology was examined. A statistically significant association was demonstrated between this physical fatigability variable and impairment, and a trend was found for an association with somatization. No association was demonstrated with psychopathology. These results are in accordance with the cognitive-behavioral model of CFS, suggesting a major contribution of avoidance behavior to functional status impairment; however, neither anxiety nor depression seem to be involved in the avoidance behavior. Aerobic work capacity was compared between CFS and healthy controls achieving THR. Physical deconditioning with early involvement of anaerobic metabolism was demonstrated in this CFS subgroup. Half of the CFS patients who did not achieve THR did not reach the anaerobic threshold. This finding argues against an association in CFS between avoidance of physically demanding tasks and early anaerobic metabolism during effort.
Fischler B, Le Bon O, Hoffmann G, Cluydts R, Kaufman L, De Meirleir K.	Department of Psychiatry, Academic Hospital, Free University of Brussels, Belgium.	Sleep anomalies in the chronic fatigue syndrome. A comorbidity study.	Neuropsychobiology 1997;35(3):115-22	Polysomnographic findings were compared between a group of patients with the chronic fatigue syndrome (CFS; n = 49) and a matched healthy control (HC) group (n = 20). Sleep initiation and sleep maintenance disturbances were observed in the CFS group. The percentage of stage 4 was significantly lower in the CFS group. A discriminant analysis allowed a high level of correct classification of CFS subjects and HC. Sleep-onset latency and the number of stage shifts/hour contributed significantly to the discriminant function. The presence of these anomalies as well as the decrease in stage 4 sleep were not limited to the patients also diagnosed with fibromyalgia or with a psychiatric disorder. No association was found between sleep disorders and the degree of functional status impairment. The mean REM latency and the percentage of subjects with a shortened REM latency were similar in CFS and HC.

Fitzgibbon EJ, Murphy D, O'Shea K, Kelleher C.	Department of Health Promotion, University College Galway, Ireland.	Chronic debilitating fatigue in Irish general practice: a survey of general practitioners' experience.	Br J Gen Pract 1997 Oct;47(423):618-22	BACKGROUND: Doctors are called upon to treat chronic debilitating fatigue without the help of a protocol of care. AIMS: To estimate the incidence of chronic debilitating fatigue in Irish general practice, to obtain information on management strategy and outcome, to explore the attitudes of practitioners (GPs) towards the concept of a chronic fatigue syndrome (CFS), and to recruit practitioners to a prospective study of chronic fatigue in primary care. METHOD: A total of 200 names were selected from the database of the Irish College of General Practitioners (ICGP); 164 of these were eligible for the study. RESULTS: Altogether, 118 questionnaires were returned (72%). Ninety-two (78%) responders identified cases of chronic fatigue, giving an estimated 2.1 cases per practice and an incidence of 1 per 1000 population. All social classes were represented, with a male to female ratio of 1:2. Eleven disparate approaches to treatment were advocated. Many (38%) were dissatisfied with the quality of care delivered, and 45% seldom or hardly ever referred cases for specialist opinion. The majority (58%) accepted CFS as a distinct entity, 34% were undecided, and 8% rejected it. Forty-two (35%) GPs volunteered for a prospective study. CONCLUSION: Chronic fatigue is found in Irish general practice among patients of both sexes and all social classes. Doctors differ considerably in their management of patients and are dissatisfied with the quality of care they deliver. Many cases are not referred for specialist opinion. A prospective database is required to accurately assess the scale of this public health problem and to develop a protocol of care.
Fohlman J, Friman G, Tuvemo T.	Infektionskliniken, Akademiska sjukhuset, Uppsala.	[Enterovirus infections in new disguise].[article in Swedish]	Lakartidningen 1997 Jul 9;94(28-29):2555-60	Enteroviruses (Coxsackie A and B, echovirus, poliovirus) belong to a group of small RNA-viruses, picomavirus, which are widespread in nature. Enteroviruses cause a number of wellknown diseases and symptoms in humans, from subclinical infections and the common cold to poliomyelitis with paralysis. The development of polio vaccines is the greatest accomplishment within the field of enterovirus research and the background work was awarded the Nobel prize in 1954. New knowledge implies that enteroviruses play a more important part in the morbidity panorama than was previously thought. Chronic (persistent) enteroviruses were formerly unknown. Serologic and molecular biology techniques have now demonstrated that enteroviral genomes, in certain situations, persist after the primary infection (which is often silent). Persistent enteroviral infection or recurrent infections and/or virus-stimulated autoimmunity might contribute to the development of diseases with hitherto unexplained pathogenesis, such as post polio syndrome, dilated cardiomyopathy, juvenile (type 1) diabetes and possibly some cases of chronic fatigue syndrome.

		syndrome. Including patients who rated themselves as a little better would have altered results.	discussion 948 Comment on: BMJ. 1997 Jun 7;314(7095):1635-6 BMJ. 1997 Jun 7;314(7095):1647-52	
Freeman R, Komaroff AL.	Department of Neurology, Beth Israel Deaconess Medical Center, Boston, Massachusetts 02215, USA.	Does the chronic fatigue syndrome involve the autonomic nervous system?	Am J Med 1997 Apr;102(4):357-64	PURPOSE: To investigate the role of the autonomic nervous system in the symptoms of patients with chronic fatigue syndrome (CFS) and delineate the pathogenesis of the orthostatic Intolerance and predisposition to neurally mediated syncope reported in this patient group. PATIENTS AND METHODS: Twenty-three CFS patients and controls performed a battery of autonomic function tests. The CFS patients completed questionnaires pertaining to autonomic and CFS symptoms, their level of physical activity, and premorbid and coexisting psychiatric disorders. The relationship between autonomic test results, cardiovascular deconditioning, and psychiatric disorders was examined with multivariate statistics and the evidence that autonomic changes seen in CFS might be secondary to a postviral, idiopathic autonomic neuropathy was explored. RESULTS: The CFS subjects had a significant increase in baseline ($P < 0.01$) and maximum heart rate (HR) on standing and tilting (both $P < 0.0001$). Tests of parasympathetic nervous system function (the expiratory inspiratory ratio, $P < 0.005$; maximum minus minimum HR difference, $P < 0.05$), were significantly less in the CFS group as were measures of sympathetic nervous system function (systolic blood pressure decrease with tilting, $P < 0.01$; diastolic blood pressure decrease with tilting, $P < 0.05$; and the systolic blood pressure decrease during phase II of a Valsalva maneuver, $P < 0.05$). Twenty-five percent of CFS subjects had a positive tilt table test. The physical activity index was a significant predictor of autonomic test results (resting, sitting, standing, and tilted HR, $P < 0.05$ to $P < 0.009$); and the blood pressure decrease in phase II of the Valvalsa maneuver, $P < 0.05$) whereas premorbid and coexistent psychiatric conditions were not. The onset of autonomic symptoms occurred within 4 weeks of a viral infection in 46% of patients-a temporal pattern that is consistent with a postviral, idiopathic autonomic neuropathy. CONCLUSION: Patients with CFS show alterations in measures of sympathetic and parasympathetic nervous system function. These results, which provide the physiological basis for the orthostatic intolerance and other symptoms of autonomic function in this patient group, may be explained by cardiovascular deconditioning, a postviral idiopathic autonomic neuropathy, or both.
Fukuda K, Dobbins JG, Wilson LJ, Dunn RA, Wilcox K, Smallwood D.	Division of Viral and Rickettsial Diseases, Centers for Disease	An epidemiologic study of fatigue with relevance for the	J Psychiatr Res 1997 Jan-Feb;31(1):19-29	We surveyed households in four rural Michigan communities to confirm a reported cluster of cases resembling chronic fatigue syndrome (CFS) and to study the epidemiology of fatigue in a rural area. Data were collected from 1698

	Control and Prevention, Atlanta, GA 30333, USA.	chronic fatigue syndrome.		households. We did not confirm the reported cluster. The prevalence of households containing at least one fatigued person was similar between communities thought to harbor the cluster and communities selected for comparison. Symptoms and features of generic forms of fatigue were very similar to those often attributed to CFS.
Fulcher KY, White PD.	National Sports Medicine Institute, St Bartholomew's, London.	Randomised controlled trial of graded exercise in patients with the chronic fatigue syndrome.	BMJ 1997 Jun 7;314(7095):1647-52Comment in: BMJ. 1997 Jun 7;314(7095):1635-6 BMJ. 1997 Oct 11;315(7113):947-8 BMJ. 1997 Oct 11;315(7113):947; discussion 948 BMJ. 1997 Oct 11;315(7113):948	OBJECTIVE: To test the efficacy of a graded aerobic exercise programme in the chronic fatigue syndrome. DESIGN: Randomised controlled trial with control treatment crossover after the first follow up examination. SETTING: Chronic fatigue clinic in a general hospital department of psychiatry. SUBJECTS: 66 patients with the chronic fatigue syndrome who had neither a psychiatric disorder nor appreciable sleep disturbance. INTERVENTIONS: Random allocation to 12 weeks of either graded aerobic exercise or flexibility exercises and relaxation therapy. Patients who completed the flexibility programme were invited to cross over to the exercise programme afterwards. MAIN OUTCOME MEASURE: The self rated clinical global impression change score, "very much better" or "much better" being considered as clinically important. RESULTS: Four patients receiving exercise and three receiving flexibility treatment dropped out before completion. 15 of 29 patients rated themselves as better after completing exercise treatment compared with eight of 30 patients who completed flexibility treatment. Analysis by intention to treat gave similar results (17/33 v 9/33 patients better). Fatigue, functional capacity, and fitness were significantly better after exercise than after flexibility treatment. 12 of 22 patients who crossed over to exercise after flexibility treatment rated themselves as better after completing exercise treatment 32 of 47 patients rated themselves as better three months after completing supervised exercise treatment 35 of 47 patients rated themselves as better one year after completing supervised exercise treatment. CONCLUSION: These findings support the use of appropriately prescribed graded aerobic exercise in the management of patients with the chronic fatigue syndrome. Randomized Controlled Trial
Galbraith DN, Nairn C, Clements GB.	Regional Virus Laboratory, Ruchill Hospital, Glasgow, UK.	Evidence for enteroviral persistence in humans.	J Gen Virol 1997 Feb;78 (Pt 2):307-12	We have sought evidence of enteroviral persistence in humans. Eight individuals with chronic fatigue syndrome (CFS) were positive for enteroviral sequences, detected by PCR in two serum samples taken at least 5 months apart. The nucleotide sequence of the 5' non-translated region (bases 174-423) was determined for each amplicon. Four individuals had virtually identical nucleotide sequences (> 97%) in both samples. The sequence pairs also each had a unique shared pattern indicating that the virus had persisted. In one individual (HO), it was clear that there had been infection with two different enteroviruses. In the remaining three individuals, the lack of unique shared features suggested that re-infection had occurred, rather than persistence. With the exception of HO, the sequences fell into a subgroup that is related to the Coxsackie B-like viruses.

Gaudino EA, Coyle PK, Krupp LB.	Department of Neurology, State University of New York at Stony Brook, USA.	Post-Lyme syndrome and chronic fatigue syndrome. Neuropsychiatric similarities and differences.	Arch Neurol 1997 Nov;54(11):1372-6	BACKGROUND: Patients with chronic fatigue syndrome (CFS) and post-Lyme syndrome (PLS) share many features, including symptoms of severe fatigue and cognitive difficulty. OBJECTIVE: To examine the neuropsychiatric differences in these disorders to enhance understanding of how mood, fatigue, and cognitive performance interrelate in chronic illness. METHODS: Twenty-five patients with CFS, 38 patients with PLS, and 56 healthy controls participated in the study. Patients with CFS met 1994 criteria for CFS and lacked histories suggestive of Lyme disease. Patients with PLS were seropositive for Lyme disease, had met the Centers for Disease Control and Prevention criteria, or had histories strongly suggestive of Lyme disease and were experiencing severe fatigue that continued 6 months or more following completion of antibiotic treatment for Lyme disease. All subjects completed self-report measures of somatic symptoms and mood disturbance and underwent neuropsychological testing. All patients also underwent a structured psychiatric interview. RESULTS: Patients with CFS and PLS were similar in several somatic symptoms and in psychiatric profile. Patients with CFS reported more flulike symptoms than patients with PLS. Patients with PLS but not patients with CFS performed significantly worse than controls on tests of attention, verbal memory, verbal fluency, and motor speed. Patients with PLS without a premorbid history of psychiatric illness did relatively worse on cognitive tests than patients with PLS with premorbid psychiatric illness compared with healthy controls. CONCLUSIONS: Despite symptom overlap, patients with PLS show greater cognitive deficits than patients with CFS compared with healthy controls. This is particularly apparent among patients with PLS who lack premorbid psychiatric illness.

Goldberg MJ, Ismael Mena, Jacques Darcourt		NeuroSPECT Findings in Children - with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1997: 3(1): 61 - 67	Background NeuroSPECT studies have described specific abnormalities in cerebral perfusion in adults with criteria for Chronic Fatigue Syndrome. This reports findings in 13 children with criteria for Chronic Fatigue Syndrome. Objective. NeuroSPECT findings in 13 CFS/CFIDS children. Methods. Thirteen children meeting CDC criteria for CFS/CFIDS, were evaluated using NeuroSPECT imaging utilizing Xenon 133 and Tc-99m-HMPAO (1). Results. In 13 children, hypoperfusion was observed at 42 ± 10 ml/min/100g, $p < 0.0001$ in the left temporal lobe and at 45 ± 11, $p < .001$ in right temporal lobe. Statistically significant hypoperfusion was also observed in both parietal lobes and at 50 and 53 ml/ min/100g, $p < 0.05$ in the frontal lobe of the right hemisphere. Quantitatcd HMPAO demonstrated bilateral orbitofrontal and anterior temporal hypoperfusion. There was also hypoperfusion in the dorsal aspects of both frontal lobes and both parietooccipital lobes. Conclusion. NeuroSPECT is

				presented as a quantifiable, reproducible tool that can allow us to document a cohort of children defined as CFS/CFIDS.
Goldenberg DL.		Fibromyalgia, chronic fatigue syndrome, and myofascial pain syndrome.	Curr Opin Rheumatol 1997 Mar;9(2):135-43	The diagnosis of fibromyalgia continues to generate heated debate. The presence of multiple lifetime psychiatric diagnoses was not intrinsically related to fibromyalgia but rather to the decision of patients to seek specialty medical care. Better outcome measures in fibromyalgia were tested. Neurally mediated hypotension may be associated with chronic fatigue syndrome (CFS). Treatment of patients with fibromyalgia and CFS continues to be of limited success, although the role of multidisciplinary group intervention appears promising. Two position papers focused on the adverse aspects of the medicolegal issues in fibromyalgia and CFS.
Goudsmit EM.		Graded exercise in chronic fatigue syndrome. Chronic fatigue syndrome is heterogeneous condition.	BMJ 1997 Oct 11;315(7113):948 Comment on: BMJ. 1997 Jun 7;314(7095):1647-52	
Greco A, Tannock C, Brostoff J, Costa DC.	MRI Department, Centre Hospitalier Princesse Grace, Principality of Monaco.	Brain MR in chronic fatigue syndrome.	AJNR Am J Neuroradiol 1997 Aug;18(7):1265-9	PURPOSE: To determine the prevalence of MR white matter abnormalities in patients with chronic fatigue syndrome (CFS). METHODS: Brain MR studies of 43 patients (29 women and 14 men, 22 to 78 years old) with a clinical diagnosis of CFS (n = 15), CFS with associated depression (n = 14), and CFS with associated other psychiatric disorders, namely, anxiety and somatization disorder (n = 14), were compared with brain MR studies in 43 age- and sex-matched control subjects. RESULTS: MR findings were abnormal in 13 (32%) of the patients in the study group (ages 34 to 78 years) and in 12 (28%) of the control subjects (ages 26 to 73 years). One patient with CFS had multiple areas of demyelination in the supratentorial periventricular white matter. Another patient with CFS and associated depression had a single focus of probable demyelination in the supratentorial periventricular white matter. In four patients with CFS (ages 34 to 48 years) MR abnormalities consisted of one or several punctate hyperintense foci in the corona radiata, centrum ovale, and frontal white matter. The remaining seven patients (ages 50 to 78 years) had frontoparietal subcortical white matter foci of high T2 signal. The prevalence of white matter hyperintensities was not different between the patients and the control subjects. CONCLUSIONS: Our findings suggest that no MR pattern of white matter abnormalities is specific to CFS.

Gupta S, Aggarwal S,	Department of	Cytokine production by	J Psychiatr Res 1997	It has been suggested that cytokines play a role in certain clinical manifestations

See D, Starr A.	Medicine, University of California, Irvine 92717, USA.	adherent and non-adherent mononuclear cells in chronic fatigue syndrome.	Jan-Feb;31(1):149-56	of chronic fatigue syndrome (CFS). In this study adherent (monocytes) and non-adherent (lymphocytes) mononuclear cells were stimulated in the presence or absence of phytohemagglutinin (PHA) or lipopolysaccharide (LPS), respectively, and supernatants were assayed for IL-6, TNF-alpha, and IL-10 by ELISA. IL-6 was also measured at the mRNA level by polymerase chain reaction. The levels of spontaneously (unstimulated) produced TNF-alpha by non-adherent lymphocytes and spontaneously produced IL-6 by both adherent monocytes and non-adherent lymphocytes were significantly increased as compared to simultaneously studied matched controls. The abnormality of IL-6 was also observed at mRNA level. In contrast, spontaneously produced IL-10 by both adherent and non-adherent cells and by PHA-activated non-adherent cells were decreased. This preliminary study suggests that an aberrant production of cytokines in CFS may play a role in the pathogenesis and in some of the clinical manifestations of CFS.

Heyll U, Wachauf P, Senger V, Diewitz M.	Gesellschaftsarztliche Abteilung der Deutschen Krankenversicherung, Koln.	[Definition of "chronic fatigue syndrome" (CFS)].[article in German]	Med Klin 1997 Apr 15;92(4):221-7	The definition of "Chronic Fatigue Syndrome" (CFS) in 1988 was an attempt to establish a uniform basis for the previously heterogeneous approaches to research of this severe and inexplicable state of fatigue. At the same time, researchers wished to narrow down a pathogenetically founded disease entity a priori by specifying precise disease criteria. The empirical data gathered in accordance with the CFS definition, however, have failed to confirm the assumption that the disease entity is pathogenetically uniform. Furthermore, the originally selected criteria have proven to be impracticable ore theoretically questionable. In the period that followed, modifications that permitted a more comprehensive and yet more differentiated classification of fatigue states of unclear etiology were proposed. The new research approach avoids postulation of causal entities and puts CFS back in a category with other descriptive states of fatigue.
Holland P.	Psychotherapy Department, Royal Edinburgh Hospital.	Coniunctio--in bodily and psychic modes: dissociation, devitalization and integration in a case of	J Anal Psychol 1997 Apr;42(2):217-36	Three years of analytical psychotherapy with a professional woman in mid-life, suffering from chronic fatigue syndrome (CFS), is described. Gradual recovery merged into mid-life changes; marriage, along with a new balance of maternal and paternal imagos, enabled her to trust enough to become pregnant-coniunctio in the most primal bodily and psychic modes. Her life-long, schizoid

		chronic fatigue syndrome.		type pattern, "the pendulum of closeness and isolation', with its extreme of psycho-physical collapse and devitalization, was replayed in therapy. The analyst's symbolic attitude is emphasized, containing the patient's initial affective explosion and validating the physicality of her condition. Mirroring and steady rhythmic attunement became a new, pre-verbal, source of trust-vitalization; differentiation and separation replaced defensive splitting and dissociation. Then the overwhelmingly powerful bodily/maternal could be counterbalanced by the masculine, and a transitional space emerged for symbolic work. Both the regressive and the dynamic aspects of CFS are located in the earliest undifferentiated, archetypal, bodily/psychic modes, when the frustration of primary needs evokes the defences of the self. It is argued that our psychodynamic understanding can contribute to the stalemate in seeing chronic fatigue syndrome as either an organic illness or depression, and that a new linking of the somatic and psychic calls for a new professional collaboration.
Holmes MJ, Diack DS, Easingwood RA, Cross JP, Carlisle B.	Department of Microbiology, University of Otago, Dunedin, New Zealand. mike.holmes@stonebow.otago.ac.nz	Electron microscopic immunocytological profiles in chronic fatigue syndrome.	J Psychiatr Res 1997 Jan-Feb;31(1):115-22	Structures consistent in size, shape and character with various stages of a Lentivirus replicative cycle were observed by electron microscopy in 12-day peripheral-blood lymphocyte cultures from 10 of 17 Chronic Fatigue Syndrome patients and not in controls. Attempts to identify a lymphoid phenotype containing these structures by immunogold labelling failed and the results of reverse-transcriptase assay of culture supernatants were equivocal. The study was blind and case-controlled, patients being paired with age, sex and ethnically matched healthy volunteers. Prescreening of subjects included the common metabolic and immunological disorders, functional conditions and a virus-screen against hepatitis B and C, Epstein-Barr Virus, Cytomegalovirus and Human Immunodeficiency Virus.
Houde SC, Kampfe-Leacher R.	MGH Institute of Health Professions, Boston, Mass, USA.	Chronic fatigue syndrome: an update for clinicians in primary care.	Nurse Pract 1997 Jul;22(7):30, 35-6, 39-40 passim	Cases of long-standing (6 months or longer) fatigue that are not explained by an existing medical or psychiatric diagnosis are referred to as chronic fatigue syndrome (CFS). CFS is a condition of unknown etiology that presents with a complex array of symptoms in patients with diverse health histories. A diagnosis of CFS is largely dependent upon ruling out other organic and psychologic causes of fatigue. CFS can present the clinician with a unique set of challenges in terms of diagnosis and treatment. A review of recent research suggests that the management of CFS requires an individualized approach for each patient. An historic overview of the condition is presented along with current theories of causation, diagnosis considerations, symptom management, and health promotion strategies. Review Literature

Jacobson SK, Daly JS, Thorne GM, McIntosh K.	Department of Pediatrics, Harvard Medical School, Boston, Massachusetts, USA.	Chronic parvovirus B19 infection resulting in chronic fatigue syndrome: case history and review.	Clin Infect Dis 1997 Jun;24(6):1048-51	The spectrum of disease caused by parvovirus B19 has been expanding in recent years because of improved and more sensitive methods of detection. There is evidence to suggest that chronic infection occurs in patients who are not detectably immunosuppressed. We report the case of a young woman with recurrent fever and a syndrome indistinguishable from chronic fatigue syndrome. After extensive investigation, we found persistent parvovirus B19 viremia, which was detectable by polymerase chain reaction (PCR) despite the presence of IgM and IgG antibodies to parvovirus B19. Testing of samples from this patient suggested that in some low viremic states parvovirus B19 DNA is detectable by nested PCR in plasma but not in serum. The patient's fever resolved with the administration of intravenous immunoglobulin.
Jason LA, Michael T. Ropacki, Nicole B. Santoro, Judith A. Richman , Wendy Heatherly, Renee Taylor, Joseph R. Ferrari , Trina M. Haney-Davis BA, Alfred Rademaker , Josée Dupuis , Jacqueline Golding , Audrius V. Plioplys Sigita Plioplys		A Screening Instrument for Chronic Fatigue Syndrome Reliability and Validity	Journal of Chronic Fatigue Syndrome 1997: 3(1): 39 - 59	Because estimates of the prevalence of Chronic Fatigue Syndrome (CFS) have been quite variable, there is a need for a screening instrument and second stage medical assessment that will produce the most valid estimate of the CFS prevalence. In the present study, four groups of 15 subjects each were recruited: patients diagnosed with (1) CFS, (2) Lupus, (3) Multiple Sclerosis (MS), and (4) a healthy control group. Participants were interviewed twice over a two week period of time with a screening instrument comprising The Fatigue Scale and a newly configured section. The screening instrument had excellent test-retest and interrater reliability. This screening instrument therefore has utility for CFS community-based epidemiologic research. However, while the instrument differentiates with CFS from those who are healthy, it is less likely to distinguish CFS from other autoimmune diseases (especially Lupus). Thus, future community-based CFS prevalence studies should encompass both a screening and a medical examination to adequately differentiate CFS from other illnesses with overlapping symptomatology. We recommend a two-stage research design with (1) a screening instrument with good sensitivity and (2) medical assessments of CFS positives from stage 1 to deal with the specificity problem.
Jason LA, Richman JA, Friedberg F, Wagner L, Taylor R, Jordan KM.	Department of Psychology, DePaul University, Chicago, IL 60614, USA.	Politics, science, and the emergence of a new disease. The case of chronic fatigue syndrome.	Am Psychol 1997 Sep;52(9):973-83Comment in: Am Psychol. 1998 Sep;53(9):1080-2	Chronic fatigue syndrome (CFS) emerged as a diagnostic category during the last decade. Initial research suggested that CFS was a relatively rare disorder with a high level of psychiatric comorbidity. Many physicians minimized the seriousness of this disorder and also interpreted the syndrome as being equivalent to a psychiatric disorder. These attitudes had negative consequences for the treatment of CFS. By the mid-1990s, findings from more representative

				epidemiological studies indicated considerably higher CFS prevalence rates. However, the use of the revised CFS case definition might have produced heterogeneous patient groups, possibly including some patients with pure psychiatric disorders. Social scientists have the expertise to more precisely define this syndrome and to develop appropriate and sensitive research strategies for understanding this disease.
Jason LA, Tryon WW, Frankenberry E, King C.	Department of Psychology, DePaul University, Chicago, IL 60613, USA.	Chronic fatigue syndrome: relationships of self-ratings and actigraphy.	Psychol Rep 1997 Dec;81(3 Pt 2):1223-6	Chronic Fatigue Syndrome is a baffling disease potentially affecting millions of Americans. Self-rating scales were developed to assess this condition but have yet to be validated with objective measures of activity. The present study of a 45-yr.-old man evaluated the relationships between scores on self-rating scales used to measure Chronic Fatigue Syndrome and actigraphy. Measured activity was related to predictors of fatigue but not to fatigue. The implications of these findings are discussed.
Jordan KM, Amy M. Kolak, Leonard A. Jason		Research with Children and Adolescents with Chronic Fatigue Syndrome Methodologies, Designs, and Special Considerations	Journal of Chronic Fatigue Syndrome 1997: 3(2): 3 - 13	Chronic fatigue syndrome (CFS) in children and adolescents presents unique challenges and opportunities to researchers. Issues specific to research conducted on children and adolescents with CFS are discussed. Such issues include the importance of utilizing a consistent definition of CFS and ascertaining that all participants meet the criteria, the need for attention to wading of questions regarding fatigue, and the significance of medical evaluations as part of a research study. Considerations pertaining to research with minors, such as confidentiality and assent, are explored. Finally, suggestions for future research on children are made.
Joyce J, Hotopf M, Wessely S.	Institute of Psychiatry, London, UK.	The prognosis of chronic fatigue and chronic fatigue syndrome: a systematic review.	QJM 1997 Mar;90(3):223-33 comment in: QJM. 1997 Nov;90(11):723 QJM. 1997 Nov;90(11):723-5	The prognosis of chronic fatigue syndrome and chronic fatigue has been studied in numerous small case series. We performed a systematic review of all studies to determine the proportion of individuals with the conditions who recovered at follow-up, the risk of developing alternative physical diagnoses, and the risk factors for poor prognosis. A literature search of all published studies which included a follow-up of patients with chronic fatigue syndrome or chronic fatigue were performed. Of 26 studies identified, four studied fatigue in children, and found that 54-94% of children recovered over the periods of follow-up. Another five studies operationally defined chronic fatigue syndrome in adults and found that < 10% of subjects return to pre-morbid levels of functioning, and the majority remain significantly impaired. The remaining studies used less stringent criteria to define their cohorts. Among patients in primary care with fatigue lasting < 6 months, at least 40% of patients improved. As the definition becomes more stringent the prognosis appears to worsen. Consistently reported risk factors for poor prognosis are older age, more chronic illness, having a comorbid psychiatric disorder and holding a belief that the illness is due to physical causes. Review, Multicase
Kane RL, Gantz NM,	Department of	Neuropsychological and	Neuropsychiatry	Although patients with chronic fatigue syndrome (CFS) typically present

DiPino RK.	Psychology, Veterans Affairs Medical Center, Baltimore, MD 21201, USA.	psychological functioning in chronic fatigue syndrome.	Neuropsychol Behav Neurol 1997 Jan;10(1):25-31	subjective complaints of cognitive and psychological difficulties, studies to date have provided mixed objective support for the existence of specific cognitive deficits. The present study was designed to examine differences in performance between individuals diagnosed with CFS and matched controls with respect to sustained attention, processing efficiency, learning, and memory. Subjects included 17 patients meeting Centers for Disease Control research criteria for CFS and 17 control subjects. Subjects were administered six measures assessing attention, memory, and word-finding ability and two measures assessing psychological distress. For the most part, the two groups did not differ on measures of neurocognitive functioning. Significant group differences were found on a single measure of attention and incidental memory. However, CFS patients differed markedly from controls with respect to reported psychological distress. The results support previous findings of notable levels of psychological distress among CFS patients. They also suggest the need for alternative research paradigms to assess the cognitive abilities of CFS patients.
Kerr JR, Anne-Marie Barrett , Martin D. Curran , Wilhelmina M.H. Behan, Derek Middleton, Peter O. Behan		Brief Communications: Parvovirus B19 and Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1997: 3(3): 101 - 107	Objective. To investigate the skeletal muscle of patients with chronic fatigue syndrome (CFS) for parvovirus B19. Methods. DNA was extracted from skeletal muscle biopsies from six patients with CFS diagnosed according to thc criteria of the Centers for Disease Control and Prevention and six control cases. Extracted DNA was checked for purity by agarose gel electrophoresis and examined for the presence of B19 DNA by a nested polymerase chain reaction (PCR) method. Results. One of the six biopsies from the CFS group and one of the six from the control group were positive for B19 DNA (Two-tailed P value = 1). Nucleotide sequencing of the PCR product from the CFS patient revealed one silent mutation from A → G at nucleotide 1530 when compared with the published sequence. Nucleotide sequencing of the PCR product from the control patient with mild arthralgia revealed 10 mutations when compared with the published sequence, all silent except the one at nt 1466 (G → C), which resulted in an amino acid change from serine to threonine. Conclusion. The incidence of parvovirus B19 detected in muscle is not increased in patients with CFS compared with controls and the virus in unlikely to play a role in the aetiology of this disorder.

Kubo K, Fujiyoshi T, Yokoyama MM, Kamei K, Richt JA, Kitze B, Herzog S, Takigawa M, Sonoda S.	Department of Neuropsychiatry, Faculty of Medicine, Kagoshima University, Japan.	Lack of association of Borna disease virus and human T-cell leukemia virus type 1 infections with psychiatric disorders among Japanese patients.	Clin Diagn Lab Immunol 1997 Mar;4(2):189-94	Borna disease virus (BDV) infection has been suspected to be a possible etiological factor in human psychiatric disorders and recently in chronic fatigue syndrome. Evidence of the correlation of BDV infection with these disorders remained unclear. Kagoshima is known to be one of the major areas in which human T-cell leukemia virus type 1 (HTLV-1) is endemic; this is the first isolated human retrovirus that causes adult T-cell leukemia with neurological symptoms. The present study aimed to clarify whether BDV and HTLV-1 infections are associated with psychiatric disorders among Japanese patients. Subjects were 346 patients with psychiatric disorders (schizophrenia, 179; mood disorder, 123; and others, 44) and 70 healthy controls. Anti-BDV antibodies from plasma samples were screened by the indirect immunofluorescence (IF) method using BDV-infected MDCK cells. Results revealed that only three samples were found to be weakly positive for BDV in the IF assay and seronegative by Western blot (immunoblot) assay. Furthermore, BDV-p24 related RNA in peripheral blood mononuclear cells from 106 of 346 psychiatric patients and 12 or 70 healthy controls by p24-reverse transcription PCR was examined. Two mood disorder patients were positive for BDV-p24 RNA but seronegative. To detect anti-HTLV-1 antibodies the plasma samples were screened by the particle agglutination method and no significant difference in seropositivity for anti-HTLV-1 antibody was found between the patients and healthy controls. These results also suggested that there is a lack of association between BDV and HTLV-1 infections with psychiatric disorders among Japanese patients.
Lakein DA, Fantie BD, Grafman J, Ross S, O'Fallon A, Dale J, Straus SE.	American University, USA.	Patients with chronic fatigue syndrome and accurate feeling-of-knowing judgments.	J Clin Psychol 1997 Nov;53(7):635-45	Many Chronic Fatigue Syndrome (CFS) patients complain of memory impairments which have been difficult to document empirically. Subjective complaints of memory impairment may be due to a deficit in metamemory judgment. CFS patients and matched controls were tested with a computerized Trivia Information Quiz that required them to rate their confidence about correctly recognizing an answer in a multiple choice format that they had been unable to remember in a fact-recall format. Even though CFS patients reported significantly greater amounts of fatigue, cognitive, and physical symptoms, the accuracy of their confidence levels and recognition responses were similar to controls. This finding suggests that a metamemory deficit is not the cause of the memory problems reported by CFS patients.

Lawrie SM, Manders DN, Geddes JR, Pelosi AJ.	Edinburgh University Department of Psychiatry, Royal Edinburgh Hospital.	A population-based incidence study of chronic fatigue.	Psychol Med 1997 Mar;27(2):343-53	BACKGROUND: Most research on syndromes of chronic fatigue has been conducted in clinical settings and is therefore subject to selection biases. We report a population-based incidence study of chronic fatigue (CF) and chronic fatigue syndrome (CFS). METHODS: Questionnaires assessing fatigue and emotional morbidity were sent to 695 adult men and women who had replied to a postal questionnaire survey 1 year earlier. Possible CFS cases, subjects with probable psychiatric disorder and normal controls were interviewed. RESULTS: Baseline fatigue score, the level of emotional morbidity and a physical attribution for fatigue were risk factors for developing CF. However, after adjusting for confounding, premorbid fatigue score was the only significant predictor. A minority of CF subjects, all female, had consulted their general practitioner; higher levels of both fatigue and emotional morbidity were associated with consultation. Possible CFS cases reported similar rates of current and past psychiatric disorder to psychiatric controls, but after controlling for fatigue or a diagnosis of neurasthenia the current rates were more similar to those of normal controls. Two new cases of CFS were confirmed. CONCLUSIONS: Both fatigue and emotional morbidity are integral components of chronic fatigue syndromes. The demographic and psychiatric associations of CFS in clinical studies are at least partly determined by selection biases. Given that triggering and perpetuating factors may differ in CFS, studies that examine the similarities and differences between chronic fatigue syndromes and psychiatric disorder should consider both the stage of the illness and the research setting.
Levine PH, Snow PG, Ranum BA, Paul C, Holmes MJ.	Department of Medicine, George Washington University Medical Center,	Epidemic neuromyasthenia and chronic fatigue syndrome in west	Arch Intern Med 1997 Apr 14;157(7):750-4	BACKGROUND: In 1984, an outbreak of an illness characterized by prolonged unexplained fatigue was reported in West Otago, New Zealand. This outbreak resembled other reported outbreaks of epidemic neuromyasthenia in that affected individuals presented with a spectrum of complaints ranging from

	Washington, DC, USA.	Otago, New Zealand. A 10-year follow-up.		transient diarrhea and upper respiratory disorders to chronic fatigue syndrome (CFS). OBJECTIVE: To obtain a perspective on the natural history of CFS not possible in clinic-based studies. METHODS: Twenty-three of the 28 patients in the original report were contacted and asked to complete written questionnaires. Interviews were obtained in person or via telephone. RESULTS: Ten (48%) of the 21 patients with satisfactory interviews appeared to meet the current Centers for Disease Control and Prevention (CDC) case definition of CFS, and 11 were classified as having prolonged or idiopathic fatigue. A return to premorbid activity was seen in most (n = 16) patients, although some reported the need to modify their lifestyle to prevent relapses. A female predominance was noted in those meeting the CDC case definition for CFS, whereas males predominated in patients diagnosed as having prolonged or idiopathic fatigue. CONCLUSIONS: The high proportion of patients recovering from CFS in the West Otago cluster suggests that epidemic-associated CFS has a better prognosis than sporadic cases. Female sex was confirmed as an important risk factor for CFS.
Levine PH.	Department of Medicine, George Washington University Medical Center, Washington, D.C. 20037, USA.	Epidemiologic advances in chronic fatigue syndrome.	J Psychiatr Res 1997 Jan-Feb;31(1):7-18	Epidemiologic studies of chronic fatigue syndrome (CFS) have been hampered by the absence of a specific diagnostic test, but with increasing interest in this disorder there has been a greater understanding of the risk factors, illness patterns, and other aspects of this multisystem disorder. Working case definitions have been developed for research purposes but they have continued to change over time and have not always been utilized precisely by various investigators. This has been a major factor in the widely varying estimates of prevalence rates, but two different studies using the same working definition and including a medical work-up have estimated the prevalence to be approximately 200/100,000. Clusters of CFS cases, which appear to be related to earlier reports of "epidemic neuromyasthenia", have attracted considerable attention and appear to be well documented, although investigated with varying methodology and often with dissimilar case definitions. Risk factors for cases occurring in clusters and sporadically appear to be similar, the most consistent ones being female gender and the co-existence of some form of stress, either physical or psychological. The prognosis of CFS is difficult to predict, although cases occurring as part of clusters appear to have a better prognosis as a group than sporadic cases, and those with an acute onset have a better prognosis than those with gradual onset. It is highly unlikely that there is a single agent, infectious or noninfectious, that is responsible for more than a small proportion of CFS cases and, at the present time, the risk factors for developing CFS appear to lie more prominently in the host rather than the environment.

Malt UF, Nerdrum P, Oppedal B, Gundersen R, Holte M, Lone J.	Department of Psychosomatic and Behavioural Medicine, National Hospital, Oslo, Norway.	Physical and mental problems attributed to dental amalgam fillings: a descriptive study of 99 self-referred patients compared with 272 controls.	Psychosom Med 1997 Jan-Feb;59(1):32-41	OBJECTIVE: The physical and mental symptomatology of 99 self-referred patients complaining of multiple somatic and mental symptoms attributed to dental amalgam fillings were compared with patients with known chronic medical disorders seen in alternative (N = 93) and ordinary (N = 99) medical family practices and patients with dental amalgam fillings (N = 80) seen in an ordinary dental practice. METHOD: The assessments included written self-reports, a 131-item somatic symptom checklist; Eysenck Personality Questionnaire, the General Health Questionnaire, and Toronto Alexithymia Scale. RESULTS: The dental amalgam sample reported significantly more physical symptoms from all body regions. Self-reports suggested that 62% suffered from a chronic anxiety disorder (generalized anxiety disorder or panic). Forty-seven percent suffered from a major depression compared with 14% in the two clinical-comparison samples and none in the dental control sample. Symptoms suggesting somatization disorder were found in 29% of the dental amalgam sample compared with only one subject in the 272 comparison subjects. One third of the dental amalgam patients reported symptoms of chronic fatigue syndrome compared with none in the dental control sample and only 2 and 6%, respectively, in the two clinical comparison samples. The dental amalgam group reported higher mean neuroticism and lower lie scores than the comparison groups. CONCLUSION: Self-referred patients with health complaints attributed to dental amalgam are a heterogeneous group of patients who suffer multiple symptoms and frequently have mental disorders. There is a striking similarity with the multiple chemical sensitivity syndrome.
Manu P		Disablility EvaluationLong-Term Disability for Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1997: 3(4): 19 - 30	To determine the quality of medical evaluations leading to long-term disability payments for chronic fatigue syndrome (CFS) we conducted a structured cross-sectional study of 76 patients receiving such benefits for an average of 2.1 years. Most of the subjects were middle-aged, white (99%), women (87%) who had been previously employed in "white-collar" jobs (96%). In all cases the claim of disability was based on subjective reports of substantial impairment in exercise tolerance and cognitive ability. The quality of disability determinations was judged by the fulfillment of four requirements: correct CFS diagnosis, psychiatric evaluation, neuropsychological testing and physical capacity measurement. The analysis indicated that none of the claims had been fully evaluated and that in 34% of cases none of the requirements had been fulfilled. The diagnosis of CFS was incorrect in 38% of cases. The majority of claimants (84%) had active

				psychiatric disorders, but only 32% had been evaluated by psychiatrists. Only 14% of claimants had their physical capacity objectively assessed and only 11% had formal testing of their cognitive abilities. The data suggest that most medical evaluations resulting in disability payments for CFS are flawed as a result of the overdiagnosis of CFS, the insufficient attention given the comorbid psychiatric disorders, and the infrequent objective testing of physical capacity and cognitive function.

Cognitive slowing and working memory difficulties in chronic fatigue syndrome.	Psychosom Med 1997 Jan-Feb;59(1):58-66 comment in: Psychosom Med. 1997 Nov-Dec;59(6):638	OBJECTIVE: Patients with chronic fatigue syndrome (CFS) commonly report problems with attention, memory, learning, and speed of cognitive processing. This study attempted to evaluate these complaints using objective test criteria. METHOD: A test battery composed of six tests assessing these cognitive functions was given on two consecutive days. Twenty CFS patients were compared with 20 healthy control subjects and 14 patients with a history of major depression or dysthymia matched by age, intelligence, education level, and sex. RESULTS: Compared with control subjects, CFS patients consistently scored lower on tests in which motor and cognitive processing speeds were a critical factor, eg, reaction-time tasks. They also had more difficulty on working-memory tests in which rapid cognitive processing speed is also an important factor. The effort made on the first day of testing did not result in a decline in cognitive function on the following day. CFS patients did not qualify as having affective disorder by several different diagnostic criteria. Nonetheless, CFS patients' test performances did not differ from patients with a history of major depression or dysthymia. CONCLUSIONS: It is concluded that, although CFS and major depression and dysthymia have distinct clinical features, these disorders have slowed motor and cognitive processing speed in common.
Martin WJ.	Center for Complex	Detection of RNA	Pathobiology	A cytopathic stealth virus was cultured from the cerebrospinal fluid of a nurse

	Infectious Diseases, Rosemead, Calif. 91770, USA. wjmartin@bcf.usc.edu	sequences in cultures of a stealth virus isolated from the cerebrospinal fluid of a health care worker with chronic fatigue syndrome. Case report.	1997;65(1):57-60	with chronic fatigue syndrome. Reverse transcriptase-polymerase chain reaction (RT-PCR) performed on the patient's culture yielded positive results with primer sets based on sequences of a previously isolated African green monkey simian-cytomegalovirus-derived stealth virus. The same primer sets did not yield PCR products when tested directly on DNA extracted from the cultures. The findings lend support to the possibility of replicative RNA forms of certain stealth viruses and have important implications concerning the choice of therapy in this type of patient.
Mawle AC, Nisenbaum R, Dobbins JG, Gary HE Jr, Stewart JA, Reyes M, Steele L, Schmid DS, Reeves WC.	Division of Viral and Rickettsial Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia 30333, USA.	Immune responses associated with chronic fatigue syndrome: a case-control study.	J Infect Dis 1997 Jan;175(1):136-41	An exploratory case-control study was conducted to assess whether the many reported differences in the immune function of chronic fatigue syndrome (CFS) patients are detectable in rigorously defined cases of CFS. Although many studies have reported differences between cases and controls in various measures of immune function, none of these differences were found in all studies. In this study, no differences were found in white blood cell numbers; immune complex, complement, or serum immunoglobulin levels; delayed type hypersensitivity and allergic responses; NK cell function; and proliferative responses to mitogens and antigens. Marginal differences were detected in cytokine responses and in cell surface markers in the total CFS population. However, when the patients were subgrouped by type of disease onset (gradual or sudden) or by how well they were feeling on the day of testing, more pronounced differences were seen.
Mawle AC.	Division of Viral and Rickettsial Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia 30333, USA.	Chronic fatigue syndrome.	Immunol Invest 1997 Jan-Feb;26(1-2):269-73	Chronic fatigue syndrome (CFS) has emerged as a public health concern over the past decade. A working case definition was created in 1988 and revised in 1994, and this has been used to establish prevalence estimates using physician-based surveillance and an a random digit dial telephone survey. Although CFS has some characteristics of an infectious disease, so far no infectious agent has been associated with the illness. Studies of immune function in CFS patients failed to detect differences between cases and healthy controls. However, when cases were subgrouped according to whether they had a sudden or gradual onset, differences in immunologic markers were detected between cases and their matched controls.
McGregor NR, R. H. Dunstan, H. L. Butt , T. K. Roberts , I. J. Klineberg , M. Zerbes		A Preliminary Assessment of the Association of SCL-90-R Psychological Inventory Responses with Changes in Urinary Metabolites in Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1997: 3(1): 17 - 37	A previous investigation of a cohort of 20 chronic fatigue syndrome (CFS) patients revealed an increased urinary excretion of an unusual metabolite, tentatively identified as amino-hydroxyN-methyl-pyrrolidine (coded CFSUMl) and ß-alanine, compared with 45 control subjects. The relative abundances of both CFSUM1 and ß-alanine were positively associated with the core diagnostic symptoms of CFS and associated changes in amino and organic acid excretion. The psychological attributes of these CFS patients and controls were assessed in this study by using the Symptom Check List-90-revised (SCL-90-R) psychological inventory. The CFS patients had increases in the SCL-90-R somatization, obsessive compulsive, depression, anxiety and phobic anxiety dimension scores. Nineteen of 20 CFS

				patients had somatization T-scores ≥ 63 (P < 0.0001), suggestive of a somatization disorder. Multiple regression analysis indicated that somatization was the most important SCL-90-R defined dimension discriminating CFS from control subjects. Depression and anxiety were not found to be important inter-group determinants. The dimension scores were each related to specific changes in the urinary excretion of organic and amino acids, suggesting that each is biochemically distinct and has an organic basis. Cluster analysis of dimension profiles revealed that the profile with increased prevalence (P < 0.0001) in CFS patients was associated with increased excretion of CFSUM1 (P < 0.005) and had increases in somatization, obsessive compulsion and depression dimension scores. The PSDI as a measure of SCL-90-R symptom severity was positively correlated with CFSUM1 (model P < 0.003). CFSUM1 was also the primary correlate for the somatization dimension (model P < 0.0008), but was not associated with any other SCL-90-R-defined dimension. Another unidentified urinary metabolite, coded UM15, was the primary correlate for depression (model P < 0.0004) and was associated with multiple dimension elevations by both cluster and logistic regression analysis; the excretion of this compound was unrelated to CFSUM1. These results indicated that, in this CFS cohort, the SCL-90-R defined psychological changes were strongly associated with changes in the biochemical homeostasis of patients, suggestive of an organic basis to CFS.
Miro O, Font C, Fernandez-Sola J, Casademont J, Pedrol E, Grau JM, Urbano-Marquez A.	Servicio de Medicina Interna, Hospital Clinic i Provincial, Universidad de Barcelona.	[Chronic fatigue syndrome: study of the clinical course of 28 cases].[article in Spanish]	Med Clin (Barc) 1997 Apr 19;108(15):561-5Comment in: Med Clin (Barc). 1997 Apr 19;108(15):577-9	BACKGROUND: Chronic fatigue syndrome (CFS) is an entity of unknown etiopathogenesis without specific markers. The diagnosis is based on clinical criteria. There are few studies evaluating the natural evolution and prognosis-related factors in CFS. OBJECTIVES: a) to evaluate the outcome of patients suffering from CFS, and b) to detect predictive factors associated with a better prognosis. MATERIAL AND METHODS: Clinical records of all patients diagnosed of CFS between January 1986 and December 1992 were retrospectively reviewed. Of these patients, we included those fulfilling the CDC criteria for CFS, with a follow-up period greater than one year. We evaluated epidemiological, clinical and evolutive data recorded by their usual physicians. Moreover, the patients were interviewed in order to know their own appreciation with respect to their current clinical status, as well as their present working situation. RESULTS: Twenty-eight patients were included in the present study. Their mean age was 38 +/- 7. Seventy-five percent of them were women. The mean time of clinical follow-up was of 3.2 +/- 1.8 years. According to evaluation, 21% of patients improved or became asymptomatic. A similar percentage (28%) of improvement was obtained from the interview. Forty-eight percent of cases had transitory or definitive laboral incapacity. Regarding to prognostic factors, we could not find any statistical differences among the analyzed variables except for marital status. In this variable, married patients had better outcome than unmarried patients.

				CONCLUSION: CFS is an entity with a poor outcome, since it evolves towards to chronicity in an important number of cases. In addition, strong functional disability may be present, leading frequently to laboral incapacity. Review, Multicase
Moorkens G, Manuel y Keenoy B, Vertommen J, Meludu S, Noe M, De Leeuw I.	Department of Internal Medicine, University Hospital, Antwerp, Belgium.	Magnesium deficit in a sample of the Belgian population presenting with chronic fatigue.	Magnes Res 1997 Dec;10(4):329-37	97 patients (25 per cent males, ages ranging from 14 to 73 years, median 38 years) with complaints of chronic fatigue (chronic fatigue syndrome, fibromyalgia or/and spasmophilia) have been enrolled in a prospective study to evaluate the Mg status and the dietary intake of Mg. An IV loading test (performed following the Ryzen protocol) showed a Mg deficit in 44 patients. After Mg supplementation in 24 patients, the loading test showed a significant decrease (p = 0.0018) in Mg retention. Mean values of serum Mg, red blood cell Mg and magnesuria showed no significant difference between patients with or without Mg deficiency. No association was found between Mg deficiency, CFS or FM. However serum Mg level was significantly lower in the patients with spasmophilia than in the other patients.
Morriss RK, Wearden AJ, Battersby L.	University of Manchester, Department of Community Psychiatry, UK.	The relation of sleep difficulties to fatigue, mood and disability in chronic fatigue syndrome.	J Psychosom Res 1997 Jun;42(6):597-605	The relationship of sleep complaints to mood, fatigue, disability, and lifestyle was examined in 69 chronic fatigue syndrome (CFS) patients without psychiatric disorder, 58 CFS patients with psychiatric disorder, 38 psychiatric out-patients with chronic depressive disorders, and 45 healthy controls. The groups were matched for age and gender. There were few differences between the prevalence or nature of sleep complaints of CFS patients with or without current DSM-IIIR depression, anxiety or somatization disorder. CFS patients reported significantly more naps and waking by pain, a similar prevalence of difficulties in maintaining sleep, and significantly less difficulty getting off to sleep compared to depressed patients. Sleep continuity complaints preceded fatigue in only 20% of CFS patients, but there was a strong association between relapse and sleep disturbance. Certain types of sleep disorder were associated with increased disability or fatigue in CFS patients. Disrupted sleep appears to complicate the course of CFS. For the most part, sleep complaints are either attributable to the lifestyle of CFS patients or seem inherent to the underlying condition of CFS. They are generally unrelated to depression or anxiety in CFS. Randomized Controlled Trial
Mounstephen A, Sharpe M.	University of Edinburgh, Royal Edinburgh Hospital, UK.	Chronic fatigue syndrome and occupational health.	Occup Med (Lond) 1997 May;47(4):217-27	Chronic fatigue syndrome (CFS) is a controversial condition that many occupational physicians find difficult to advise on. In this article we review the nature and definition of CFS, the principal aetiologic hypotheses and the evidence concerning prognosis. We also outline a practical approach to patient assessment, diagnosis and management. The conclusions of this review are then applied to the disability discrimination field. The implications of the new UK occupational health legislation are also examined. Despite continuing controversy about the status, aetiology and optimum management of CFS, we argue that

				much can be done to improve the outcome for patients with this condition. The most urgent needs are for improved education and rehabilitation, especially in regard to employment. Occupational physicians are well placed to play an important and unique role in meeting these needs.
Nakaya T, Kuratsune H, Kitani T, Ikuta K.	Section of Serology, Hokkaido University.	[Demonstration on Borna disease virus in patients with chronic fatigue syndrome].[article in Japanese]	Nippon Rinsho 1997 Nov;55(11):3064-71	Chronic fatigue syndrome (CFS), a recently named heterogeneous disorder, is an illness of unknown etiology. The association between CFS and several viral infection has been suggested. Here, we centered on the possible link between CFS and Borna disease virus (BDV) infection. BDV is a neurotropic, nonsegmented negative-strand (NNS) RNA virus. Recent epidemiological data have suggested that BDV may be closely associated with depression and schizophrenia in humans. In Japanese patients with CFS, the prevalence of BDV infection was 34% (30/89) and 12% (7/57) by immunoblotting and PCR analysis, respectively. Furthermore, anti-BDV antibodies and BDV RNA were detected in a family cluster with CFS. These results suggested that this virus contributes to or initiates CFS, although the single etiologic role of BDV is unlikely. Review Literature

Owens PE, O'Brien ET.	Blood Pressure Unit, Beaumont Hospital, Dublin, Republic of Ireland.	Hypotension: a forgotten illness?.	Blood Press Monit 1997 Dec;2(1):3-14	Low blood pressure is a frequently encountered phenomenon in clinical practice. Few practitioners in the Western world however regard chronic low blood pressure as a genuinely pathological disease state. Evidence is emerging that chronic hypotension is associated with considerable morbidity in the community. It has recently been implicated as the causative mechanism in patients with the chronic fatigue syndrome. Identification of low blood pressure can prove probjlematic, so ambulatory blood pressure monitoring may prove a more reliable method both for determining mean blood pressure levels and for identifying episodes of marked hypotension. Low blood pressure is broadly divided into two categories, chronic constitutional hypotension and hypotension associated with abnormal postural control. The causes are examined and the clinical presentations are discussed. An approach to investigation and diagnosis is outlined, and current options regarding treatment and management are described. The clinical spectrum of low blood pressure is wide. From young patients with vagally mediated syncope or patients with iatrogenic hypotension to elderly patients with autonomic degenerative conditions, there exists a substantial body of patients with potentially avoidable or treatable morbidity. Such a group requires more rigorous scientific investigation and a more sympathetic clinical approach.

Peakman M, Deale A, Field R, Mahalingam M, Wessely S.	Department of Immunology, King's College School of Medicine & Dentistry, London, United Kingdom.	Clinical improvement in chronic fatigue syndrome is not associated with lymphocyte subsets of function or activation.	Clin Immunol Immunopathol 1997 Jan;82(1):83-91	The relationship between markers of immune function and chronic fatigue syndrome (CFS) is controversial. To examine the relationship directly, 43 subjects with CFS entering a randomized controlled trial of a nonpharmacological treatment for CFS gave samples for immunological analysis before and after treatment. Percentage levels of total CD3+ T cells, CD4 T cells, CD8 T cells, and activated subsets did not differ between CFS subjects and controls. Naive (CD45RA+ RO-) and memory (CD45RA- RO+) T cells did not differ between subjects and controls. Natural killer cells (CD16+/CD56+/CD3-) were significantly increased in CFS patients compared to controls, as was the percentage of CD11b+ CD8 cells. There were no correlations between any immune variable and measures of clinical status, with the exception of a weak correlation between total CD4 T cells and fatigue. There was a positive correlation between memory CD4 and CD8 T cells and depression scores and a negative correlation between naive CD4 T cells and depression. No immune measures changed during the course of the study, and there was no link between clinical improvement as a result of the treatment program and immune status. Immune measures did not predict response or lack of response to treatment. In conclusion, we have been unable to replicate previous findings of immune activation in CFS and unable to find any important associations between clinical status, treatment response, and immunological status. Randomized Controlled Trial

Hosp Pract (Off Ed) 1997 Jun 15;32(6):147-50, 153-6, 160-1, passim	Patients face long-term disability, a variable prognosis, and too often, skeptical or misinformed doctors. Physicians lack laboratory markers or definitive treatment. Nevertheless, the diagnosis can be made with confidence by applying established diagnostic criteria- and selected laboratory studies to exclude other disorders- while symptomatic medication can provide support until recovery begins.
Plioplys AV, Plioplys S.	Chronic Fatigue Syndrome Center, Department of	Amantadine and L-carnitine treatment of Chronic Fatigue	Neuropsychobiology 1997;35(1):16-23	Carnitine is essential for mitochondrial energy production. Disturbance in mitochondrial function may contribute to or cause the fatigue seen in Chronic Fatigue Syndrome (CFS) patients. Previous investigations have reported

	Research, Mercy Hospital Chicago, Ill 60616, USA.	Syndrome.		decreased carnitine levels in CFS. Orally administered L-carnitine is an effective medicine in treating the fatigue seen in a number of chronic neurologic diseases. Amantadine is one of the most effective medicines for treating the fatigue seen in multiple sclerosis patients. Isolated reports suggest that it may also be effective in treating CFS patients. Formal investigations of the use of L-carnitine and amantadine for treating CFS have not been previously reported. We treated 30 CFS patients in a crossover design comparing L-carnitine and amantadine. Each medicine was given for 2 months, with a 2-week washout period between medicines. L-Carnitine or amantadine was alternately assigned as fist medicine. Amantadine was poorly tolerated by the CFS patients. Only 15 were able to complete 8 weeks of treatment, the others had to stop taking the medicine due to side effects. In those individuals who completed 8 weeks of treatment, there was no statistically significant difference in any of the clinical parameters that were followed. However, with L-carnitine we found statistically significant clinical improvement in 12 of the 18 studied parameters after 8 weeks of treatment. None of the clinical parameters showed any deterioration. The greatest improvement took place between 4 and 8 weeks of L-carnitine treatment. Only 1 patient was unable to complete 8 weeks of treatment due to diarrhea. L-Carnitine is a safe and very well tolerated medicine which improves the clinical status of CFS patients. In this study we also analyzed clinical and laboratory correlates of CFS symptomatology and improvement parameters. Randomized Controlled Trial
Plioplys AV.	Chronic Fatigue Syndrome Center, Mercy Hospital, Chicago, IL, USA.	Antimuscle and anti-CNS circulating antibodies in chronic fatigue syndrome.	Neurology 1997 Jun;48(6):1717-9	Chronic fatigue syndrome (CFS) patients suffer from disabling physical and mental fatigue. Circulating autoimmune antibodies may produce symptoms of muscular fatigue by reacting with acetylcholine receptors or calcium binding channels. They can also produce mental status changes by reacting with central nervous system (CNS) antigens. We thoroughly investigated the presence of circulating antimuscle and anti-CNS antibodies in 10 CFS patients and 10 controls. We were unable to detect any pathogenic antibodies.

Pourmand R.	Department of Neurology, Indiana University School of Medicine, Indianapolis, USA.	Myasthenia gravis.	Dis Mon 1997 Feb;43(2):65-109	Adult-onset myasthenia gravis is an acquired autoimmune disorder of neuromuscular transmission in which acetylcholine receptor antibodies attack the postsynaptic membrane of the neuromuscular junction. Although the cause of this disease is unknown, the role of immune responses in its pathogenesis is well established. Circulating acetylcholine receptor antibodies are present in 80% to 90% of patients with the generalized form of myasthenia gravis. Most patients

				have ptosis, diplopia, dysarthria and dysphagia. The weakness and fatigue worsen on exertion and improve with rest. Respiratory muscle and limb weakness are rare at the onset of the disease. For the past two decades, there has been considerable progress in understanding the diagnosis and management of myasthenia gravis. The diagnosis is based on clinical presentation, neurologic examination, and confirmation by means of electrophysiologic testing and immunologic studies. Myasthenia gravis mimics many neuromuscular diseases and even illnesses such as depression and chronic fatigue syndrome. One should always exclude drug-induced myasthenia gravis for all patients. With the introduction of new modalities of treatment, particularly immunosuppressive or immunomodulating drugs, plasma exchange and thymectomy, the morbidity and mortality of myasthenia gravis have decreased dramatically to the point that myasthenia gravis should not be considered as serious a disease as it once was. Although the several therapeutic options are usually effective and have meant independence in daily life to many patients with myasthenia gravis, well-designed, controlled, prospective studies are still lacking.
Ray C, Jefferies S, Weir WR.	Department of Human Sciences, Brunel University, Uxbridge, Middlesex, UK.	Coping and other predictors of outcome in chronic fatigue syndrome: a 1-year follow-up.	J Psychosom Res 1997 Oct;43(4):405-15	In this prospective study, 137 patients with chronic fatigue syndrome were followed-up at a 1-year interval to determine factors relating to outcomes. Nearly two thirds reported an improvement on direct ratings of change. In analyses with fatigue and functional impairment at follow-up as the criteria, and controlling for earlier status, poorer outcomes were predicted by illness duration, subjective cognitive difficulty, and somatic symptoms; there was no influence of anxiety, depression, or general emotional distress. Fatigue was also predicted by information-seeking, and impairment by behavioral disengagement and a low internal locus of control. The belief that one's actions can influence outcomes modified the relationship between illness accommodation and both fatigue and impairment; adverse outcomes were associated with accommodating to illness only in the context of lower levels of perceived control. Thus, it is suggested that interventions that either discourage avoidance of activity or enhance perceived control could benefit the course of the illness.
Redmond G.	Women's Hormone Center Beachwood, Ohio, USA.	Mood disorders in the female patient.	Int J Fertil Womens Med 1997 Mar-Apr;42(2):67-72	Disruptive changes in mood and low energy level are among the most common reasons women consult a physician. Usually no clear physiological explantation for these changes can be found. Many physicians feel uncomfortable dealing with patients with these complaints. The purpose of this paper is to discuss a practical approach to helping women with such conditions. A variety of terms have been utilized to refer to the situation in which a female patient has decreased energy or labile mood. Premenstrual Syndrome (PMS) and chronic fatigue syndrome (CFS) are currently popular terms. An association of low mood with menstrual cycle phase is undoubted, with the late luteal-early premenstrual phase most commonly associated with depression and irritability. It seems likely that women

				with PMS and those without it do not differ in circulating hormone levels during their cycles but rather in the brain response to these. Estrogen and progesterone receptors exist in the brain and change during the cycle. Elaborate diagnostic efforts are rarely rewarding in managing mood and energy disorders. Of more value is a careful history particularly concerned with the pattern of mood changes and with life stresses, accompanied by a thorough physical examination and laboratory tests. In most cases, changes in mood and energy are a variant of clinical depression. Changes in energy and sleep may be more evident than low affect. Treatment with an appropriate antidepressant, usually a selective serotonin re-uptake inhibitor (SSRI), benefits most of these patients. Allowing the patient to express concerns about stressful life situations is often of great value.
Regland B, Andersson M, Abrahamsson L, Bagby J, Dyrehag LE, Gottfries CG.	Institute of Clinical Neuroscience, Goteborg University, Sweden.	Increased concentrations of homocysteine in the cerebrospinal fluid in patients with fibromyalgia and chronic fatigue syndrome.	Scand J Rheumatol 1997;26(4):301-7	Twelve outpatients, all women, who fulfilled the criteria for both fibromyalgia and chronic fatigue syndrome were rated on 15 items of the Comprehensive Psychopathological Rating Scale (CPRS-15). These items were chosen to constitute a proper neurasthenic subscale. Blood laboratory levels were generally normal. The most obvious finding was that, in all the patients, the homocysteine (HCY) levels were increased in the cerebrospinal fluid (CSF). There was a significant positive correlation between CSF-HCY levels and fatiguability, and the levels of CSF-B12 correlated significantly with the item of fatiguability and with CPRS-15. The correlations between vitamin B12 and clinical variables of the CPRS-scale in this study indicate that low CSF-B12 values are of clinical importance. Vitamin B12 deficiency causes a deficient remethylation of HCY and is therefore probably contributing to the increased homocysteine levels found in our patient group. We conclude that increased homocysteine levels in the central nervous system characterize patients fulfilling the criteria for both fibromyalgia and chronic fatigue syndrome.
Richmond C.		Mad cows and Englishmen: the aftermath of a BSE scare.	CMAJ 1997 Apr 1;156(7):1043-4	The consumption of prime beef cuts is down, animals have been slaughtered by the thousand and 3 farmers have committed suicide as the mad-cow issue continues to cause concern in the United Kingdom. In this report from London, Caroline Richmond also notes that the royal colleges have published a report stating that chronic fatigue syndrome is a real illness and patients need help.
Robbins JM, Kirmayer LJ, Hemami S.	Department of Pediatrics, University of Arkansas for Medical Sciences, Arkansas Children's Hospital, Little Rock 72202, USA.	Latent variable models of functional somatic distress.	J Nerv Ment Dis 1997 Oct;185(10):606-15	Latent variable models of functional somatic symptoms were estimated for a sample of 686 family medicine patients. Symptom items from the NIMH Diagnostic Interview Schedule were selected to approximate diagnoses of fibromyalgia syndrome (FMS), chronic fatigue syndrome (CFS), and irritable bowel syndrome (IBS). Confirmatory factor analysis demonstrated that hypothesized latent variables of somatic depression, somatic anxiety, FM-like, CF-like, and IB-like syndromes fit the observed covariations better than models hypothesizing fewer latent variables. Results offer tentative confirmation of functional somatic syndromes as discrete entities and suggest that relaxing the

				diagnostic criteria for somatization may identify individuals with distress limited to a single functional system.
Rosenfeld WD, Walco GA.	Adolescent/Young Adult Center for Health, Morristown Memorial Hospital, 100 Madison Avenue, Morristown, NJ 07962, USA.	One Test Too Many: Toward an Integrated Approach to Psychosomatic Disorders.	Adolesc Med 1997 Oct;8(3):483-487	Conditions such as chronic fatigue syndrome (CFS), fibromyalgia, and several others belong to the group of disorders in which both physiologic and psychologic factors are substantially involved, and in some cases there may be no real distinction between the two. However, primary patient assessment usually employs an array of clinical tools, and only after known physiologic factors are excluded is the patient referred for psychologic or psychiatric evaluation. This chapter suggests that clinical evaluation should initially include both physiologic and psychosocial assessment, which would minimize the division and greatly improve the efficacy of the treatment.
Rowe KS.	Department of Paediatrics, University of Melbourne Royal Children's Hospital, Victoria, Australia.	Double-blind randomized controlled trial to assess the efficacy of intravenous gammaglobulin for the management of chronic fatigue syndrome in adolescents.	J Psychiatr Res 1997 Jan-Feb;31(1):133-47	A double blind randomized controlled trial was conducted in 71 adolescents aged 11-18 years. Inclusion in the trial required fulfilment of the diagnostic criteria, (Fukuda et al., 1994). Three infusions of 1 gm/kg (max 1 litre of 6 gm/100 ml in 10% w/v maltose solution) were given one month apart. The dummy solution was a 10% w/v maltose solution with 1% albumin of equivalent volume for weight. Efficacy was assessed by difference in a mean functional score including school attendance, school work, social activity and physical activity, between baseline, three months and six months after the final infusion. There was a significant mean functional improvement at the six month follow-up of 70 adolescents with Chronic Fatigue Syndrome of average duration 18 months. There was also a significant improvement for both groups from the beginning of the trial to the six month post infusion follow-up. Adverse effects were common with both solutions but not predictive of response. Neither solution could be identified by recipients. Randomized Controlled Trial

Salit IE.	Division of Infectious Diseases, Toronto Hospital, Ontario, Canada. irving.salit@utoronto.ca	Precipitating factors for the chronic fatigue syndrome.	728: J Psychiatr Res 1997 Jan-Feb;31(1):59-65	The etiology of the Chronic Fatigue Syndrome (CFS) is unknown but it is usually considered to be postinfectious or postviral. Many infecting agents have been suspected as causative but none has been proven. We investigated precipitating factors in 134 CFS patients through the use of a questionnaire, interview, clinical examination and serology for infecting agents; 35 healthy controls completed a similar questionnaire. CFS started with an apparently infectious illness in 96 (72%) but a definite infection was only found in seven of these 96 (7%). Thirty-eight (28%) had no apparent infectious onset: 15/38 (40%) had noninfectious precipitants (trauma, allergy, surgery). There was no apparent precipitating event in 23/38 (61%). Immunization was not a significant precipitant. Stressful events

				were very common in the year preceding the onset of CFS (114/134, 85%) but these occurred in only 2/35 (6%) of the controls (p < .0001). The onset of CFS may be associated with preceding stressful events and multiple other precipitants. An infectious illness is not uniformly present at the onset and no single infectious agent has been found; CFS is most likely multifactorial in origin.

See DM, Broumand N, Sahl L, Tilles JG.	Department of Medicine, U.C. Irvine Medical Center, Orange 92668, USA.	In vitro effects of echinacea and ginseng on natural killer and antibody-dependent cell cytotoxicity in healthy subjects and chronic fatigue syndrome or acquired immunodeficiency syndrome patients.	Immunopharmacology 1997 Jan;35(3):229-35	Extracts of Echinacea purpurea and Panax ginseng were evaluated for their capacity to stimulate cellular immune function by peripheral blood mononuclear cells (PBMC) from normal individuals and patients with either the chronic fatigue syndrome or the acquired immunodeficiency syndrome. PBMC isolated on a Ficoll-hypaque density gradient were tested in the presence or absence of varying concentrations of each extract for natural killer (NK) cell activity versus K562 cells and antibody-dependent cellular cytotoxicity (ADCC) against human herpesvirus 6 infected H9 cells. Both echinacea and ginseng, at concentrations > or = 0.1 or 10 micrograms/kg, respectively, significantly enhanced NK-function of all groups. Similarly, the addition of either herb significantly increased ADCC of PBMC from all subject groups. Thus, extracts of Echinacea purpurea and Panax ginseng enhance cellular immune function of PBMC both from normal individuals and patients with depressed cellular immunity.
Sendrowski DP, Buker EA, Gee SS.	Southern California College of Optometry, Fullerton, USA.	An investigation of sympathetic hypersensitivity in chronic fatigue syndrome.	Optom Vis Sci 1997 Aug;74(8):660-3	BACKGROUND: There are many theories, but the etiology of chronic fatigue syndrome (CFS) remains unknown. Diagnosticians have set guidelines to try to classify the condition, but its clinical definition is one of exclusion rather than defined by specific clinical testing. The primary goal of this investigation was to find a diagnostic key to define CFS. CFS patients and those diagnosed with the sympathetic hypersensitivity condition called fibromyalgia syndrome (FMS) exhibit identical brain single photon emission computerized tomography (SPECT) images. Therefore, this investigation was initiated to see if CFS patients also had denervation hypersensitivity of the sympathetic system. METHODS: A standardized supersensitivity test was performed using an ocular instillation of two drops of 1.0% phenylephrine. Sixty-two subjects (29 CFS patients and 33 normals) participated in the study. Measurements of pupil size were recorded by pupil gauge and flash photography. A pupillary dilation of greater than 2.5 mm would suggest a sympathetic denervation hypersensitivity. RESULTS: For all

				participants, a small, but statistically significant increase in pupil size was found (mean of 0.788 mm in normals and 0.931 mm in CFS patients). The change in pupil size in the CFS patients and controls showed substantial overlap and was not statistically significant (t = 0.83, p = 0.42, dF = 60). CONCLUSION: In conclusion, the results suggest that a denervation hypersensitivity of the pupil does not occur in CFS patients. The use of 1.0% topical phenylephrine had no diagnostic value in detecting CSF patients vs. normals.
Sharpe M, Chalder T, Palmer I, Wessely S.	University of Edinburgh, UK.	Chronic fatigue syndrome. A practical guide to assessment and management.	Gen Hosp Psychiatry 1997 May;19(3):185-99	Chronic fatigue and chronic fatigue syndrome (CFS) have become increasingly recognized as a common clinical problem, yet one that physicians often find difficult to manage. In this review we suggest a practical, pragmatic, evidence-based approach to the assessment and initial management of the patient whose presentation suggests this diagnosis. The basic principles are simple and for each aspect of management we point out both potential pitfalls and strategies to overcome them. The first, and most important task is to develop mutual trust and collaboration. The second is to complete an adequate assessment, the aim of which is either to make a diagnosis of CFS or to identify an alternative cause for the patient's symptoms. The history is most important and should include a detailed account of the symptoms, the associated disability, the choice of coping strategies, and importantly, the patient's own understanding of his/her illness. The assessment of possible comorbid psychiatric disorders such as depression or anxiety is mandatory. When the physician is satisfied that no alternative physical or psychiatric disorder can be found to explain symptoms, we suggest that a firm and positive diagnosis of CFS be made. The treatment of CFS requires that the patient is given a positive explanation of the cause of his symptoms, emphasizing the distinction among factors that may have predisposed them to develop the illness (lifestyle, work stress, personality), triggered the illness (viral infection, life events) and perpetuated the illness (cerebral dysfunction, sleep disorder, depression, inconsistent activity, and misunderstanding of the illness and fear of making it worse). Interventions are then aimed to overcoming these illness-perpetuating factors. The role of antidepressants remains uncertain but may be tried on a pragmatic basis. Other medications should be avoided. The only treatment strategies of proven efficacy are cognitive behavioral ones. The most important starting point is to promote a consistent pattern of activity, rest, and sleep, followed by a gradual return to normal activity; ongoing review of any 'catastrophic' misinterpretation of symptoms and the problem solving of current life difficulties. We regard chronic fatigue syndrome as important not only because it represents potentially treatable disability and suffering but also because it provides an example for the positive management of medically unexplained illness in general.

Clements A, Cowen PJ.	of Psychiatry, Warneford and Littlemore Hospitals, Oxford.	serotonin function in men with chronic fatigue syndrome.	19;315(7101):164-5	
Sharpe M.	University of Edinburgh, Royal Edinburgh Hospital, United Kingdom.	Cognitive behavior therapy for functional somatic complaints. The example of chronic fatigue syndrome.	Psychosomatics 1997 Jul-Aug;38(4):356-62	Somatic complaints such as pain and fatigue that are unexplained by conventional disease are common in medical practice and are referred to as functional, somatoform, or somatization symptoms. Despite frequent chronicity, disability, and high associated medical costs, patients with these complaints are rarely offered either constructive explanations or effective treatment. In this perspective, a cognitive-behavioral approach to the problem is described, using chronic fatigue syndrome as an example. It is concluded that the utility of the cognitive-behavioral theory and the proven effectiveness cognitive behavior therapy provide the basis for a new evidence-based approach to psychosomatics.
Sharpley A, Clements A, Hawton K, Sharpe M.	Department of Psychiatry, University of Oxford, United Kingdom.	Do patients with "pure" chronic fatigue syndrome (neurasthenia) have abnormal sleep?	Psychosom Med 1997 Nov-Dec;59(6):592-6	OBJECTIVE: To determine whether patients with "pure" chronic fatigue syndrome (neurasthenia) have sleep abnormalities which may contribute to subjective measures of daytime fatigue. METHOD: Sleep characteristics of 20 patients meeting research criteria for chronic fatigue syndrome (CFS) but not depression, anxiety, or sleep disorder were compared with sleep characteristics of 20 healthy subjects matched for age and sex. Measures of sleep included a) subjective interview reports and sleep diaries and b) home-based polysomnography. RESULTS: Patients with CFS complained of poor quality unrefreshing sleep. They also napped during the day. Polysomnograph data showed no difference in actual nocturnal sleep time between the two groups although patients with CFS spent significantly longer in bed ($p < .01$), slept less efficiently ($p < .03$), and spent longer awake after sleep onset ($p < .05$). The polysomnographs of seven patients with CFS and one healthy subject were regarded as significantly abnormal. Five patients and one healthy subject had difficulty maintaining sleep. One patient had a disorder of both initiating and maintaining sleep and one patient woke early. CONCLUSIONS: Patients with "pure" CFS complain of unrefreshing sleep but only a minority have a clearly abnormal polysomnograph. The most common abnormality is of long periods spent awake after initial sleep onset. Although sleep abnormalities may play a role in the etiology of CFS, they seem to be unlikely to be an important cause of daytime fatigue in the majority of patients. However, pharmacological and behavioral methods that improve sleep quality may be an important component of a pragmatically based treatment package for patients who do have abnormal sleep.
Shefer A, Dobbins JG, Fukuda K, Steele L, Koo D, Nisenbaum R, Rutherford GW.	Epidemic Intelligence Service Program, Centers for Disease Control and Prevention,	Fatiguing illness among employees in three large state office buildings, California,	J Psychiatr Res 1997 Jan-Feb;31(1):31-43	The objective was to determine if a cluster of chronic fatigue syndrome (CFS)-like illness had occurred among employees in two large state office buildings in northern California, and to identify risk factors for and features of fatiguing illness in this population. DESIGN: case-control study. POPULATION AND SETTING: Over

	Atlanta, GA 30333, USA.	1993: was there an outbreak?		3300 current employees in two state office buildings and employees in a comparable "control" building. Information was collected on demographic and occupational variables, the occurrence of fatiguing illness for at least one month in the previous year, and the presence of 36 symptoms. A total of 3312 (82%) of 4035 employees returned questionnaires. Overall, 618 (18.7%) persons reported fatigue lasting at least one month; including 382 (11.5%) with fatigue of at least six months' duration and 75 (2.3%) with symptoms compatible with a CFS-like illness. Independent risk factors for fatigue lasting one month or longer were found to be Native American ethnicity (OR 2.4, CI 1.1,5.3), Hispanic ethnicity (OR 1.7, CI 1.3,2.3), female sex (OR 1.5, CI 1.2,1.9), gross household incomes of less than $50,000 (OR 1.3, CI 1.1,1.6), and less than a college education (OR 1.3, CI 1.1,1.6). Similar risks were observed for persons who reported fatigue lasting six months or longer. Female sex (OR 3.2, CI 1.7, 6.4) was the only independent risk factor found for those persons classified as having a CFS-like illness. Case prevalence rates for all three categories of fatigue, as determined by multivariate analysis, were not significantly different among buildings. Despite finding a substantial number of employees with fatiguing illness in the two state office buildings, the prevalence was not significantly different than that for a comparable control building. Previously unidentified risk factors for fatigue of at least one month and at least six months identified in this population included Hispanic ethnicity, not having completed college, and income below $50,000.

Sheridan TF		Disability Policy and CFIDS A Washington Perspective	Journal of Chronic Fatigue Syndrome 1997: 3(4): 63 - 67	"Disability Policy and CFIDS: A Washington Perspective" provides a follow-up to Mr. Sheridan's remarks at the American Association for Chronic Fatigue Syndrome's clinical conference in San Francisco on October 16, 1996. In this article, Mr. Sheridan explains that the difficulty for people with CFIDS (PWCs) in obtaining disability benefits stems from the fact that disability determination is based on a person's functional impairments resulting from a particular diagnosis. In other words, the Social Security Administration does not consider a CFIDS diagnosis alone sufficient criteria to win a disability claim. The article also describes the advocacy efforts carried out over the past five years by The CFIDS Association of America and The Sheridan Group and the achievements of that collaboration. Mr. Sheridan concludes his article with advice for PWCs who are considering an application for SSA disability benefits.
Shorter E.	History of Medicine Program, Faculty of Medicine, University of Toronto, Ontario, Canada.	Somatization and chronic pain in historic perspective.	Clin Orthop 1997 Mar;(336):52-60	Practitioners today are confronted with an avalanche of difficult to treat patients with chronic pain for 2 reasons: (1) The culture increasingly encourages patients to conceive vague and nonspecific symptoms as evidence of real disease and to seek specialist help for them; and (2) the rising ascendancy of the media and the breakdown of the family encourage patients to acquire the fixed belief that they have a given illness, often a trendy nondisease such as repetition strain injury or chronic fatigue syndrome. In historic terms, many of these complaints, especially sensory ones featuring chronic pain and chronic fatigue, are relatively new. Patients tend to adopt them on the basis of what the culture considers to be legitimate illness, whereby different patterns exist for men and women.
Simpson M, Bennett A, Holland P.		Chronic fatigue syndrome/myalgic encephalomyelitis as a twentieth-century disease: analytic challenges.	J Anal Psychol 1997 Apr;42(2):191-9	The challenges of chronic fatigue syndrome (often called myalgic encephalomyelitis, especially in the UK) (CFS/ME) to analytical and medical approaches are connected with our inability to understand its distressing somatic symptoms in terms of a single identifiable and understandable disease entity. The evidence for the roles of viral aetiologies remains inconclusive, as does our understanding of the involvement of the immune system. The history and social context of CFS/ME, and its relation to neurasthenia and psychasthenia are sketched. A symbolic attitude to the condition may need to be rooted in an awareness of psychoid levels of operation, and the expression and spread of CFS/ME may sometimes be aided by the ravages of projective identification. Psychic denial, sometimes violent, in sufferers (especially children and adolescents) and their families may be important in the aetiology of CFS/ME. We draw out common threads from psychodynamic work with five cases, four showing some symptomatic improvement, analytic discussions of three cases being presented elsewhere in this issue of JAP.
Simpson M.		A body with chronic	J Anal Psychol 1997	I describe the therapy of a 20-year-old women who believed that her difficulties

		fatigue syndrome as a battleground for the fight to separate from the mother.	Apr;42(2):201-16	in concentrating and remembering were caused by her "ME' (Myalgic encephalomyelitis, Chronic fatigue syndrome, or CFS). She had been fathered by a man who never left his own wife. Work with her dreams revealed a within-body drama in which she was locked in an unspeakable fight to the death with her mother. Her symptoms improved after parallels between a dream and an accident showed her own self-destructive hand in her story. Another dream, reflecting her first 'incestuous' affair, showed her search for her original father-self as someone separate from mother, and a later affair provided a between-body drama, helping her to own the arrogant and abject traits she had before seen only as her mother's. I show how we worked in the area of Winnicott's first 'primitive agony' as experienced by a somatizing patient, stuck in a too-close destructive relationship with her mother-body. I discuss how analytical work can be done with the primitive affects and conflicts against which the ME symptoms may be defending.

Spring SB, Eveline Lee Tierney, Heidi M. Jolson		Meeting Reports: Development of Outcome Measures for Therapeutic Trials of Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1997: 3(3): 69 - 95	"The chronic fatigue syndrome (CFS) is a clinically defined condition characterized by severe disabling fatigue and a combination of symptoms that prominently features self-reported impairments in concentration and short-term memory, sleep disturbances and musculoskeletal pain" (1). The variability of the course and severity of CFS combined with slow and infrequent full recovery and the lack of a defined etiology have complicated the implementation of therapeutic clinical trials. The goal of the workshop was to begin a systematic consideration of clinical trials issues and outcome measures that could be used to evaluate CFS therapies in a definitive manner for safety and efficacy. The focus of the workshop was on common issues applicable across therapies rather than on the merits of individual therapies. Careful study design is critical to all trials. New methods and measures of health status will aid in determining the extent of change related to therapeutic interventions. Approaches and methods used in the study and therapy of other chronic illnesses may provide important insights for designing clinical trials and choosing outcome measures for CFS interventions. Short-term outcomes in small groups of patients need to be validated by other research groups, by additional and even larger studies, and by long-term studies. To insure enrollment and compliance, patient concerns need to be considered in

				study design.
Strom SS, Baldwin BJ, Sigurdson AJ, Schusterman MA.	Department of Epidemiology, The University of Texas M. D. Anderson Cancer Center, Houston 77030, USA.	Cosmetic saline breast implants: a survey of satisfaction, breast-feeding experience, cancer screening, and health.	Plast Reconstr Surg 1997 Nov;100(6):1553-7	Saline breast implants have been used for the past 30 years for cosmetic and reconstructive purposes. Data based on a large number of patients are needed to evaluate patient satisfaction, cancer screening practices, problems associated with breast-feeding, and health effects. We conducted a follow-up study of 292 cosmetic saline breast implant patients from Texas and Louisiana who consented to a telephone interview. Using a Likert scale, we measured the patients' degree of satisfaction with the implants. The results indicated that 80.5 percent were satisfied, 73.3 percent would recommend saline breast implants to others, and 65.1 percent felt that implants improved their quality of life. The extent of satisfaction was independent of the number of additional surgeries, age at implant, and follow-up time. Mammography use and breast self-examination were reported with high frequency in this survey. Ninety-one percent of study participants who were between 40 and 49 years of age at time of interview and 94 percent of those 50 or older reported having had at least one mammogram. Breast self-examination was practiced by 75 percent of the women, and 61 percent reported checking their breasts at least once a month. Of the 46 women who had children after augmentation, 28 reported breast-feeding and 8 (28.6 percent) reported having implant-related problems. The patients were asked to provide information regarding a series of conditions for which they sought medical attention. They reported: atypical rheumatoid syndrome (n = 1), Sjogren syndrome (n = 1), atypical autoimmune disorder (n = 1), and chronic fatigue syndrome (n = 2). Overall, women who elected to have saline breast implants were satisfied with their augmentations, had mammograms and performed breast self-examinations more often than nonaugmented women. A few had problems when breast-feeding that could be related to their implants. There were no reports of breast cancer, but five women reported autoimmune conditions.
Suhadolnik RJ, Peterson DL, O'Brien K, Cheney PR, Herst CV, Reichenbach NL, Kon N, Horvath SE, Iacono KT, Adelson ME, De Meirleir K, De Becker P, Charubala R, Pfleiderer W.	Department of Biochemistry, Temple University School of Medicine, Philadelphia, PA, USA.	Biochemical evidence for a novel low molecular weight 2-5A-dependent RNase L in chronic fatigue syndrome.	J Interferon Cytokine Res 1997 Jul;17(7):377-85	Previous studies from this laboratory have demonstrated a statistically significant dysregulation in several key components of the 2',5'-oligoadenylate (2-5A) synthetase/RNase L and PKR antiviral pathways in chronic fatigue syndrome (CFS) (Suhadolnik et al. Clin Infect Dis 18, S96-104, 1994; Suhadolnik et al. In Vivo 8, 599-604, 1994). Two methodologies have been developed to further examine the upregulated RNase L activity in CFS. First, photoaffinity labeling of extracts of peripheral blood mononuclear cells (PBMC) with the azido 2-5A photoaffinity probe, [32P]pApAp(8-azidoA), followed by immunoprecipitation with a polyclonal antibody against recombinant, human 80-kDa RNase L and analysis under denaturing conditions. A subset of individuals with CFS was identified with only one 2-5A binding protein at 37 kDa, whereas in extracts of PBMC from a second subset of CFS PBMC and from healthy controls, photolabeled/immunoreactive 2-

				5A binding proteins were detected at 80, 42, and 37 kDa. Second, analytic gel permeation HPLC was completed under native conditions. Extracts of healthy control PBMC revealed 2-5A binding and 2-5A-dependent RNase L enzyme activity at 80 and 42 kDa as determined by hydrolysis of poly(U)-3'-[32P]pCp. A subset of CFS PBMC contained 2-5A binding proteins with 2-5A-dependent RNase L enzyme activity at 80, 42, and 30 kDa. However, a second subset of CFS PBMC contained 2-5A binding and 2-5A-dependent RNase L enzyme activity only at 30 kDa. Evidence is provided indicating that the RNase L enzyme dysfunction in CFS is more complex than previously reported.

The chronic fatigue syndrome and hyperventilation. Bazelmans E, Bleijenberg G, Vercoulen JH, van der Meer JW, Folgering H.	Department of Medical Psychology, University Hospital Nijmegen, The Netherlands.	Erratum in: J Psychosom Res 1998 Mar-Apr;44(3-4):517	J Psychosom Res 1997 Oct;43(4):371-7	Chronic fatigue syndrome (CFS) is characterized by severe fatigue, lasting for at least 6 months, for which no somatic explanation can be found. Because hyperventilation can produce substantial fatigue, it seems worthwhile to investigate the relationship between it and CFS. It might be hypothesized that hyperventilation plays a causal or perpetuating role in CFS. CFS patients, non-CFS patients known to experience hyperventilation, and healthy controls were compared on complaints of fatigue and hyperventilation. CFS patients and non-CFS patients known to experience hyperventilation offered substantial complaints of fatigue and hyperventilation, both to a similar degree. Physiological evidence of hyperventilation was found significantly more often in CFS patients than in healthy controls. However, no significant differences between CFS patients with and CFS patients without hyperventilation were found on severity of fatigue, impairment, number of complaints, activity level, psychopathology, and depression. It is concluded that hyperventilation in CFS should probably be regarded as an epiphenomenon.
Tiersky LA, Johnson SK, Lange G, Natelson BH, DeLuca J.	Department of Physical Medicine and Rehabilitation, UMDNJ-New Jersey Medical School, Kessler Institute for Rehabilitation, West Orange 07052, USA.	Neuropsychology of chronic fatigue syndrome: a critical review.	J Clin Exp Neuropsychol 1997 Aug;19(4):560-86	This article provides a comprehensive and critical review of the neuropsychological and related literature on chronic fatigue syndrome (CFS). Despite the methodological limitations observed in several studies, some consistent findings are noted. The most consistently documented neuropsychological impairments are in the areas of complex information processing speed and efficiency. General intellectual abilities and higher order cognitive skills are intact. Emotional factors influence subjective report of cognitive difficulty, whereas their effect on objective performance remains uncertain. Although the neuropathological processes underlying cognitive dysfunction in CFS are not yet known, preliminary evidence suggests the involvement of cerebral white matter. Directions for future research are outlined. Review, Academic
Twemlow SW, Bradshaw SL Jr, Coyne	University of Kansas School of Medicine,	Patterns of utilization of medical care and	Psychol Rep 1997 Apr;80(2):643-58	To what extent do personal constructs affect the relationship between doctor and patient when the ill patient does not readily recover with treatment?

L, Lerma BH.	Wichita, USA.	perceptions of the relationship between doctor and patient with chronic illness including chronic fatigue syndrome.		Questionnaires were returned anonymously by 609 patients with a self-reported diagnosis of chronic fatigue syndrome, who were considered chronically ill. Findings were compared with those of an earlier study of a population of 397 general medical patients. The chronically ill patients lost an average of 65 days of work per year due to illness compared to general medical patients who missed six or fewer days per year because they were ill. The chronically ill patients also reported a 66% higher frequency of iatrogenic illness, spent more money on health care, took more medication, saw more specialists, and were more litigious than the general medical population. Research suggested several patterns of relationships between doctors and patients, and attitudes to health and illness, which may alert doctors to patients' perceptions, beliefs, encoded constructs, and patterns of relating that affect responses to treatment. More attention by doctors to patients who are experiencing the stress of chronic illness is indicated.
Uslan D		Perspectives on CFS and Impairment Proposed Guidelines for Disability Determination	Journal of Chronic Fatigue Syndrome 1997: 3(4): 75 - 85	Chronic Fatigue syndrome (CFS) is a difficult condition for which to determine work limitations and disability. This paper discusses the current problems in the state-of-the-art, and proposes framework standards for multi-disciplinary rehabilitation efforts to assess, prevent or limit disability, and multi-disciplinary standards for disability determination
van der Meer JW, Elving LD.	Academisch Ziekenhuis, afd. Algemeen Interne Geneeskunde, Nijmegen.	[Chronic fatigue--'tired with 23 i's'].[article in Dutch]	Ned Tijdschr Geneeskd 1997 Aug 2;141(31):1505-7Comment in: Ned Tijdschr Geneeskd. 1997 Nov 29;141(48):2358-9 Ned Tijdschr Geneeskd. 1997 Nov 29;141(48):2360	Two patients, a woman aged 32 years and a man aged 49, presented with severe chronic fatigue. The woman had chronic fatigue syndrome; she recovered slowly. The man suffered from a pituitary adenoma producing follicle stimulating hormone; he recovered after transsphenoidal hypophysectomy. In patients with chronic fatigue, the history and a thorough physical examination to exclude underlying illness are very important; secondary symptom criteria must not be overemphasized (as is the case with the Holmes and Fukuda criteria), chronic fatigue syndrome should not be diagnosed if the condition has a shorter duration than 6 months, but it should be diagnosed if the clinical picture is compatible. The prognosis is not poor: in patients with a median disease duration of 4.5 years, 20% show significant improvement over an 18-month period.
van der Meer JW, Rijken PM, Bleijenberg G, Thomas S, Hinloopen RJ, Bensing JM.	Afd. Algemeen Interne Geneeskunde, Academisch Ziekenhuis, Nijmegen.	[Indications for management in long-term, physically unexplained fatigue symptoms].[article in Dutch]	Ned Tijdschr Geneeskd 1997 Aug 2;141(31):1516-9Comment in: Ned Tijdschr Geneeskd. 1997 Nov 29;141(48):2361-2 Ned Tijdschr Geneeskd. 1997 Nov 29;141(48):2362-3	In meetings arranged by the minister of Public Health, Welfare and Sports between general practitioners and specialists concerning chronic fatigue syndrome (CFS), suggestions for the diagnosis, treatment and assistance and support of patients with protracted physically unexplained fatigue symptoms, were established in the light of current scientific insight. The term 'CFS' is applicable in cases of fatigue complaints, of at least 6 months' standing, reported by the patient himself and evaluated medically, for which no physical explanation has been found and which cause considerable disabilities in professional social and/or personal functioning. The management depends on the duration of the illness. A distinction is made between an acute phase (up to one month after the first consultation; the policy is mostly expectative), a subacute phase (until 6

				months after the onset of the complaints and disabilities; the management is aimed at making the patient accept the condition and persuading him or her to make an effort to promote health) and a chronic phase (from 6 months after the onset of the complaints and disabilities; the management is aimed at health-promoting behaviour and cognitions). Further (laboratory) examinations are useful only if the symptoms have not disappeared after one month (this is the case in approximately 20% of the patients); such examinations may be useful in older patients earlier. It is important that the CFS patient learns to realize that it is useless to continue to spend energy on searching for causes and possible therapies, but that he should try to promote his own health, for instance by means of a quantified programme of activities linked to a time schedule (instead of to a level of fatigue).
van der Meer JW.	Academisch Ziekenhuis, afd. Algemeen Interne Geneeskunde, Nijmegen.	[Chronic fatigue syndrome].[article in Dutch]	Ned Tijdschr Geneeskd 1997 Aug 2;141(31):1507-9	Chronic fatigue syndrome is a controversial disease entity. Opinions range from non-disease via psychiatric disorder to a somatic disturbance. Somatic pathogenetic hypotheses include persisting infections, intoxications, metabolic or immunologic disturbances, nervous system diseases and endocrine pathology. None of these hypotheses has been substantiated as yet. Psychological factors are important in the course of the disorder and can be used in the therapeutic approach of patients with chronic fatigue syndrome.

Vedhara K, Llewelyn MB, Fox JD, Jones M, Jones R, Clements GB, Wang EC, Smith AP,	Department of Medicine, University of Wales College of Medicine, Cardiff, UK.	Consequences of live poliovirus vaccine administration in chronic fatigue	J Neuroimmunol 1997 May;75(1-2):183-95	The effect of live oral polio virus vaccination on chronic fatigue syndrome (CFS) patients was examined in a double-blind study. CFS patients were allocated randomly to placebo (N = 7) or vaccine (N = 7) conditions. All controls subjects received the vaccine (9). Vaccine administration was not associated with clinical

Borysiewicz LK.	k.vedhara@bristol.ac.uk	syndrome.		exacerbation of CFS. However, objective responses to the vaccine revealed differences between patients and controls: increased poliovirus isolation, earlier peak proliferative responses, lower T-cell subsets on certain days post vaccination and a trend for reduced gamma-interferon in the CFS-vaccine group. Polio vaccination was not found to be clinically contraindicated in CFS patients, however, there was evidence of altered immune reactivity and virus clearance. Randomized Controlled Trial
Vercoulen JH, Bazelmans E, Swanink CM, Fennis JF, Galama JM, Jongen PJ, Hommes O, Van der Meer JW, Bleijenberg G.	Department of Medical Psychology, University Hospital Nijmegen, The Netherlands.	Physical activity in chronic fatigue syndrome: assessment and its role in fatigue.	J Psychiatr Res 1997 Nov-Dec;31(6):661-73	This paper describes the assessment of physical activity in chronic fatigue syndrome (CFS) and investigated the following questions: Do patients with CFS have low levels of physical activity; is there a relationship between actual level of physical activity and fatigue; can self-report measures adequately assess actual level of physical activity; what is the role of cognitions with respect to physical activity; and are results with respect to physical activity specific to CFS? Three different types of activity measures were used: self-report questionnaires, a 12-day self-observation list, and a motion-sensing device (Actometer) which was used as a reference for actual activity level. Fifty-one patients with CFS, 50 fatigued patients with multiple sclerosis (MS), and 53 healthy subjects participated in this study. Although none of the self-report questionnaires showed high correlations with the Actometer, questionnaires that require simple ratings of specified activities were related to the Actometer and can be used as acceptable substitutes, in contrast to instruments that require general subjective interpretations of activity that had low or non-significant correlations with the Actometer. Actometer results showed that CFS patients and MS patients had similar activity levels and both groups were significantly less active than healthy subjects. Compared to MS patients, CFS patients were more likely to indicate that they had been less active than other persons they knew. Activities which patients expected to result in higher fatigue levels were less frequently performed. Patients with CFS had significantly higher scores on this measure than MS patients and healthy subjects. Low levels of physical activity were related to severe fatigue in CFS but not in MS. In conclusion, although CFS patients have similar low activity levels than MS patients, there are also important differences between both groups: in CFS cognitive factors are more prominently involved in producing the low activity levels than in MS and in CFS patients activity level is related to fatigue but not in MS. Randomized Controlled Trial
Versluis RG, de Waal MW, Opmeer C, Petri H, Springer MP.	Rijksuniversiteit, vakgroep Huisartsgeneeskunde, Leiden.	[Prevalence of chronic fatigue syndrome in 4 family practices in Leiden].[article in Dutch]	Ned Tijdschr Geneeskd 1997 Aug 2;141(31):1523-6	OBJECTIVE: To determine the prevalence of chronic fatigue syndrome (CFS) in general practice. DESIGN: Descriptive. SETTING: General practice and primary health care centres in Leyden region, the Netherlands. METHOD: RNUH-LEO is a computerized database which contains the anonymous patient information of one general practice (with two practitioners) and four primary health care centres. The fourteen participating general practitioners were asked what

				International Classification of Primary Care (ICPC) code they used to indicate a patient with chronic fatigue or with CFS. With these codes and with the code for depression patients were selected from the database. It then was determined whether these patients met the criteria of CFS by Holmes et al. RESULTS: The general practitioners used 10 codes. Including the code for depression a total of 601 patients were preselected from a total of 23,000 patients in the database. Based on the information from the patients' records in the database, 42 of the preselected patients were selected who might fulfill the Holmes' criteria of CFS. According to the patients' own general practitioner, 25 of the 42 patients would fulfil the Holmes' criteria. The men:women ratio was 1:5. The prevalence of CFS in the population surveyed was estimated to be at least 1.1 per 1,000 patients.
Vojdani A, Ghoneum M, Choppa PC, Magtoto L, Lapp CW.	Immunosciences Laboratory Inc., Beverly Hills, California, USA.	Elevated apoptotic cell population in patients with chronic fatigue syndrome: the pivotal role of protein kinase RNA.	J Intern Med 1997 Dec;242(6):465-78Comment in: J Intern Med. 1999 Apr;245(4):409-10	OBJECTIVES: A prominent feature of chronic fatigue syndrome (CFS) is a disordered immune system. Recent evidence indicates that induction of apoptosis might be mediated in a dysregulated immune system by the upregulation of growth inhibitory cytokines. Therefore, the purpose of this study was to evaluate the apoptotic cell population, interferon-alpha (IFN-alpha) and the IFN-induced protein kinase RNA (PKR) gene transcripts in peripheral blood lymphocytes (PBL) of CFS individuals, as compared to healthy controls. SUBJECTS AND METHODS: PBL were isolated from CFS (n = 29) and healthy control individuals (n = 15) and subjected to quantitative analysis of apoptotic cell population and cell cycle progression by flow cytometry. Quantitative competitive polymerase chain reaction (Q/C PCR) and Western blot analysis were used to assess the levels of PKR mRNA and protein in control and CFS individuals. In addition, circulating IFN-alpha was measured by ELISA assay. RESULTS: Increased apoptotic cell population was observed in CFS individuals, as compared to healthy controls (26.6 +/- 12.9% and 9.9 +/- 4.2%, respectively). The increased apoptotic subpopulation in CFS individuals was accompanied by an abnormal cell arrest in the S phase and the G2/M boundary of the cell cycle as compared to the control group (8.6 +/- 1.2 to 22.8 +/- 2.4 and 3.6 +/- 0.82 to 24.3 +/- 3.4, respectively). In addition, CFS individuals exhibited enhanced PKR mRNA and protein levels (mean basal level 3538 +/- 1050 and 2.7 +/- 0.26, respectively) as compared to healthy controls (mean basal level 562 +/- 162 and 0.89 +/- 0.18, respectively). In 50% of the CFS samples (n = 29) treated with 2-aminopurine (2-AP) (a potent inhibitor of PKR) the apoptotic population was reduced by more then 50%. CONCLUSIONS: PKR-mediated apoptosis in CFS individuals may contribute to the pathogenesis and the fatigue symptomatology associated with CFS.
Vollmer-Conna U, Hickie I, Hadzi-Pavlovic D, Tymms K, Wakefield	Inflammation Research Unit, School of Pathology, University of	Intravenous immunoglobulin is ineffective in the	Am J Med 1997 Jul;103(1):38-43	PURPOSE: To determine whether the reported therapeutic benefit of intravenous immunoglobulin in patients with chronic fatigue syndrome (CFS) is dose dependent. PATIENTS AND METHODS: Ninety-nine adult patients, who fulfilled

D, Dwyer J, Lloyd A.	New South Wales, Sydney, Australia.	treatment of patients with chronic fatigue syndrome.		diagnostic criteria for CFS, participated in this double-blind, randomized, and placebo-controlled trial. Patients received intravenous infusions with either a placebo solution (1% albumin) or one of three doses of immunoglobulin (0.5, 1, or 2 g/kg) on a monthly basis for 3 months, followed by a treatment-free follow-up period of 3 months. Outcome was assessed by changes in a series of self-reported measures (quality-of-life visual analog scales, standardized diaries of daily activities, the profile of mood states questionnaire) and the Karnofsky performance scale. Cell-mediated immunity was evaluated by T-cell subset analysis and delayed-type hypersensitivity (DTH) skin testing. RESULTS: No dose of intravenous immunoglobulin was associated with a specific therapeutic benefit. Adverse reactions, typically constitutional symptoms, were reported by 70% to 80% of patients, with no relationship to immunoglobulin treatment. CONCLUSIONS: Intravenous immunoglobulin cannot be recommended as a therapy for the treatment of CFS. A better understanding of the pathophysiology of this disorder is needed before effective treatment can be developed. Randomized Controlled Trial
Vollmer-Conna U, Wakefield D, Lloyd A, Hickie I, Lemon J, Bird KD, Westbrook RF.	Inflammation Research Unit, School of Pathology, University of New South Wales, Sydney, Australia. u.vollmer-conna@unsw.edu.au	Cognitive deficits in patients suffering from chronic fatigue syndrome, acute infective illness or depression.	Br J Psychiatry 1997 Oct;171:377-81	BACKGROUND: Patients with chronic fatigue syndrome (CFS) report neuro-psychological symptoms as a characteristic feature. We sought to assess cognitive performance in patients with CFS, and compare cognitive performance and subjective workload experience of these patients with that of two disease comparison groups (non-melancholic depression and acute infection) and healthy controls. METHOD: A computerized performance battery employed to assess cognitive functioning included tests of continuous attention, response speed, performance accuracy and memory. Severity of mood disturbance and subjective fatigue were assessed by questionnaire. RESULTS: All patient groups demonstrated increased errors and slower reaction times, and gave higher workload ratings than healthy controls. Patients with CFS and non-melancholic depression had more severe deficits than patients with acute infection. All patient groups reported more severe mood disturbance and fatigue than healthy controls, but patients with CFS and those with acute infection reported less severe mood disturbance than patients with depression. CONCLUSIONS: As all patients demonstrated similar deficits in attention and response speed, it is possible that common pathophysiological processes are involved. The differences in severity of mood disturbance, however, suggest that the pathophysiological processes in patients with CFS and acute infection are not simply secondary to depressed mood.
von Mikecz A, Konstantinov K, Buchwald DS, Gerace L, Tan EM.	Institut fur Umwelthygiene, Heinrich Heine Universitat Dusseldorf,	High frequency of autoantibodies to insoluble cellular antigens in patients with	Arthritis Rheum 1997 Feb;40(2):295-305 comment in: Arthritis Rheum. 1997	OBJECTIVE: To elucidate the humoral immune response in patients with chronic fatigue syndrome (CFS), by identification and characterization of autoantibodies. METHODS: Initial immunofluorescence histochemistry studies of sera using human HEp-2 cell substrate were followed by antibody class subtyping and

	Germany.	chronic fatigue syndrome.	Nov;40(11):2095-7	colocalization studies with reference antibodies. Association of CFS autoantigens with insoluble cellular components was determined by in situ extraction of soluble components and subsequent immunofluorescence histochemistry studies on the extracted cell substrate. RESULTS: Of 60 CFS patients, 41 (68%) were positive for antinuclear antibodies. Localization of nuclear staining was found at the nuclear envelope (52%), in reticulated speckles (25%), in nucleoli (13%), and in dense fine speckles (5%). Twenty-eight CFS sera (47%) also had antibodies to cytoplasmic antigens. The major cytoplasmic staining pattern was of the intermediate filament type (35%). The observed nuclear envelope pattern of staining co-localized with lamina-associated polypeptide 2 (an integral nuclear membrane protein), the reticulated speckle pattern co-localized with non-small nuclear RNP splicing factor SC-35, and the intermediate filament pattern co-localized with vimentin. The intermediate filament antigen was shown to be vimentin in immunoblotting experiments using recombinant human vimentin, and one of the nuclear envelope antigens was shown previously to be lamin B1. Fifty of the 60 CFS patients (83%) had antibodies to one or another of these antigens, all of which are relatively insoluble cellular antigens, whereas a control group of patients without chronic fatigue had a significantly lower frequency of such antibodies (17%). CONCLUSION: The high frequency of autoantibodies to insoluble cellular antigens in CFS represents a unique feature which might help to distinguish CFS from other rheumatic autoimmune diseases.
Vooren PH.		[Chronic fatigue syndrome].[article in Dutch]	Ned Tijdschr Geneeskd 1997 Nov 29;141(48):2359 Comment on: Ned Tijdschr Geneeskd. 1997 Aug 2;141(31):1526-30	
Wagner LI, Jason LA.	Medical College of Wisconsin, Milwaukee, USA.	Outcomes of occupational stressors on nurses: chronic fatigue syndrome--related symptoms.	Nursingconnections 1997 Fall;10(3):41-9	Considering the types and number of occupational stressors involved in caring for patients, nurses may represent a population at high risk for physical illnesses. A sample of 3400 nurses who belong to a statewide or a national nurses organization were randomly chosen for participation. Of this group, 202 reported 6 months or more of debilitating fatigue and completed a three-page questionnaire assessing symptoms related to chronic fatigue syndrome (CFS) and comorbid medical conditions. This group (N = 202) was mailed a follow-up questionnaire 1 year later that reassessed symptoms of CFS and occupational stressors. Many sampled nurses reported a high degree of occupationally related stress but did not report CFS symptoms; however, perceived exposure to the threat of an accident as a nurse and poor physical working conditions were significantly related to symptoms reported. These findings are consistent with previous research.

Watson WS, GT McCreathm A. Chaudhuri, Peter O. Behan		Possible Cell Membrane Transport Defect in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1997: 3(3): 1 - 13	Cardiac thallium-201 single photon emission computerised tomography has been carried out on 10 adult patients with chronic fatigue syndrome. Seven of the patients had defects in the thallium tracer distribution within the left ventricle; this was significantly greater than would be expected in a normal adult population. Similar abnormal scans have been observed in patients with syndrome X, a condition which has a symptom overlap with chronic fatigue syndrome. It has been suggested that an abnormally high efflux of cellular potassium may be the cause of the abnormal scans in syndrome X, and it is proposed that this mechanism may also have a role to play in chronic fatigue syndrome.
Wearden A, Appleby L.	Department of Psychiatry, University Hospital of South Manchester.	Cognitive performance and complaints of cognitive impairment in chronic fatigue syndrome (CFS).	Psychol Med 1997 Jan;27(1):81-90	Patients with chronic fatigue syndrome (CFS) complain that they have difficulties with concentration and memory but studies to date have not found consistent objective evidence of performance deficits. Two groups of CFS patients, depressed and non-depressed, and healthy controls, were asked about concentration problems in general and specifically when reading. CFS subjects were more likely than controls to report that they had concentration problems when reading, that they needed to re-read text and that they failed to take in what they were reading. Subjects then performed a task in which their reading behaviour and text recall was measured. While all CFS subjects complained of general cognitive failures and of difficulties with reading, only depressed CFS subjects recalled significantly less of the text than controls. Severity of complaints about reading problems was not related to amount of text recalled, but was related to severity of depressed mood. However, subjects were able to evaluate accurately their ability to remember the text immediately after reading it and before being tested for recall. Additionally, subjects performed a paired-associate learning task on which no significant differences between the subject groups was found. It is concluded that deficits in cognitive functioning in CFS patients are more likely to be found on naturalistic than on laboratory tasks. Controlled Clinical Trial
Wessely S, Chalder T, Hirsch S, Wallace P, Wright D.	Department of Psychological Medicine, King's College School of Medicine and Dentistry, London, England.	The prevalence and morbidity of chronic fatigue and chronic fatigue syndrome: a prospective primary care study.	Am J Public Health 1997 Sep;87(9):1449-55	OBJECTIVES: This study examined the prevalence and public health impact of chronic fatigue and chronic fatigue syndrome in primary care patients in England. METHODS: There were 2376 subjects, aged 18 through 45 years. Of 214 subjects who fulfilled criteria for chronic fatigue, 185 (86%) were interviewed in the case-control study. Measures included chronic fatigue, psychological morbidity, depression, anxiety, somatic symptoms, symptoms of chronic fatigue syndrome, functional impairment, and psychiatric disorder. RESULTS: The point prevalence of chronic fatigue was 11.3%, falling to 4.1% if comorbid psychological disorders were excluded. The point prevalence of chronic fatigue syndrome was 2.6%, falling to 0.5% if comorbid psychological disorders were excluded. Rates did not vary by social class. After adjustment for psychological disorder, being female

				was modestly associated with chronic fatigue. Functional impairment was profound and was associated with psychological disorder. CONCLUSIONS: Both chronic fatigue and chronic fatigue syndrome are common in primary care patients and represent a considerable public health burden. Selection bias may account for previous suggestions of a link with higher socioeconomic status.
Wessely S.	Institute of Psychiatry, Department of Psychological Medicine, King's College Hospital, London, United Kingdom.	Chronic fatigue syndrome: a 20th century illness?	Scand J Work Environ Health 1997;23 Suppl 3:17-34	The chronic fatigue syndrome has become the fin de siecle illness, now getting similar attention to that of neurasthenia, which dominated medical thinking at the turn of the century. Myalgic encephalomyelitis was an early term introduced in the United Kingdom in 1957 for this state, but it had little or no public or professional prominence. Until then "chronic fatigue had become invisible", with "no name, no known etiology, no case illustrations or clinical accounts in the medical textbook, no ongoing research activity--nothing to relate it to current medical knowledge". The reconstruction of chronic fatigue began in the mid-1980s, with the emergence of "chronic Epstein-Barr virus syndrome", which was later converted to chronic fatigue syndrome. The former term, which first emerged in the mid-1980s, is now regarded as a misnomer and should be abandoned. In the popular American literature the term "chronic fatigue and immune deficiency syndrome" is preferred by the most active of the patient lobbies, while myalgic encephalomyelitis continues to be the usual label in the United Kingdom. The relevant research linking chronic fatigue syndrome with somatization is reviewed in this article. Understanding the nature of somatization can still shed some light on the meaning of chronic fatigue at the end of the 20th century. Review, Academic
White PD, Cleary KJ.	Department of Psychological Medicine, St Bartholomew's and the Royal London Medical School, UK.	An open study of the efficacy and adverse effects of moclobemide in patients with the chronic fatigue syndrome.	Int Clin Psychopharmacol 1997 Jan;12(1):47-52	There is a strong association between the chronic fatigue syndrome and both depressive illness and sleep disturbance, but the efficacy of antidepressants is uncertain. We studied the efficacy and adverse effects of moclobemide in patients with chronic fatigue syndrome, stratifying the sample both by co-morbid major depressive illness and by sleep disturbance. Forty-nine patients with chronic fatigue syndrome were recruited. Patients were given moclobemide up to 600 mg a day for 6 weeks. Four (8%) patients dropped out, three because of adverse effects. Adverse effects wee otherwise mild and transient. On analysing the whole sample, there were significant but small reductions in fatigue, depression, anxiety and somatic amplification, as well as a modest overall improvement. The greatest improvement occurred in those individuals who had a co-morbid major depressive illness, with seven out of 14 (50%) of such individuals rating themselves as "much better" by 6 weeks, compared to six out of 31 (19%) of those who were not depressed (31% difference, 95% CI 1-60%, P = 0.04). Sleep disturbance had no effect on outcome. Moclobemide may be indicated in patients with chronic fatigue syndrome and a co-morbid major depressive disorder. A randomized, placebo-controlled trial is needed to confirm

				this. These results do not support moclobemide as an effective treatment of chronic fatigue syndrome in the absence of a major depressive disorder.
Wijlhuizen T, Hamerslag M.		Chronic fatigue syndrome].[article in Dutch]	Ned Tijdschr Geneeskd 1997 Nov 29;141(48):2361-2 Comment on: Ned Tijdschr Geneeskd. 1997 Aug 2;141(31):1516-9	
Yataco A, Talo H, Rowe P, Kass DA, Berger RD, Calkins H.	Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD 21287, USA.	Comparison of heart rate variability in patients with chronic fatigue syndrome and controls.	615: Clin Auton Res 1997 Dec;7(6):293-7	Recent studies have reported a close association between chronic fatigue syndrome and neurally mediated hypotension. We hypothesized that this association may result from an abnormality in autonomic function among patients with chronic fatigue syndrome, which may be detectable using an analysis of heart rate variability. We prospectively studied 19 patients who fulfilled the Centers for Disease Control criteria for chronic fatigue syndrome and 11 controls. Each subject underwent a two-stage tilt-table test while wearing a Holter monitor. Heart rate variability was assessed in the supine baseline position and during upright tilt using frequency domain parameters. In the baseline supine position, high frequency (HF) power, low frequency (LF) power, and the ratio of low frequency power to high frequency power (LF/HF ratio) were similar. In both patient groups, upright tilt resulted in a similar decrease in HF power, increase in LF power, and increase in the LH/HF ratio. In conclusion, autonomic function, as assessed using an analysis of heart rate variability, does not differ in the baseline supine state, nor in response to upright tilt among patients with chronic fatigue syndrome and healthy controls.
Ziem G, McTamney J.	Occupational and Environmental Medicine, Baltimore, Maryland, USA.	Profile of patients with chemical injury and sensitivity.	Environ Health Perspect 1997 Mar;105 Suppl 2:417-36	Patients reporting sensitivity to multiple chemicals at levels usually tolerated by the healthy population were administered standardized questionnaires to evaluate their symptoms and the exposures that aggravated these symptoms. Many patients were referred for medical tests. It is thought that patients with chemical sensitivity have organ abnormalities involving the liver, nervous system (brain, including limbic, peripheral, autonomic), immune system, and porphyrin metabolism, probably reflecting chemical injury to these systems. Laboratory results are not consistent with a psychologic origin of chemical sensitivity. Substantial overlap between chemical sensitivity, fibromyalgia, and chronic fatigue syndrome exists: the latter two conditions often involve chemical sensitivity and may even be the same disorder. Other disorders commonly seen in chemical sensitivity patients include headache (often migraine), chronic fatigue, musculoskeletal aching, chronic respiratory inflammation (rhinitis, sinusitis, laryngitis, asthma), attention deficit, and hyperactivity (affected younger children). Less common disorders include tremor, seizures, and mitral valve prolapse. Patients with these overlapping disorders should be evaluated for

				chemical sensitivity and excluded from control groups in future research. Agents whose exposures are associated with symptoms and suspected of causing onset of chemical sensitivity with chronic illness include gasoline, kerosene, natural gas, pesticides (especially chlordane and chlorpyrifos), solvents, new carpet and other renovation materials, adhesives/glues, fiberglass, carbonless copy paper, fabric softener, formaldehyde and glutaraldehyde, carpet shampoos (lauryl sulfate) and other cleaning agents, isocyanates, combustion products (poorly vented gas heaters, overheated batteries), and medications (dinitrochlorobenzene for warts, intranasally packed neosynephrine, prolonged antibiotics, and general anesthesia with petrochemicals). Multiple mechanisms of chemical injury that magnify response to exposures in chemically sensitive patients can include neurogenic inflammation (respiratory, gastrointestinal, genitourinary), kindling and time-dependent sensitization (neurologic), impaired porphyrin metabolism (multiple organs), and immune activation.

Ablashi DV, Levine PH, De Vinci C, Whitman JE Jr, Pizza G, Viza D.	Advanced Biotechnologies Inc., Columbia, MD 21046, USA.	Use of anti HHV-6 transfer factor for the treatment of two patients with chronic fatigue syndrome (CFS). Two case reports.	Biotherapy 1996;9(1-3):81-6	Specific Human Herpes virus-6 (HHV-6) transfer factor (TF) preparation, administered to two chronic fatigue syndrome patients, inhibited the HHV-6 infection. Prior to treatment, both patients exhibited an activated HHV-6 infection. TF treatment significantly improved the clinical manifestations of CFS in one patient who resumed normal duties within weeks, whereas no clinical improvement was observed in the second patient. It is concluded that HHV-6 specific TF may be of significant value in controlling HHV-6 infection and related illnesses.
Anisman H, Baines MG, Berczi I, Bernstein CN, Blennerhassett MG, Gorczynski RM, Greenberg AH, Kisil FT, Mathison RD, Nagy E, Nance DM, Perdue MH, Pomerantz DK, Sabbadini ER, Stanisz A, Warrington RJ.	Department of Psychology, Carloton University, Ottawa, Ont.	Neuroimmune mechanisms in health and disease: 2. Disease.	CMAJ 1996 Oct 15;155(8):1075-82	In the second part of their article on the emerging field of neuroimmunology, the authors present an overview of the role of neuroimmune mechanisms in defence against infectious diseases and in immune disorders. During acute febrile illness, immune-derived cytokines initiate an acute phase response, which is characterized by fever, inactivity, fatigue, anorexia and catabolism. Profound neuroendocrine and metabolic changes take place: acute phase proteins are produced in the liver, bone marrow function and the metabolic activity of leukocytes are greatly increased, and specific immune reactivity is suppressed. Defects in regulatory processes, which are fundamental to immune disorders and inflammatory diseases, may lie in the immune system, the neuro endocrine system or both. Defects in the hypothalamus-pituitary-adrenal axis have been observed in autoimmune and rheumatic diseases, chronic inflammatory disease, chronic fatigue syndrome and fibromyalgia. Prolactin levels are often elevated in patients with systemic lupus erythematosus and other autoimmune diseases, whereas the bioactivity of prolactin is decreased in patients with rheumatoid arthritis. Levels of sex hormones and thyroid hormone are decreased during severe inflammatory disease. Defective neural regulation of inflammation likely plays a pathogenic role in allergy and asthma, in the symmetrical form of rheumatoid arthritis and in gastrointestinal inflammatory disease. A better understanding of neuroimmunoregulation holds the promise of new approaches to the treatment of immune and inflammatory diseases with the use of hormones, neurotransmitters, neuropeptides and drugs that modulate these newly recognized immune regulators.
Anon		Chronic fatigue syndrome: any closer to an answer?	413: Consum Rep 1996 Sep;61(9):60-1	
Arnetz BB.	Department of Medicine, Karolinska Institute, Huddinge University Hospital,	Causes of change in the health of populations: a biopsychosocial viewpoint.	Soc Sci Med 1996 Sep;43(5):605-8	In the current review, a biopsychosocial perspective is applied to current changes in the health of populations. It is proposed that the psychosocial environments either promote health or precipitate disease. Changes in the types of stress that people experience as well as its prevalence over time are discussed. In addition,

	Sweden.			possible biological mechanisms linking the psychosocial environments to health are presented. "Food for thought" is the possible interaction between the physical/chemical and the psychosocial environments and changes in health of individuals. Clearly, our traditional view of disease mechanisms is not sufficient to understand recent phenomena, such as environmental illness and chronic fatigue syndrome. Issues worthy of further discussions are the role of the "just-in-time" society, where individuals increasingly have to change jobs, cope with reorganizations and increased production pressure, and its impact on health and well-being. Further, in what way can we develop better models to truly assess the impact of an increasingly complex interaction between individual and environmental factors on health? A major obstacle to enhancing our understanding of causes of change in the health of populations is the use of inappropriate or outdated statistical analytical models. Finally, it is suggested that prospectively controlled studies of the impact on health of changes in the health and welfare systems are carried out. This would further add to our understanding of factors contributing to changes in the health of population.

Bennett AL, Fagioli LR, Schur PH, Schacterle RS, Komaroff AL.	Chronic Fatigue Syndrome Cooperative Research Center, Division of General Medicine and Primary Care, Brigham and Women's Hospital, Boston, Massachusetts 02115, USA.	Immunoglobulin subclass levels in chronic fatigue syndrome.	J Clin Immunol 1996 Nov;16(6):315-20	The levels of immunoglobulin subclasses were determined for 46 patients meeting the original Centers for Disease Control case definition of chronic fatigue syndrome and were compared to values obtained for 50 age- and gender-matched healthy volunteer blood donor controls. The levels of immunoglobulin subclasses in these groups were further compared to a third group of additional chronic fatigue syndrome cases from whom samples had been obtained and frozen prospectively over a period of 7 years. These data do not demonstrate significant immunoglobulin subclass deficiencies in patients with chronic fatigue syndrome.

Bombardier CH, Buchwald D.	Department of Rehabilitation Medicine, University of Washington, Seattle, USA.	Chronic fatigue, chronic fatigue syndrome, and fibromyalgia. Disability and health-care use.	795: Med Care 1996 Sep;34(9):924-30	OBJECTIVES: Disabling chronic fatigue that does not meet criteria for chronic fatigue syndrome (CFS) or fibromyalgia (FM) is a condition thought to be associated with substantial disability and an apparently high use of health-care services. The authors compare patients who have chronic fatigue, CFS, FM, or CFS and FM together (CFS+FM) on employment status, self-reported disability, number of medical care visits, type of services obtained, and other diagnoses received. METHODS: The authors studied 402 patients from a university-based chronic fatigue clinic. All patients underwent an initial structured diagnostic assessment. One hundred forty-seven patients met case criteria for CFS, 28 for FM, 61 for CFS+FM, and 166 fell in the residual chronic fatigue group. Of these patients, 388 completed a follow-up questionnaire an average of 1.7 years later. Chi-squared tests and analysis of variance were used to compare groups on follow-up measures of health-care use and disability. RESULTS: Patients with chronic fatigue, CFS, FM, and CFS+FM were similar in terms of disability and health-care use, though those with CFS+FM were significantly more likely to be unemployed and to use more chiropractic and "other" provider services. Rates of unemployment ranged from 26% (chronic fatigue) to 51% (CFS+FM). Overall, patients reported a mean of 21 visits to a wide variety health-care providers during the previous year, with no significant differences between groups. CONCLUSIONS: Chronic fatigue, CFS, and FM are associated with considerable personal and occupational disability and low rates of employment. The potentially large economic burden of these disorders underscores the need for accurate estimates of direct and indirect costs, the relative contribution of individual factors to disability, and the need to develop targeted rehabilitation programs.
Borok G.		Committee to investigate chronic fatigue syndrome.	S Afr Med J 1996 Oct;86(10):1301 comment on: S Afr Med J. 1995 Aug;85(8):780-2	
Brown MT, Sam A. Fleishman, Manuel F. Casanova		Gulf War Syndrome Polysormographic Study of Eight Cases	Journal of Chronic Fatigue Syndrome 1996: 2(1): 41 - 51	Our purpose was to explore whether patients complaining of the "Gulf War Syndrome" might have hidden sleep disorders, or psychiatric disorders, similar to what has been described in patients with chronic fatigue syndrome and fibromyalgia. Eight consecutive Gulf War veterans from the VA Gulf War Registry and Evaluation program complaining of fatigue, as well as other symptoms, were psychiatrically and polysomnographically screened. One was found to have major depression and Post-traumatic Stress Disorder (PTSD), while another had PTSD alone. The sleep diagnoses assigned to the 8 patients were as follows: Three had sleep apnea syndrome, one of whom also had periodic limb movements of sleep disorder. Four others met criteria for periodic limb movements (PLMs) of sleep disorder. Four of the patients had clinically significant sleep state-misperceptions.

				All of the patients' symptoms were reported as occurring subsequent to Gulf War deployment, and not prior to deployment. As with the classic fatigue syndromes such as chronic fatigue syndrome and fibromyalgia, Gulf War Syndrome patients may benefit from a more thorough investigation of their sleep and psychiatric status. In view of these findings, consideration of polysomnographic screening would appear appropriate in Gulf War Veterans with fatigue or sleep-related complaints.
Bruno RL, Nancy M. Frick, Susan Creange, Jerald R. Zimmerman, Todd Lewis		Polioencephalitis and the Brain Fatigue Generator Model of Post-Viral Fatigue Syndromes	Journal of Chronic Fatigue Syndrome 1996: 2(2/3): 5 - 27	Fatigue is the most commonly reported and most debilitating Post-Polio Sequelae (PPS), affecting millions of polio survivors world-wide. Post-polio fatigue is associated with: (1) subjective reports of difficulty with attention, cognition, word-finding and maintaining wakefulness; (2) clinically significant deficits on neuropsychological tests of information processing speed and attention; (3) gray and white matter hyperintensities in the reticular activating system on magnetic resonance imaging of the brain; (4) neuroendocrine evidence of impaired activation of the HPA axis. Many of these findings are identical to those documented following a variety of viral encephalitides, including acute poliovirus infection, lethargic encephalitis, Iceland Disease, myalgic encephalomyelitis, and, most recently, Chronic Fatigue Syndrome. The clinical, historic, neuropsychologic, neuroanatomic and physiologic parallels between poliovirus infection, post-polio fatigue and post-viral fatigue syndromes (PVFS) will be explored in an attempt to describe the pathophysiology of PVFS. The disinhibition of a putative Brain Fatigue Generator will be implicated as a cause of the subjective symptoms and objective signs that accompany PVFS. The results of a pilot placebo-controlled study of a dopamine 2 receptor agonist to treat post-polio fatigue will also be described.
Buchwald D, Ashley RL, Pearlman T, Kith P, Komaroff AL.	Department of Medicine, University of Washington, Seattle, USA.	Viral serologies in patients with chronic fatigue and chronic fatigue syndrome.	J Med Virol 1996 Sep;50(1):25-30	Chronic fatigue syndrome (CFS) is an illness characterized by disabling fatigue associated with complaints of fevers, sore throat, myalgia, lymphadenopathy, sleep disturbances, neurocognitive difficulties, and depression. A striking feature of CFS is its sudden onset following an acute, presumably viral, illness and the subsequent recurrent "flu-like" symptoms. It has been speculated that both CFS and debilitating chronic fatigue (CF) that does not meet strict criteria for CFS may be the direct or indirect result of viral infections. We therefore tested 548 chronically fatigued patients who underwent a comprehensive medical and psychiatric evaluation for antibodies to 13 viruses. Our objectives were to compare the seroprevalence and/or geometric mean titer (GMT) of antibodies to herpes simplex virus 1 and 2, rubella, adenovirus, human herpesvirus 6, Epstein-Barr virus, cytomegalovirus, and Cox-sackie B virus, types 1-6 in patients with CF to healthy control subjects. Other goals were to determine if greater rates of seropositivity or higher GMTs occurred among subsets of patients with CFS, fibromyalgia, psychiatric disorders, a self-reported illness onset with a viral

				syndrome, and a documented temperature > 37 degrees C on physical examination. Differences in the seroprevalence or GMTs of antibodies to 13 viruses were not consistently found in those with CF compared with control subjects, or in any subsets of patients including those with CFS, an acute onset of illness, or a documented fever. These particular viral serologies were not useful in evaluating patients presenting with CF.
Buchwald D, Pearlman T, Umali J, Schmaling K, Katon W.	Department of Medicine, University of Washington, Seattle, USA.	Functional status in patients with chronic fatigue syndrome, other fatiguing illnesses, and healthy individuals.	Am J Med 1996 Oct;101(4):364-70	BACKGROUND: Chronic fatigue syndrome (CFS) is a condition that may be associated with substantial disability. The Medical Outcomes Study Short-Form General Health Survey (SF-36) is an instrument that has been widely used in outpatient populations to determine functional status. Our objectives were to describe the usefulness of the SF-36 in CFS patients and to determine if subscale scores could distinguish patients with CFS from subjects with unexplained chronic fatigue (CF), major depression (MD), or acute infectious mononucleosis (AIM), and from healthy control subjects (HC). An additional goal was to ascertain if subscale scores correlated with the signs and symptoms of CFS or the presence of psychiatric disorders and fibromyalgia. DESIGN: Prospectively collected case series. SETTING: Patients with CFS and CF were seen in a university-based referral clinic and had undergone a complete medical and psychiatric evaluation. Other study subjects were recruited from the community to participate in research studies. PARTICIPANTS: The study included 185 patients with CFS, 246 with CF, 111 with AIM, and 25 with MD. There were 99 HC subjects. MEASURES: The SF-36 and a structured psychiatric interview were used. The SF-36 contains 8 subscales: physical, emotional, social, and role functioning, body pain, mental health, vitality, and general health- and a structured psychiatric interview. RESULTS: Performance characteristics (internal reliability coefficients, convergent validity) of the SF-36 were excellent. A strikingly consistent pattern was found for the physical functioning, role functioning, social functioning, general health, and body pain subscales, with the lowest scores in CFS patients, intermediate scores in AIM patients, and the highest scores in the HC subjects. The CFS patients had significantly lower scores than patients with CF alone on the physical functioning ($P < or = 0.01$), role functioning ($P < or = 0.01$), and body pain ($P < or = 0.001$) subscales. The emotional functioning and mental health scores were worst among those with MD. The presence of fibromyalgia, being unemployed, and increasing fatigue severity all were associated with additional functional limitations across multiple functional domains, with increasing fatigue appearing to have the greatest effect. CONCLUSIONS: The SF-36 is useful in assessing functional status in patients with fatiguing illnesses. Patients with CFS and CF have marked impairment of their functional status. The severity and pattern of impairment as documented by the SF-36 distinguishes patients with CFS and CF from those with MD and AIM, and from HC, but does not discriminate between

				CF and CFS.
Buchwald D, Spero M. Manson , Tsilke Pearlman, Jovine Umali, Phalla Kith		Race and Ethnicity in Patients with Chronic Fatigue	Journal of Chronic Fatigue Syndrome 1996: 2(1): 53 - 66	Purpose: Chronic fatigue (CF) is a common complaint in ambulatory settings. Chronic fatigue syndrome (CFS) is characterized by profound fatigue associated with other symptoms that is rarely reported in racial/ethnic minorities. Our objectives were to determine if differences exist between Caucasian and minority patients presenting with CF, particularly in the frequency meeting criteria for CFS. Patients: 690 patients with CF seen in a university-based referral clinic. Design/Methods: Demographic, historical, physical examination, laboratory, and psychosocial information was prospectively collected and compared. Psychosocial assessment consisted of a structured psychiatric interview, the Medical Outcomes Study Short-Form Health Survey to assess functional status, the General Health Questionnaire to ascertain psychological distress, and measures of health locus of control, illness attribution, social support, and coping. Results: With the exception of less social support from friends, no significant race/ethicity-related differences were identified. Minority patients tended less commonly to report a moderate level of fatigue, and to have poorer social function, less social support from families, and lower rates of lifetime major depression and alcohol abuse. Conclusions: Demographic, clinical, and psychosocial factors do not distinguish Caucasian from minority CF patients. Help-seeking behaviors, access to care, and the significance attributed to the central complaints should be examined as potentially competing explanations for these findings.
Buchwald D, Umali J, Pearlman T, Kith P, Ashley R, Wener M.	Department of Medicine, University of Washington, Seattle, USA.	Postinfectious chronic fatigue: a distinct syndrome?	Clin Infect Dis 1996 Aug;23(2):385-7	Chronic fatigue syndrome (CFS) is often preceded by a viral illness and has recurrent "flu-like" symptoms. We compared demographic, clinical, and laboratory features (markers of inflammation and viral infection) among 717 patients with chronic fatigue (CF) with and without a self-reported postinfectious onset to identify associated clinical and biologic findings and to examine the subset of patients with CFS. Only subjective fever, chills, sore throat, lymphadenopathy, poorer functional status, and attribution of illness to a physical condition were significantly associated with a postinfectious onset. The features of patients with CFS were virtually identical to those of the broader category of patients with CF. We conclude that a postinfectious onset was not associated with a pattern of abnormalities across multiple psychosocial and biologic parameters.
Buchwald D, Umali J, Stene M.	Department of Medicine, University of Washington, Seattle, USA.	Insulin-like growth factor-I (somatomedin C) levels in chronic fatigue syndrome and fibromyalgia.	J Rheumatol 1996 Apr;23(4):739-42	OBJECTIVE. Fibromyalgia (FM) and chronic fatigue syndrome (CFS) are similar conditions characterized by substantial fatigue, diffuse myalgias, sleep disturbances and a variety of other symptoms. Many patients with CFS meet strict criteria for FM. Recently, low insulin-like growth factor-I (IGF-I) levels have been demonstrated in patients with FM, suggesting that disruption of the growth hormone-IGF-I axis might explain the link between the muscle pain and poor

				sleep. Our goal was to determine whether IGF-I levels are decreased in CFS, and whether such findings are restricted to patients with concurrent FM. METHODS. Radioimmunoassays were used to determine serum concentrations of IGF-I and its binding protein, (IGFBP-3). Subjects were 3 patients seen in a referral clinic for chronic fatigue: 15 patients with CFS, 15 who met criteria for both CFS and FM (CFS-FM), 27 with FM alone; and 15 healthy control (HC) subjects. RESULTS. Patients and control subjects had similar demographic and clinical characteristics. No significant differences were observed among any of the 3 patient groups and control subjects in the mean concentration of either IGF-I or IGFBP-3. Likewise, the proportion of subjects with values above or below the laboratory's reference range did not differ for IGF-I or IGFBP-3. CONCLUSIONS. These findings suggest the disruption of the growth hormone-IGF-I axis previously demonstrated in FM patients is not evident in a referral population of patients with CFS, CFS-FM, or FM.
Buchwald D.	Department of Medicine, University of Washington, Seattle, USA.	Fibromyalgia and chronic fatigue syndrome: similarities and differences.	Rheum Dis Clin North Am 1996 May;22(2):219-43	CFS and FM are clinical conditions characterized by a variety of nonspecific symptoms including prominent fatigue, myalgia, and sleep disturbances. There are no diagnostic studies or widely accepted, pathogenic, explanatory models for either illness. Despite remarkably different diagnostic criteria, CFS and FM have many demographic and clinical similarities. More specifically, few differences exist in the domains of symptoms, examination findings, laboratory tests, functional status, psychosocial features, and psychiatric disorders. FM appears to represent an additional burden of suffering among those with CFS, however, underscoring the importance of recognizing concurrent CFS and FM. Further clarification of the similarities (and differences) between CFS and FM may be useful in studies of prognosis and help define subsets of patients who may benefit from specific therapeutic interventions.
Bujak DI, Weinstein A, Dornbush RL.	Department of Medicine, New York Medical College, Valhalla 10595, USA.	Clinical and neurocognitive features of the post Lyme syndrome.	J Rheumatol 1996 Aug;23(8):1392-7	OBJECTIVE: To evaluate neurocognitive impairment in patients with persistent arthralgia, fatigue, and subjective memory loss in patients after Lyme disease (post-Lyme syndrome, PLS). METHODS: We compared the clinical, neurocognitive, and psychological features of 23 patients with PLS to 23 age, sex, and education matched recovered patients (REC). All met Centers for Disease Control criteria for Lyme disease, were ELISA positive at onset of Lyme disease and were previously treated with standard antibiotic regimens. RESULTS: Of the patients with PLS, 7 (30%) had fibromyalgia (FM), 3 (13%) had chronic fatigue syndrome, and 10 (43%) had similar but milder symptoms but did not meet the criteria for either. 22 of 23 patients with PLS complained of decreased memory or concentration problems. Patients with PLS had significantly lower scores on the attention/concentration scale ($p = 0.012$) of the Wechsler Memory Scale-Revised (WMS-R), indicating lowered attention/concentration. 52% of patients with PLS and 35% in the REC group had significantly lower ($p < 0.05$) WMS-R verbal

				memory scores than visual memory scores. The PLS group had subjectively more problems with sleep and mood changes and higher scores on several scales of Symptom Check List 90-R ($p < 0.01$), indicating greater physical distress. Beck Depression Inventory scores were also higher for the PLS than the REC group ($p < 0.005$), but were within the normal range. CONCLUSION: Despite antibiotic treatment, a sequelae of Lyme disease may be a PLS characterized by persistent arthralgia, fatigue, and neurocognitive impairment that is probably induced by Lyme disease.

Conti F, Magrini L, Priori R, Valesini G, Bonini S.	Universita di Roma La Sapienza, I Clinica Medica, Italy.	Eosinophil cationic protein serum levels and allergy in chronic	Allergy 1996 Feb;51(2):124-7	Chronic fatigue syndrome (CFS) is a syndrome of uncertain etiopathogenesis characterized by disabling fatigue associated with a variable number of somatic and/or neuropsychologic symptoms. In patients with CFS, several immunologic

		fatigue syndrome.		abnormalities can be detected, including a higher prevalance of allergy. The aim of this study was to determine whether CFS patients, well studied for their allergy profile, show signs of eosinophil activation, as detectable by the measurement in serum of eosinophil cationic protein (ECP) levels. In 35 consecutive CFS outpatients (diagnosis based on the Centers for Disease Control case definition), ECP was measured in serum by a competitive enzyme immunoassay (ECP-FEIA kit, Kabi Pharmacia Diagnostics, Uppsala, Sweden). Fourteen disease-free subjects with no history of CFS or allergy were selected as controls. ECP serum levels were significantly higher in CFS patients than in controls (18.0 +/- 11.3 micrograms/l vs 7.3 +/- 2.1 micrograms/l; P < 0.01). In the CFS population, the prevalence of RAST positivity to one or more allergens was 77%, while no control showed positive RAST. Twelve of the 14 CFS patients with increased ECP serum levels were RAST-positive. However, CFS RAST-positive patients had no significantly higher ECP serum levels than CFS RAST-negative patients (19.3 +/- 12.4 micrograms/l vs 13.6 +/- 3.7 micrograms/l; P = 0.4). This is the first report of increased serum levels of ECP in CFS. On the basis of the available data, it is discussed whether eosinophil activation has a pathogenetic role in CFS or is linked to the frequently associated allergic condition, or, finally, whether a common immunologic background may exist for both atopy and CFS.
Cope H, David AS.		Neuroimaging in chronic fatigue syndrome.	J Neurol Neurosurg Psychiatry 1996 May;60(5):471-3	
Cope H, Mann A, Pelosi A, David A.	Department of Psychological Medicine, King's College Hospital, London.	Psychosocial risk factors for chronic fatigue and chronic fatigue syndrome following presumed viral illness: a case-control study.	Psychol Med 1996 Nov;26(6):1197-209	This study investigated psychosocial morbidity, coping styles and health locus of control in 64 cases with and without chronic fatigue identified from a cohort of primary care patients recruited 6 months previously with a presumed, clinically diagnosed viral illness. A significant association between chronic fatigue and psychosocial morbidity, somatic symptoms and escape-avoidance coping styles was shown. Chronic fatigue cases were significantly more likely to have a past psychiatric history and a current psychiatric diagnosis based on a standardized clinical interview. Twenty-three of the cases fulfilled criteria for chronic fatigue syndrome (CFS). Such cases were significantly more fatigued than those not fulfilling criteria, but had little excess psychiatric disorder. A principal components analysis provided some evidence for chronic fatigue being separable from general psychosocial morbidity but not from the tendency to have other somatic complaints. Past psychiatric history and psychological distress at the time of the viral illness were risk factors for psychiatric 'caseness' 6 months later, while presence of fatigue, psychologising attributional style and sick certification were significant risk factors for CFS. These findings extend a previous questionnaire study of predictors of chronic 'post-viral' fatigue.
Cordero DL, Sisto SA,	Fatigue Research	Decreased vagal power	Clin Auton Res 1996	The purpose of this study was to determine if patients with the chronic fatigue

Tapp WN, LaManca JJ, Pareja JG, Natelson BH.	Center, DVA Medical Center, East Orange, NJ 07018, USA.	during treadmill walking in patients with chronic fatigue syndrome.	Dec;6(6):329-33	syndrome have less vagal power during walking and rest periods following walking, in comparison to a group of healthy controls. Eleven patients (ten women and one man) who fulfilled the case definition for chronic fatigue syndrome modified to reduce heterogeneity and eleven healthy, but sedentary, age- and sex-matched controls walked on a treadmill at 2.5 mph four times each for 4 min duration. Between each period of walking, subjects were given a 4-min seated rest period. Vagal power, a Fourier-based measure of cardiac, parasympathetic activity in the frequency range of 0.15 to 1.0 Hz, was computed. In each period of walking and in one period of rest, patients had significantly less vagal power than the control subjects despite there being no significant group-wise differences in mean heart rate, tidal volume, minute volume, respiratory rate, oxygen consumption or total spectrum power. Further, patients had a significant decline in resting vagal power after periods of walking. These results suggest a subtle abnormality in vagal activity to the heart in patients with the chronic fatigue syndrome and may explain, in part, their post-exertional symptom exacerbation.
Crofford LJ, Demitrack MA.	Department of Internal Medicine, University of Michigan, Ann Arbor, USA.	Evidence that abnormalities of central neurohormonal systems are key to understanding fibromyalgia and chronic fatigue syndrome.	Rheum Dis Clin North Am 1996 May;22(2):267-84	Fibromyalgia (FM) and chronic fatigue syndrome (CFS) fall into the spectrum of what might be termed stress-associated syndromes by virtue of frequent onset after acute or chronic stressors and apparent exacerbation of symptoms during periods of physical or emotional stress. These illnesses also share perturbation of the hypothalamic-pituitary-adrenal axis and sympathetic stress response systems. In this article, the authors discuss the specific neurohormonal abnormalities found in FM and CFS and potential mechanisms by which dysfunction of neurohormonal stress-response systems could contribute to vulnerability to stress-associated syndromes and to the symptoms of FM and CFS.

De Lorenzo F, Hargreaves J, Kakkar VV.	Thrombosis Research Institute, London, UK.	Possible relationship between chronic fatigue and postural tachycardia syndromes.	Clin Auton Res 1996 Oct;6(5):263-4	Postural tachycardia syndrome refers to the development of symptoms such as light-headedness, visual blurring, palpitations and weakness on assuming an upright posture; these symptoms are relieved by resuming a supine posture. This syndrome is occasionally associated with idiopathic hypovolemia, impaired vasomotor tone, deconditioning and autonomic neuropathy, but has not been reported in association with chronic fatigue syndrome (CFS). We describe five

				patients who satisfied the CFS criteria of the Centres for Disease Control and Prevention. Upright tilt-table testing induced significant hypotension and increased heart rate in all five patients, consistent with clinical and autonomic manifestation of postural tachycardia syndrome.

DiPino RK, Kane RL.	Department of Psychology, Veterans Administration Medical Center, Baltimore, Maryland 21201, USA.	Neurocognitive functioning in chronic fatigue syndrome.	Neuropsychol Rev 1996 Mar;6(1):47-60	Although substantial research has been conducted on chronic fatigue syndrome (CFS) over the past decade, the syndrome remains poorly understood. The most recent case definition describes CFS as being characterized both by disabling fatigue and by subjective reports of difficulty with concentration and "short-term" memory. However, research into the neurocognitive and psychological functioning of individuals with CFS has provided mixed objective results. The current paper reviews studies that have examined the neurocognitive and/or psychological functioning of individuals with CFS. Changes in research design and instruments employed to study individuals with CFS are suggested.
Djaldetti R, Ziv I, Achiron A, Melamed E.	Department of Neurology, Beilinson Medical Center, Petah	Fatigue in multiple sclerosis compared with chronic fatigue	Neurology 1996 Mar;46(3):632-5	Fatigue, a common complaint among patients with multiple sclerosis (MS), is poorly characterized. We developed a computerized method that quantitatively measures fatigue, and defined a fatigue index (FI), which is the ratio between the

	Tiqva 49100, Israel.	syndrome: A quantitative assessment.		integral of muscle strength decay over time and maximal voluntary contraction. Thirty patients (mean age, 37.4 +/- 10.3 years) were examined - 20 patients with pyramidal tract involvement and 10 patients with involvement of other neurological systems. We evaluated 10 patients during relapse and 3 months afterwards, and compared their results with those of four patients with chronic fatigue syndrome (CFS) and 13 age-matched health subjects. The FI was significantly higher in the MS patients as compared with the CFS patients and normal controls: 34.2 +/- 6.4% versus 27.5 +/- 1.0% and 23.6 +/- 6.8%, $p < 0.05$. Within the MS group, the FI correlated with the presence of pyramidal signs- 43.5% compared with 33% in patients without pyramidal signs, $p < 0.01$. In MS patients, fatigue worsened during a relapse affecting the pyramidal tract, but not during a relapse in other systems. These results demonstrate that fatigue can be quantitatively measured in MS patients, and that pyramidal dysfunction leads to increased fatigability.
Drago F, Ranieri E, Pastorino A, Casazza S, Crovato F, Rebora A.	Department of Dermatology, University of Genoa, Italy.	Epstein-Barr virus-related primary cutaneous amyloidosis. Successful treatment with acyclovir and interferon-alpha.	Br J Dermatol 1996 Jan;134(1):170-4	Cutaneous lesions related to chronic active Epstein-Barr virus (EBV) infection have been rarely documented in immunocompetent patients. A 30-year-old woman, fulfilling the diagnostic criteria for the chronic fatigue syndrome, had a 10-year history of pruritic brownish macules and papules on her chest and back. Her EBV serology was abnormal; the EBV genome was present in the epidermis of lesions, in oral secretions, and in peripheral mononuclear cells (PMC). Her blood lymphocytes spontaneously outgrew in culture. Histology revealed deposits of amyloid in the papillary dermis. Treatment with acyclovir and interferon-alpha rapidly improved her condition, stopped the lymphocyte outgrowth in culture, and reduced the EBV DNA content in oral secretions and in PMC. These data support an endogenous reactivation of EBV infection and suggest a causal relationship with primary amyloidosis.

Dyck D, Allen S, Barron J, Marchi J, Price BA, Spavor L, Tateishi S.		Management of chronic fatigue syndrome: case study.	AAOHN J 1996 Feb;44(2):85-92	1. Chronic fatigue syndrome (CFS) is a complex disorder marked by incapacitating fatigue of uncertain etiology which has resulted in a least a 50% reduction in activity and is of at least 6 months' duration. 2. Definitive diagnosis can be very challenging. Because no markers objectively identify the presence of CFS, diagnosis depends heavily on the presence of subjective complaints. 3. The current philosophy of CFS management is to use a multidisciplinary approach incorporating these rehabilitation goals: restore a sense of self efficacy and control; gradually increase physical activity; and decrease the restrictions imposed by CFS.

Euga R, Chalder T, Deale A, Wessely S.	Academic Department of Psychological Medicine, King's College School of Medicine and Dentistry, London.	A comparison of the characteristics of chronic fatigue syndrome in primary and tertiary care.	Br J Psychiatry 1996 Jan;168(1):121-6	BACKGROUND: To evaluated the characteristics of Chronic Fatigue Syndrome (CFS) in primary and tertiary care. METHOD: A comparison of subjects fulfilling criteria for CFS, identified as part of a prospective cohort study in primary care, compared to 79 adults fulfilling the same criteria referred for treatment to a specialist CFS clinic. RESULTS: Hospital cases were more likely to belong to upper socio-economic groups, and to have physical illness attributions. They had higher levels of fatigue and more somatic symptoms, and were more impaired functionally, but had less overt psychological morbidity. Women were over-represented in both primary care and hospital groups. Nearly half of those referred to a specialist clinic did not fulfil operational criteria for CFS. CONCLUSION: The high rates of psychiatric morbidity and female excess that characterise CFS in specialist settings are not due to selection bias. On the other hand higher social class and physical illness attributions may be the result of selection bias and not intrinsic to CFS.
Farmer A, Chubb H, Jones I, Hillier J, Smith A, Borysiewicz L.		Screening for psychiatric morbidity in subjects presenting with chronic fatigue syndrome.	Br J Psychiatry 1996 Mar;168(3):354-8	BACKGROUND. There is a need for a valid self-rating questionnaire to screen for psychiatric morbidity in patients with chronic fatigue syndrome (CFS). This study had the aim of assessing the utility and validity of two commonly used measures. METHOD. Scores obtained on the General Health Questionnaire (GHQ) and the Beck Depression Inventory (BDI) were compared with various diagnostic and severity ratings obtained via a validating clinical interview, the Schedules for the Clinical Assessment of Neuropsychiatry (SCAN) in 95 consecutively referred subjects at a medical out-patient clinic who fulfilled standard criteria for CFS, and 48 healthy controls. Outcome measures were validating coefficients and receiver operating characteristics (ROC) for different thresholds and scoring on GHQ and BDI and index of definition (ID) as measured by SCAN; and Pearson and point by serial correlation coefficients for different diagnostic groups derived via SCAN and defined according to ICD-10 and DSM-III-R. RESULTS. GHQ and BDI perform poorly as screeners of psychiatric morbidity in CFS subjects when compared with various SCAN derived ratings although results for controls are comparable with other studies. CONCLUSIONS. Neither the GHQ nor BDI alone can be recommended as screeners for psychiatric morbidity in CFS subjects.
Few J, Thompson NW, Angelos P, Simeone D, Giordano T, Reeve T.	Department of Surgery, University of Michigan, Ann Arbor, USA.	Riedel's thyroiditis: treatment with tamoxifen.	Surgery 1996 Dec;120(6):993-8; discussion 998-9	BACKGROUND: Riedel's thyroiditis is an often disabling disease with clinical and histologic similarity to several other fibrous inflammatory disorders. Surgical treatment alone is often unsatisfactory in permanently alleviating airway compression, dysphagia, neck immobility, pain, or chronic fatigue syndrome.

				Investigation of drugs shown to be of benefit in the treatment of related fibrous disorders in which hormonal factors or inflammatory deregulation appear to be important is indicated. Tamoxifen has not been previously used in the treatment of Riedel's thyroiditis. METHODS: Four patients with clinical and histologic diagnoses of Riedel's thyroiditis were evaluated before and after treatment with tamoxifen. Each had progressive symptomatic disease of 3 to 16 years' duration despite one or more surgical procedures and steroid therapy. Subjective improvement was noted in all cases, and objective changes were confirmed by periodic physical and computed tomographic examinations. RESULTS: Patients have been monitored for 1 to 4 years with subjective improvement in 100% and objective disease regression ranging from 50% to 100% in all patients. One patient had complete regression within 6 months, and another had more than 50% regression within 3 months. All have returned to predisease activity levels. There were no significant side effects of the therapy. CONCLUSIONS: Tamoxifen has proved to be the most effective drug therapy available for managing Riedel's thyroiditis. Our studies suggest that this is unrelated to antiestrogen activity. Tamoxifen's effectiveness may be caused by a mechanism by which it stimulates the release of transforming growth factor-beta, which may inhibit the fibroblastic proliferation characteristic of Riedel's thyroiditis.
Fiedler N, Kipen H, Natelson B, Ottenweller J.	UMDNJ-Robert Wood Johnson Medical School, Environmental & Occupational Health Sciences Institute, Piscataway 08855, USA.	Chemical sensitivities and the Gulf War: Department of Veterans Affairs Research Center in basic and clinical science studies of environmental hazards.	800: Regul Toxicol Pharmacol 1996 Aug;24(1 Pt 2):S129-38	The purpose of the New Jersey Center for Environmental Hazards Research is to define the illness referred to as Persian Gulf Syndrome (PGS). Our preliminary data indicated that more than half of the Persian Gulf Registry (PGR) veterans reported illness characterized by severe fatigue and symptoms consistent with chemical sensitivities. Therefore, our research approach focuses on investigations of veterans with chronic fatigue syndrome (CFS) and multiple chemical sensitivities (MCS). Project 1 is an epidemiological study of 2800 PGR veterans. Symptoms, indices of Chronic Fatigue (CF) and Chemical Sensitivity (CS), and risk factors will be surveyed with mailed questionnaires. Risk factors include demographics, past medical history, psychosocial variables, Gulf War experiences such as prophylactic medication use, occupational and environmental exposures, and pesticide exposures. Symptoms will be clustered to define Gulf War Syndromes. Significant associations between risk factors and these symptom clusters will also be investigated Subjects identified as CF, CS, or both will be recruited into Projects 2 and 3. In Project 2, healthy veterans will be compared to veterans with CF, CS, and CF concurrent with CS. Veterans will undergo four studies: (1) viral-immunological, (2) psychiatric, psychological, behavioral, and neuropsychological, (3) autonomic dysregulation, and (4) marker of P4501A2 induction resulting from exposure to combusting material. The purpose of Project 3 is to test the autonomic, immunologic, neuropsychologic, and psychologic responses of veterans with CS or CF to two stressors: controlled

				chemical exposure and exercise. CS subjects will undergo chemical exposures in our Controlled Environment Facility (CEF) to assess their biologic and psychologic response to low-level exposure. CF subjects will undergo a maximal treadmill exercise test. Circadian patterns of catecholamines and axillary temperature, viral burden, and cardiovascular and endocrine reactivity will be measured in response to this physical stressor. Project 4 is an animal study evaluating the interaction between stress and pathology/physiology when rats are predisposed to disease by exposure to Soman or to Dioxin. Two strains of rats that differ in stress reactivity will be used to determine the interaction of hereditary factors and chemical exposure.

Fiedler N, Kipen HM, DeLuca J, Kelly-McNeil K, Natelson B.	Department of Environmental and Community Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, New Jersey 08855, USA.	A controlled comparison of multiple chemical sensitivities and chronic fatigue syndrome.	Psychosom Med 1996 Jan-Feb;58(1):38-49	The present study had two objectives: 1) to determine the characteristics that differentiated subjects with multiple chemical sensitivities (MCS), chemical sensitivities (CS), and chronic fatigue syndrome (CFS); and 2) to evaluate the psychiatric and neuropsychological complaints of these groups relative to normal controls. A cross-sectional comparison was made of the following groups matched for age, sex, and education: 1) patients whose sensitivities to multiple low level chemical exposures began with a defined exposure (MCS; N = 23); 2) patients with sensitivities to multiple chemicals without a clear date of onset (CS; N = 13); 3) patients meeting CDC criteria for Chronic Fatigue Syndrome (CFS; N = 18); and 4) normal controls (N = 18). Subjects with sensitivities to chemicals (MCS and CS) reported significantly more lifestyle changes due to chemical sensitivities and significantly more chemical substances that made them ill compared with chronic fatigue and normal controls. MCS, CS, and CFS patients had significantly higher rates of current psychiatric disorders than normal controls and reported significantly more physical symptoms with no medical explanation. Seventy-four percent of MCS and 61% of CFS did not qualify for any current Axis I psychiatric diagnosis. Chemically sensitive subjects without a defined date of onset (CS) had the highest rate of Axis I psychiatric disorders (69%). On the MMPI-2, 44% of MCS, 42% of CS, 53% of CFS, and none of the controls achieved clinically significant elevations on scales associated with somatoform disorders. With the exception of one complex test of visual memory, no significant differences were noted among the groups on tests of neuropsychological function. Standardized measures of psychiatric and neuropsychological function did not differentiate subjects with sensitivities to chemicals from those with chronic fatigue. Subjects with sensitivities to chemicals and no clear date of onset had the highest rate of psychiatric morbidity. Standardized neuropsychological tests did not substantiate the cognitive impairment reported symptomatically. Cognitive deficits may become apparent under controlled exposure conditions.
Fischler B, D'Haenen H, Cluydts R, Michiels V, Demets K, Bossuyt A, Kaufman L, De Meirleir K.	Department of Psychiatry, Academic Hospital, Free University of Brussels, Belgium.	Comparison of 99m Tc HMPAO SPECT scan between chronic fatigue syndrome, major depression and healthy controls: an exploratory study of clinical correlates of regional cerebral blood flow.	Neuropsychobiology 1996;34(4):175-83	An explorative analysis of the relationship between symptomatology and cerebral blood flow in the chronic fatigue syndrome (CFS) as assessed with 99mTc HMPAO SPECT scan reveals statistically significant positive correlations between frontal blood flow on the one hand and objectively and subjectively assessed cognitive impairment, self-rating of physical activity limitations and total score on Hamilton Depression Rating Scale on the other. A pathophysiological role of frontal blood flow in the cognitive impairment and physical activity limitations in CFS is hypothesized. A comparison of cerebral blood flow between CFS, major depression (MD) and healthy controls (HC) has been performed. A lower superofrontal perfusion index is demonstrated in MD as compared with both CFS and HC. There is neither a global nor a marked regional hypoperfusion

				in CFS compared with HC. Asymmetry (R > L) of tracer uptake at parietotemporal level is demonstrated in CFS as compared with MD.
Fry AM, Martin M.	University of Oxford Department of Psychiatry, Park Hospital for Children, U.K.. AMFRY@VAX.OX.AC.UK	Cognitive idiosyncrasies among children with the chronic fatigue syndrome: anomalies in self-reported activity levels.	J Psychosom Res 1996 Sep;41(3):213-23	The possibility that children with the chronic fatigue syndrome (CFS) and their parents tend to display idiosyncratic cognitive processing concerning levels of activity was examined by means of subjective and objective measures of current activity, together with subjective and objective measures of desired and expected future activity. The degree to which subjective reports of current activity level reflect objectively measured activity level was examined in a group of children with CFS and a healthy control group. All subjects were assessed over a 3-day period by means of ambulatory activity monitoring, and self-reports and parent-reports of current activity level were collected by means of visual analog scales. Analysis of variance revealed a significant interaction between the method of measurement (objective versus subjective) and the participant group (CFS versus Healthy) with the CFS children and their parents underestimating actual level of activity relative to the healthy group. Desired and expected levels of future activity were also assessed by means of subjective report. Child and parent expected levels of future activity were compared with their desired levels. Although expected levels of future activity were similar in the two groups, the divergence between expected levels and corresponding desired levels was significantly greater in the CFS group. These results are discussed in terms of idiosyncratic cognitive processes, which are hypothesized to be associated with CFS and which may play a role in the maintenance of the disorder.
Fry AM, Martin M.	Department of Experimental Psychology, University of Oxford, UK. AMFRY@VAX.OX.AC.UK	Fatigue in the chronic fatigue syndrome: a cognitive phenomenon?	J Psychosom Res 1996 Nov;41(5):415-26	What is the source of the perception of excessive fatigue in the chronic fatigue syndrome (CFS)? Studies of physiological response to aerobic activity, of muscle pathology and muscle function in CFS, are reviewed, and suggest that the subjective report of fatigue is not due to any peripheral impairment. In addition, current technological methods such as electroencephalography have failed to uncover the nature of any abnormality in the central motor unit. A physiological model which proposes that patients with CFS possess a reduced threshold for sensory fatigue signals is rejected, because it fails to account for recent findings. Instead, it is suggested that the perception of fatigue in CFS is enhanced by idiosyncrasies in cognitive processing. The implications of this view to our understanding of the perpetuation of CFS as a whole are explored. Publication Types: Review Review Literature
Fukazawa T, Sasaki H, Kikuchi S, Hamada T, Tashiro K.	Hokuyukai Neurology Hospital, Sapporo, Japan.	Serum carnitine and disabling fatigue in multiple sclerosis.	Psychiatry Clin Neurosci 1996 Dec;50(6):323-5	The serum concentrations of total, free and acylcarnitine were compared in 25 patients with multiple sclerosis (MS) and among age- and sex-matched normal controls by the new enzymatic cycling method in order to clarify whether the fatigue in MS might be due to possible carnitine-related fatty acid metabolic abnormalities in the mitochondria of skeletal muscles. Patients with MS were divided into those with and those without excessive fatigue. Levels of total and

				free carnitine were not significantly different between MS patients and normal controls. Levels of acylcarnitine, whose decrease in chronic fatigue syndrome has been reported, were also similar between MS patients and normal controls. There was no difference in these carnitine levels between MS patients with and without excessive fatigue. We argue that acylcarnitine deficiency and fatty acid metabolic dysfunction in mitochondria are not relevant to the excessive fatigue in patients with MS, and further explanatory investigations are to be sought.

Goldenberg DL.	Newton-Wellesley Hospital, Newton, MA 02162, USA.	Fibromyalgia, chronic fatigue syndrome, and myofascial pain.	Curr Opin Rheumatol 1996 Mar;8(2):113-23	The prevalence of fibromyalgia in the general population was found to be 2% and increased with age. Multiple traumatic factors, including sexual and physical abuse, may be important initiating events. The most important pathophysiologic studies in fibromyalgia included evidence of altered blood flow to the brain and hypothalamic-pituitary-adrenal dysfunction. The prevalence of chronic fatigue syndrome is much less than that of fibromyalgia. Epidemiologic studies demonstrated that chronic fatigue and symptoms of fibromyalgia are distributed as continuous variables in the general population. No association between chronic fatigue and initial infections was seen in primary care practices.
Gonzalez MB, Cousins JC, Doraiswamy PM.	Department of Psychiatry, Duke University Medical Center, Durham, NC, USA.	Neurobiology of chronic fatigue syndrome.	Prog Neuropsychopharmacol Biol Psychiatry 1996 Jul;20(5):749-59	1. Chronic fatigue syndrome (CFS) is characterized by a new onset of significant fatigue for a period of six months or longer usually following an infection, injury or period of high stress. 2. The exact etiology of CFS is not known and a diagnostic test is not available. Hence, the diagnosis is made by exclusion of other explanations for the patient's symptoms and by meeting the CDC research case definitions. Early studies supported an infectious or immune dysregulation hypothesis for the pathophysiology of CFS. 3. Subsequent studies documented that neurological, affective and cognitive symptoms also occur at high rates in CFS patients. Neuropsychological, neuroendocrine studies and brain imaging have now confirmed the occurrence of neurobiological abnormalities in most patients with CFS. 4. In this article, the authors review these findings in relation to the clinical neurobiology of CFS and their potential relevance to biological psychiatry.

Chronic fatigue syndrome and dieting disorders: diagnosis and management problems.	Aust N Z J Psychiatry 1996 Dec;30(6):834-8	OBJECTIVE: This paper illustrates the importance of conducting an initial and ongoing psychiatric assessment of patients with chronic fatigue syndrome in order to diagnose dieting disorders. The diagnostic issues and management problems of three case vignettes, two with anorexia nervosa and one with bulimia nervosa, are described. METHOD: The treatment response of dieting disordered patients is generally prolonged after a previous diagnosis of chronic fatigue syndrome has been made and the patient and family favour a disease diagnosis. RESULTS: Several management problems arise and family members may also be reluctant to accept a dieting disorder diagnosis. CONCLUSIONS: Early detection of dieting disorders by adequate screening and assessment is necessary so that a significant reduction in morbidity may occur.
Gruber AJ, Hudson JI, Pope HG Jr.	Biological Psychiatry Laboratory, McLean Hospital, Belmont, Massachusetts, USA.	The management of treatment-resistant depression in disorders on the interface of psychiatry and medicine. Fibromyalgia, chronic fatigue syndrome, migraine, irritable bowel syndrome, atypical facial pain, and premenstrual dysphoric disorder.	Psychiatr Clin North Am 1996 Jun;19(2):351-69	We have reviewed studies examining the efficacy of various psychotropic medications, primarily antidepressant agents, in the treatment of a group of disorders that appear to exhibit some phenomenologic and genetic relationship to major depression. These disorders all appear to benefit (albeit to varying degrees) from antidepressant medications of several different chemical families. This observation has important theoretical and clinical implications. From a theoretical perspective, these results invite the hypothesis that these various disorders may share some particular etiologic "step" in common with major depression-and that the various antidepressant classes benefit these various disorders and major depression via a common action at this hypothetical "step". Although there is an appealing parsimony to this hypothesis, several reservations must be considered. First, it must be recognized that the quality of the available studies varies widely. As noted in the text, these studies used numerous different designs, varying diagnostic criteria for the disorders under study, and diverse methods of rating outcome. Interpretation is further complicated by the fact that many studies included other concomitant medications or therapeutic interventions in addition to the psychotropic drugs administered. Also, the dose of antidepressant medications administered in many of these studies, especially those using TCAs, was often much less than that normally administered in the treatment of major depressive disorder itself. Finally, many of the studies did not systematically evaluate improvement in both the physical and psychological symptoms of a given disorder. For all of these reasons, any theoretic discussion of the results must be tentative. Nevertheless, the overall tally of results strongly favors the hypothesis that antidepressant agents, regardless of their chemical class, are generally useful in the treatment of these disorders. At a minimum,

				therefore, we can conclude that antidepressant treatment in these disorders deserves aggressive further investigation in studies with modern, rigorous designs. Second, even allowing that multiple antidepressant agents are effective in these various disorders, it still may be premature to conclude that these disorders are related to major depressive disorder. In particular, many of the studies found little correlation between improvement in psychological symptoms and physical symptoms of a given disorder. This observation would seem to argue against a relationship with major depressive disorder. The alternative hypothesis, however, namely, that these disorders do not share a common etiologic "step," seems even less attractive. It would be a remarkable coincidence if, say, fluoxetine possessed an antidepressant property, an independent antimigraine property, and a third, independent, antipremenstrual dysphoric disorder property. And it would be even more peculiar if various other antidepressant medications chemically unrelated to fluoxetine also, by chance alone, benefited all of these same disorders via still other independent mechanisms. Although we cannot, of course, rule out the possibility of multiple mechanisms and multiple causes, the experience of scientific research often has been that the simpler explanation of a phenomenon has proved to be correct. Therefore, the possibility of a link among these various antidepressant-responsive disorders deserves investigation. From a clinical perspective, too, these results are important. They suggest that trials of antidepressant medications should be strongly considered in patients with these disorders. Furthermore, other types of psychotropic medication appear to have a role in the treatment of individual disorders, as discussed in the corresponding sections.(ABSTRACT TRUNCATED) Review Literature
Gushue J.		Increasing workplace stress means occupational medicine will be a growth area.	CMAJ 1996 Nov 1;155(9):1310-3	Physicians attending a recent annual meeting on occupational medicine heard wide-ranging discussions about chronic fatigue syndrome and the effect of increased stress on workers. They also learned that occupational medicine is likely to be one of the growth specialties in the coming decade.
Hakimi R.	Stabsabteilung arztlicher Dienst der Hallesche-Nationale Krankenversicherung a.G Stuttgart.	[Chronic fatigue syndrome--also an insurance medicine problem].[article in German]	Versicherungsmedizin 1996 Apr 1;48(2):59-61	Not everybody who is chronically tired has a chronic fatigue syndrome. The diagnosis of the chronic fatigue syndrome is still a problem, and is becoming a problem in health insurance medicine too. There is a lack of knowledge concerning the causes, the diagnosis and the therapy of the chronic fatigue syndrome. And there is still the question if the chronic fatigue syndrome is an entity of its own. For these reasons we should apply the few facts we really know about the chronic fatigue syndrome. This is the working case definition of Kaplan et al. from 1988. Otherwise there will be done hundreds of expensive laboratory tests, which are useless for the patient and very costly for the health insurance companies.
Hall SR, Smith AP.	School of Psychology,	Behavioural effects of	Neuropsychobiology	The aim of the present study was to provide preliminary information on the

	University of Birmingham, UK.	infectious mononucleosis.	1996;33(4):202-9	acute and chronic effects of infectious mononucleosis (IM) on memory, attention, psychomotor performance and mood. These issues were examined by comparing individuals with acute IM, those who had the initial illness some months before, and matched healthy controls. Objective measures of memory, attention, motor skills and visual functions were obtained, as were subjective reports of mood. The results showed selective effects of acute IM on performance and mood, with the profile of impairments being very similar to those observed in previous studies of influenza. Different impairments were observed in subjects who had the primary illness several months before, and the effects observed in this group were similar to those observed in recent studies of chronic fatigue syndrome patients. Both acute and chronic IM subjects reported similar levels of symptoms and psychopathology, with both groups having greater scores than the controls. However, the performance impairments did not reflect symptoms or psychopathology. One may conclude that the study of IM will provide important data on both the acute and longer lasting effects of viral infections on the brain and behaviour.

Hana I, Vrubel J, Pekarek J, Cech K.	Dept. of Immunology, Institute for Clinical and Experimental Medicine, Prague, Czechia.	The influence of age on transfer factor treatment of cellular immunodeficiency, chronic fatigue syndrome and/or chronic viral infections.	Biotherapy 1996;9(1-3):91-5	A group of 222 patients suffering from cellular immunodeficiency (CID), frequently combined with chronic fatigue syndrome (CFS) and/or chronic viral infections by Epstein-Barr virus (EBV) and/or cytomegalovirus (CMV), were immunologically investigated and treated with transfer factor (TF). The age range was 17-77 years. In order to elucidate the influence of aging on the course of the disease and on treatment, 3 subgroups were formed: 17-43 years, 44-53 years, and 54-77 years. Six injections of Immodin (commercial preparation of TF by SEVAC, Prague) were given in the course of 8 weeks. When active viral infection was present, IgG injections and vitamins were added. Immunological investigation was performed before the start of therapy, and subsequently according to need, but not later than after 3 months. The percentages of failures to improve clinical status of patients were in the individual subgroups, respectively: 10.6%, 11.5% and 28.9%. The influence of increasing age on the percentage of failures to normalize low numbers of T cells was very evident: 10.6%, 21.2% and 59.6%. In individuals uneffected by therapy, persistent

				absolute lymphocyte numbers below 1,200 cells were found in 23.1%, 54.5% and 89.3% in the oldest group. Statistical analysis by Pearson's Chi-square test, and the test for linear trend proved that the differences among the individual age groups were significant. Neither sex, nor other factors seemed to influence the results. The results of this pilot study show that age substantially influences the failure rate of CID treatment using TF. In older people, it is easier to improve the clinical condition than CID: this may be related to the diminished number of lymphocytes, however, a placebo effect cannot be totally excluded.
Hausotter W.		[Expert assessment of chronic fatigue syndrome].[article in German]	Versicherungsmedizin 1996 Apr 1;48(2):57-9	The Chronic-Fatigue-Syndrome (CFS) has been first described in 1988 and has been also in Germany recently more frequently diagnosed. It is similar to a lot of other terms, especially to "neurasthenia", which has been introduced 1869 from Beard and is now again content of ICD-10. CFS is defined by primary and secondary criteria, which are however largely subjective. There are no objective signs. It is unknown if this syndrome represents a disease entity of its own. The explanation is either exclusive organic based on immunological and virological findings or exclusive psychogenic as a special form of anxiety psychosis. Possibly are both factors involved as part of "psycho-neuro-immunology". CFS is increased subject of medical certification. It has been tried to give a practical guidance to the assessment of CFS.
Hilgers A, Johannes Frank		Chronic Fatigue Syndrome Evaluation of a 30-Criteria-Score and Correlation with Immune Activation	Journal of Chronic Fatigue Syndrome 1996: 2(4): 35 - 47	Objective: The development of a score for severity of Chronic Fatigue Syndrome (CFS), the correlation of CFS with parameters of immune activation and the association with pathogens. Methods: Five hundred five patients with suspicion of Chronic Fatigue Syndrome and no other definitive diagnosis were checked by a 45-criteria-score, basic laboratory programs and immunological profiles. In most of the patients further tests concerning complement system, immune activation markers, hormones and serology of herpesviruses, Chlamydia and Borrelia could be evaluated. Comparison of the symptoms of CFS patients with healthy controls lead to a 30-criteria-score and this score was correlated with laboratory parameters (Spearman rank-correlation-coefficient rs, ties corrected). Results: Three hundred eighty-five patients fulfilling stronger criteria according to the Centers for Disease Control (CDC) definition showed significant differences to 53 healthy controls in 40 of the 45 criteria ($p < 0.001$, twitches and food allergies $p < 0.05$). Thirteen symptoms corresponding to CDC criteria were all significant ($p < 0.001$), 17 further significant criteria of descending precision were added: respiratory infections, palpitations, dizziness, dyspepsia, dryness of mouth/eyes, allergies, nausea, paresthesia, loss of hair, skin alterations, dyscoordination, chest pain, personality changes, eczema, general infections, twitches, urogenital infections. A correlation between the 30-criteria-score and immunological parameters could be evaluated in 472 of the 505 patients. Significant positive correlation with the 30-criteria-score was found in numbers of CD8+ T-

				lymphocytes, HLA-DR+ T-lymphocytes, gamma globulins, IgM, IgG, and for the number of types of autoantibodies (mainly ANA, ACA, antithyroid and antiparietal cell antibodies). Significant negative correlation was found in albumin-globulin-ratio, eosinophils and IgE. Most of these parameters also correlated with one another. On the other hand, in subgroups of the 505 patients the Frequency of positivity in serological tests for HHV-6 (49.9%), EBV (35.4%), HSV (29.2%), CMV (12.5%) and Chlamydia (35.0%) was striking. Borrelia Western blots showed 3 or more specific IgG-bands in 54 of 131 patients (41.2%). In some cases infection with EBV, HHV-6 and CMV, respectively, was confmed by DNA-PCR-test and antigen detection. Summary: In increasingly larger groups of patients with CFS and related constellations we often see clinical signs and longer anamnesis of other symptoms besides the classical criteria of CFS, especially a high prevalence of local and general susceptibility to infections and hints to prolonged inflammation processes. Together with other results, the data confirm the hypothesis that a reduced or unstable immune control or delayed immune reaction to persisting viruses or bacterial intracellular pathogens, possibly triggered by common infections or other environmental factors, can lead to a chronic neuroimmune activation state and auto-immune disorders. Hypersensitivity symptoms of the patients might not be mediated by classical allergies alone but also result from a type-IV-hypersensitivity.
Ho-Yen DO.		Cognitive behaviour therapy for the chronic fatigue syndrome. Patients' beliefs about their illness were probably not a major factor.	BMJ 1996 Apr 27;312(7038):1097-8 comment on: BMJ. 1996 Jan 6;312(7022):22-6

Hotopf M, Noah N, Wessely S.	Institute of Psychiatry, Denmark Hill, London, UK.	Chronic fatigue and minor psychiatric morbidity after viral meningitis: a controlled study.	J Neurol Neurosurg Psychiatry 1996 May;60(5):504-9	OBJECTIVE--To test the hypotheses that patients exposed to viral meningitis would be at an increased risk of developing chronic fatigue syndrome and would have an excess of neurological symptoms and physical impairment. METHODS--Eighty three patients were followed up 6-24 months after viral meningitis and a postal questionnaire was used to compare outcome with 76 controls who had had non-enteroviral, non-CNS viral infections. RESULTS--For the 159 patients and controls the prevalence of chronic fatigue syndrome was 12.6%, a rate higher than previously reported from primary care attenders, suggesting that moderate

				to severe viral infections may play a part in the aetiology of some fatigue states. Those with a history of meningitis showed a slight, non-significant increase in prevalence of chronic fatigue syndrome (OR 1.4; 95% CI 0.5-3.6) which disappeared when logistic regression and analysis was used to correct for age, sex, and duration of follow up (OR 1.0; 95% CI 0.3-2.8). Controls showed marginally higher psychiatric morbidity measured on the general health questionnaire-12 (adjusted OR 0.6; 95% CI 0.3-1.3) Both groups had similar rates of neurological symptoms and physical impairment. The best predictor of chronic fatigue was a prolonged duration time of off work after the illness (OR 4.93, 95% CI 1.3-18.8). The best predictor of severe chronic fatigue syndrome diagnosed by Center for Disease Control criteria was past psychiatric illness (OR 7.82, 95% CI 1.8-34.3). Duration of viral illness, as defined by days in hospital, did not predict chronic fatigue syndrome. CONCLUSIONS--(1) The prevalence of chronic fatigue syndrome is higher than expected for the range of viral illnesses examined; (2) enteroviral infection is unlikely to be a specific risk factor for its development; (3) onset of chronic fatigue syndrome after a viral infection is predicted by psychiatric morbidity and prolonged convalescence, rather than by the severity of the viral illness itself.
Hyams KC, Wignall FS, Roswell R.	U.S. Naval Medical Research Institute, Rockville, Maryland, USA.	War syndromes and their evaluation: from the U.S. Civil War to the Persian Gulf War.	Ann Intern Med 1996 Sep 1;125(5):398-405	PURPOSE: To better understand the health problems of veterans of the Persian Gulf War by analyzing previous war-related illnesses and identifying possible unifying factors. DATA SOURCE: English-language articles and books on war-related illnesses published since 1863 that were located primarily through a manual search of bibliographies. DATA EXTRACTION: Publications were assessed for information on the clinical characteristics of war-related illnesses and the research methods used to evaluate such illnesses. DATA SYNTHESIS: Poorly understood war syndromes have been associated with armed conflicts at least since the U.S. Civil War. Although these syndromes have been characterized by similar symptoms (fatigue, shortness of breath, headache, sleep disturbance, forgetfulness, and impaired concentration), no single recurring illness that is unrelated to psychological stress is apparent. However, many types of illness were found among evaluated veterans, including well-defined medical and psychiatric conditions, acute combat stress reaction, post-traumatic stress disorder, and possibly the chronic fatigue syndrome. No single disease is apparent, but one unifying factor stands out: A unique population was intensely scrutinized after experiencing an exceptional, life-threatening set of exposures. As a result, research efforts to date have been unable to conclusively show causality, have been subject to reporting bias, and have lacked similar control populations. In addition to research limitations, war syndromes have involved fundamental, unanswered questions about the importance of chronic somatic symptoms and the factors that create a personal sense of ill health.

				CONCLUSION: Until we can better understand what constitutes health and illness in all adult populations, we risk repeated occurrences of unexplained symptoms among veterans after each war.
James LC, Folen RA.	Department of Psychology, Tripler Army Medical Center, Honolulu, USA.	EEG biofeedback as a treatment for chronic fatigue syndrome: a controlled case report.	Behav Med 1996 Summer;22(2):77-81	EEG neurofeedback has been identified as a potential diagnostic and treatment protocol with chronic fatigue syndrome (CFS) symptoms. In the present case study, the authors applied an EEG neurofeedback biofeedback paradigm as a treatment modality with a CFS patient. Baseline data were acquired using the Wechsler Adult Intelligence Scale-Revised and qualitative and subjective ratings of cognitive improvement. Test results and clinical findings revealed improvements in the patient's cognitive abilities, functional skill level, and quality of life. The patient showed significant differences in pre- and posttest levels on the Wechsler scale.
Jason LA, Ferrari JR, Taylor RR, Slavich SP, Stenzel CL.	Department of Psychology, DePaul University, Chicago, IL 60614, USA.	A national assessment of the service, support, and housing preferences by persons with chronic fatigue syndrome. Toward a comprehensive rehabilitation program.	Eval Health Prof 1996 Jun;19(2):194-207	Persons with Chronic Fatigue Syndrome (PWCs) completed and returned by mail a brief survey of open- and closed-ended items designed to assess their utilization and preferences for a variety of services. A total of 984 middle-aged adults diagnosed with Chronic Fatique Syndrome (CFS) from across North America returned the survey. During the past 12 months, many of these PWCs reported utilization of a primary care physician, gynecologist, CFS specialist, and self-help group to assist in their recovery from CFS. Most PWCs believed it was important to educate both health-care practitioners and the general public about CFS. In terms of their desire for specific recovery needs, factor analysis of responses indicated that these PWCs preferred self-help/social support services and general advocacy services in the treatment of their illness. The implications of these results for developing rehabilitation programs for PWCs are discussed.
Johnson SK, DeLuca J, Diamond BJ, Natelson BH.	Chronic Fatigue Syndrome Research Center, Research Department, Kessler Institute for Rehabilitation, West Orange, NJ 07052, USA.	Selective impairment of auditory processing in chronic fatigue syndrome: a comparison with multiple sclerosis and healthy controls.	Percept Mot Skills 1996 Aug;83(1):51-62	The most consistent deficit observed in individuals with Chronic Fatigue Syndrome has been in efficiency of information processing. To examine the possibility of a modality-specific impairment, the present study examined subjects with Chronic Fatigue Syndrome, multiple sclerosis, and healthy controls on an auditory-versus visual-paced serial-addition test. 20 subjects with Chronic Fatigue Syndrome, 20 subjects with clinically definite Multiple Sclerosis, and 20 sedentary healthy controls were compared. One-half of the subjects in each group were administered the Paced Auditory Serial Addition Test and the other half were administered the Paced Visual Serial Addition Test. The group with Chronic Fatigue Syndrome was differentially impaired on the auditory relative to the visual processing task. The group with Multiple Sclerosis was equally impaired on both versions of the task. The results are discussed within the framework of Baddeley's model of working memory.
Johnson SK, DeLuca J, Natelson BH.	Research Department, Kessler Institute for Rehabilitation, West	Assessing somatization disorder in the chronic fatigue syndrome.	Psychosom Med 1996 Jan-Feb;58(1):50-7	This study was conducted to examine the rates of somatization disorder (SD) in the chronic fatigue syndrome (CFS) relative to other fatiguing illness groups. It further addressed the arbitrary nature of the judgments made in assigning

	Orange, N.J. 07052, USA.			psychiatric vs. physical etiology to symptoms in controversial illnesses such as CFS. Patients with CFS (N = 42), multiple sclerosis (MS) (N = 18), and depression (N = 21) were compared with healthy individuals (N = 32) on a structured psychiatric interview. The SD section of the Diagnostic Interview Schedule (DIS) III-R was reanalyzed using different criteria sets to diagnose SD. All subjects received a thorough medical history, physical examination, and DIS interview. CFS patients received diagnostic laboratory testing to rule out other causes of fatigue. This study revealed that changing the attribution of SD symptoms from psychiatric to physical dramatically affected the rates of diagnosing SD in the CFS group. Both the CFS and depressed subjects endorsed a higher percentage of SD symptoms than either the MS or healthy groups, but very few met the strict DSM-III-R criteria for SD. The present study illustrates that the terminology used to interpret the symptoms (ie, psychiatric or physical) will determine which category CFS falls into. The diagnosis of SD is of limited use in populations in which the etiology of the illness has not been established.
Johnson SK, DeLuca J, Natelson BH.	Chronic Fatigue Syndrome Research Center, West Orange, NJ 07052, USA.	Personality dimensions in the chronic fatigue syndrome: a comparison with multiple sclerosis and depression.	J Psychiatr Res 1996 Jan-Feb;30(1):9-20 comment in: J Psychiatr Res. 1996 Jan-Feb;30(1):3-7	This study investigated the relative rates of personality disturbance in chronic fatigue syndrome (CFS). Individuals who met the CDC criteria for CFS were compared to two other fatiguing illness groups, mild multiple sclerosis and depression, as well as sedentary healthy controls. Subjects were administered a structured psychiatric interview to determine Axis I psychiatric disorders and two self-report instruments to assess Axis II personality disorders and the personality trait of neuroticism. The depressed group had significantly more personality disorders and elevated neuroticism scores compared with the other three groups. The CFS and MS subjects had intermediary personality scores which were significantly higher than healthy controls. The CFS group with concurrent depressive disorder (34% of the CFS group) was found to account for most of the personality pathology in the CFS sample. The results are discussed in the context of the relationship between personality variables and fatiguing illness.
Johnson SK, DeLuca J, Natelson BH.	Chronic Fatigue Syndrome Center, University of Medicine and Dentistry of New Jersey--New Jersey Medical School, West Orange, USA.	Depression in fatiguing illness: comparing patients with chronic fatigue syndrome, multiple sclerosis and depression.	J Affect Disord 1996 Jun 20;39(1):21-30	Because depression is commonly observed in the chronic fatigue syndrome (CFS), the present study sought to determine whether the symptom pattern is similar to that seen in clinically depressed subjects (DEP). Individuals with multiple sclerosis (MS) were chosen as an additional comparison group because MS is a fatiguing illness of known organic etiology. The Beck Depression Inventory (BDI) was used to compare categories of depressive symptomatology. Absolute scores on the BDI were higher for the depressed group on mood and self-reproach symptoms, but were not higher than the CFS group on somatic and vegetative items. Analysis of symptoms as a percentage of total BDI score revealed no significant differences in mood or vegetative items among the three groups. The CFS and MS groups exhibited a significantly lower percentage of self-reproach symptoms than DEP, whereas the DEP group showed a lower percentage of somatic symptoms

				than the CFS and MS groups.
Josevic M, Nikolic S, Dulovic O, Jovanovic L, Zerjav S, Radivojevic M.	Dr. Kosta Todorovitsh Institute of Infectious and Tropical Diseases, Belgrade.	[Neural manifestations in Lyme disease (Lyme borreliosis of the nervous system)].[article in Serbo-Croatian (Cyrillic)]	Srp Arh Celok Lek 1996 Mar-Apr;124(3-4):87-92	The involvement of the nervous system is common during Lyme's disease, and the term neuroborreliosis has been established. All structures of the nervous system, from meninges to periferial nerves, can be involved. Neurological manifestations are most common in the second stage (dissemination). The article deals with the most important neurological manifestations, as well as with the contemporary pathogenetic considerations and therapy. Eleven patients with neuroborreliosis who were treated at Dr. Kosta Todorovitsh Institute of Infectious and Tropical Diseases, are reviewed. Five of them had acute meningoencephalitis, of whom two had concurrent neuritis; one patient had Banawart's syndrome with arthralgias, arthritis and fatigue syndrome; two patients had neuritis; one had bilateral facial palsy; two had chronic fatigue syndrome.
Joyce E, Blumenthal S, Wessely S.	Academic Department of Psychiatry, Charing Cross and Westminster Medical School, London, UK.	Memory, attention, and executive function in chronic fatigue syndrome.	J Neurol Neurosurg Psychiatry 1996 May;60(5):495-503	OBJECTIVES--To examine cognitive function in chronic fatigue syndrome. METHODS--Twenty patients with chronic fatigue syndrome recruited from primary care and 20 matched normal controls were given CANTAB computerised tests of visuospatial memory, attention, and executive function, and verbal tests of letter and category fluency and word association learning. RESULTS: Patients with chronic fatigue syndrome were impaired, predominantly in the domain of memory but their pattern of performance was unlike that of patients with amnesic syndrome or dementia. They were normal on tests of spatial pattern recognition memory, simultaneous and delayed matching to sample, and pattern-location association learning. They were impaired on tests of spatial span, spatial working memory, and a selective reminding condition of the pattern-location association learning test. An executive test of planning was normal. In an attentional test, eight subjects with chronic fatigue syndrome were unable to learn a response set; the remainder exhibited no impairment in the executive set shifting phase of the test. Patients with chronic fatigue syndrome were also impaired on verbal tests of unrelated word association learning and letter fluency. CONCLUSION--Patients with chronic fatigue syndrome have reduced attentional capacity resulting in impaired performance on effortful tasks requiring planned or self ordered generation of responses from memory.

Kodama M, Kodama T, Murakami M.	Kodama Research Institute of Preventive Medicine, Nagoya, Japan.	The value of the dehydroepiandrosterone-annexed vitamin C infusion treatment in the clinical control of chronic fatigue syndrome (CFS). I. A Pilot study of the new vitamin C infusion treatment with a volunteer CFS patient.	In Vivo 1996 Nov-Dec;10(6):575-84	A series of publications from our laboratory have indicated that the practice of megadose vitamin C drip infusion treatment enhanced the activity of endogenous glucocorticoids in such a way as to improve the clinical course of allergy and autoimmune disease-a disease entity that is known to respond to the therapeutic effect of glucocorticoids. The present paper represents an extention of our vitamin C studies, and intends to investigate the problem whether or not chronic fatigue syndrome (CFS), an acquired immunodeficiency disease, can also be counted as one of the candidate diseases for the vitamin C infusion treatment. We prepared two kinds of vitamin C infusion sets for the clinical use: the dehydroepiandrosterone-annexed vitamin C infusion set (the new set) and the annex-free vitamin C infusion set (the old set). The new set was expected to enhance the endogenous activities of both glucocorticoids and gonadal steroids. We followed the clinical course of a male CFS patient using the old and new vitamin C infusion sets, and with and without the oral intake of erythromycin and chloramphenico. Results obtained are as follows: a) the observation period of a study subject covered a period of August 1995 to May 1996. Combination of pneumonia signs and dermatomyositis signs marked the onset of his CFS. b) Old infusion treatment together with the short term antibiotics treatment was found effective for the control of pneumonia in the first stage of the disease (from August to October, 1995). c) Signs of pneumonia recurrence gradually became eminent in the second stage of disease (from November, 1995, to January, 1996) in spite of the moderate frequency of the old treatment together with stepwise prolongation of the antibiotics treatment. d) The alternate practice of the old and new infusion treatments together with the long-term antibiotics treatment, as conducted in the 3rd stage of disease (from February to May, 1996) led to substantial extinction of pneumonia signs (leucocytosis, tachycardia etc). e) The practice of the new infusion treatment markedly increased the excretion of both 17-ketosteroids and 17-hydroxycorticosteroids in the urine. Evidence was also available to indicate that the dehydroepiandrosterone annex was converted to testosterone, which in turn made a contribution to the control of CFS. f) The immunological survey of lymphocyte subsets including NK cell percent failed to

				find a coherent change in a study subject with CFS. In conclusion, the above results could be taken as evidence to indicate that the new vitamin C infusion treatment effectuates the clinical control of CFS by fortifying the endogenous activities of both cortisol and testosterone. The significance of parallelism between pulmonary infection and CFS, as observed in the clinical course of the test subject, was discussed in the light of the focal infection theory of nephritis.
Kodama M, Kodama T, Murakami M.	Kodama Research Institute of Preventive Medicine, Nagoya, Japan.	The value of the dehydroepiandrosterone-annexed vitamin C infusion treatment in the clinical control of chronic fatigue syndrome (CFS). II. Characterization of CFS patients with special reference to their response to a new vitamin C infusion treatment.	In Vivo 1996 Nov-Dec;10(6):585-96	This study is a counterpart of the pilot study on the clinical management of chronic fatigue syndrome (CFS) by the combined use of the old (annex-free) and the new (dehydro-epiandrosterone- annexed) vitamin C infusion treatments with and without oral intake of erythromycin and chloramphenicol. We were motivated to start this clinical study by 2 reasons: i) we have made a success in the clinical management of autoimmune disease and allergy by use of the old megadose vitamin C infusion treatment, and we therefore took up CFS as a good candidate for vitamin C infusion treatment; ii) In 1995, we received a total of 313 chronic pneumonia patients whose clinical course showed a good fitness to the criteria of CFS. We assessed the nature of the disease by investigating the clinicoepidemiological aspect of our patients on the one hand and the response of the disease to both the old and new vitamin C infusion treatments with and without the use of 2 antibiotics on the other hand. Results are summarized as follows: a) the analysis of the medical records of our outpatients revealed that chronic type pneumonia epidemic in Nagoya Japan, with its onset of January 1995, showed no sign of its extinction by the end of May 1996. The patient population contained no patients under 15 years of age, and showed a distinct female predominance in the patient number (207 females versus 106 males). In 1995, we also experienced a simple cold epidemic with its onset of January 1995 (162 males and 224 females). The majority of simple cold patients were under 25 years of age in both sexes. b) A chronic type pneumonia patient was distinguished from a simple cold patient in 2 respects: firstly the former required prolonged medical care (over 1 month) resulting in an incomplete cure and return to medical care upon the recurrence of disease, whereas the latter required short-term medical care (mostly within 1 week) ending up with complete cure. Secondly, the former required the long term use of 2 antibiotics (erythromycin and chloramphenicol) together with regular practice of the old and new vitamin C infusion treatments for disease control, whereas the latter recovered from the disease after the short time use of a set of conventional cold remedies. c) The clinical manifestations of our chronic pneumonia patients showed good fitness to the criteria of CFS. d) CFS was distinguished from autoimmune disease-allergy complex by the method of clinical control: the former required the long-term use of 2 antibiotics together with regular practice of the old and new vitamin C infusion treatments, whereas the latter was

				controllable by the single use of the old vitamin C infusion treatment. e) The combined use of the old and new vitamin C infusion treatments rather than the single use of the old vitamin C infusion treatment was more effective for the control of CFS-a finding which suggests that deficient activities of both endogenous glucocorticoid and endogenous androgen in a CFS patient are somehow related to the genesis and further development of CFS. f) Evidence was available to indicate that the sole use of the new vitamin C infusion treatment may induce a state of gonadal steroid excess together with various other problems in the recipient. The maintenance of a good balance between the old vitamin C infusion set (glucocorticoid-inducer) and the new vitamin C infusion set (inducer of both glucocorticoid and gonadal steroids) in their use was of prime importance for the successful control of CFS. g) The historical significance of CFS epidemic in 1995, and in Nagoya-Japan, is discussed in the light of the new infection concept.
Komaroff AL, Fagioli LR, Doolittle TH, Gandek B, Gleit MA, Guerriero RT, Kornish RJ 2nd, Ware NC, Ware JE Jr, Bates DW.	Department of Medicine, Brigham and Women's Hospital, Boston, Massachusetts 02115, USA.	Health status in patients with chronic fatigue syndrome and in general population and disease comparison groups.	Am J Med 1996 Sep;101(3):281-90	PURPOSE: To measure the functional status and well-being of patients with chronic fatigue syndrome (CFS), and compare them with those of a general population group and six disease comparison groups. PATIENTS AND METHODS: The subjects of the study were patients with CFS (n = 223) from a CFS clinic, a population-based control sample (n = 2,474), and disease comparison groups with hypertension (n = 2,089), congestive heart failure (n = 216), type II diabetes mellitus (n = 163), acute myocardial infarction (n = 107), multiple sclerosis (n = 25), and depression (n = 502). We measured functional status and well-being using the Medical Outcomes Study 36-Item Short-Form Health Survey (SF-36), which is a self-administered questionnaire in which lower scores are indicative of greater impairment. RESULTS: Patients with CFS had far lower mean scores than the general population control subjects on all eight SF-36 scales. They also scored significantly lower than patients in all the disease comparison groups other than depression on virtually all the scales. When compared with patients with depression, they scored significantly lower on all the scales except for scales measuring mental health and role disability due to emotional problems, on which they scored significantly higher. The two SF-36 scales reflecting mental health were not correlated with any of the symptoms of CFS except for irritability and depression. CONCLUSION: Patients with CFS had marked impairment, in comparison with the general population and disease comparison groups. Moreover, the degree and pattern of impairment was different from that seen in patients with depression.
Komaroff AL, Fagioli LR, Geiger AM, Doolittle TH, Lee J, Kornish RJ, Gleit MA, Guerriero RT.	Department of Medicine, Brigham and Women's Hospital, Boston, Massachusetts	An examination of the working case definition of chronic fatigue syndrome.	Am J Med 1996 Jan;100(1):56-64	PURPOSE: Chronic fatigue syndrome (CFS) currently is defined by a working case definition developed under the leadership of the United States Centers for Disease Control and Prevention (CDC) based on a consensus among experienced clinicians. We analyzed the experience from one large center to examine the

	02115, USA.			adequacy of the case definition. PATIENTS AND METHODS: Predefined clinical and laboratory data were collected prospectively from 369 patients with debilitating fatigue, of whom 281 (76%) met the major criteria of the original CDC case definition for CFS: (1) fatigue of at least 6 months' duration, seriously interfering with the patient's life; and (2) without evidence of various organic or psychiatric illnesses that can produce chronic fatigue. The same clinical data were obtained from 311 healthy control subjects and two comparison groups with diseases that can present in a similar fashion; relapsing-remitting multiple sclerosis (n = 25) and major depression (n = 19). RESULTS: All of the minor criteria symptoms from the original CDC case definition distinguished patients with debilitating chronic fatigue from healthy control subjects, and many distinguished the patients with chronic fatigue from the comparison groups with multiple sclerosis and depression: myalgias, postexertional malaise, headaches, and a group of infectious-type symptoms (ie, chronic fever and chills, sore throat, swollen glands in the neck or underarm areas). In addition, two other symptoms not currently part of the case definition discriminated the chronic fatigue patients from the control/comparison groups: anorexia and nausea. Physical examination criteria only infrequently contributed to the diagnosis. Patients meeting the CDC major criteria for CFS also met the minor criteria in 91% of cases. CONCLUSION: Patients meeting the major criteria of the current CDC working case definition of CFS reported symptoms that were clearly distinguishable from the experience of healthy control subjects and from disease comparison groups with multiple sclerosis and depression. Eliminating three symptoms (ie, muscle weakness, arthralgias, and sleep disturbance) and adding two others (ie, anorexia and nausea) would appear to strengthen the CDC case definition of CFS.
Konstantinov K, von Mikecz A, Buchwald D, Jones J, Gerace L, Tan EM.	Autoimmune Disease Center and Department of Cell Biology, The Scripps Research Institute, La Jolla, California 92037, USA.	Autoantibodies to nuclear envelope antigens in chronic fatigue syndrome.	J Clin Invest 1996 Oct 15;98(8):1888-96	We have identified and partially characterized the autoantibodies in sera of 60 patients with chronic fatigue syndrome. Approximately 52% of the sera were found to react with nuclear envelope antigens. The combination of nuclear rim staining observed in immunofluorescence microscopy and immunoblot analysis of highly purified nuclear envelope proteins provided initial characterization of these autoantibodies. Further characterization showed that some sera immunoprecipitated the in vitro transcription and translation product of a human cDNA clone encoding the nuclear envelope protein lamin B1. The autoantibodies were of the IgG isotype. The occurrence of autoantibodies to a conserved intracellular protein like lamin B1 provides new laboratory evidence for an autoimmune component in chronic fatigue syndrome.

Lawrie SM.		Cognitive behaviour therapy for the chronic fatigue syndrome. Essential elements of the treatment must be identified.	BMJ 1996 Apr 27;312(7038):1097; discussion 1098 comment on: BMJ. 1996 Jan 6;312(7022):22-6	
Leese G, Chattington P, Fraser W, Vora J, Edwards R, Williams G.	Department of Medicine, University of Liverpool, United Kingdom.	Short-term night-shift working mimics the pituitary-adrenocortical dysfunction in chronic fatigue syndrome.	J Clin Endocrinol Metab 1996 May;81(5):1867-70	The purpose of this study was to determine whether a short period (5 days) of night-shift work affected the pituitary-adrenal responses to CRH. Ten nurses (8 female and 2 male; age 28.1 +/- 1.7 yr: mean +/- SEM) working at the Royal Liverpool University Hospital, and who regularly undertook periods of night and day shift work were enrolled. Measurements were made of basal ACTH and cortisol concentrations, and their responses to iv ovine CRH (1 microgram.kg-1). Basal ACTH concentrations were higher during the night shift than during the day shift (12.9 +/- 5.1 pmol.L-1 vs. 4.7 +/- 1.2 pmol.L-1, P < 0.01) whereas cortisol concentrations were lower (551 +/- 48 nmol.L - 1 vs. 871 +/- 132 nmol.L - 1, P < 0.01). After CRH injection, ACTH concentrations remained consistently higher during the night shift, but the integrated increase in ACTH concentration was lower (P < 0.05) than during the day shift. Conversely, the increase in cortisol concentration was greater during the night shift than the day shift (283 +/- 53 nmol.L-1 vs. 134 +/- 41 nmol.L-1, P < 0.05). We conclude that the pituitary-adrenal responses to CRH are markedly disrupted after only 5 days of nighttime work. These abnormalities mimic those previously observed in patients with chronic fatigue syndrome. Neuroendocrine abnormalities reported to be characteristic of chronic fatigue syndrome may be merely the consequence of disrupted sleep and social routine.
Lemke MR.	Psychiatrische Klinik, Klinikum Ingolstadt.	[Chronic fatigue syndrome--psychiatric aspects].[article in German]	Fortschr Neurol Psychiatr 1996 Apr;64(4):132-41	Diagnosis of the chronic fatigue syndrome depends on various somatic and psychopathological symptoms. Somatic symptoms of the syndrome have been subject of an extensive body of literature. In comparison, psychiatric aspects have caught relatively less attention. Psychiatric aspects of etiological, diagnostic, and therapeutic concepts are essential for evaluation of the syndrome. Application of CDC-criteria to a well known disease does not solve the nosological problem, but may define the syndrome more accurately. In this respect, issues including psychiatric comorbidity and specificity of neuropathological symptoms are discussed. Psychological variables seem to have a high predictor value for time course and outcome of the symptoms. Etiological concepts emphasize on biological or psychosocial factors. Alterations of biological parameters including immune functions, sleep regulation, and hypothalamic-pituary-adrenocortical function have been reported. The role of cultural factors has been discussed extensively. Somatic and psychological stress may result in the same clinical

				syndrome via psychoimmunological mechanisms. An integrated, interdisciplinary approach to further refine diagnostic criteria, understanding of etiology and development of adequate therapeutic measures seems necessary.
Levine PH		The Elusive Gulf War Syndrome	Journal of Chronic Fatigue Syndrome 1996: 2(2/3): 55 - 63	In 1990/1991, approximately 697,000 U.S. service members joined coalition forces in the Middle East for Operations Desert Shield and Desert Storm (ODS/S). Following the military action, a number of service men and women reported a variety of signs and symptoms which they attributed to their participation in the operation; the term Gulf War Syndrome was proposed to facilitate evaluation of what was perceived as a possible new entity. Subsequent studies failed to identify a discrete syndrome, and a series of reports have raised questions as to whether or not Gulf War Syndrome exists or if indeed any of the reported disorders can be attributed to participation in ODS/S. This report reviews the history of U.S. participation in the Gulf War, the medical threats and exposures considered by the U.S. Armed Services, and the U.S. Government's approach to investigating the complaints of the returning servicemen. In the context of the reports from non-U.S. veterans with similar complaints, the elusive Gulf War Syndrome is an important unresolved issue that could provide a model for a number of disorders, including chronic fatigue syndrome.

A cluster of cases of chronic fatigue and chronic fatigue syndrome: clinical and immunologic studies.	Clin Infect Dis 1996 Aug;23(2):408-9	
Levine PH.	Viral Epidemiology Branch, National Cancer Institute, Bethesda, MD, USA.	The use of transfer factors in chronic fatigue syndrome: prospects and problems.	Biotherapy 1996;9(1-3):77-9	Chronic fatigue syndrome (CFS) is a heterogeneous disorder characterized by severe prolonged unexplained fatigue and a variety of associated symptoms such as arthralgias, myalgias, cognitive dysfunction, and severe sleep disturbances. Many patients initially present with an acute onset of apparent infectious origin with either an upper respiratory or gastrointestinal illness, fever, chills, tender lymphadenopathy, and malaise suggestive of a flu-like illness. In some cases, specific viral infections can be identified at the outset, particularly herpes viruses such as Epstein-Barr virus (EBV), human herpes virus-6 (HHV-6), and cytomegalovirus (CMV). Transfer factors (TF) with specific activity against these herpes viruses has been documented. With some studies suggesting that persistent viral activity may play a role in perpetuation of CFS symptoms, there appears to be a rationale for the use of TF in patients with CFS and recent reports have suggested that transfer factor may play a beneficial role in this disorder. This report focuses on the heterogeneity of CFS, the necessity for randomized coded studies, the importance of patient selection and sub-classification in

				clinical trials, and the need to utilize specific end-points for determining efficacy of treatment.
Lieb K, Dammann G, Berger M, Bauer J.	Universitatsklinik fur Psychiatrie und Psychosomatik, Universitat, Freiburg.	[Chronic fatigue syndrome. Definition, diagnostic measures and therapeutic possibilities].[article in German]	Nervenarzt 1996 Sep;67(9):711-20 comment in: Nervenarzt. 1997 Nov;69(11):924-5	This article reviews the chronic fatigue syndrome (CFS), a disorder whose etiology is unknown. The diagnostic criteria proposed in 1994 by the CDC and the International Chronic Fatigue Syndrome Study Group are introduced. In contrast to widespread belief, there are no laboratory tests available to underpin the diagnosis of CFS; the diagnosis is made solely on the basis of clinical criteria. In the differential diagnosis, the exclusion of other conditions that can cause chronic fatigue, such as neuropsychiatric or sleep disorders, is of critical importance. In this context, the question as to whether CFS is a clinical entity that can be differentiated from psychiatric diagnoses, such as depression, somatoform disorder, or neurasthenia, is discussed. At the moment, there is no specific therapy for CFS. Therefore, therapeutic approaches are limited to symptomatic management of the concomitant sleep disturbances, pain, or psychiatric symptoms, such as depression. Patients may benefit from cognitive behavioral therapy, as this may help then to identify and exclude factors contributing to and maintaining chronic fatigue. An integrated medical and psychological approach should be adopted, with the aim of preventing significant secondary negative results of the illness, such as interpersonal conflicts or chronic disability.

Lindh G, Samuelson A, Hedlund KO, Evengard B, Lindquist L, Ehrnst A.	Division of Infectious Diseases, Huddinge University Hospital, Karolinska Institutet, Stockholm, Sweden.	No findings of enteroviruses in Swedish patients with chronic fatigue syndrome.	Scand J Infect Dis 1996;28(3):305-7	Enteroviruses have been proposed to cause an immune complex disease in the chronic fatigue syndrome. Altogether 34 patients with the chronic fatigue syndrome, according to criteria of the Centers for Disease Control, USA, were studied evenly over the seasons for the possible presence of a chronic enterovirus infection. In 11 patients, 1-5 faecal samples were collected at about 6 month intervals for virus isolation before and after acid treatment, followed by ultracetrifugation at pH 3 to dissolve possible enterovirus-antibody complexes. Another 14 fecal samples were subjected to routine virus isolation alone. Seven pairs of serum-cerebrospinal fluid samples were analysed for cross-reactive IgG antibody activity to enteroviruses. In 29 patients a muscle biopsy was collected for enterovirus polymerase chain reaction (PCR). We were unable to identify enteroviruses in any of these samples by any of these techniques. Our study does not confirm evidence for persistent enterovirus infection in the chronic fatigue syndrome.
Lohmann K, Prohl A,	Schleswig, Christian-	[Multiple chemical	Gesundheitswesen 1996	The data of 466 subjects suffering from neurologic disorders which are suggested

Schwarz E.	Albrechts-Universitat, Kiel.	sensitivity disorder in patients with neurotoxic illnesses].[article in German]	Jun;58(6):322-31 comment in: Gesundheitswesen. 1997 Jan;59(1):56	to be caused by neurotoxic agents in their environment retrospectively was evaluated and documented. Among these cases there were 151 subjects with symptoms of Multiple Chemical Sensitivity Disorder (MCSD). The relationship between the neurological health impairments and neurotoxic agents in the environment of these patients was characterised using five different categories (probable = A, possible = B, uncertain = C, unclarified = D, not probable = E). From the 466 patients 320 subjects (69%) could be assigned to the categories A and B, respectively. Within theses 320 cases with chronic neurotoxic health impairments 136 subjects (79 females and 57 males) showed signs of MCSD. Age and gender of cases as well as duration and character of exposure to neurotoxic substances retrospectively were assessed from the explicit files of the patients, which had been made anonymous for this purpose. Frequency of characteristic symptoms of neurotoxicity were analysed. Results are given for patients with neurotoxic health impairments with MCSD (n = 136) and without MCSD (n = 184). Neurotoxic substances which were used as indoor wood preservatives (mainly Pentachlorophenol and/or Lindane) were found to be the causative agents in 63% of the cases with neurotoxic health impairments and MCSD. Other important neurotoxic substances to which the patients were mainly exposed were organic solvents (25%), formaldehyde (15%), dental materials (15%), pyrethroides (13%), and other biocides (19%) (multiple exposures were possible). The time of exposure was calculated as being > or = 10 years for 55% of the patients with MCSD and for 50% of the group with neurotoxic health impairments but without MCSD. Out of the 184 cases with neurotoxic health impairments but without MCSD there were 22%, and out of the 136 cases with MCSD there were 39% who showed all symptoms of chronic fatigue syndrome. 53% of the cases with MCSD had an allergic disposition compared to only 20% of the cases without MCSD. This work is not a controlled epidemiological study but a retrospective documentation and evaluation of data related to environmental medicine. With the present documentation in this purely descriptive manner the proof of a causal relationship was not possible or intended. But because corresponding epidemiological studies are lacking, this documentation can give important information on characteristic features of Multiple Chemical Sensitivity Disorder and chronic neurotoxic health impairments. Such information is essential for planning and carrying out epidemiological studies urgently needed in this field.
Lynch S, Seth R.		Fluoxetine and chronic fatigue syndrome.	Lancet 1996 Jun 22;347(9017):1771; discussion 1171-2	
MacDonald KL, Osterholm MT, LeDell	Minnesota Department of Health, Minneapolis,	A case-control study to assess possible triggers	Am J Med 1996 May;100(5):548-54	PURPOSE: To assess possible triggers and cofactors for chronic fatigue syndrome (CFS) and to compare levels of selected cytokines between cases and an

KH, White KE, Schenck CH, Chao CC, Persing DH, Johnson RC, Barker JM, Peterson PK.	55440-9441, USA.	and cofactors in chronic fatigue syndrome.	Comment in: Am J Med. 1997 Apr;102(4):422-3	appropriately matched control group. PATIENTS AND METHODS: We conducted a case-control study of 47 cases of CFS obtained through a regional CFS research program maintained at a tertiary care medical center. One age-, gender-, and neighborhood-matched control was identified for each case through systematic community telephone sampling. Standardized questionnaires were administered to cases and controls. Sera were assayed for transforming growth factor-beta (TGF-beta), interleukin-1 beta, interleukin-6, tumor necrosis factor-alpha, and antibody to Borrelia burgdorferi and Babesia microti. RESULTS: Cases were more likely to have exercised regularly before illness onset than controls (67% versus 40%; matched odds ratio (MOR) = 3.4; 95% CI = 1.2 to 11.8; P = 0.02). Female cases were more likely to be nulliparous prior to onset of CFS than controls (51% versus 31%; MOR = 8.0; 95% CI = 1.03 to 170; P = 0.05). History of other major factors, including silicone-gel breast implants (one female case and one female control), pre-morbid history of depression (15% of cases, 11% of controls) and history of allergies (66% of cases, 51% of controls) were similar for cases and controls. However, cases were more likely to have a diagnosis of depression subsequent to their diagnosis of CFS compared to a similar time frame for controls (MOR = undefined; 95% CI lower bound = 2.5; P < 0.001). Positive antibody titers to B burgdorferi (one case and one control) and B microti (zero cases and two controls) were also similar. CONCLUSIONS: Further investigation into the role of prior routine exercise as a cofactor for CFS is warranted. This study supports the concurrence of CFS and depression, although pre-morbid history of depression was similar for both groups.
MacFarlane JG, Shahal B, Mously C, Moldofsky H.	University of Toronto, Centre for Sleep and Chronobiology, Toronto Hospital (Western Division), Ontario, Canada.	Periodic K-alpha sleep EEG activity and periodic limb movements during sleep: comparisons of clinical features and sleep parameters.	Sleep 1996 Apr;19(3):200-4	The K-alpha sleep electroencephalographic (EEG) phenomenon is characterized by periodic (approximately 20-40 seconds) K-complexes, immediately followed by alpha-EEG activity (7.5-11 Hz) of 0.5- to 5.0-second duration. A group of 14 subjects with the periodic K-alpha anomaly was found to have a similar distribution pattern of interevent intervals as compared with previously published data for sleep-related periodic limb movements during sleep (PLMS). Sleep parameters and somatic symptoms of 30 patients with K-alpha were compared with 30 patients with PLMS. The periodic K-alpha group was predominantly female, younger, exhibiting more slow-wave sleep, gastrointestinal symptoms and muscular complaints and fewer movement arousals on overnight polysomnography. The K-alpha group presented uniformly with complaints of unrefreshing sleep, often associated with fibromyalgia and chronic fatigue syndrome. The PLMS group was predominantly male, showed greater sleep disruption and presented with a variety of sleep-related symptoms.
Manu P, Affleck G, Tennen H, Morse PA, Escobar JI.	Department of Psychiatry, Long Island Jewish Medical Center,	Hypochondriasis influences quality-of-life outcomes in patients	Psychother Psychosom 1996 Mar-Apr;65(2):76-81	BACKGROUND: To determine how hypochondriacal symptoms influence the quality-of-life outcomes of patients with a chief complaint of chronic fatigue. METHODS: Cross-sectional cohort study of a consecutive sample of 71 patients

	New Hyde Park, N.Y., USA.	with chronic fatigue.		(mean duration of fatigue of 4.1 years). Forty-eight (68%) patients met criteria for current major depression and 32 (45%) met criteria for chronic fatigue syndrome (CFS). All patients received a comprehensive medical and psychiatric evaluation. Quality-of-life and physical, depressive and hypochondriacal symptom scores were assessed through reliable self-report questionnaires and a structured interview. A path model expressing the relation between predictor variables (hypochondriasis and depression), intervening variables (physical symptoms) and quality of life was postulated and evaluated using structural equation methods. RESULTS: The paths linking hypochondriasis with physical symptoms and mental health and the path connecting physical symptoms and quality of life were each statistically significant. The model applied especially well to patients who fulfilled CFS criteria. CONCLUSIONS: The quality of life of chronic fatigue patients correlates with the severity of their physical symptoms and their hypochondriacal disposition toward illness.
Marcel B, Komaroff AL, Fagioli LR, Kornish RJ 2nd, Albert MS.	Department of Psychiatry, Massachusetts General Hospital, Charlestown, MA 02129, USA.	Cognitive deficits in patients with chronic fatigue syndrome.	Biol Psychiatry 1996 Sep 15;40(6):535-41	Twenty-nine subjects with chronic fatigue syndrome (CFS) and 25 healthy control subjects were administered a lengthy neuropsychological battery that included standard neuropsychological tests and a computerized set of tasks that spanned the same areas of ability. The primary significant differences between patients and controls were found on tests of learning and memory. These differences remained when the degree of psychiatric symptomatology in the subjects was covaried. Patients on and off psychoactive medications did not differ in their performance on these tasks. These results suggest that at least a subset of CFS patients may experience significant impairments in learning and memory.
Marsh S, Kaplan M, Asano Y, Hoekzema D, Komaroff AL, Whitman JE Jr, Ablashi DV.	Advanced Biotechnologies Inc, Columbia, MD 21046, USA.	Development and application of HHV-6 antigen capture assay for the detection of HHV-6 infections.	J Virol Methods 1996 Sep;61(1-2):103-12	An HHV-6 antigen capture assay measuring gp116/64/54 antigen was developed. This ELISA is specific for HHV-6 Variants A and B, does not cross react with other human herpesviruses, is sensitive, stable, quantitative, and can detect antigen in body fluids and cell cultures. Relative to virus isolation or techniques for measuring HHV-6 nucleic acids, the assay is much simpler and less expensive to perform. Plasmas/sera (413) obtained from healthy donors, children with Exanthem subitum, febrile illnesses, patients with Chronic Fatigue Syndrome, and AIDS patients tested by antigen capture assay demonstrated that the assay is useful in clinical laboratory settings. The capture assay can also be used to monitor cell cultures for virus isolation, production, quantitation, and antiviral agent screening.
Marshall PS, Watson D, Steinberg P, Cornblatt B, Peterson PK, Callies A, Schenck CH.	Department of Psychiatry, Hennepin County Medical Center, Minneapolis, MN 55415, USA.	An assessment of cognitive function and mood in chronic fatigue syndrome.	Biol Psychiatry 1996 Feb 1;39(3):199-206	Data were gathered regarding the associates of chronic fatigue syndrome (CFS) with: (1) speed of cognitive processing, (2) motor speed, (3) ability to sustain attention, and (4) mood. Patients were given a brief neuropsychological test battery before and after double-blind treatment with terfenadine or placebo and completed a daily mood rating scale (Positive and Negative Affect Schedule) during the study. CFS patients exhibited slower cognitive processing and motor

				speed and lower positive affect, as compared to data reported from previous studies of healthy subjects and other patient groups; however, CFS patients did not exhibit deficits in sustained attention in comparison to other groups. The CFS patients' ability to attend to verbal versus figural stimuli and mood ratings were different from those reported in studies of patients with depression. Because of methodological limitations, these findings are preliminary, but they encourage further assessment of cognitive dysfunction and mood in CFS.
Martin WJ.	Center for Complex Infectious Diseases, Rosemead, Calif 91770, USA.	Severe stealth virus encephalopathy following chronic-fatigue-syndrome-like illness: clinical and histopathological features.	Pathobiology 1996;64(1):1-8	The clinical histories and brain biopsy findings of 3 patients with severe stealth virus encephalopathy are reviewed. The patients initially developed symptoms consistent with a chronic fatigue syndrome. One patient has remained in a vegetative state for several years, while the other 2 patients have shown significant, although incomplete, recovery. Histological and electron-microscopic studies revealed vacuolated cells with distorted nuclei and various cytoplasmic inclusions suggestive of incomplete viral expression. There was no significant inflammatory response. Viral cultures provided further evidence of stealth viral infections occurring in these patients.
Martin WJ.	Center for Complex Infectious Diseases, Rosemead, Calif 91770, USA.	Genetic instability and fragmentation of a stealth viral genome.	Pathobiology 1996;64(1):9-17	Partial sequencing was performed on cloned DNA obtained from cultures of a stealth virus isolated from a patient with the chronic fatigue syndrome. The results extend earlier findings showing regions of homology to cytomegalovirus (CMV). Although the virus is much more closely related to simian CMV than to human CMV, many of the cloned viral segments could be aligned with the human CMV genome. The aggregate size of the aligned segments exceeds 100 kilobase pairs (kbp). Undigested viral DNA has a mobility in agarose gel electrophoresis corresponding to approximately 20 kbp. The virus, therefore, apparently exists in multiple fragments. Considerable sequence variation exists between individual clones which overlap to similar regions of the human CMV genome. The fragmented genome and sequence microheterogeneity suggest that both the processivity and the fidelity of replication of the viral genome are defective. An unstable viral genome may provide a potential mechanism of recovery from stealth viral illness.
Martin WJ.	Center for Complex Infectious Diseases, Rosemead, CA 91770, USA.	Simian cytomegalovirus-related stealth virus isolated from the cerebrospinal fluid of a patient with bipolar psychosis and acute encephalopathy.	Pathobiology 1996;64(2):64-6	A cytopathic 'stealth' virus was cultured from the cerebrospinal fluid of a patient with a bipolar psychotic disorder who developed a severe encephalopathy leading to a vegetative state. DNA sequencing of a polymerase chain reaction-amplified product from infected cultures has identified the virus as an African green monkey simian cytomegalovirus (SCMV)-related stealth virus. The virus is similar to the SCMV-related stealth virus isolated from a patient with chronic fatigue syndrome. The findings support the concepts that stealth viruses can account for a spectrum of dysfunctional brain diseases and that some of these viruses may have arisen from live polio viral vaccines.

		syndrome.	16;348(9038):1384-5 comment in: Lancet. 1997 Jan 4;349(9044):57-8 comment on: Lancet. 1996 Oct 12;348(9033):971	
McArdle A, McArdle F, Jackson MJ, Page SF, Fahal I, Edwards RH.	Department of Medicine, University of Liverpool, U.K.	Investigation by polymerase chain reaction of enteroviral infection in patients with chronic fatigue syndrome.	Clin Sci (Colch) 1996 Apr;90(4):295-300	1. Chronic fatigue syndrome is characterized by muscle fatigue and pain at rest, symptoms which are usually exacerbated with exercise. Although various studies have shown minor, non-specific morphological and biochemical changes in muscle of patients with chronic fatigue syndrome, no consistent defect has been identified. Some have suggested that an enteroviral infection in muscle may cause the chronic muscle fatigue seen in patients with chronic fatigue syndrome, with acute infection directly and irreversibly impairing mitochondrial function, and persistent infection depressing muscle protein synthesis and metabolism. 2. To clarify the involvement of enterovirus infection in chronic fatigue syndrome, muscle biopsies from a group of patients with chronic fatigue syndrome were examined for the presence of enteroviral RNA by reverse transcriptase-polymerase chain reaction techniques in relation to functional studies of muscle mitochondria and the muscle RNA/DNA ratio. 3. Fifty-eight percent of patients reported an uncharacterized 'viral infection' before the onset of their illness, but none of the muscle samples from 34 patients contained detectable amounts of enteroviral RNA. Muscle tissue had a general reduction in the RNA/DNA ratio and mitochondrial enzyme activities with no specific abnormality in the activity of enzymes encoded partially on the mitochondrial genome (cytochrome-c oxidase) or nuclear genome (citrate synthase, succinate reductase). 4. These data provide no evidence of an enteroviral infection in muscle of patients with chronic fatigue syndrome, although this does not exclude a role of enterovirus in initiating the disease process. The general reduction in RNA/DNA ratio and mitochondrial enzyme activities is consistent with a general reduction in habitual activity.
McCully KK, Natelson BH, Iotti S, Sisto S, Leigh JS Jr.	Department of Medicine, Medical College of Pennsylvania, Philadelphia 19131, USA.	Reduced oxidative muscle metabolism in chronic fatigue syndrome.	Muscle Nerve 1996 May;19(5):621-5 comment in: Muscle Nerve. 1997 Jun;20(6):765-6	The purpose of this study was to determine if chronic fatigue syndrome (CSF) is characterized by abnormalities in oxidative muscle metabolism. Patients with CFS according to Centers for Disease Control (CDC) criteria (n = 22) were compared to normal sedentary subjects (n = 15). CFS patients were also tested before and 2 days after a maximal treadmill test. Muscle oxidative capacity was measured as the maximal rate of postexercise phosphocreatine (PCr) resynthesis using the ADP model (Vmax) in the calf muscles using 31P magnetic resonance spectroscopy. Vmax was significantly reduced in CFS patients (39.6 +/- 2.8 mmol/L/min, mean +/- SE) compared to controls (53.8 +/- 2.8 mmol/L/min). Two days postexercise there was no change in resting inorganic phosphate (Pi)/PCr or

				Vmax in the CFS patients (n = 14). In conclusion, oxidative metabolism is reduced in CFS patients compared to sedentary controls. In addition, a single bout of strenuous exercise did not cause a further reduction in oxidative metabolism, or alter resting Pi/PCr ratios.
McCully KK, Sisto SA, Natelson BH.	Department of Medicine, Medical College of Pennsylvania, USA.	Use of exercise for treatment of chronic fatigue syndrome.	Sports Med 1996 Jan;21(1):35-48	Chronic fatigue syndrome (CFS) is a condition that results in moderate to severe disability, the primary feature of which is fatigue of unknown origin. There is a lot of interest in classifying, characterising and treating patients with CFS. Currently, the two major theories of a medical cause of CFS are viral infection and immune dysregulation. Patients report critical reductions in levels of physical activity, and many experience 'relapses' of severe symptoms following even moderate levels of exertion. Despite this, most studies report CFS patients to have normal muscle strength and either normal or slightly reduced muscle endurance. Histological and metabolic studies report mixed results: CFS patients have either no impairment or mild impairment of mitochondria and oxidative metabolism compared with sedentary controls. Current treatments for CFS are symptom-based, with psychological, pharmacological and rehabilitation treatments providing some relief but no cure. Immunological and nutritional treatments have been tried but have not provided reproducible benefits. Exercise training programmes are thought to be beneficial (if 'relapses' can be avoided), although few controlled studies have been performed. CFS is a long-lasting disorder that can slowly improve with time, but often does not. Further studies are needed to better understand the multiple factors that can cause chronic fatigue illness, as well as the effect that exercise training has on the symptoms of CFS.
McGregor NR, Dunstan RH, Zerbes M, Butt HL, Roberts TK, Klineberg IJ.	Collaborative Pain Research Unit, University of Sydney, Westmead Hospital, NSW, Australia.	Preliminary determination of a molecular basis of chronic fatigue syndrome.	Biochem Mol Med 1996 Apr;57(2):73-80	Chronic fatigue syndrome (CFS/ME) is a debilitating fatigue illness that has an unknown etiology. We studied 20 chronic fatigue syndrome (CFS) patients, who complied with the Oxford and American CDC definitions, and 45 non-CFS subjects. Participants completed questionnaires, were clinically examined, and had first morning urine specimens collected, which were screened by gas chromatography-mass spectrometry for changes in metabolite excretion. Multivariate analysis of the urinary metabolite profiles differed significantly in the CFS patients compared to the non-CFS patients ($P < 0.004$). The CFS patients had increases in aminohydroxy-N-methylpyrrolidine ($P < 0.00003$, referred to as chronic fatigue symptom urinary marker 1, or CFSUM1), tyrosine ($P < 0.02$), beta-alanine ($P < 0.02$), aconitic acid ($P < 0.05$), and succinic acid ($P < 0.05$) and reductions in an unidentified urinary metabolite, CFSUM2 ($P < 0.0007$), alanine ($P < 0.005$), and glutamic acid ($P < 0.02$). CFSUM1, beta-alanine, and CFSUM2 were found by discriminant function analysis to be the first, second, and third most important metabolites, respectively for discriminating between CFS and non-CFS subjects. The abundances of CFSUM1 and beta-alanine were positively correlated with symptom incidence ($P < 0.01$ and $P < 0.001$, respectively), symptom severity,

				core CFS symptoms, and SCL-90-R somatization (P < 0.00001), suggesting a molecular basis for CFS.
McGregor NR, Dunstan RH, Zerbes M, Butt HL, Roberts TK, Klineberg IJ.	Collaborative Pain Research Unit, University of Sydney, Australia.	Preliminary determination of the association between symptom expression and urinary metabolites in subjects with chronic fatigue syndrome.	Biochem Mol Med 1996 Jun;58(1):85-92	Chronic fatigue syndrome (CFS) patients have a urinary metabolite labeled CFSUM1 with increased incidence (P < 0.004) and relative abundance (P < 0.00003). The relative abundances of urinary CFSUM1 and beta-alanine were associated with alterations in metabolite excretion and symptom incidence. In 20 CFS patients and 45 non-CFS subjects, symptom/metabolite associations were investigated by assessing symptom sensitivity and specificity, and symptom indices of total symptom incidence, CFS core symptoms, cognitive, neurological, musculoskeletal, gastrointestinal, infection-related and genitourinary symptom indices, as well as a visual analogue pain scale of average pain intensity. Thirty-three symptoms had significant (P < 0.005) sensitivity and specificity in the CFS patients compared to that in the non-CFS controls. Severe fatigue was the only symptom with 100% sensitivity and specificity and CFSUM1 excretion was the primary metabolite for expression of this symptom. All nine symptom indices had elevated responses in the CFS patients (all P < 0.0000001). Multiple regression analyses indicated that all the symptom indices had significant correlations (R) with changes in the urinary excretion of metabolites (P < 0.0001). CFSUM1 and beta-alanine were the first and second metabolites correlated with the CFS core symptom index and CFSUM1 was primarily associated with infection-related and musculoskeletal indices whereas beta-alanine was primarily associated with gastrointestinal and genitourinary indices. The strong associations of CFSUM1 and beta-alanine with CFS symptom expression provide a molecular basis for developing an objective test for CFS.

Michiels V, Cluydts R, Fischler B, Hoffmann G, Le Bon O, De Meirleir K.	Department of Psychology, Free University of Brussels (VUB), Belgium.	Cognitive functioning in patients with chronic fatigue syndrome.	J Clin Exp Neuropsychol 1996 Oct;18(5):666-77	A comprehensive battery of neuropsychological tests was administered to 35 outpatients suffering from Chronic Fatigue Syndrome (CFS). They were compared to 33 normal controls matched for age, gender, intelligence, and education. The patients displayed psychomotor slowing and impaired attention. The learning rate of verbal and visual material for patients with CFS was slower, and delayed recall of verbal and visual information was impaired. Because there was a high variability in cognitive impairment within the CFS group, it would be inappropriate to generalize results to the entire CFS population. Two neuropsychological variables indicating aspects of psychomotor performance and verbal memory were found to discriminate best between patients and controls.
Minowa M, Jiamo M.	Department of Epidemiology, National	Descriptive epidemiology of chronic	J Epidemiol 1996 Jun;6(2):75-80	In order to clarify the epidemiological features of chronic fatigue syndrome (CFS), a nationwide survey was conducted using the Japanese version of the CDC

	Institute of Public Health, Tokyo, Japan.	fatigue syndrome based on a nationwide survey in Japan.		Criteria prepared by the CFS Research Group of Japan. All clinical departments of internal medicine, pediatrics, psychiatry and neurology at university hospitals and at ordinary hospitals with 200 or more beds were surveyed. Major results were as follows: (1) Period prevalence adjusted for response rate was 0.85 (0.63 for males and 1.02 for females) per 100,000 population during the year 1992; (2) Based on the first and final dates of hospital visits, the prevalences on January 1 of 1992 and 1993 were 0.40 and 0.60 per 100,000 population, respectively, suggesting an increasing trend; (3) Reported new cases during 1992 were 301, and the response adjusted-incidence was estimated to be 0.46 per 100,000 person-years; (4) The proportion of post-infectious CFS cases was 14.8% for both sexes, and tended to be slightly higher among females than males, but was not related to age. Three clusterings of two cases were reported.

Nakaya T, Takahashi H, Nakamura Y, Asahi S, Tobiume M, Kuratsune H, Kitani T, Yamanishi K, Ikuta K.	Section of Serology, Hokkaido University, Sapporo, Japan.	Demonstration of Borna disease virus RNA in peripheral blood mononuclear cells derived from Japanese patients with chronic fatigue syndrome.	FEBS Lett 1996 Jan 8;378(2):145-9	CFS, a recently named heterogeneous disorder, is an illness of unknown etiology. The association of CFS with viral infections has been suggested. A common association between CFS and several viruses examined has not been confirmed. Here, we centered on the possible link between CFS and BDV infection. By nested RT-PCR followed by hybridization, BDV RNA was demonstrated as a clear signal in PBMCs in 3 out of 25 CFS patients. The amplified cDNA fragments were cloned and sequenced. A total of 16 clones were studied. Intra-patients divergencies of the p24 were 2-9%, 3-20%, and 3-11% in the deduced amino acids. Inter-patient divergencies among the 16 clones were 3-24%. Antibodies to recombinant BDV p24 protein were detected in 6 CFS patients including one carrying BDV RNA. Overall, these gave the prevalence of 32% (8/25) in Japanese CFS patients, suggesting that Japanese CFS is highly associated with active infection of BDV, or a related agent.
Natelson BH, Cheu J, Pareja J, Ellis SP, Policastro T, Findley TW.	CFS Center, New Jersey Medical School, East Orange 07018, USA.	Randomized, double blind, controlled placebo-phase in trial of low dose phenelzine in the chronic fatigue syndrome.	Psychopharmacology (Berl) 1996 Apr;124(3):226-30	Because of the striking similarity of the clinical manifestations produced by use of the drug reserpine and seen in patients with the chronic fatigue syndrome (CFS), we theorized that CFS was a disorder of reduced central sympathetic drive. Because of the pharmacology of control of this central sympathetic system, we further postulated that CFS symptoms would respond quickly to low dose treatment with a monamine oxidase inhibitor. To test these hypotheses, we designed a randomized, double blind placebo controlled study using phenelzine. No patient in the trial had a diagnosis of lifetime or current psychiatric disorder

				and none had depressed mood in the range of clinically depressed patients on a paper and pencil test of depression. Patients in the placebo group received placebo for 6 weeks while those in the drug treatment group were treated in three 2-week segments-placebo, 15 mg phenelzine every other day, and then 15 mg daily. This treatment regimen produced a significant pattern of improvement compared to worsening in 20 self report vehicles of CFS symptoms, illness severity, mood or functional status. Thus the data support our hypothesis of reduced sympathetic drive, although an alternative hypothesis of pain alleviation is also possible. The study design also allowed us to evaluate patients for a placebo effect: no evidence for this was found, suggesting that CFS is not an illness due to patients' being overly suggestible. Randomized Controlled Trial
Neri G, Bianchedi M, Croce A, Moretti A.	Clinica Otorinolaringoiatrica, Universita G. d'Annunzio di Chieti.	["Prolonged" decay test and auditory brainstem responses in the clinical diagnosis of the chronic fatigue syndrome].[article in Italian]	Acta Otorhinolaryngol Ital 1996 Aug;16(4):317-23	The chronic fatigue syndrome (CFS) was formally defined to describe disabling fatigue of unknown etiology with immunologic disfunctions. In most cases occur abnormalities of neurophysiological tests. In this paper the Authors use the low (11 pps) and high (51-71 pps) frequency ABR for detecting the electrophysiological function of auditory brainstem responses and propose the "Prolonged Decay Test", a modified impedenzometric technique that explores any alterations of the stapedial contraction, as a new diagnostic test for CFS. Twenty-one patients with suspected CFS, with an age between 17 and 50 years, were examined and the instrumental data were correlated with the clinical findings. The results of the ABR study showed in the examined subjects no many abnormalities in the 11 pps frequency test. The high frequency stimulation trials (with 51 and 71 pps) proved many alterations in 10 patients (absence of the first wave in 6 cases, in 5 many wave latency delay and in 1 patient absence of the first wave and many wave latency delay). The high frequency trials showed no abnormalities in the 11 remaining patients. The clinical-audiological correlation showed a 61.9% of comparison with 33.3% of false negatives and 4.8% of false positives. The Prolonged Decay Test showed a 71.4% of clinical-audiological comparison with 23.8% of false negatives and 4.8% of false positives. The Prolonged Decay Test together with the ABR showed a 81.8% of clinical-audiological comparison with 18.2% of false negatives and 0% of false positives. These preliminary data show that the stapedial reflex together with the ABR test could be useful for the diagnosis of CFS.
Nishikai M, Akiya K, Tojo T, Onoda N, Tani M, Shimizu K.	Department of Internal Medicine, Second Tokyo National Hospital, Japan.	'Seronegative' Sjogren's syndrome manifested as a subset of chronic fatigue syndrome.	Br J Rheumatol 1996 May;35(5):471-4	We determined the extent to which chronic fatigue syndrome (CFS) patients with sicca symptoms fulfil the diagnostic criteria for Sjogren's syndrome (SS). Three sets of diagnostic criteria for SS, formulated by the Japanese, Europeans and Fox, were used. One-third of the CFS patients with sicca symptoms fulfilled the diagnostic criteria for SS. However, they were 'seronegative', differing from the ordinary primary SS.
Oberg K.	Uppsala University,	Interferon-alpha versus	Digestion 1996;57 Suppl	Interferon-alpha (IFN-alpha) has a direct anti-tumour effect and is an

	Sweden.	somatostatin or the combination of both in gastro-enteropancreatic tumours.	1:81-3	immunomodulator. Somatostatin analogues, by contrast, when used to treat neuroendocrine tumours, control the secretion and peripheral effects of hormones, although at high doses they induce apoptosis. We have used IFN-alpha to treat > 350 patients with neuroendocrine tumours, and combining our and published data gives a median 44% biochemical response rate and 11% tumour response rate. Side-effects are mainly flu-like symptoms, then low-grade chronic fatigue syndrome. 15% may develop autoimmune reactions. The side-effects profile of somatostatin analogues is better but patients must take frequent injections and may have bile problems. We combined IFN-alpha and octreotide treatment in 24 patients with malignant carcinoid tumours who did not respond biochemically to high-dose (300 micrograms/day) octreotide alone. Biochemical response occurred in 77% but no significant anti-tumour effect was noted besides disease stabilisation in 4 cases. The combination therapy had an effect on clinical symptoms rather than tumour mass. Interferon was better tolerated when in the combination.

Patarca R, Nancy Klimas Dmitry Sandler, Maria N. Garcia , Mary Ann Fletcher		Interindividual Immune Status Variation Patterns in Patients with Chronic Fatigue Syndrome Association with Gender and the Tumor Necrosis Factor System	Journal of Chronic Fatigue Syndrome 1996: 2(1): 13 - 39	Changes in soluble immune mediator levels in association with the chronic fatigue syndrome (CFS) usually occur within normal ranges and are apparent mainly as changes in the skewness of population distributions. The latter finding undermines the usefulness of cytokine levels as clinical tools at the individual level as has been seen in sepsis syndrome where a similar overlap occurs. Nonetheless, changes in cytokine levels at the population level can contribute to an understanding of the disease process. For example, we reported previously that significant proportions of CFS patients showed elevated serum levels of either soluble tumor necrosis factor-receptor I (sTNF-RI, sCD120a) or TNF-a as compared to controls. The latter results could reflect different disease processes or extremes of a common disease process. Using sera collected over a five-year period, we have now studied an extended cohort of 108 CFS patients and our results are consistent with a common graded disease process. When we assessed the effect of gender on the distributions of serum levels of immune mediators, levels of sTNF-RI, sTNF-RII (sCD 12Ob), sIL-6R (sCDl26), and sICAM-1 were found to be consistently higher among males than females and among CFS patients as compared to controls regardless of gender. Moreover, differences in soluble immune mediator levels between CFS and control individuals were more clearly defined when restricting the analysis to the female gender. These observations are consistent with endocrine influences on immunological changes.

Pearce J.		Cognitive behaviour therapy for the chronic fatigue syndrome. Cognitive behavior therapy should be compared with placebo treatments.	BMJ 1996 Apr 27;312(7038):1097; discussion 1098 comment on: BMJ. 1996 Jan 6;312(7022):22-6	
Pearn J		Chronic Ciguatera One Organic Cause of the Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1996: 2(2/3): 29 - 34	Ciguatera is a distressing form of fish poisoning, caused by the ingestion of one or more of a series of ciguatoxins. These poisons, some of the most potent mammalian neurotoxins known, are manufactured in reef-dwelling dinoflagellates and concentrated up the piscine food chain. Human victims, not uncommon in the Pacific, Atlantic and Indian Ocean tropical and subtropical littorals, become poisoned by eating risk species of fish. The acute intoxication is clinically dramatic, resulting in paraesthesiae, dysaesthesiae, prostration, myalgia and arthralgia. In some 20 percent of cases, symptoms of fatigue, reduced exercise tolerance and non-specific aches and pains persist for months and, in a small percentage of cases, for years. Such cases would, in the absence of the prior episode of acute poisoning, satisfy the diagnostic criteria for the chronic fatigue syndrome (CFS). Occasionally, patients are encountered who have been diagnosed as having CFS because of lack of awareness of the ciguatera syndrome, but in whom in retrospect the episode of acute fish poisoning can be established. The fact that at least one potent mammalian toxin can cause a chronic syndrome indistinguishable from CFS opens the way for further research into this enigmatic condition.
Reiffenberger DH, Amundson LH.	Brown Clinic, Watertown, South Dakota, USA.	Fibromyalgia syndrome: a review.	Am Fam Physician 1996 Apr;53(5):1698-712	Fibromyalgia syndrome includes symptoms of widespread, chronic musculoskeletal aching and stiffness and soft tissue tender points. It is frequently accompanied by fatigue and sleep disturbance. Fibromyalgia is more common in women than in men, and it occurs at a mean age of 49 years. Differential diagnosis includes myofascial pain syndrome and chronic fatigue syndrome. Fibromyalgia is a multifactorial problem and no universal treatment guidelines apply to all cases. Pharmacologic therapy may incude tricyclic antidepressants. In addition to commonly used pharmacologic therapies, patient education, reassurance and an exercise program can each play an important role in relieving the symptoms associated with this common musculoskeletal syndrome.
Reyes M, James G. Dobbins , Alison C. Mawle , Lea Steele , Howard E. Gary , Hina Malani , Scott Schmid , Keiji Fukuda John		Risk Factors for Chronic Fatigue Syndrome A Case-Control Study	Journal of Chronic Fatigue Syndrome 1996: 2(4): 17 - 33	Objective: To study various risk factors previously reported to be associated with chronic fatigue syndrome (CFS). Design: Case-control study. Setting: Metropolitan Atlanta CFS surveillance registry consisting of physicians and clinics that evaluate patients with fatiguing illness. Patients: Twenty-five CFS patients identified from the Centers for Disease Control and Prevention, Atlanta CFS study site, were matched by race, sex, and age to two randomly selected controls. Cases were

Stewart Rosane Nisenbaum , William C. Reeves				further subgrouped by type of illness onset-sudden, occurring within a few days, or gradual, occurring over a longer time period. Main outcome measures: A broad panel of risk factors previously associated with CFS. Results: CFS patients were significantly more likely than controls to report a history of stress, persistent nasal symptoms, ear infections, and ingestion of B-complex vitamins during the year prior to the case's onset of illness. In addition, women patients were significantly more likely to have had a hysterectomy. The subset of patients (n = 17) who reported a gradual onset were significantly more likely than patients reporting a sudden onset of illness or controls to report stressful events in the year prior to onset, certain dental procedures, sinusitis, exposures to herbicides, pesticides, or insecticides, and a history of hysterectomy. We could not confirm previously reported associations of CFS with a history of asthma or eczema; exposure to sick animals; exposure to solvents, paint, or other chemicals; ingestion of raw-milk, or travel, occupation, or recreational activity. Conclusions: While no risk factors were identified that effectively distinguish CFS cases from controls, the data do suggest that gradual and sudden onset CFS constitute distinct subclasses of the syndrome. Future studies should subgroup patients based on type of illness onset and further evaluate risk factors of interest, focusing on the role
Ross E.		The history and treatment of chronic fatigue syndrome.	Nurs Times 1996 Oct 30-Nov 5;92(44):34-6	This article looks at chronic fatigue syndrome, a common condition affecting 1-2.5% of the population. The criteria for diagnosis are described and the nurse's role in treatment is discussed.
Rouillon F, Delhommeau L, Vinceneux P.	Service de Psychiatrie, Hopital Louis Mourier, Colombes.	[Chronic fatigue syndrome].[article in French]	Presse Med 1996 Dec 21;25(40):2031-6	Fatigue is one of the most common medical complaints. Sometimes, fatigue is chronic, unexplained and induces significant distress or impairment in social, occupational or other important areas of functioning. This condition was described as neurasthenia by Beard at the end of the 19th Century; more recently the United States Centers for Disease Control and Prevention (CDC) suggested to call it "Chronic Fatigue Syndrome" (SFC). Both are considered as physical diseases and share certain therapeutic measures. Pathophysiology is still unknown and may involve viral agents, immunological processes or psychiatric disorders. Similarly most of the treatments which have been properly evaluated seem to be more or less inefficacious.

Samii A, Wassermann EM, Ikoma K, Mercuri B, George MS, O'Fallon A, Dale JK, Straus SE, Hallett M.	Human Motor Control Section, National Institute of Neurological Disorders and Stroke, Bethesda, MD 20892-	Decreased postexercise facilitation of motor evoked potentials in patients with chronic fatigue syndrome or	Neurology 1996 Dec;47(6):1410-4	We studied the effects of exercise on motor evoked potentials (MEPs) elicited by transcranial magnetic stimulation (TMS) in 18 normal (control) subjects, 12 patients with chronic fatigue syndrome, and 10 depressed patients. Subjects performed repeated sets of isometric exercise of the extensor carpi radialis muscle until they were unable to maintain half maximal force. MEPs were

	1428, USA.	depression.		recorded before and after each exercise set and for up to 30 minutes after the last set. The mean amplitude of MEPs recorded from the resting muscle immediately after each exercise set was 218% of the mean pre-exercise MEP amplitude in normal subjects, 126% in chronic fatigue patients, and 155% in depressed patients, indicating postexercise MEP facilitation in all three groups. The increases in the patient groups, however, were significantly lower than normal. The mean amplitudes of MEPs recorded within the first few minutes after the last exercise sets in all three groups were approximately half their mean pre-exercise MEP amplitudes. This postexercise MEP depression was similar in all groups. We conclude that postexercise cortical excitability is significantly reduced in patients with chronic fatigue syndrome and in depressed patients compared with that of normal subjects.
Scheurlen M.	Medizinische Poliklinik, Universitat, Wurzburg.	[Pathogenicity of fungi in the intestines--current status of the discussion].[article in German]	Fortschr Med 1996 Sep 20;114(26):319-21	The hypothesis that colonization of the intestinal tract by yeasts (e.g. Candida albicans) can lead to disease in immunocompromised individuals is currently being discussed controversially. Proponents assume that toxins produced by the fungi can trigger such complaints as irritable bowel syndrome of the chronic fatigue syndrome, and that such chronic or recurrent infections may be caused by an intestinal reservoir of yeasts. Opponents of the hypothesis, however, point out that no hard data on the pathogenetic significance of an intestinal reservoir of yeasts are available, controlled studies have failed to demonstrate the effectiveness of antifungal treatment. Discussions are however, hampered by a lack of objective data. The postulated pathomechanisms therefore need to be clarified, diagnostic criteria developed, and the efficacy of the proposed therapeutic measures shown by controlled studies. Until this has been done, assumption about the pathogenicity of yeasts in the bowel, cannot be taken as a basis for binding therapeutic recommendations.
Schmaling KB, Jones JF.	Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle 98105, USA.	MMPI profiles of patients with chronic fatigue syndrome.	J Psychosom Res 1996 Jan;40(1):67-74	Fifty-three patients with chronic fatigue syndrome (CFS) and 43 healthy nonpatient controls completed the Minnesota Multiphasic Personality Inventory (MMPI). All subjects varied in their degree of seropositivity to active Epstein-Barr virus (EBV) as measured by their anti-early antigen titers. EBV titers were higher among CFS patients and were associated with being more symptomatic. Differences in patient status were associated with statistically significant elevations on 8 of 9 clinical scales, 4 of which also showed clinically significant elevations (T scores > or = 70): scales 1, 2, 3, and 8. These results are discussed in terms of their implications for intervention strategies associated with MMPI-based CFS subtypes.
Schnitzer TJ, Penmetcha M.	Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612, USA.	Viral arthritis.	Curr Opin Rheumatol 1996 Jul;8(4):341-5	Viral infections can present with different patterns of joint and soft tissue involvement, and the etiologic role of viruses in various rheumatic diseases is a subject of continued great interest. Recently, new immunoenzymatic assays have brought a better understanding of the relationship between hepatitis C virus

				serotypes and their immunologic manifestations. Our knowledge of the consequences of parvovirus B19 infection has broadened to include the variable clinical spectrum the role of inflammatory cytokine production in parvovirus-induced arthritis, a postulated causative role for B19 in rheumatoid arthritis, and a negative association between parvovirus and Still's disease as well as chronic fatigue syndrome. New, specific antibodies to nonstructural protein NS-1 in parvovirus B19-associated arthritis have been detected. Arthritis related to hepatitis B virus vaccination or measles and mumps vaccination was also reported. The papers reviewed here demonstrate the continuing efforts in defining the etiopathogenesis of virus-induced rheumatic diseases.
Scott LV, T. G. Dinan		The Neuroendocrinology of Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1996: 2(4): 49 - 59	Since the introduction of operationalized criteria, there has been considerable interest in the pathophysiology of chronic fatigue syndrome (CFS). There is an increasing volume of evidence to support the view that patients with this syndrome have unique neuroendocrinology patterns. Central to this endocrine dysfunction is altered hypothalamic-pituitary-adrenal axis (HPA) activity. The cardinal findings include attenuated adrenocorticotrophic hormone (ACTH) responses to corticotropin-releasing hormone (CRH) and low 24-hour urinary cortisol. These are compatible with a mild central adrenal insufficiency. Adrenal steroids have widespread impact in the brain, and of particular importance is their dense concentration on serotonergic and noradrenergic neurotransmitter pathways. Using a variety of different challenge drugs, a supersensitivity of the serotonergic 5-HT 1A receptor has been demonstrated although the results have not been entirely consistent. A blunting of dexamethasone-induced growth hormone release has been described and may reflect a relative subsensitivity of the steroid receptor. It is proposed that the disruption of the HPA, which may be triggered by a number of stressors including infections, may represent a primary phenomenon, and that the neurotransmitter abnormalities described are in fact secondarily heralded by prolonged HPA dysregulation.
See DM, Tilles JG.	Department of Medicine School of Medicine, University of California at Irvine Orange 92668, USA.	alpha-Interferon treatment of patients with chronic fatigue syndrome.	Immunol Invest 1996 Jan-Mar;25(1-2):153-64	Thirty patients who fulfilled clinical criteria defined by the CDC for Chronic Fatigue Syndrome were treated with alfa 2a interferon or placebo in a double-blind crossover study. Outcome was evaluated by Natural Killer (NK) cell function, lymphocyte proliferation to mitogens and soluble antigens, CD4/CD8 counts and a 10 item Quality of Life (QOL) survey. Although mean NK function rose from 87.8 +/- 19.6 to 129.3 +/- 20.7 lytic untis (LU; $p < .05$) with 12 weeks of interferon therapy, there was no significant change in the other immunologic parameters or QOL scores. When the 26 patients who completed the study were stratified according to their baseline NK function and lymphocyte proliferation, 4 groups were identified: 3 patients had normal NK cell function and lymphocyte proliferation when compared to normal, healthy controls, 9 had isolated deficiency in lymphocyte proliferation, 7 had diminished NK function only, and 7

				had abnormalities for both parameters. QOL scores were not significantly different for the four groups at baseline. After 12 weeks of interferon therapy, QOL score significantly improved in each of the seven patients with isolated NK cell dysfunction (mean score, 16.3 +/- 7.9) compared to baseline (39.7 +/- 12.1; p < .05). In these patients the mean NK function increased from 35.1 +/- 11.7 to 91.5 +/- 22.7 LU (p < .01). Significant improvement was not recorded for QOL in the other three groups. Thus, therapy with alpha interferon has a significant effect on the QOL of that subgroup of patients with CFS manifesting an isolated decrease in NK function. Randomized Controlled Trial
Selden SM, Cameron AS.	Communicable Disease Control Unit, South Australian Health Commission, Adelaide, SA.	Changing epidemiology of Ross River virus disease in South Australia.	Med J Aust 1996 Sep 16;165(6):313-7 comment in: Med J Aust. 1997 Aug 18;167(4):229-30 Med J Aust. 1997 Mar 17;166(6):333; discussion 334 Med J Aust. 1997 Mar 17;166(6):334	OBJECTIVE: To investigate changes in epidemiology and symptoms of Ross River virus (RRV) disease in South Australia. DESIGN: Longitudinal questionnaire-based survey of notified cases from one to 36 months after infection. SUBJECTS: All patients with recent serologically confirmed RRV infection notified to the Communicable Disease Control Unit, South Australian Health Commission, between 1 October 1992 and 30 June 1993. OUTCOME MEASURES: Sociodemographic data, source of infection, symptoms and ability to carry out daily activities (at onset of illness and at time of questionnaire, up to 36 months after infection), symptom duration, economic impact of the illness, cases recovery time, factors predictive of delayed recovery. RESULTS: Information was obtained on the acute illness from 698 of the 821 subjects and at 15 months after infection from 436. At 15 months, 51% of respondents still had joint pain and 45% had persistent tiredness and lethargy. Other common symptoms included myalgia (34%), lymphadenopathy (25%), headache (23%) and depression (22%). These symptoms were still common 30 months after infection. Increasing age was the only statistically significant predictor of delayed recovery. Infections were acquired across the State, away from previously recognised RRV-endemic areas. CONCLUSIONS: For many people, RRV disease is debilitating, with long term symptoms similar to those of chronic fatigue syndrome. The geographic range of the infection has expanded in SA.
Sharma A, Kendall MJ, Oyebode F, Jones D.		Fluoxetine and chronic fatigue syndrome.	Lancet 1996 Jun 22;347(9017):1770-1; discussion 1771-2	
Sharpe M, Clements A, Hawton K, Young AH, Sargent P, Cowen PJ.	University Department of Psychiatry, Warneford and Littlemore Hospitals, Oxford, UK.	Increased prolactin response to buspirone in chronic fatigue syndrome.	J Affect Disord 1996 Nov 4;41(1):71-6	We studied the endocrine and subjective responses that followed acute administration of the 5-HT1A receptor agonist buspirone (0.5 mg/kg orally) in 11 male patients with chronic fatigue syndrome (CFS) and a group of matched healthy controls. Patients with CFS had significantly higher plasma prolactin concentrations and experienced more nausea in response to buspirone than did controls. However, the growth hormone response to buspirone did not distinguish CFS patients from controls. Our data question whether the enhancement of buspirone-induced prolactin release in CFS is a consequence of

				increased sensitivity of post-synaptic 5-HT1A receptors. It is possible that the increased prolactin response to buspirone in CFS could reflect changes in dopamine function.
Sharpe M, Hawton K, Simkin S, Surawy C, Hackmann A, Klimes I, Peto T, Warrell D, Seagroatt V.	University Department of Psychiatry, Warneford Hospital, Oxford.	Cognitive behaviour therapy for the chronic fatigue syndrome: a randomized controlled trial.	BMJ 1996 Jan 6;312(7022):22-6 comment in: ACP J Club. 1996 May-Jun;124(3):71 BMJ. 1996 Apr 27;312(7038):1096-7; discussion 1098 BMJ. 1996 Apr 27;312(7038):1096; discussion 1098 BMJ. 1996 Apr 27;312(7038):1097-8 BMJ. 1996 Apr 27;312(7038):1097; discussion 1098	OBJECTIVE--To evaluate the acceptability and efficacy of adding cognitive behaviour therapy to the medical care of patients presenting with the chronic fatigue syndrome. DESIGN--Randomised controlled trial with final assessment at 12 months. SETTING--An infectious diseases outpatient clinic. SUBJECTS--60 consecutively referred patients meeting consensus criteria for the chronic fatigue syndrome. INTERVENTIONS--Medical care comprised assessment, advice, and follow up in general practice. Patients who received cognitive behaviour therapy were offered 16 individual weekly sessions in addition to their medical care. MAIN OUTCOME MEASURES--The proportions of patients (a) who achieved normal daily functioning (Karnofsky score 80 or more) and (b) who achieved a clinically significant improvement in functioning (change in Karnofsky score 10 points or more) by 12 months after randomisation. RESULTS--Only two eligible patients refused to participate. All randomised patients completed treatment. An intention to treat analysis showed that 73% (22/30) of recipients of cognitive behaviour therapy achieved a satisfactory outcome as compared with 27% (8/30) of patients who were given only medical care (difference 47 percentage points; 95% confidence interval 24 to 69). Similar differences were observed in subsidiary outcome measures. The improvement in disability among patients given cognitive behaviour therapy continued after completion of therapy. Illness beliefs and coping behaviour previously associated with a poor outcome changed more with cognitive behaviour therapy than with medical care alone. CONCLUSION--Adding cognitive behaviour therapy to the medical care of patients with the chronic fatigue syndrome is acceptable to patients and leads to a sustained reduction in functional impairment. Randomized Controlled Trial
Sharpe M.	Department of Psychiatry, University of Oxford, United Kingdom.	Chronic fatigue syndrome.	Psychiatr Clin North Am 1996 Sep;19(3):549-73	Chronic fatigue syndrome (CFS) is a medically unexplained illness characterized by chronic, disabling fatigue, impaired concentration, muscle pain, and other somatic symptoms. The conceptual difficulties associated with all medically unexplained illnesses contribute to the controversy surrounding CFS, which has centered around whether it is best regarded as a medical or as a psychiatric condition. Clinically, such an approach is not helpful, and current research suggests that both pathophysiologic changes and psychosocial factors are important. Pragmatic management based on a detailed assessment of the individual is outlined.

		as much benefit as cognitive behaviour therapy.	Jan 6;312(7022):22-6	
Sisto SA, LaManca J, Cordero DL, Bergen MT, Ellis SP, Drastal S, Boda WL, Tapp WN, Natelson BH.	Department of Neurosciences, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark, USA.	Metabolic and cardiovascular effects of a progressive exercise test in patients with chronic fatigue syndrome.	Am J Med 1996 Jun;100(6):634-40 comment in: Am J Med. 1997 Jul;103(1):83-4 Am J Med. 1997 Jul;103(1):84-6	PURPOSE: To evaluate the aerobic power (as maximum volume of oxygen consumed [VO2 max]) of women with chronic fatigue syndrome (CFS). PATIENTS AND METHODS: Twenty-one women with CFS and 22 sedentary healthy controls (CON) were studied at the CFS Cooperative Research Center Exercise Laboratory at the VA Medical Center, East Orange, New Jersey. Performance was measured on an incremental treadmill protocol walking to exhaustion. Expired gases were analyzed by a metabolic system, heart rate was recorded continuously, and ratings of perceived exertion (RPE) were taken at each workload. The groups were divided into those who achieved VO2 max (CFS-MAX and CON-MAX) and those who stopped at a submaximal level (CFS-NOMAX and CON-NOMAX) by using standard criteria. RESULTS: Seventeen CON and 10 CFS subjects achieved VO2 max. The VO2 max (mL/kg/min) of the CFS-MAX (28.1 +/- 5.1) was lower than that of the CON-MAX (32.1 +/- 4.3, P = 0.05). The CFS-MAX achieved 98 +/- 11% of predicted VO2 max. The CFS group had a higher RPE at the same absolute workloads as controls (P < 0.01) but not the same relative workloads. CONCLUSION: Compared with normal controls, women with CFS have an aerobic power indicating a low normal fitness level with no indication of cardiopulmonary abnormality. Our CFS group could withstand a maximal treadmill exercise test without a major exacerbation in either fatigue or other symptoms of their illness.
Snorrason E, Arni Geirsson, Kari Stefansson		Trial of a Selective Acetylcholinesterase Inhibitor, Galanthamine Hydrobromide, in the Treatment of Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1996: 2(2/3): 35 - 54	The purpose of the study was to search for a means of diminishing the plight of patients with chronic fatigue syndrome (CFS) and to test the hypothesis that central to the pathogenesis of CFS is a cholinergic defect. Forty-nine patients who fulfilled consensus criteria for CFS were treated with the acetylcholinesterase inhibitor, galanthamine hydrobromide. Thirty-nine patients finished the study according to the protocol with 43% reporting 50% improvement in fatigue, myalgia and sleep and 70% reporting 30% improvement whereas patients in the placebo group reported only 10% improvement in the same parameters of CFS. The improvement of patients on galanthamine was in most cases gradual and reached significance for the group only after four to eight weeks. The improvement was stable, and no patients who reported over 50% improvement on galanthamine relapsed to a pretrial level of any symptom. One of the most surprising effects was the dramatic improvement of sleep disturbances that occurred in most patients on this medication: more than 60% of the patients who finished the study reported over 70% improvement in sleep deficit. If the subjective report by patients can be proved by objective means, this would be the first demonstration of a drug that can be used to correct a sleep disturbance that also influences a specific stage in normal sleep. The most common adverse

				effect of galanthamine, as given in this study, was nausea that was dose-dependent and reversible. Galanthamine hydrobromide is relatively safe and appears to be an effective medication against many symptoms of CFS. But the positive results of this study have to be interpreted cautiously because of methodological limitations of this trial. First, this study was originally organized as a double-blind, placebo-controlled trial but was changed to an optional crossover after two weeks of treatment. Also, the adverse effects of the active drug in 30% of patients could compromise the double-blind. With these limitations in mind, it is nevertheless tempting to conclude that this study lends an indirect support to our hypothesis that a cholinergic deficit may play a role in the pathogenesis of the syndrome.
St George IM.	Wellington School of Medicine, New Zealand.	Did Cook's sailors have Tapanui 'flu? --chronic fatigue syndrome on the Resolution.	N Z Med J 1996 Jan 26;109(1014):15-7	The 1982 publication of the Resolution journal of Johann George Reinhold Forster provided justification for his recognition as a scientist, and gave a remarkable insight into his character. It also included an account of an illness suffered by many of the sloop's crew, including Forster, after a period ashore at Queen Charlotte Sound. The symptoms of the illness were remarkably similar to those now clustered as the chronic fatigue syndrome.
Steinberg P, McNutt BE, Marshall P, Schenck C, Lurie N, Pheley A, Peterson PK.	Department of Medicine, Hennepin County Medical Center, Minneapolis, MN 55415, USA.	Double-blind placebo-controlled study of the efficacy of oral terfenadine in the treatment of chronic fatigue syndrome.	J Allergy Clin Immunol 1996 Jan;97(1 Pt 1):119-26	BACKGROUND: There is no established treatment for chronic fatigue syndrome (CFS), an illness characterized by disabling fatigue exacerbated by physical activity. A variety of immunologic abnormalities have been reported, including a high incidence of atopy and hypoergy or anergy. OBJECTIVE: Because of anecdotal reports and uncontrolled trials showing antihistamine efficacy in CFS, we evaluated the clinical efficacy of the antihistamine terfenadine (60 mg twice daily) in a placebo-controlled study. METHODS: Thirty patients with CFS were enrolled in a 2-month, double-blind, placebo-controlled trial of terfenadine. Participants underwent a battery of both immediate- and delayed-type hypersensitivity skin tests and completed a self-assessment questionnaire used to measure severity of symptoms, physical and social functioning, health perceptions, and mental health before each of six biweekly visits. RESULTS: Twenty-eight patients completed the trial. History of atopy and positive immediate skin test results were prevalent, 73% and 53%, respectively. No evidence for hypoergy or anergy after delayed-type hypersensitivity skin testing was found. No therapeutic benefit from terfenadine could be detected in terms of symptom amelioration, improved physical or social functioning, health perceptions, or mental health. A high incidence of atopy in patients with CFS was confirmed. CONCLUSION: Although this trial involved a small number of patients, the results suggest that terfenadine is unlikely to be of clinical benefit in treating CFS symptoms. Randomized Controlled Trial

Sterzl I, Zamrazil V.	Endokrinologicky ustav, Praha.	[Endocrinopathy in the differential diagnosis of chronic fatigue syndrome].[article in Czech]	Vnitr Lek 1996 Sep;42(9):624-6	Fatigue is a frequent and sometimes dominant symptom of some endocrinopathies. It may be associated with other symptoms which are included among the criteria of the chronic fatigue syndrome. These units are not always quite distinct and frequently endocrine diseases and chronic fatigue syndrome (CFS) overlap. From this ensue differential diagnostic problems and ideas on possible causal relations. The authors concentrate in articular on autoimmune endocrinopathies and the polyglandular autoimmune syndrome (APS) with emphasis on the necessity of an accurate endocrinological diagnosis, where is some patients with suspected CFS a defined endocrinopathy was revealed. Attention will be also paid to recent views on the possible participation of disorders of the hypothalamus-pituitary-adrenal axis in the etiopathogenesis of CFS where endocrine and immune regulation overlap and condition each other.

Department of General Internal Medicine, University Hospital Nijmegen, Netherlands.	Lymphocyte subsets, apoptosis, and cytokines in patients with chronic fatigue syndrome.	J Infect Dis 1996 Feb;173(2):460-3	Whether immunologic abnormalities correlate with fatigue severity and functional impairment in chronic fatigue syndrome (CFS) was investigated. Blood mononuclear cells were immunophenotyped and circulating ex vivo-produced cytokines were measured in 76 CFS patients and 69 healthy matched controls. Expression of CD11b on CD8 cells was significantly decreased in CFS patients. However, the previously reported increased expression of CD38 and HLA-DR was not confirmed. There was no obvious difference in apoptosis in leukocyte cultures, circulating cytokines, and ex vivo production of interleukin (IL)-1 alpha and IL-1 receptor antagonist. Endotoxin-stimulated ex vivo production of tumor necrosis factor-alpha and IL-beta was significantly lower in CFS. The immunologic test results did not correlate with fatigue severity or psychologic well-being was measured by Checklist Individual Strength, Beck Depression Inventory, and Sickness Impact Profile. Thus, these immunologic tests cannot be used as diagnostic tools in individual CFS patients.

van Waveren EK.		The rise and fall of the chronic fatigue syndrome as defined by Holmes et al.	Med Hypotheses 1996 Feb;46(2):63-6	This paper is a sequel to my monograph on neurocirculatory asthenia and chronic fatigue syndrome. It pays special attention to the nature of chronic fatigue syndrome, to the forms of neurocirculatory asthenia, and above all to the 6th form in which profound fatigue is the dominant symptom. All forms including the 6th are characterized by the presence of concomitant symptoms due to dysfunction of the autonomic nervous system. Chronic fatigue syndrome as defined by Holmes et al is devoid of these symptoms. Up till the present day no case histories of it have been published. It is argued that chronic fatigue syndrome sensu Holmes et al does not exist, the 6th form of neurocirculatory asthenia having to take up its place.
Vecchiet L, Montanari G, Pizzigallo E, Iezzi S, de Bigontina P, Dragani L, Vecchiet J, Giamberardino MA.	Institute of Medical Pathophysiology, 'G. D'Annunzio' University of Chieti, Italy.	Sensory characterization of somatic parietal tissues in humans with chronic fatigue syndrome.	Neurosci Lett 1996 Apr 19;208(2):117-20	Patients with chronic fatigue syndrome (CFS) mainly complain of symptoms in the musculoskeletal domain (myalgias, fatigue). In 21 CFS patients the deep (muscle) versus superficial (skin, subcutis) sensitivity to pain was explored by measuring pain thresholds to electrical stimulation unilaterally in the deltoid, trapezius and quadriceps and overlying skin and subcutis in comparison with normal subjects. Thresholds in patients were normal in skin and subcutis but significantly lower than normal (hyperalgesia) in muscles ($P < 0.001$) in all sites. The selective muscle hypersensitivity corresponded also to fiber abnormalities at muscle biopsy (quadriceps) performed in nine patients which were absent in normal subjects (four cases): morphostructural alterations of the sarchomere, fatty degeneration and fibrous regeneration, inversion of the cytochrome oxidase/succinate dehydrogenase ratio, pleio/polymorphism and monstruosity of mitochondria, reduction of some mitochondrial enzymatic activities and increments of common deletion of 4977 bp of mitochondrial DNA 150-3000 times the normal values. By showing both sensory (diffuse hyperalgesia) and anatomical (degenerative picture) changes at muscle level, the results suggest a role played by peripberal mechanisms in the genesis of CFS symptoms. They would exclude the heightened perception of physiological signals from all districts hypothesized by some authors, especially as the hyperalgesia is absent in skin/subcutis.
Vercoulen JH, Hommes OR, Swanink CM, Jongen PJ, Fennis JF, Galama JM, van der Meer JW, Bleijenberg G.	Department of Medical Psychology, University Hospital Nijmegen, The Netherlands.	The measurement of fatigue in patients with multiple sclerosis. A multidimensional comparison with patients with chronic fatigue syndrome and healthy subjects.	Arch Neurol 1996 Jul;53(7):642-9	OBJECTIVE: To provide a multidimensional characterization of fatigue in patients with multiple sclerosis (MS). DESIGN: Cross-sectional design. Fifty patients with clinically definite MS were compared on the dimensions of fatigue with 51 patients with chronic fatigue syndrome (CFS) and 53 healthy subjects. RESULTS: Fourty-six percent of the patients with MS reported fatigue to be present at least once a week. Patients with MS and patients with CFS had significantly higher subjective fatigue severity scores than healthy subjects. Patients with MS and patients with CFS had significantly higher scores on measures of psychological well-being than healthy subjects. Patients with MS had scores similar to those of

				patients with CFS, except that patients with CFS had significantly higher somatization scores. High somatization scores reflect strong focusing on bodily sensations. Both groups of patients were significantly less active than the healthy subjects. The Kurtzke Expanded Disability Status Scale (EDSS) and the Beck Depression Inventory scores were not related to subjective fatigue severity. In patients with MS and in patients with CFS, subjective fatigue severity was related to impairment in daily life, low sense of control over symptoms, and strong focusing on bodily sensations. In CFS, but not in MS, evidence was found for a relationship between low levels of physical activity and attributing symptoms to a physical cause and between subjective fatigue severity and physical activity. CONCLUSIONS: Patients with MS experienced significant fatigue, which had a significant impact on daily functioning and was not related to depression on Expanded Disability Status Scale score. Psychological factors, such as focusing on bodily sensations and low sense of control play a role in the experience of fatigue in MS and CFS.
Vercoulen JH, Swanink CM, Fennis JF, Galama JM, van der Meer JW, Bleijenberg G.	Department of Medical Psychology, University Hospital Nijmegen, The Netherlands.	Prognosis in chronic fatigue syndrome: a prospective study on the natural course.	J Neurol Neurosurg Psychiatry 1996 May;60(5):489-94	OBJECTIVE--To determine spontaneous improvement after a follow up interval of 18 months in patients with chronic fatigue syndrome and to identify factors that predict improvement. METHODS--A longitudinal study was used. Of 298 initially assessed self referred patients fulfilling criteria for chronic fatigue syndrome, 246 patients completed self report questionnaires at follow up (response rate 83%). A multidimensional assessment method was used, measuring behavioural, emotional, cognitive, and social functioning. Comparison data from 53 healthy subjects matched for age, sex, and educational level were available. RESULTS--Three per cent of patients reported complete recovery and 17% reported improvement. At follow up, there were considerable problems at work and consumption of medication was high. Subjective improvement was confirmed by dimensional change: at follow up recovered patients had similar scores to healthy subjects and improved patients showed significant improvement on four out of seven outcome measures and had higher scores than healthy subjects in all dimensions. Sociodemographic variables or treatment by specialists and alternative practitioners did not predict improvement. Predictors of improvement were: subjective sense of control over symptoms, less fatigue, shorter duration of complaints, and a relative absence of physical attributions. CONCLUSION--The improvement rate in patients with a relatively long duration of complaints is small. Psychological factors are related to improvement, especially cognitive factors.
Vercoulen JH, Swanink CM, Zitman FG, Vreden SG, Hoofs MP, Fennis JF, Galama JM, van der	Department of Medical Psychology, University Hospital, Nijmegen, The Netherlands.	Randomised, double-blind, placebo-controlled study of fluoxetine in chronic	Lancet 1996 Mar 30;347(9005):858-61	BACKGROUND: No somatic treatment has been found to be effective for chronic fatigue syndrome (CFS). Antidepressant therapy is commonly used. Fluoxetine is recommended in preference to tricyclic agents because it has fewer sedative and autonomic nervous system effects. However, there have been no randomised,

Meer JW, Bleijenberg G.		fatigue syndrome.		placebo-controlled, double-blind studies showing the effectiveness of antidepressant therapy in CFS. We have carried out such a study to assess the effect of fluoxetine in depressed and non-depressed CFS patients. METHODS: In this randomised, double-blind study, we recruited 44 patients to the depressed CFS group, and 52 to the non-depressed CFS group. In each group participants were randomly assigned to receive either fluoxetine (20 mg once daily) or placebo for 8 weeks. The effect of fluoxetine was assessed by questionnaires, self-observation lists, standard neuropsychological tests, and a motion-sensing device (Actometer), which were applied on the day treatment started and on the last day. FINDINGS: The two groups were well matched in terms of age, sex distribution, employment and marital status, and duration of CFS. There were no significant differences between the placebo and fluoxetine-treated groups in the change during the 8-week treatment period for any dimension of CFS. There was no change in subjective assessments of fatigue, severity of depression, functional impairment, sleep disturbances, neuropsychological function, cognitions, or physical activity in the depressed or the non-depressed subgroup. INTERPRETATION: Fluoxetine in a 20 mg daily dose does not have a beneficial effect on any characteristic of CFS. The lack of effect of fluoxetine on depressive symptoms in CFS suggests that processes underlying the presentation of depressive symptoms in CFS may differ from those in patients with major depressive disorder. Randomized Controlled Trial
Wagner M, Gerhard R. F. Krueger, Dharam V. Ablashi, James E. Whitman		Chronic Fatigue Syndrome (CFS): A Critical Evaluation of Testing for Active Human Herpesvirus-6 (HHV-6) Infection Review of Data of 107 Cases	Journal of Chronic Fatigue Syndrome 1996: 2(4): 3 - 16	Aim: To conduct a virologic study in patients with chronic fatigue syndrome (CFS, ICD-10: G 93.3) for identification of reactivated human herpesvirus-6 (HHV-6) infection. Patients and Method: One hundred seven patients (60 women, 47 men, f/m ratio: 1.27/1; age: between 7 and 76 years, medium 41.8 years) with clinical CFS were studied with follow-up periods from 10 months to 7.5 years. Patients were recruited for the study by answering a standard questionnaire and by matching the Holmes' criteria for CFS. This was followed by physical examination, conventional hematological and chemistry testing, lymphocyte phenotyping, and control of other immunologic parameters. Testing for HHV-6 infection included indirect immunofluorescence assays (IFA), antigen capture enzyme linked immunosorbent assay (antigen capture ELISA, ACE), nested polymerase chain reaction (nPCR) on peripheral blood cells, and virus isolation. Results: HHV-6 seroprevalence in CFS patients was 97%. Seventy-two percent of the CFS patients had elevated serum anti-HHV-6 IgG titers, but active HHV-6 infection was detected in only 38.6% of the cases as identified by ACE, nPCR, and virus isolation. In absence of anti-HHV-6-IgM, anti-HHV-6-IgG titers were less reliable for monitoring virus activity. Among other infections EBV was seen in 19.6% of the cases and, less frequently, HSV, Chlamydia, Campylobacter, coxsackie, CMV, Yersinia or Candida. In 46% of the patients there were evident

				signs of immune deficiency. In additional 20% evidence was less clear (e.g., decreased lymphocyte stimulation: PHA/ConA 46%; low NK cell levels: 35%; and low CD4/CD8 cell ratio: 21%). Conclusion: Active HHV-6 infection was prevalent in one third of our CFS patients, much less than expected. Additional testing besides routine IFA is necessary for confirminig virus activity.
Ward MH, DeLisle H, Shores JH, Slocum PC, Foresman BH.	Department of Medicine, University of North Texas Health Science Center, Fort Worth, USA.	Chronic fatigue complaints in primary care: incidence and diagnostic patterns.	J Am Osteopath Assoc 1996 Jan;96(1):34-46, 41	The complaint of chronic fatigue is ubiquitous in the primary care setting. Because of the nonspecific nature of chronic fatigue, practitioners do not focus on this complaint. Furthermore, most physicians use a problem-based approach. Such a prematurely narrowed focus could overlook the chronic fatigue complaint. Omissions in the data collection process would prove this oversight. Therefore, we postulated that a retrospective review of evaluations for chronic fatigue would demonstrate significant categorical deficiencies. These deficiencies would indicate a problem focus different than the chronic fatigue complaint itself. The authors reviewed the current literature to establish historical, physical, and laboratory findings pertinent to the evaluation of chronic fatigue. Six major categories and the associated data elements were identified for use in analyzing patient records. The patient records from the preceding 6 months were reviewed to find those containing a complaint of chronic fatigue. These records were analyzed to determine if a complete data set had been sought and if an associated diagnosis was made. A total of 425 consecutive charts from an academic family practice clinic were retrospectively reviewed; 9.9% (42) mentioned chronic fatigue. Physicians were lax in performing the mental status and physical examinations; taking the patient's psychiatric and sleep history, as well as the history of chief complaint; and ordering laboratory evaluations. The physician diagnoses included: depression (40.4%), nonspecific fatigue (35.7%), general medical disorders (16.6%), chronic fatigue syndrome (2.4%), fibromyalgia (2.4%), and sleep apnea (2.4%). From these data, the investigators conclude that the workup for chronic fatigue is often incomplete or lacks documentation. This oversight is likely due to a problem focus not directed at the chronic fatigue complaints. Also complicating the evaluation process are the multiple associated disorders, the prevalence of the complaint, and cost/benefit issues facing the primary care physician.
Wearden AJ, Appleby L.	Department of Psychiatry, University Hospital of South Manchester, UK. awearden@psy.man.ac.uk	Research on cognitive complaints and cognitive functioning in patients with chronic fatigue syndrome (CFS): What conclusions can we draw?	J Psychosom Res 1996 Sep;41(3):197-211	People with chronic fatigue syndrome (CFS) complain of difficulties with concentration and memory yet studies suggest that they do not suffer gross deficits in cognitive functioning. Depressed patients make similar cognitive complaints, and there is symptomatic overlap between CFS and depression. Cognitive complaints and depressed mood are positively correlated in CFS patients but, except on tasks which are particularly sensitive to depression, cognitive performance and depression are not. The inconsistency between cognitive complaints and results of tests of cognitive functioning resembles that

				found in other subject groups and may be due in part to the inappropriate use of laboratory memory tests for assessing "everyday" cognitive functioning. Even when cognitive capacity is intact, cognitive performance may be affected by factors such as arousal, mood, and strategy. In CFS patients, everyday cognitive tasks may require excessive processing resources leaving patients with diminished spare attentional capacity or flexibility.
Wessely S, Chalder T, Hirsch S, Wallace P, Wright D.	Department of Psychological Medicine, King's College School of Medicine and Dentistry, London.	Psychological symptoms, somatic symptoms, and psychiatric disorder in chronic fatigue and chronic fatigue syndrome: a prospective study in the primary care setting.	Am J Psychiatry 1996 Aug;153(8):1050-9	OBJECTIVE: This study assessed relationships among psychological symptoms, past and current psychiatric disorder, functional impairment, somatic symptoms, chronic fatigue, and chronic fatigue syndrome. METHOD: A prospective cohort study was followed by a nested case-control study. The subjects, aged 18-45 years, had been in primary care for either clinical viral infections or a range of other problems. Questionnaire measures of fatigue and psychological symptoms were completed by 1,985 subjects 6 months later; 214 subjects with chronic fatigue were then compared with 214 matched subjects without fatigue. Assessments were made with questionnaires, interviews, and medical records of fatigue, somatic symptoms, psychiatric disorder, and functional impairment. RESULTS: Subjects with chronic fatigue were at greater risk than those without chronic fatigue for current psychiatric disorder assessed by standardized interview (60% versus 19%) or by questionnaire (71% versus 31%). Chronic fatigue subjects were more likely to have received psychotropic medication or experienced psychiatric disorder in the past. There was a trend for previous psychiatric disorder to be associated with comorbid rather than noncomorbid chronic fatigue. Most subjects with chronic fatigue syndrome also had current psychiatric disorder when assessed by interview (75%) or questionnaire (78%). Both the prevalence and incidence of chronic fatigue syndrome were associated with measures of previous psychiatric disorder. The number of symptoms suggested as characteristics of chronic fatigue syndrome was closely related to the total number of somatic symptoms and to measures of psychiatric disorder. Only postexertion malaise, muscle weakness, and myalgia were significantly more likely to be observed in chronic fatigue syndrome than in chronic fatigue. CONCLUSIONS: Most subjects with chronic fatigue or chronic fatigue syndrome in primary care also meet criteria for a current psychiatric disorder. Both chronic fatigue and chronic fatigue syndrome are associated with previous psychiatric disorder, partly explained by high rates of current psychiatric disorder. The symptoms thought to represent a specific process in chronic fatigue syndrome may be related to the joint experience of somatic and psychological distress.
Wessely S.	King's College School of Medicine and Dentistry, London.	Chronic fatigue syndrome. Summary of a report of a joint committee of the Royal	J R Coll Physicians Lond 1996 Nov-Dec;30(6):497-504	Chronic Fatigue Syndrome (CFS) is not a single diagnostic entity. It is a symptom complex which can be reached by many different routes. The conceptual model of CFS needs to be changed from one determined by a single cause/agent to one in which dysfunction is the end stage of a multifactorial process. Although it is

		Colleges of Physicians, Psychiatrists and General Practitioners.		important to recognise the role of factors that precipitate the condition, greater understanding is required of factors that predispose individuals to develop the illness, and those that perpetuate disability.
Wiebe E.	Department of Family Practice, University of British Columbia, Vancouver.	N of 1 trials. Managing patients with chronic fatigue syndrome: two case reports.	Can Fam Physician 1996 Nov;42:2214-7	Chronic fatigue syndrome is a heterogeneous condition with as proves effective treatment. I present two case reports in which N of 1 trials helped me make management decisions. High-dose vitamin B12 injections were ineffective in one case; nimodipine was very effective in the other case.

Williams DC.	Virginia-Carolina Sleep Disorders Center in Danville, USA.	Periodic limb movements of sleep and the restless legs syndrome.	Va Med Q 1996 Fall;123(4):260-5	Periodic limb movements of sleep and the restless legs syndrome are not diagnoses but rather an indication that there is some CNS disturbance and are associated with an ever-growing number of conditions. They are very common, exist in many forms and are often overlooked by physicians. It is the author's opinion that they are parts of what has been called an akathisia syndrome in the most severe situations and may include the same mechanisms that underlie attention disorders, chronic fatigue syndrome and "sun-downing." They are likely parts of a syndrome caused by dysfunction in a complex brainstem center. This center's normal function is to maintain a smooth electrical template on which discrete neuronal impulses sculpture the rich repertoire we recognize as sensory and motor function awake and to effect a smooth "switching" mechanism allowing sleep to occur without motor and sensory input invading consciousness (awakening). While the DA-ergic CNS pathways have been thought to be the primary neurotransmitter involved, the opioids secondary, there is mounting evidence that the situation is far more complicated, that many neurotransmitter, including stimulating and inhibiting amino acids, play a part. These patients agonize with their indisposition but can be helped by various treatments. Treatment alleviates not only the distress caused by the symptoms but also the devastating insomnia and excessive daytime sleepiness associated with it.
Williams G, Pirmohamed J, Minors D, Waterhouse J, Buchan I, Arendt J, Edwards RH.	Department of Medicine, University of Liverpool, UK.	Dissociation of body-temperature and melatonin secretion circadian rhythms in patients with chronic	Clin Physiol 1996 Jul;16(4):327-37	Many patients with chronic fatigue syndrome (CFS) display features of hypothalamic dysfunction. We have investigated aspects of circadian rhythmicity, an important hypothalamic function, in 20 CFS patients and in 17 age- and sex-matched healthy control subjects. There were no differences between the two groups in the amplitude, mesor (mean value) or timing of the peak (acrophase) of

		fatigue syndrome.		the circardian rhythm of core temperature, or in the timing of the onset of melatonin secretion. However, the CFS patients showed no significant correlation between the timing of the temperature acrophase and the melatonin onset ($P < 0.5$), whereas the normal significant correlation was observed in the controls ($P < 0.05$). Dissociation of circadian rhythms could be due to the sleep deprivation and social disruption, and/or the reduction in physical activity which typically accompany CFS. By analogy with jet-lag and shift-working, circadian dysrhythmia could be an important factor in initiating and perpetuating the cardinal symptoms of CFS, notably tiredness, impaired concentration and intellectual impairment.
Zorzenon M, Gull Rukh, Giuseppe A. Botta, Roberto Colle, Laura A. Barsanti , Luca Ceccherini-Nelli		Active HHV-6 Infection in Chronic Fatigue Syndrome Patients from Italy New Data	Journal of Chronic Fatigue Syndrome 1996: 2(1): 3 - 12	Primary Human Herpesvirus-6 (HHV-6) infection has been related to different clinical pictures and, notably, to Chronic Fatigue Syndrome (CFS). We studied 52 patients fulfilling the criteria of Centers for Disease Control (CDC) for CFS and a control group of 51 matched healthy blood donors. HHV-6 was recovered by culture and confirmed by immunofluorescence assay (IFA) and by PCR in 30/52 patients (57.7%) and in 6/51 (11.7%) of blood donors.

Ablashi DV, Kristine L. Ablashi, Bernhard Kramarsky, John Bernbaum, James E. Whitman , Gary R. Pearson		Viruses and Chronic Fatigue Syndrome Current Status	Journal of Chronic Fatigue Syndrome 1995: 1(2): 4 - 22	Because of the sudden onset of "flu-like" symptoms in he vast majority of cases, followed by persistent illness and fatigue over several years, bolh RNA (retroviruses) and DNA (herpesviruses and enteroviruses) viruses have been suspected to be implicated in the pathogenesis of CFS. In recent years, evidence of the association of some viruses wilh CFS has progressed, whereas, with some others it has weakened considerably. Thus far, no single virus has been found to be the causative agent of CFS. Reactivation, however, of latent virus or viruses could contribute to the symptomatology of CFS by damaging the immune system either directly or indirectly. In this report we have provided a comprehensive review of the status of research on viral agents which have been investigated for their role in the pathogenesis of CFS.

Ash-Bernal R, Wall C 3rd, Komaroff AL, Bell D, Oas JG, Payman RN, Fagioli LR.	Department of Otology and Laryngology, Massachusetts Eye and Ear Infirmary, Harvard Medical School, Boston, USA.	Vestibular function test anomalies in patients with chronic fatigue syndrome.	Acta Otolaryngol 1995 Jan;115(1):9-17	Chronic fatigue syndrome (CFS) is distinguished by the new onset of debilitating fatigue that lasts at least 6 months, concomitant with other symptoms to be described later. Many CFS patients complain of disequilibrium, yet the exact type of the balance dysfunction and its function and its location (peripheral vs. central) have not been described. Herein we report results of vestibular function testing performed on 11 CFS patients. These results revealed no predominant pattern of abnormalities. Patients typically performed below average in dynamic posturography testing, with a significant number of falls in the tests requiring subjects to depend heavily on the vestibular system. One patient had abnormal caloric testing, while 3 had abnormally low earth vertical axis rotation (EVA) gains at the higher frequencies tested. As a group, the average gain of EVA was significantly lower than normals in the 0.1 - 1.0 Hz range ($p < 0.05$). In earth horizontal axis rotation, the CFS group had a higher than normal bias value for the optokinetic (OKN) and eyes open in the dark conditions ($p < 0.05$), but had normal scores during visual vestibular reflex testing. Five of the 11 subjects had an abnormal OKN bias build up over the course of the run, equal to or actually exceeding the 60 degrees/s target velocity by as much as 14 degrees/s. Altogether, these results are more suggestive of central nervous system deficits than of peripheral vestibular disfunction.

Bates DW, Buchwald D, Lee J, Kith P, Doolittle T, Rutherford C, Churchill WH, Schur PH, Wener M, Wybenga D, et al.	Department of Medicine, Brigham and Women's Hospital, Boston, Mass.	Clinical laboratory test findings in patients with chronic fatigue syndrome.	Arch Intern Med 1995 Jan 9;155(1):97-103 comment in: Arch Intern Med. 1995 Jun 26;155(12):1332	BACKGROUND: Results of readily available clinical laboratory tests in patients with chronic fatigue syndrome were compared with results in healthy control subjects. METHODS: Cases consisted of all 579 patients who met either the Centers for Disease Control and Prevention, Atlanta, Ga, British, or Australian case definition for chronic fatigue syndrome. They were from chronic fatigue clinics in Boston, Mass, and Seattle, Wash. Control subjects consisted of 147 blood donors who denied chronic fatigue. Outcome measures were the results of 18 clinical laboratory tests. RESULTS: Age- and sex-adjusted odds ratios of abnormal results, comparing cases with control subjects, were as follows: circulating immune complexes, 26.5 (95% confidence interval [CI] 3.4-206), atypical lymphocytosis, 11.4 (95% CI, 1.4-94); elevated immunoglobulin G, 8.5 (95% CI, 2.0-37); elevated alkaline phosphatase, 4.2 (95% CI, 1.6-11); elevated total cholesterol, 2.1 (95% CI, 1.2-3.4); and elevated lactic dehydrogenase, 0.30 (95% CI, 0.16-0.56). Also, antinuclear antibodies were detected in 15% of cases vs 0% in the control subjects. The results of these tests were generally comparable for the cases from Seattle and Boston. Although these tests served to discriminate the population of patients from healthy control subjects, at the individual level they were not as useful. CONCLUSIONS: Patients with chronic fatigue syndrome who were located in two geographically distant areas had abnormalities in the results of several readily available clinical laboratory tests compared with healthy control subjects. The immunologic abnormalities are in accord with a growing body of evidence suggesting chronic, low-level activation of the immune system in chronic fatigue syndrome. While each of these laboratory findings supports the diagnosis of chronic fatigue syndrome, each lacks sufficient sensitivity to be a diagnostic test. Furthermore, the specificity of

				these findings relative to other organic and psychiatric conditions that can produce fatigue remains to be established.
Bearn J, Allain T, Coskeran P, Munro N, Butler J, McGregor A, Wessely S.	Department of Psychiatry, Institute of Psychiatry, London, UK.	Neuroendocrine responses to d-fenfluramine and insulin-induced hypoglycemia in chronic fatigue syndrome.	Biol Psychiatry 1995 Feb 15;37(4):245-52	Chronic fatigue syndrome (CFS) is a disorder characterized by severe physical and mental fatigue and fatiguability of central rather than peripheral origin. We hypothesized that CFS is mediated by changes in hypothalamopituitary function and so measured the adrenocorticotrophic hormone (ACTH), cortisol, growth hormone, and prolactin responses to insulin-induced hypoglycemia, and the ACTH, cortisol, and prolactin responses to serotoninergic stimulation with dexfenfluramine in nondepressed CFS patients and normal controls. We have shown attenuated prolactin responses to hypoglycemia in CFS. There was also a greater ACTH response and higher peak ACTH concentrations (36.44 +/- 4.45 versus 25.60 +/- 2.78 pg ml), whereas cortisol responses did not differ, findings that are compatible with impaired adrenal cortical function. This study provided evidence for both pituitary and adrenal cortical impairment in CFS and further studies are merited to both confirm and determine more precisely their neurobiological basis so that rational treatments can be evolved.
Bell DS		Chronic Fatigue Syndrome in Children	Journal of Chronic Fatigue Syndrome 1995: 1(1): 9 - 33	Chronic fatigue syndrome (CFS), formerly called chronic Epstein-Barr virus syndrome, chronic mononucleosis, and numerous other names, is a symptom complex characterized by marked functional limitation which affects children as well as adults. The symptom complex, physical examination, laboratory evaluation, clinical course, and differential diagnosis are reviewed with particular emphasis upon CFS in children. Management consists of a comprehensive treatment plan including medical, educational, and psychosocial support wiih the aim of reducing both symptom and activity limitation. While etiology is unknown, the use of the term "chronic fatigue syndrome" is appropriate for children with marked functional limitation due to unexplained fatigue who have the associated symptom complex and physical examination findings characteristic of this condition.
Bell DS		Diagnosis of Chronic Fatigue Syndrome in Children and Adolescents: Special Considerations	Journal of Chronic Fatigue Syndrome 1995: 1(3/4): 29 - 36	It has been a common occurrence that children with chronic, unexplained fatigue receive no specific diagnosis because of difficulties posed by the 1988 research criteria for chronic fatigue syndrome (CFS). The lack of a specific diagnosis creates medical uncertainty and may lead to increased psychosocial and educational disruption. With the recent publication of new research criteria these problems may be improved as the new criteria are less restrictive. In the process of developing new research criteria, data was collected for children who presented for evaluation of chronic unexplained fatigue over a two year period. Diagnosis of CFS was based upon the 1988 CDC criteria or clinical criteria based upon activity limitation and the associated symptom complex. Comparison of these two groups showed differences in symptom severity and degree of activity limitation, while demographics, psychosocial variables, and symptom pattern were similar. These

				results would suggest that chronic fatigue syndrome exists in a continuum of severity and that definition based solely upon severity of fatigue is arbitrary. While severe and debilitating fatigue should remain the basis of any research definition, clinical criteria based upon the symptom pattern of CFS may improve long term management by providing a working clinical diagnosis.
Berelowitz GJ, Burgess AP, Thanabalasingham T, Murray-Lyon IM, Wright DJ.	Department of Psychiatry, Charing Cross Hospital, London, UK.	Post-hepatitis syndrome revisited.	J Viral Hepat 1995;2(3):133-8	To examine the role of acute hepatitis A and B infection in the aetiology of chronic fatigue syndrome and psychiatric morbidity we studied 40 patients with acute viral hepatitis A or B consecutively admitted to an infectious diseases unit and studied at least 6 months after recovery. Liver function tests (LFT) had returned to normal in each case. Forty-seven patients with other infectious diseases, of which 12 were presumed viral, admitted immediately after each hepatitis patient during the same period acted as controls. The main outcome measures were scores on a fatigue and muscle pain questionnaire, general health questionnaire (GHQ-12) and supplementary questions. The hepatitis cases scored significantly higher fatigue scores, GHQ-12 scores and muscle pain scores. Length of time since recovery from illness, age and sex were not confounding factors. Hepatitis cases were also less energetic, had greater weight change, had altered alcohol tolerance, had less exercise tolerance and felt less fit than the control group and compared with their premorbid state. Hence fatigue is more common after recovery in patients hospitalized for hepatitis A and B up to 30 months post-infection compared with matched controls hospitalized for other infectious diseases. Hepatitis A and B infection is a risk factor for post-infection fatigue, intermittent fatigue, as well as for psychiatric morbidity.

Bianchedi M, Croce A, Moretti A, Neri G, Barberio A, Iezzi A, Pizzigallo E.	Clinica Otorinolaringoiatrica, Universita, G. D'Annunzio di Chieti.	[Auditory brain stem evoked potentials in the evaluation of chronic fatigue syndrome].[article in Italian]	908: Acta Otorhinolaryngol Ital 1995 Dec;15(6):403-10	The Chronic Fatigue Syndrome (CFS) was formally defined to describe disabling fatigue of multifactorial ethology with depression and immunologic dysfunctions linked to some currently recognized infectious agents. In most cases neurophysiological tests reveal abnormalities. In this paper the Authors use low (11 pps) and high (51-71 pps) frequency ABR to evaluate the electrophysiological function of auditory brainstem responses. Eighteen patients with suspected CFS, between the ages of 17 and 63, were examined. Eleven subjects had clinically diagnosed "true" CFS (CDC criteria modified by Fukuda). The 11 pps frequency test did not reveal a high number of abnormalities in the patients in question. However, the high frequency stimulation test (with 51 and 71 pps) which was statistically significant (P = 0.009) revealed numerous aberrations in 7 patients; absence of the first wave in 1 case, in 5 numerous wave gap delays and in 1 patient absence of the first wave and numerous wave gap delays. The high frequency test did not show many abnormalities for the 4 remaining patients. For

				the 7 "non CFS" subjects, the clinical-audiological comparison showed no statistical significance (P = 0.920). The Authors hypothesize that the absence of the first wave in the CFS Subject may well indicate a cyto-neural junction disease in the organ of Corti. The combined analysis of clinical and audiological data showed that the described tests are more reliable when employed in dealing with patients with clinically assessed "true" CFS.
Boda WL, Natelson BH, Sisto SA, Tapp WN.	Department of Physical Medicine and Rehabilitation, University of Medicine and Dentistry of New Jersey, New Jersey Medical School, East Orange, USA.	Gait abnormalities in chronic fatigue syndrome.	948: J Neurol Sci 1995 Aug;131(2):156-61	To evaluate our clinical impression that patients with the chronic fatigue syndrome (CFS) did not walk normally, we assessed gait kinematics at slow walking speeds (i.e., 0.45, 0.89 and 1.34 m/sec) and 30 m run time speeds on CFS patients and on a comparison group of sedentary controls. Run time was significantly slower for CFS than control subjects ($p < 0.001$). There was a significant interaction ($p < 0.01$) between group and speed for maximum hip angle during stance and swing phase with hip angle being significantly larger at 1.34 m/sec for CFS than controls subjects for both cases ($p < 0.05$). Knee flexion during stance and swing phases was significantly larger for controls than CFS subjects at 0.45 m/sec ($p < 0.01$). Ratio of stride length divided by leg length was significantly larger for the control subjects than for the CFS subjects with differences occurring at 0.45 and 0.89 m/sec ($p < 0.01$) but not 1.34 m/sec. The data indicate that CFS patients have gait abnormalities when compared to sedentary controls. These could be due to balance problems, muscle weakness, or central nervous system dysfunction; deciding which will require further research. Evaluation of gait may be a useful tool to measure outcome following therapeutic interventions.
Bohr TW.	Department of Neurology, Loma Linda University School of Medicine, California, USA.	Fibromyalgia syndrome and myofascial pain syndrome. Do they exist?	991: Neurol Clin 1995 May;13(2):365-84	"It is in the healing business that the temptations of junk science are the strongest and the controls against it the weakest." Despite their subjective nature, these syndromes (particularly MPS) have little reliability and validity, and advocates paint them as "objective." Despite a legacy of poor-quality science, enthusiasts continue to cite small, methodologically flawed studies purporting to show biologic variables for these syndromes. Despite a wealth of traditional pain research, disciples continue to ignore the placebo effect, demonstrating a therapeutic hubris despite studies showing a dismal natural history for FS. In reviewing the literature on MPS and FS, F.M.R. Walshe's sage words come to mind that the advocates of these syndromes are "better armed with technique than with judgment." A sympathic observer might claim that labeling patients with monikers of nondiseases such as FS and MPS may not be such a bad thing. After all, there is still a stigma for psychiatric disease in our society, and even telling a sufferer that this plays only a partial role may put that patient on the defensive. Labeling may have iatrogenic consequences, however, particularly in the setting of the work place. Furthermore, review of a typical support group newsletter gives ipso facto proof of this noxious potential. The author of a flyer

				stuffed inside the newsletter complains that getting social security and disability benefits for "the invisible disability" can be "an uphill battle. But don't loose (sic) hope." Apparently the "seriousness of the condition" is not appreciated by the medical community at large, and "clinician bias may well be the largest threat," according to Boston epidemiologist Dr. John Mason. Sufferers are urged to trek to their local medical library and pull four particular articles claiming FS patients have more "stress," "daily hassles," and difficulty working compared with arthritis patients. If articles can't be located, patients are told to ask their lawyers for help. Although "Chronic Fatigue Syndrome" and FS are not considered by everyone to be the same malady, the "National Institute of Health (sic) has lumped these two conditions together. This could work in your favor." (A U.S. political advocacy packet is available for $8, but a list of U.S. senators with Washington, DC addresses is freely provided.) These persons see themselves as victims worthy of a star appearance on the Oprah Winfrey show. A sense of bitterness emerges; one literally bed-bound Texas homemaker writes in Parents magazine that "Some doctors may give up and tell you that you are a hypochondriac."(ABSTRACT TRUNCATED AT 400 WORDS)
Bombardier CH, Buchwald D.	Department of Rehabilitation Medicine, University of Washington School of Medicine, Seattle, USA.	Outcome and prognosis of patients with chronic fatigue vs chronic fatigue syndrome.	920: Arch Intern Med 1995 Oct 23;155(19):2105-10	BACKGROUND: There are few data on the natural history and prognosis of persons with chronic fatigue (CF) or CF syndrome (CFS). Therefore, we compared functional outcomes in patients with each condition and tested the validity of various prognostic indicators. METHODS: Four hundred forty-five (89%) of 498 consecutive referral patients were surveyed an average of 1.5 years after an initial evaluation. Data from the initial evaluation were used to predict outcomes. RESULTS: Sixty-four percent of all patients reported improvement, but only 2% reported complete resolution of symptoms. Patients initially diagnosed as having CFS reported greater symptom severity and lower level of functioning at follow-up than did patients with CF. Major depression predicted unemployment in the CF group. Older age, longer duration of illness, and a lifetime history of dysthymia predicted less improvement in the CF group. Current dysthymia predicted less improvement for the CFS group. CONCLUSIONS: The case definition of CFS according to the Centers for Disease Control and Prevention identifies chronically fatigued patients with poorer prognosis. In a tertiary care setting, recovery from CF or CFS is rare, but improvement is common. Prognostic indicators vary for the two groups, but the coexistence of dysthymia suggests poorer outcomes generally.
Bou-Holaigah I, Rowe PC, Kan J, Calkins H.	Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, Md, USA.	The relationship between neurally mediated hypotension and the chronic fatigue syndrome.	931: JAMA 1995 Sep 27;274(12):961-7 comment in: JAMA. 1996 Feb 7;275(5):359-60 JAMA. 1996 Feb	OBJECTIVE--To compare the clinical symptoms and response evoked by upright tilt-table testing in healthy individuals and in a sample of those satisfying strict criteria for chronic fatigue syndrome. DESIGN--Case-comparison study with mean (SD) follow-up of 24 (5) weeks. SETTING--Tertiary care hospital. PATIENTS AND OTHER PARTICIPANTS--A sample of 23 patients with chronic fatigue syndrome

			7;275(5):359; discussion 360	(five men and 18 women; mean age, 34 years), each of whom fulfilled the strict diagnostic criteria of the Centers for Disease Control and Prevention, was recruited from regional chronic fatigue support groups and from the investigators' clinical practices. There were 14 healthy controls (four men and 10 women; mean age, 36 years). INTERVENTIONS--Each subject completed a symptom questionnaire and underwent a three-stage upright tilt-table test (stage 1, 45 minutes at 70 degrees tilt; stage 2, 15 minutes at 70 degrees tilt with 1 to 2 micrograms/min of isoproterenol; and stage 3, 10 minutes at 70 degrees with 3 to 4 micrograms/min of isoproterenol). Patients were offered therapy with fludrocortisone, beta-adrenergic blocking agents, and disopyramide, alone or in combination, directed at neurally mediated hypotension. MAIN OUTCOME MEASURES--Response to upright tilt and scores on symptom questionnaires prior to and during follow-up. RESULTS--An abnormal response to upright tilt was observed in 22 of 23 patients with chronic fatigue syndrome vs four of 14 controls ($P < .001$). Seventy percent of chronic fatigue syndrome patients, but no controls, had an abnormal response during stage 1 ($P < .001$). Nine patients reported complete or nearly complete resolution of chronic fatigue syndrome symptoms after therapy directed at neurally mediated hypotension. CONCLUSIONS--We conclude that chronic fatigue syndrome is associated with neurally mediated hypotension and that its symptoms may be improved in a subset of patients by therapy directed at this abnormal cardiovascular reflex.
Buchwald D, Umali P, Umali J, Kith P, Pearlman T, Komaroff AL.	University of Washington, Seattle, USA.	Chronic fatigue and the chronic fatigue syndrome: prevalence in a Pacific Northwest health care system.	951: Ann Intern Med 1995 Jul 15;123(2):81-8	OBJECTIVES: To investigate the point prevalence of the chronic fatigue syndrome and unexplained debilitating chronic fatigue in a community-based sample of persons and to describe demographic, clinical, and psychosocial differences among those with the chronic fatigue syndrome, those with chronic fatigue, and healthy controls. DESIGN: Prospective cohort study. SETTING: A health maintenance organization in Seattle, Washington. PARTICIPANTS: A random sample of 4000 members of the health maintenance organization was surveyed by mail for the presence of chronic fatigue. MEASUREMENTS: Persons with chronic fatigue were evaluated using a questionnaire that requested information about medical history and fatigue and related symptoms; validated measures of functional status and psychological distress; a physical examination; and standardized blood tests. A structured psychiatric interview was done in persons who appeared to meet the original Centers for Disease Control and Prevention (CDC) criteria for the chronic fatigue syndrome. Participants completed self-report measures at 12 and 24 months. Those with chronic fatigue were reevaluated in person 1 year after study enrollment. RESULTS: 3066 (77%) of the 4000 members surveyed responded. Chronic fatigue was reported by 590 persons (19%). Of these, 388 (66%) had a medical or psychiatric condition that could account for the fatigue. Of the 74 persons (37%) with chronic fatigue who

				were enrolled in the study, only 3 met the CDC criteria for the chronic fatigue syndrome. The remaining 71 persons were designated as having chronic fatigue alone. Seventy-four healthy, age- and sex-matched controls who were drawn from the same sample but who denied having chronic fatigue were also studied. Demographic characteristics were similar in persons with the chronic fatigue syndrome, persons with chronic fatigue alone, and controls. Those with the chronic fatigue syndrome or chronic fatigue alone had more frequent cervical and axillary adenopathy, poorer functional status, and greater psychological distress than controls. Women and minorities were not overrepresented among cases with chronic fatigue. CONCLUSIONS: Using different assumptions about the likelihood that persons who did not participate in the study had the chronic fatigue syndrome, the estimated crude point prevalence of the syndrome in this community ranged from 75 to 267 cases per 100,000 persons. The point prevalence of chronic fatigue alone was strikingly higher; it ranged from 1775 to 6321 cases per 100,000 persons.

Cater RE 2nd.		Chronic intestinal candidiasis as a possible etiological factor in the chronic fatigue syndrome.	984: Med Hypotheses 1995 Jun;44(6):507-15	The chronic candidiasis syndrome, also known as the Candida-related complex, putatively caused by the overgrowth of Candida albicans in the gastrointestinal tract and secondarily in the genital organs, is briefly described. Patients with this disorder have many of the same symptoms as those with the chronic fatigue syndrome, except for the recurrent flu-like symptoms of the latter disorder. The positive response of a large number of patients with the chronic fatigue syndrome (CFS) to an oral antifungal agent and a diet for intestinal candidiasis has been described by another clinician. There is evidence that Candida albicans infection of the mucous membranes depresses T cell and natural killer (NK) cell function. Similar abnormalities of immune function are found in the CFS. The function of cytotoxic T cells, T helper cells, and NK cells is important in preventing reactivation of infections from Epstein-Barr virus, cytomegalovirus, and other herpesviruses. Reactivation of one or more of these viruses could lead to the expression of the flu-like symptoms in the CFS. Yet the immune dysfunction found in this disorder has been considered the primary underlying causal factor. It is proposed that chronic intestinal candidiasis may be an agent which leads to immune depression in many CFS patients and therefore that it could be a causal factor in CFS.

Clark MR, Katon W, Russo J, Kith P, Sintay M, Buchwald D.	Department of Psychiatry and Behavioral Sciences, Johns Hopkins Hospital, Baltimore, Maryland 21287-5371.	Chronic fatigue: risk factors for symptom persistence in a 2 1/2-year follow-up study.	Am J Med 1995 Feb;98(2):187-95	BACKGROUND: The prolonged disability of patients suffering from chronic fatigue may be due to sustaining factors that are independent of the cause and subject to intervention. This study reexamined a cohort of patients with chronic fatigue to define medical and psychiatric predictors of persistent symptoms. METHODS: Seventy-eight patients with chronic fatigue present for 6 months or more (not required to meet the Centers for Disease Control case definition for chronic fatigue syndrome [CFS]) completed a self-report, follow-up questionnaire to measure the overall improvement or worsening of their condition at a mean of 2.5 years after their initial examination. At the time of initial evaluation, patients underwent a structured psychiatric examination, physical examination, laboratory studies, and self-report measures of psychological distress and functional disability. The psychiatric examination queried the patient about 28 somatic symptoms that are separate from those associated with CFS. Discriminant analysis was used to determine which variables present at the initial examination were significant predictors of persistent symptoms and disability at 2.5 years. RESULTS: The factors most important at the time of initial presentation in predicting persistent illness were: (1) more than eight medically unexplained

				physical symptoms separate from those associated with CFS case definition; (2) lifetime history of dysthymia; (3) duration of chronic fatigue symptoms greater than 1.5 years; (4) less than 16 years of formal education; and (5) age older than 38 years. None of the results of the initial physical examination, or immunologic, general laboratory, or viral antibody measurements were significant in predicting persistence of symptoms. Recovery rates for those who met the criteria for CFS by either of two case definitions were lower than the rate of noncases, but the differences were not statistically significant. The five aforementioned variables formed a significant discriminative function, correctly classifying 78% of those who recovered and 74% of those with persistent symptoms. CONCLUSIONS: At initial examination, patients with chronic fatigue, more than eight medically unexplained physical symptoms (excluding symptoms in the case criteria for CFS), a lifetime history of dysthymic disorder, longer than 1.5 years of chronic fatigue, less than 16 years of formal education, and who were older than 38 years were the most likely to have persistence of symptoms of chronic fatigue at the 2.5-year follow-up.
Clauw DJ.	Georgetown University Medical Center, Washington, DC 20007, USA.	The pathogenesis of chronic pain and fatigue syndromes, with special reference to fibromyalgia.	987: Med Hypotheses 1995 May;44(5):369-78	Syndromes characterized by chronic pain and fatigue have been described in the medical literature for centuries. Fibromyalgia is the term currently used to describe this symptom complex, and considerable research has been performed in the last decade to delineate the epidemiology, pathophysiology, and genesis of this entity. Although fibromyalgia is defined by its musculoskeletal features, it is clear that there are a large number of non-musculoskeletal symptoms, such that we now understand that there is considerable overlap with allied conditions such as the chronic fatigue syndrome, migraine and tension headaches, irritable bowel syndrome, and affective disorders. This article will review our current state of knowledge regarding fibromyalgia and these allied conditions, and present a unifying hypothesis that describes both the pathophysiology of symptoms and the genesis of these disorders.
Cleare AJ, Bearn J, Allain T, McGregor A, Wessely S, Murray RM, O'Keane V.	Maudsley Hospital, Denmark Hill, London, UK.	Contrasting neuroendocrine responses in depression and chronic fatigue syndrome.	940: J Affect Disord 1995 Aug 18;34(4):283-9	Hypothalamic-pituitary-adrenal (HPA) axis and central 5-HT function were compared in chronic fatigue syndrome (CFS), depression and healthy states. 10 patients with CFS and 15 patients with major depression were matched for age, weight, sex and menstrual cycle with 25 healthy controls. Baseline-circulating cortisol levels were highest in the depressed, lowest in the CFS and intermediate between the two in the control group (P = 0.01). Prolactin responses to the selective 5-HT-releasing agent d-fenfluramine were lowest in the depressed, highest in the CFS and intermediate between both in the healthy group (P = 0.01). Matched pair analysis confirmed higher prolactin responses in CFS patients than controls (P = 0.05) and lower responses in depressed patients than controls (P = 0.003). There were strong inverse correlations between prolactin and cortisol responses and baseline cortisol values. These data confirm that depression is

				associated with hypercotisolaemia and reduced central 5-HT neurotransmission and suggest that CFS may be associated with hypocortisolaemia and increased 5-HT function. The opposing responses in CFS and depression may be related to reversed patterns of behavioural dysfunction seen in these conditions. These findings attest to biological distinctions between these disorders.
Committee for Science and Education, Medical Association of South Africa.		Chronic fatigue syndrome.	946: S Afr Med J 1995 Aug;85(8):780-2 comment in: S Afr Med J. 1996 Oct;86(10):1301	OBJECTIVE: To acknowledge the clinical syndrome chronic fatigue syndrome (CFS) and outline the diagnostic criteria and reasonable management. OUTCOMES: Attempt at containment of treatment cost and improvement of the quality of care of patients with CFS. EVIDENCE: Delphi-type commentary from 20 expert clinicians and appropriate organisations. Limited literature survey. VALUES: To clarify the reasonable management of CFS amid conflicting clinical opinion on a condition of concern to patients, funders and doctors. An adaptation of an existing guideline was sent to organisations and individuals for comment. Comments received were included in this guideline where possible. BENEFITS, HARMS AND COSTS. To acknowledge a clinical syndrome with a reasonable approach to management considering the cost implications. No cost analysis was done. RECOMMENDATIONS: To recommend the following: (i) diagnostic criteria for CFS; (ii) potential differential diagnoses and possible investigations; and (iii) management protocol. VALIDATION: The draft guidelines were subjected to external review by individual doctors who are acknowledged CFS treaters, doctor groups and the patient support group. There were major disputes about the content, with the responses falling into two groups: those who do not believe CFS is a distinguishable illness, and those who do. DEVELOPER AND FUNDING: The Committee for Science and Education, Medical Association of South Africa. ENDORSEMENTS: Medical Association of South Africa and national health care organisations (see list at the end of the document).
Cope H, David A, Pelosi A, Mann A.		Chronic fatigue syndrome.	Lancet 1995 Jan 14;345(8942):131 comment on: Lancet. 1994 Nov 26;344(8935):1514	
Cope H, Pernet A, Kendall B, David A.	Section of Neuropsychiatry, Institute of Psychiatry, London.	Cognitive functioning and magnetic resonance imaging in chronic fatigue.	965: Br J Psychiatry 1995 Jul;167(1):86-94	BACKGROUND. This study examines whether cognitive dysfunction in chronic fatigue may be accounted for by depression and anxiety or is due to brain pathology evident on magnetic resonance imaging (MRI). METHOD. Twenty-six subjects with chronic fatigue, with and without coexisting depression, and 18 age-matched normal controls were recruited from primary care following a presumed viral illness six months previously. Comparison was made with 13 psychiatric controls with depressive illness on standardised cognitive tests. MRI determined the presence of cerebral white-matter lesions. RESULTS. No substantial differences in performance were shown between subjects with

				chronic fatigue, most of whom met the criteria for chronic fatigue syndrome, and controls. Subjective cognitive dysfunction increased with psychopathology. White-matter lesions were found in a minority from all groups. Improvement in fatigue and depression coincided with improved performance on cognitive measures. CONCLUSIONS. Subjective complaints of cognitive impairment are a prominent feature of chronic fatigue, but objective cognitive and MRI abnormalities are not. Such complaints probably reflect psychopathology rather than a post-viral process.
Costa DC, Tannock C, Brostoff J.	Department of Psychiatry, UCL Medical School, London, UK.	Brainstem perfusion is impaired in chronic fatigue syndrome.	918: QJM 1995 Nov;88(11):767-73 comment in: QJM. 1996 Feb;89(2):163-4	We looked for brain perfusion abnormalities in patients with myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). An initial pilot study revealed widespread reduction of regional brain perfusion in 24 ME/CFS patients, compared with 24 normal volunteers. Hypoperfusion of the brainstem (0.72 +/- 0.05 vs. 0.80 +/- 0.04, $p < 0.0001$) was marked and constant. We then tested whether perfusion to the brainstem in ME/CFS patients differs from that in normals, patients with major depression, and others with epilepsy. Data from a total of 146 subjects were included in the present study: 40 normal volunteers, 67 patients with ME/CFS (24 in the pilot study, 16 with no psychiatric disorders, 13 with ME/CFS and depression, 14 with ME/CFS and other psychiatric disorders), 10 epileptics, 20 young depressed patients and 9 elderly depressed individuals. Brain perfusion ratios were calculated using 99Tcm-hexamethylpropylene amine oxime (99Tcm-HMPAO) and single-photon emission tomography (SPET) with a dedicated three-detector gamma camera computer/system (GE Neurocam). Brain-stem hypoperfusion was confirmed in all ME/CFS patients. Furthermore, the 16 ME/CFS patients with no psychiatric disorders and the initial 24 patients in the pilot study showed significantly lower brainstem perfusion (0.71 +/- 0.03) than did depressed patients (0.77 +/- 0.03; ANOVA, $p < 0.0001$). Patients with ME/CFS have a generalized reduction of brain perfusion, with a particular pattern of hypoperfusion of the brainstem.
Cuellar ML, Gluck O, Molina JF, Gutierrez S, Garcia C, Espinoza R.	Department of Medicine, LSU Medical Center at New Orleans, USA.	Silicone breast implant--associated musculoskeletal manifestations.	915: Clin Rheumatol 1995 Nov;14(6):667-72	Three hundred consecutive women with silicone breast implants (SBI), referred to the arthritis clinic with a variety of musculoskeletal complaints, were evaluated for the presence of underlying connective tissue disease. A complete history and physical examination were performed, as well as laboratory testing for C-reactive protein, rheumatoid factor; and autoantibody determination by indirect immunofluorescence and immunodiffusion. The group mean age was 44.4 years (range 25-69), the mean time from initial implant surgery to appearance of symptoms was 6.8 years (range: 6m-19y) and 83.3% of women studied had clinical manifestations highly suggestive of an underlying connective tissue disorder. Fifty-four percent met criteria for fibromyalgia and/or chronic fatigue syndrome, distinct connective tissue diseases was detected in 11%, undifferentiated connective tissue disease or human adjuvant disease was found

				in 10.6%, and a variety of disorders such as angioneurotic oedema, frozen shoulder, multiple sclerosis-like syndrome were present. Several other miscellaneous conditions including recurrent unexplained low grade fever, hair loss, skin rash, sicca symptoms, Raynaud's phenomenon, carpal tunnel syndrome, memory loss, headaches, chest pain, and shortness of breath were also seen accompanying specific and non-specific conditions. Seventy percent of patients who underwent explanation of the implants reported improvement of their systemic symptomatology. A significant proportion of SBI patients referred for rheumatic evaluation have clinical manifestations highly suggestive of an underlying connective tissue disease. Furthermore, improvement of their symptomatology follows explanation of the implants in over half of the patients.

DeLuca J, Johnson SK, Beldowicz D, Natelson BH.	Department of Research and Psychology, Kessler Institute for Rehabilitation, West Orange, New Jersey.	Neuropsychological impairments in chronic fatigue syndrome, multiple sclerosis, and depression.	J Neurol Neurosurg Psychiatry 1995 Jan;58(1):38-43	To examine the degree and nature of cognitive impairments in chronic fatigue syndrome, a comprehensive neuropsychological battery was given to patients with chronic fatigue syndrome, multiple sclerosis, depressed patients, and healthy controls. The battery included tests of attention and concentration, information processing speed, verbal and visual memory, intellectual ability, and concept formation. Measures of depression and anxiety were also obtained. The chronic fatigue syndrome group did not differ from the depressed group in overall neuropsychological performance, but differed from the multiple sclerosis and control groups. The most significant impairment was in information processing speed in the chronic fatigue syndrome group. Depression and anxiety were not related to neuropsychological performance. The influence of reduced information processing on other areas of cognition is discussed.
DeLuca J, Karen B. Schmaling		Neurocognitive Testing in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1995: 1(3/4): 21 - 26	
Di Luca D, Zorzenon M, Mirandola P, Colle R, Botta GA, Cassai E.	Institute of Microbiology, University of Ferrara, Italy.	Human herpesvirus 6 and human herpesvirus 7 in chronic fatigue syndrome.	976: J Clin Microbiol 1995 Jun;33(6):1660-61	We analyzed lymphocytes of patients with chronic fatigue syndrome (CFS) for the presence of human herpesvirus 6 (HHV-6) and HHV-7 DNA. HHV-7 was present in over 80% of CFS patients and healthy controls, while the prevalence of HHV-6 variant A increased significantly in CFS cases (22 versus 4%; P = 0.05).
Dobbins JG, Benjamin Natelson, Ira Brassloff,		Physical, Behavioral, and Psychological Risk	Journal of Chronic Fatigue Syndrome 1995:	In spite of the distinct epidemiologic features of chronic fatigue syndrome, its cause remains unknown and no risk factors for the illness have been identified. In

Susan Drastal, Sue-Ann Sisto		Factors for Chronic Fatigue Syndrome A Central Role for Stress?	1(2): 43 - 58	order to better characterize CFS, we conducted a case-control study of well-defined CFS cases to identify physical, behavioral, and psychological factors related to the occurrence of CFS. The study, conducted in the metropolitan area surrounding Newark, New Jersey, USA, included 20 patients who fulfilled the CFS case definition and 20 matched controls. All subjects completed a self-administered questionnaire. The greatest difference between cases and controls was the reported level of stress from any of five sources in the 5 years prior to onset of illness (95% vs. 55%; P = 0.01 1). In addition, the risk of CFS was significantly related to the number of sources of stress, especially
Dodge JH, Kita MW.		The chronic fatigue syndrome.	960: Ann Intern Med 1995 Jul 1;123(1):75; discussion 76 comment on: Ann Intern Med. 1994 Dec 15;121(12):953-9	
Dunstan RH, Donohoe M, Taylor W, Roberts TK, Murdoch RN, Watkins JA, McGregor NR.	Department of Biological Sciences, University of Newcastle, NSW.	A preliminary investigation of chlorinated hydrocarbons and chronic fatigue syndrome.	934: Med J Aust 1995 Sep 18;163(6):294-7	OBJECTIVE: To determine whether serum levels of chlorinated hydrocarbons are elevated in patients with chronic fatigue syndrome. METHODS: Chlorinated hydrocarbon levels were measured in 22 patients with chronic fatigue syndrome (CFS) (as defined by the Centers for Disease Control [CDC]); in 17 patients with CFS symptoms whose history of exposure to toxic chemicals excluded them from the research definition of CFS; and in 34 non-CFS control subjects matched for age and sex. RESULTS: DDE (1,1-dichloro-2,2-bis (p-chlorophenyl) ethene) was detected in all serum samples at levels over 0.4 ppb. The incidence of hexachlorobenzene (HCB) contamination (> 2.0 ppb) was 45% in the CFS group, compared with 21% in the non-CFS control group (P < 0.05). The CFS group had a significantly higher total organochlorine level (15.9 ppb; SEM, 4.4) than the control group (6.3 ppb; SEM, 1.1; P < 0.05). The toxic exposure group also had a higher mean organochlorine level (13.6 ppb; SEM, 6.2) than the control group, but the difference was not statistically significant. DDE and HCB comprised more than 90% of the total organochlorines measured in each of the groups. CONCLUSION: The results suggest that recalcitrant organochlorines may have an aetiological role in CFS. There were no significant differences in serum organochlorine concentrations between CFS patients and chronic fatigue patients with a history of toxic chemical exposure. Therefore, exclusion of patients from the CDC research definition of CFS on the basis of a reported history of known exposure to toxic chemicals is not valid. The role of low-level organochlorine bioaccumulation in the development of CFS symptoms requires further investigation.
Farmer A, Jones I, Hillier J, Llewelyn M,	Department of Psychological Medicine,	Neuraesthenia revisited: ICD-10 and DSM-III-R	925: Br J Psychiatry 1995 Oct;167(4):503-6	BACKGROUND: Different definitions of chronic fatigue syndrome (CFS) have different psychiatric exclusion criteria and this affects the type and frequency of

Borysiewicz L, Smith A.	University of Wales College of Medicine, Heath Park, Cardiff.	psychiatric syndromes in chronic fatigue patients and comparison subjects.		associated psychiatric morbidity found. The operational criteria for neuraesthenia in ICD-10 vary in this and other respects from the Centers for Disease Control and Prevention (CDC) criteria for CFS. Neuraesthenia and associated psychiatric morbidity in CDC-defined CFS are evaluated. METHOD: CFS subjects and controls were interviewed with the Schedule for the Clinical Assessment of Neuropsychiatry (SCAN). The computerised scoring program for SCAN (CATEGO5) facilitates the assignment of operational definitions according to DSM-III-R and ICD-10. Subjects were re-interviewed with SCAN an average of 11 months later. No specific treatments or interventions were given during this period. RESULTS: The majority of subjects fulfilled ICD-10 operational criteria for neuraesthenia and had two and a half times the rate of psychiatric morbidity as the healthy comparison group according to the CATEGO5 Index of Definition (ID). Approximately 80% of subjects fulfilled both DSM-III-R and ICD-10 criteria for sleep disorders. There was a significant fall in the number of subjects fulfilling criteria for depression and anxiety disorders and a significant increase in the number of subjects with no diagnosis for DSM-III-R criteria over time. There were no significant changes over time for any diagnosis according to ICD-10 criteria or for overall levels of psychopathology as reflected in CATEGO5 ID levels. CONCLUSIONS: The ICD-10 'neuraesthenia' definition identifies almost all subjects with CDC-defined CFS. Fifty percent of CFS subjects also had depressive or anxiety disorders, some categories of which remit spontaneously over time.
Farrar DJ, Locke SE, Kantrowitz FG.	Department of Psychiatry, Beth Israel Hospital, Harvard Medical School, Boston, USA.	Chronic fatigue syndrome. 1: Etiology and pathogenesis.	Behav Med 1995 Spring;21(1):5-16	Chronic fatigue syndrome (CFS) is a disorder of unknown etiology characterized by debilitating fatigue and other somatic and neuropsychiatric symptoms. A range of heterogeneous clinical and laboratory findings have been reported in patients with CFS. Various theories have been proposed to explain the underlying pathophysiologic processes but none has been proved. Research findings of immunologic dysfunction and neuroendocrine changes suggest the possible dysregulation of interactions between the nervous system and the immune system. Without a clear understanding of its etiopathogenesis, CFS has no definitive treatment. Management approaches have been necessarily speculative, and they have evolved separately in a number of medical and nonmedical disciplines. The results of several controlled treatment studies have been inconclusive. An accurate case definition identifying homogeneous subtypes of CFS is needed. The integration of medical and psychologic treatment modalities and the use of both biologic and psychologic markers to evaluate treatment response will enhance future treatment strategies.
Fennell PA		CFS Sociocultural Influences and Trauma: Clinical Considerations	Journal of Chronic Fatigue Syndrome 1995: 1(3/4): 159 - 173	An integrated model of the assessment and treatment of the CFS population needs to include the sociocultural influences that affect CFS patients as well as their treating clinicians. These sociocultural factors include: (1) the pre-existing cultural climate toward disease, (2) cultural intolerance of ambiguity, (3) cultural

				intolerance of chronic vs. acute illness, (4) the ongoing psyche-soma duality among health care providers, and (5) initial disease illegitimacy and subsequent enculturation. These specific influences, as well as the patient's medical status, need to be carefully considered in the assessment and treatment of CFS patients and their families. The traumatogenic effects of these sociocultural influences on CFS patients will be discussed and specific treatment strategies will be suggested
Fennell PA		The Four Progressive Stages of the CFS Experience: A Coping Tool for Patients	Journal of Chronic Fatigue Syndrome 1995: 1(3/4): 69 - 79	The CFS experience may be construed as a series of adaptations and adjustments that begin at the onset of symptoms. The ability of the CFS-affected individual to cope with symptoms and disabilities is strongly influenced by sociocultural factors. The purpose of this paper is to present a comprehensive multistage model of the CFS experience that recognizes the influences of cultural, psychosocial and medical factors in CFS assessment and treatment. The patient's awareness of these stages of adjustment can be an important coping tool in reconstructing the illness experience.
Fisk JW.		Chronic fatigue syndrome.	932: N Z Med J 1995 Sep 22;108(1008):393 comment on: N Z Med J. 1995 Jul 28;108(1004):301	
Flanigan MJ, Morehouse RL, Shapiro CM.	Department of Psychiatry, University of Toronto, Ontario, Canada.	Determination of observer-rated alpha activity during sleep.	927: Sleep 1995 Oct;18(8):702-6	Patients suffering from chronic fatigue syndrome (CFS) have been described as having alpha intrusion into sleep. In a separate study of the relationship between depression and CFS, we investigated the sleep of CFS patients. We could not detect any observable alpha anomaly in our group of CFS patients. It is possible that there is a subgroup of CFS patients in whom no alpha anomaly is present. However, the sleep electroencephalogram (EEG) montage used in our study was different to that employed by previous researchers. This paper investigates the influence of electrode derivations on the outcome of observable alpha ratings. We compared simultaneous recordings of sleep EEG using three commonly employed montages. Our results indicate that use of the mastoid reference (montage 1) results in the highest observer-related alpha. This may suggest that data regarding alpha intrusion should always be collected using montage 1. However, there is a possibility that the mastoid electrode is not electrically silent and is contaminating the data of the referenced channels. The implications of these findings are discussed in relation to the validity of alpha intrusion measurement of CFS and fibromyalgia.
Friedberg F		The Stress/Fatigue Link in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1995: 1(3/4): 147 - 152	This paper cites preliminary evidence for the relationship between fatigue and stress in chronic fatigue syndrome. Stress may intensify symptoms of CFS and erode positive mood and affect. A model of the stress/fatigue link in CFS will be presented and a specific coping technique will be described as a tool to interrupt the stress/symptom interaction in CFS.

Friedberg F		Clinical Assessment of Coping in CFS Patients	Journal of Chronic Fatigue Syndrome 1995: 1(3/4): 53 - 58	The controversy regarding psychosocial factors in the onset and maintenance of chronic fatigue syndrome (CFS) is briefly outlined. The primary purpose of this presentation is to describe coping assessments and possible cognitive-behavioral interventions for CFS patients.

Galbraith DN, Nairn C, Clements GB.	Regional Virus Laboratory, Ruchill Hospital, Glasgow, UK.	Phylogenetic analysis of short enteroviral sequences from patients with chronic fatigue syndrome.	953: J Gen Virol 1995 Jul;76 (Pt 7):1701-7	This study used phylogenetic analysis based on a region of the 5' non-translated region (5'NTR) of a variety of enteroviral sequences to compare sequences associated with chronic fatigue syndrome (CFS) and those from enteroviruses causing acute infections. Direct sequencing of PCR products was used to obtain the nucleic acid sequences from CFS patients. The inferred phylogenetic tree identified three groupings, one correlating with the diagnosis of CFS. The analysis identified a close relationship between the chronic fatigue enteroviral sequences, and showed that 19/20 were distinct from previously described enteroviruses. These results suggest there is persistence of enterovirus infection in some CFS patients and indicate the presence of distinct novel enterovirus sequences.

Adolesc Med 1995 Feb;6(1):101-114	Despite its new name, chronic fatigue syndrome is not a new disease. This chapter reviews current definitions, emphasizing that chronic fatigue syndrome is a diagnosis of exclusion. The author also discusses viral infections that are associated with CFS, including Epstein-Barr virus, cytomegalovirus, herpesvirus type 6, enteroviruses, and retroviruses.
Gold PW, Licinio J, Wong ML, Chrousos GP.	Clinical Neuroendocrinology Branch, NIMH, Bethesda, Maryland 20892, USA.	Corticotropin releasing hormone in the pathophysiology of melancholic and atypical depression and in the mechanism of action of antidepressant drugs.	906: Ann N Y Acad Sci 1995 Dec 29;771:716-29	Hypercortisolism in depression seems to preferentially reflect activation of hypothalamic CRH secretion. Although it has been postulated that this hypercortisolism is an epiphenomenon of the pain and stress of major depression, our data showing preferential participation of AVP in the hypercortisolism of chronic inflammatory disease suggest specificity for the pathophysiology of hypercortisolism in depression. Our findings that imipramine causes a down-regulation of the HPA axis in experimental animals and healthy controls support an intrinsic role for CRH in the pathophysiology of melancholia and in the mechanism of action of psychotropic agents. Our data suggest that hypercortisolism is not the only form of HPA dysregulation in major depression. In a series of studies, commencing in patients with Cushing's disease, and extending to hyperimmune fatigue states such as chronic fatigue syndrome and examples of atypical depression such as seasonal affective disorder, we have advanced data suggesting hypofunction of hypothalamic CRH neurons. These data raise the question that the hyperphagia, hypersomnia, and fatigue associated with syndromes of atypical depression could reflect a central deficiency of a potent arousal-producing anorexogenic neuropeptide. In the light of data presented elsewhere in this symposium regarding the role of a hypofunctioning hypothalamic CRH neuron in susceptibility to inflammatory disease, these data also raise the question of a common pathophysiological mechanism in syndromes associated both with inflammatory manifestations and atypical depressive symptoms. This concept of hypofunctioning of hypothalamic CRH neurons in these disorders also raises the question of novel forms of neuropharmacological intervention in both inflammatory diseases and atypical depressive syndromes. Review, Academic

There were further studies reporting that fibromyalgia-chronic

	Massachusetts, USA.	syndrome.		fatigue syndrome may follow well treated Lyme disease or mimic Lyme disease. The longest therapeutic trial to date in fibromyalgia demonstrated an initial modest effect of tricyclic medications, but at 6 months that efficacy was no longer evident. Investigation in both fibromyalgia and chronic fatigue syndrome now focuses on the central nervous system. The use of new technology, eg, neurohormonal assays and imaging such as single-photon emission computed tomography scan, may be important in understanding these elusive conditions.
Goldstein JA, Ismael Mena, Eugenio Jouanne, Ira Lesser		The Assessment of Vascular Abnormalities in Late Life Chronic Fatigue Syndrome by Brain SPECT: Comparison with Late Life Major Depressive Disorder	Journal of Chronic Fatigue Syndrome 1995: 1(1): 55 - 79	We report on brain SPECT analysis of regional cerebral blood flow (rCBF) in late life chronic fatigue syndrome (CFS) patients and compare their results with patients with late life depression and elderly normal controls 45 years and older. We attempted to distinguish CFS from normals and patients with depression and applied the findings to understand the pathophysiology of the illness. We studied 33 patients with CFS (55 ± 10 years), 26 patients with late life depression (62 ± 8 years), and 19 normal controls (66 ± 8 years); 43 other normal controls had only ^{133}Xe rCBF measurements (66 ± 8 years). We evaluated rCBF quantitatively with ^{133}Xe images and qualitatively with high resolution imaging using 99mTc-HMPAO. We found that rCBF in CFS measured by ^{133}Xe varied between 35 and 41 ml/min/l00g in both hemispheres, $p < 0.0001$ and 0.05; similar findings were observed in depression. In CFS 99mTc-HMPAO imagain demonstrated right orbitofrontal and marked right dorsofrontal hypoperfusion at 58% to 66% of the maximal activity in the brain, p , 0.001. In late life depression, hypoperfusion was primarily limited to the right orbitofrontal lobe, 42% and 57%, p , 0.001. In depression, the abnormalities were most striking in the left temporal lobe and particularly in the left anterior frontal lobes. CFS patients with major depressive disorder by DMS-III-R criteria did not differ in regional cerebral hypoperfusion from those without major depression. The pathophysiology of the illness may involve the dysregulation of a neural network which includes circuits between the hippocampus (located in the anterior temporal lobe) and the dorsolateral prefrontal cortex.
Hamre HJ.		[Chronic fatigue syndrome--a review of the literature].[article in Norwegian]	923: Tidsskr Nor Laegeforen 1995 Oct 10;115(24):3042-5	Chronic fatigue syndrome is a clinical condition characterized by abnormal fatigue, subfebrile body temperature, sore throat, lymphadenopathy, arthralgia, myalgia and neuropsychiatric symptoms. Typically, the syndrome develops after a flu-like illness and is markedly exacerbated by exercise. The etiology is unknown and there is no single diagnostic test. The patients may have cognitive dysfunction, immunological and endocrinological abnormalities and abnormal mitochondria. Magnetic resonance imaging scans may show increased uptake of signals in the brain, and single photon emission computerized tomography reveals regional hypoperfusion of the brain. The author discusses similarities and distinctions between the syndrome and depression.

Harrison AL		Development and Evaluation of Claims Involving Chronic Fatigue Syndrome (CFS) Under the Social Security Disability Provisions	Journal of Chronic Fatigue Syndrome 1995: 1(3/4): 131 - 133	
Heiman TH		Chronic Fatigue Syndrome and Vocational Rehabilitation: Unserved and Unmet Needs	Journal of Chronic Fatigue Syndrome 1995: 1(3/4): 105 - 118	Individuals with chronic fatigue syndrome (CFS) are largely unserved by the health care and rehabilitation professions. Their numbers are growing and their needs are complex and extensive. Some persons with CFS (PWCs), who have the least functional impairment, may benefit from vocational rehabilitation services. While employment options or accommodations, as well as support services, may be available to PWCs, their disabilities are gravely misunderstood, requiring long-term, intermittent, knowledgeable, professional counseling, and support. Given the frequency of reports by consumers and advocates concerning unserved, unmet needs of PWCs, a survey was conducted among PWCs throughout Wisconsin to identify their needs both for independent living support services and for employment accommodations. A weighted scale was developed based upon self-reports of 119 respondents regarding importance and satisfaction levels for such services. Results provided rankings of PWC needs, to the degree that such needs were perceived as unserved and unmet. Furthermore, subjects reported the number of good days and bad days experienced monthly, describing dfferential levels of symptoms and function for these days on a CFIDS Disability Scale, created by David Bell, M.D. Results indicated the devastating impact of CFS upon health, daily activities, personal relationships, income, and work. PWC's reported significantly-unmet or highly-unmet needs for the great majority of the selected support services and employment accomodations.
Hickie I, Lloyd A, Hadzi-Pavlovic D, Parker G, Bird K, Wakefield D.	School of Psychiatry, University of New South Wales, Australia.	Can the chronic fatigue syndrome be defined by distinct clinical features?	937: Psychol Med 1995 Sep;25(5):925-35	To determine whether patients diagnosed as having chronic fatigue syndrome (CFS) constitute a clinically homogeneous class, multivariate statistical analyses were used to derive symptom patterns and potential patient subclasses in 565 patients. The notion that patients currently diagnosed as having CFS constitute a single homogeneous class was rejected. An alternative set of clinical subgroups was derived. The validity of these subgroups was assessed by sociodemographic, psychiatric, immunological and illness behaviour variables. A two-class statistical solution was considered most coherent, with patients from the smaller class (27%

				of the sample) having clinical characteristics suggestive of somatoform disorders. The larger class (73% of sample) presented a more limited combination of fatigue and neuropsychological symptoms, and only moderate disability but remained heterogeneous clinically. The two patient groups differed with regard to duration of illness, spontaneous recovery, severity of current psychological morbidity, utilization of medical services and CD8 T cell subset counts.The distribution of symptoms among patients was not unimodal, supporting the notion that differences between the proposed subclasses were not due simply to differences in symptom severity. This study demonstrated clinical heterogeneity among patients currently diagnosed as CFS, suggesting aetiological heterogeneity. In the absence of discriminative clinical features, current consensus criteria do not necessarily reduce the heterogeneity of patients recruited to CFS research studies.
Hickie I, Lloyd A.	School of Psychiatry, University of New South Wales, Sydney, Australia.	Are cytokines associated with neuropsychiatric syndromes in humans?	943: Int J Immunopharmacol 1995 Aug;17(8):677-83	Traditional aetiological models in neuropsychiatry have placed little emphasis on the abnormal behavioural responses (decreased psychomotor activity, anorexia, weight loss, decreased social exploration and sexual behaviour, impaired cognitive function and increased somnolence) that are common to both psychiatric syndromes, notably depression, and the illness behaviour of sick animals. In recent years, the possible role of cytokines, as mediators of not only the immunological and metabolic responses to infection and inflammation but also a co-ordinated behavioural response, has been described. Further, a range of possible mechanisms for these effects has been postulated, notably involving corticotropin releasing factor (CRF) and prostaglandins of the E series (PgE) with the central nervous system (CNS). Here we outline a series of human clinical conditions where neuropsychiatric syndromes co-occur with a host response to infection or inflammation. These may be characterized by cytokine production (e.g. acute, recurrent and chronic viral illness, systemic autoimmune diseases and chronic fatigue syndrome). Other clinical situations characterized by exposure to or in vivo production of cytokines (e.g. treatment of chronic infections and malignancies, progression and/or recurrence of malignancies) are also discussed. We postulate that the stereotyped behavioural repertoire observed is mediated by cytokine-dependent mechanisms within the CNS. Systematic studies of the behavioural responses of such patient groups are suggested, noting specifically correlations between the time course and severity of immune and neuroendocrine and behavioural responses and dose-response effects.
Hickie IB, Lloyd AR, Wakefield D.	University of New South Wales, Sydney.	Chronic fatigue syndrome: current perspectives on evaluation and management.	933: Med J Aust 1995 Sep 18;163(6):314-8 comment in: Med J Aust. 1996 Mar 18;164(6):384	OBJECTIVE: To describe clinical and laboratory guidelines for assessment and management of patients presenting with chronic fatigue syndrome (CFS). DATA SOURCES: Relevant international consensus diagnostic criteria and research literature on the epidemiology, pathophysiology, concurrent medical and psychological disturbance and clinical management of CFS. CONCLUSIONS:

				Medical and psychiatric morbidity should be carefully assessed and actively treated, while unnecessary laboratory investigations and extravagant treatment regimens should be avoided. No single infective agent has been demonstrated as the cause of CFS, and immunopathological hypotheses remain speculative. The aetiological role of psychological factors is debated, but they do predict prolonged illness. The rate of spontaneous recovery appears to be high. Effective clinical management requires a multidisciplinary approach, with consideration of the medical, psychological and social factors influencing recovery.

Ilaria RL Jr, Komaroff AL, Fagioli LR, Moloney WC, True CA, Naides SJ.	Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, USA.	Absence of parvovirus B19 infection in chronic fatigue syndrome.	989: Arthritis Rheum 1995 May;38(5):638-41	OBJECTIVE. To evaluate the presence of infection with parvovirus B19 in patients with chronic fatigue syndrome (CFS) who also had rheumatologic symptoms and mild hematologic abnormalities. METHODS. Seven patients meeting the Centers for Disease Control and Prevention working case definition for CFS who also had mild leukopenia, thrombocytopenia, or anemia were studied. Bone marrow was aspirated from each patient, and examined for morphologic abnormalities, including features seen in marrow infections with parvovirus B19, as well as for parvoviral DNA, using polymerase chain reaction (PCR) amplification. Serum obtained at the time of marrow aspiration was also evaluated for parvoviral DNA, using the PCR method, and was examined for the presence of IgM and IgG antibodies to the virus. RESULTS. No evidence of marrow involvement with parvovirus B19 was found in any patient. One patient had antibody evidence of a transient parvoviral infection, during which time an underlying thrombocytopenia worsened. CONCLUSION. Despite examining a selected group of patients thought most likely to have parvoviral infection, based on clinical and hematologic measures, no evidence of clinically important parvoviral infection was noted. Thus, it seems unlikely that parvovirus B19 plays a role in CFS, even though it has

				been associated with fibromyalgia, a clinically similar syndrome.

Jason LA, Taylor R, Wagner L, Holden J, Ferrari JR, Plioplys AV, Plioplys S, Lipkin D, Papernik M.	Department of Psychology, DePaul University, Chicago, Illinois 60614, USA.	Estimating rates of chronic fatigue syndrome from a community-based sample: a pilot study.	947: Am J Community Psychol 1995 Aug;23(4):557-68	Most of the Chronic Fatigue Syndrome (CFS) epidemiological studies have relied on physicians who refer patients having at least six months of chronic fatigue and other symptoms. However, there are a number of potential problems when using this method to derive prevalence statistics. For example, some individuals with CFS might not have the economic resources to access medical care. Other individuals with CFS might be reluctant to use medical personnel, particularly if they have encountered physicians skeptical of the authenticity of their illness. In addition, physicians that are skeptical of the existence of CFS might not identify cases. In the present pilot study, a random community sample (N = 1,031) was interviewed by telephone in order to identify and comprehensively evaluate individuals with symptoms of CFS and those who self-report having CFS. Different definitions of CFS were employed, and higher rates (0.2%) of CFS were found than in previous studies. Methodological benefits in using more rigorous epidemiological methods when estimating CFS prevalence rates are discussed.
Jenzer G.		[Clinical aspects and neurologic expert assessment in sequelae of whiplash injury to the cervical spine].[article in German]	929: Nervenarzt 1995 Oct;66(10):730-5	Whiplash injury to the cervical spine and its possible long-term sequelae, the late (or chronic) whiplash syndrome, are analysed based on a clearly defined accident mechanism and an initial battery of investigations to exclude lesions other than those affecting the soft tissue of the neck region (i.e. the consequences of strain and sprain). Predictors are discussed that may point to a delayed and complicated recovery, with development of a complex array of symptoms. The pattern of this symptomatology, as reviewed on the basis of different neuropsychological investigations, appears inhomogeneous. Comparison with other non-traumatic conditions, such as the chronic fatigue syndrome, the fibromyalgia syndrome and chronic daily headache, as well as with chronic disturbances of cervical origin, reveals striking similarities. In cases of litigation, these circumstances require careful assessment of the patient's previous history and an extensive differential diagnosis. Whiplash injury to the cervical spine rarely results in disability and, if so, is only minor.

Scand J Infect Dis 1995;27(6):551-7	53 patients with acute B19 infection were studied; symptoms at acute infection were rash and arthralgia (n = 26), rash (n = 7), arthralgia (n = 16), aplastic crisis (n = 3), and intrauterine fetal death (n = 1). These patients were followed for 26-85 months (mean 57 months) and re-assessed for persistent symptoms, anti-B19 antibodies, and B19 DNA. At follow-up, 7 individuals were positive for serum B19 DNA, compared with none of the controls (2-tailed p value = 0.016). All 7 of those persistently infected were women, 3 of whom had symptoms; 1 had a chronic haemolytic anaemia (initial presentation was aplastic crisis); 1 had persistent arthralgia in both knees (initial presentation was bilateral knee arthralgia); and 1 had arthralgia in one knee and chronic fatigue syndrome (initial presentation was bilateral arthralgia in knees and shoulders). For the 7 persistently infected patients, serum from the time of diagnosis of acute B19 infection was available for 4, all of which contained B19 DNA. With single-stranded conformational polymorphism (SSCP) assay of these 11 PCR products, identical SSCP types were demonstrated in 5 of 7 follow-up isolates. In 2 of the 4 cases for which both acute

				and follow-up PCR product was available, the SSCP type of the follow-up product was different from that of the acute product. Two B19 virus types were demonstrated in one patient (with persistent arthralgia and chronic fatigue syndrome) at follow-up assessment.

Klein R, Berg PA.	Department of Internal Medicine, University of Tubingen, Germany.	High incidence of antibodies to 5-hydroxytryptamine, gangliosides and phospholipids in patients with chronic fatigue and fibromyalgia syndrome and their relatives: evidence for a clinical entity of both disorders.	619: Eur J Med Res 1995 Oct 16;1(1):21-6	The fibromyalgia syndrome (FMS) is one of the most frequent rheumatic disorders showing a wide spectrum of different symptoms. An association with the chronic fatigue syndrome (CFS) has been discussed. Recently, a defined autoantibody pattern consisting of antibodies to serotonin (5-hydroxytryptamine, 5-HT), gangliosides and phospholipids was found in about 70% of the patients with FMS. We were therefore interested in seeing whether patients with CFS express similar humoral immunoreactivity. Sera from 42 CFS patients were analysed by ELISA for these antibodies, and the results were compared with those previously observed in 100 FMS patients. 73% of the FMS and 62% of the CFS patients had antibodies to serotonin, and 71% or 43% to gangliosides, respectively. Antibodies to phospholipids could be detected in 54% of the FMS and 38% of the CFS patients. 49% of FMS and 17% of the CFS patients had all three antibodies in parallel, 70% and 55%, respectively had at least two of these antibody types. 21% of FMS and 29% of CFS patients were completely negative for these antibodies. Antibodies to 5-HT were closely related with FMS/CFS while antibodies to gangliosides and phospholipids could also be detected in other disorders. The observation that family members of CFS and FMS patients also had these antibodies represents an argument in favour of a genetic predisposition. These data support the concept that FMS and CFS may belong to the same clinical entity and may manifest themselves as 'psycho-neuro-endocrinological autoimmune diseases'.

Lawrie SM, Pelosi AJ.	Edinburgh University Department of Psychiatry, Royal Edinburgh Hospital.	Chronic fatigue syndrome in the community. Prevalence and associations.	974: Br J Psychiatry 1995 Jun;166(6):793-7	BACKGROUND. Chronic fatigue syndrome (CFS) is a poorly understood condition, apparently related to both psychiatric disturbance and infectious illness. Little progress has been made in identifying aetiology, owing to a lack of epidemiological studies using case-definition criteria. METHOD. A community postal survey of a random sample of over 1000 patients registered at a local health centre comprised a fatigue questionnaire and the 12-item General Health Questionnaire (GHQ). RESULTS. Total fatigue scores were modestly higher in women than men. Fatigue was most frequently attributed to psychosocial factors. Fatigue and GHQ scores were strongly correlated. Two men and two women satisfied British criteria for CFS, a prevalence of 0.56% (95% Cl 0.16-1.47%); three were probable psychiatric cases. CONCLUSIONS. Previously reported sociodemographic associations of CFS may reflect medical referral patterns. A strong association exists with psychological morbidity, but relabelling CFS as a psychiatric disorder is not justified.

Lutgendorf S, Nancy G. Klimas, Michael Antoni , Andrew Brickman, Mary Ann Fletcher		Relationships of Cognitive Difficulties to Immune Measures, Depression and Illness Burden in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1995: 1(2): 23 - 41	Objective. We related the subjective assessment of cognitive difficulties with lymphocyte phenotypes, cellmediated immunity (CMI), cytokine and neopterin levels in patients with chronic fatigue syndrome (CFS), in order to determine if CFS patients complaining of greater cognitive difficulties would show greater impairments in cell-mediated immunity and a greater degree of immune system dysregulation, and to determine if these cognitive difficulties would correlate with the other non-affective measures of CFS associated illness burden. We also assessed whether these relationships would hold independent of depression in two ways, by statistically covarying depression severity scores and by comparing subsets of CFS patients with and without a concurrent diagnosis of major depressive disorder. Design. A case series of CFS patients. Setting. Outpatient tertiary referral clinic at the University of Miami School of Medicine, Miami, FL. Patienrs. Consecutive sample of 65 patients who were referred as CFS to the University of Miami Diagnostic Immunology Clinic, who met the Centers for Disease Control and Prevention (CDC) criteria for diagnosis of CFS and consented to participate. Main Measures. Self-assessment of cognitive difficulties, depression and illness burden, clinician-assessed depression and CFS symptoms, lymphocyte phenotype, proliferative response to mitogens, serum levels of cytokines and neopterin. Results. Among CFS patients, high Cognitive Difficulty Scale (CDS) scores were significantly related to lower lymphocyte proliferative responses to mitogens, higher neopterin levels, and higher CD4 and lower CD8 lymphocyte counts. These relationships, with the exception of T cell subset percentages, were maintained when depression severity was used as a co-variate. High CDS scores were also significantly related to lower Karnofsky scores, and greater illness burden as measured by the Sickness Impact Profile. Conclusions. Evidence is presented that CFS patients with higher cognitive difficulty scores have more immune and clinical dysfunction than those patients with less cognitive difficulty, and that these relationships are independent of depression. These observations provide support for the concept that although

				both cognitive difficulties and immunologic abnormalities, such as immune activation and impaired cell-mediated immunity, may represent secondary sequence to the same event(s), they are not likely to be secondary sequence to depression.
Lutgendorf SK, Antoni MH, Ironson G, Fletcher MA, Penedo F, Baum A, Schneiderman N, Klimas N.	Department of Psychology, University of Miami, Coral Gables, FL 33124, USA.	Physical symptoms of chronic fatigue syndrome are exacerbated by the stress of Hurricane Andrew.	967: Psychosom Med 1995 Jul-Aug;57(4):310-23	This study examined the effects of Hurricane Andrew on physical symptoms and functional impairments in a sample of chronic fatigue syndrome (CFS) patients residing in South Florida. In the months after Hurricane Andrew (September 15-December 31, 1992), 49 CFS patients were assessed for psychosocial and physical functioning with questionnaires, interviews, and physical examinations. This sample was made up of 25 CFS patients living in Dade county, a high impact area, and 24 patients in Broward and Palm Beach counties, areas less affected by the hurricane. Based on our model for stress-related effects on CFS, we tested the hypothesis that the patients who had the greatest exposure to this natural disaster would show the greatest exacerbation in CFS symptoms and related impairments in activities of daily living (illness burden). In support of this hypothesis, we found that the Dade county patients showed significant increases in physician-rated clinical relapses and exacerbations in frequency of several categories of self-reported CFS physical symptoms as compared to the Broward/Palm Beach county patients. Illness burden, as measured on the Sickness Impact Profile, also showed a significant increase in the Dade county patients. Although extent of disruption due to the storm was a significant factor in predicting relapse, the patient's posthurricane distress response was the single strongest predictor of the likelihood and severity of relapse and functional impairment. Additionally, optimism and social support were significantly associated with lower illness burden after the hurricane, above and beyond storm-related disruption and distress responses. These findings provide information on the impact of environmental stressors and psychosocial factors in the exacerbation of CFS symptoms.

McComas AJ, Miller RG, Gandevia SC.	Department of Biomedical Sciences, McMaster University, Hamilton, Canada.	Fatigue brought on by malfunction of the central and peripheral nervous systems.	Adv Exp Med Biol 1995;384:495-512	Increased fatigability necessarily occurs in every patient with muscle weakness, regardless of whether the latter is due to a central or peripheral neurological disorder. The tendency for disuse to increase fatigability, as a secondary phenomenon, must also be considered; disuse affects both motoneuron recruitment and the biochemical and physiological properties of the muscle fibers. In recent studies impaired recruitment has been observed in postpolio patients, while patients with multiple sclerosis or spinal cord injury have shown, in addition, altered neuromuscular function. Findings are also presented in ALS and the chronic fatigue syndrome. In general, the most dramatic increases in fatigability take place in disorders of the peripheral nervous system and almost any cell component can be incriminated. There is a need to study fatigability systematically in neurology and rehabilitation.
McKenzie M, Lucy Dechene , Fred Friedberg , Robert Fontanetta		Coping Reports of Patients with Long-Term Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1995: 1(3/4): 59 - 67	Two hundred sixty-five patients with chronic fatigue syndrome, who had been ill for a minimum of 10 years, responded to an open-ended questionnaire with detailed descriptions of major illness issues and coping techniques. Their predominant illness concerns and personal accounts of coping strategies as well as an analysis of style of coping and illness progression will be presented.

It is characterized by activated and morphologically atypical B lymphocytes and polyclonal IgM production and has been associated with female sex, cigarette smoking, and HLA-DR7 expression. We report a case of PPBL with intermitting symptoms compatible with a chronic fatigue syndrome, recurrent erythema nodosum and multiforme. Serological findings suggested a chronic active Epstein-Barr virus (EBV) infection. Messenger RNA of EBV immediate early gene transactivation BZLF1 was detected in peripheral blood lymphocytes by reverse transcriptase PCR indicating a persistent replication of the virus. Over 2 years of observation we detected varying numbers of atypical lymphocytes. These cells hybridized with a probe specific for the EBV internal repeat region (BamHI W) which indicates a productive infection. Of interest, no reaction was observed with a probe specific for the latency-associated small RNAs (EBERs). The immunological phenotype of the polyclonal B cells was similar to B-cell lines immortalized by EBV in vitro, expressing a number of activation molecules (CD23, CD25, CD54) and the bcl-2 protein. In summary, our findings suggest that persistent EBV replication might be crucial in the development of lymphoproliferative disorders such as PPBL.
Moldofsky H.	Centre for Sleep and Chronobiology, Toronto Hospital, Western Division, Canada.	Sleep, neuroimmune and neuroendocrine functions in fibromyalgia and chronic fatigue syndrome.	Adv Neuroimmunol 1995;5(1):39-56	The justification for disordered chronobiology for fibromyalgia and chronic fatigue syndrome (CFS) is based on the following evidence: The studies on disordered sleep physiology and the symptoms of fibromyalgia and CFS; the experimental studies that draw a link between interleukin-1 (IL-1), immune-neuroendocrine-thermal systems and the sleep-wake cycle; studies and preliminary data of the inter-relationships of sleep-wakefulness, IL-1, and aspects of peripheral immune and neuroendocrine functions in healthy men and in women during differing phases of the menstrual cycle; and the observations of alterations in the immune-neuroendocrine functions of patients with fibromyalgia and CFS (Moldofsky, 1993b, d). Time series analyses of measures of the circadian pattern of the sleep-wake behavioural system, immune, neuroendocrine and temperature functions in patients with fibromyalgia and CFS should determine whether alterations of aspects of the neuro-immune-endocrine systems that accompany disordered sleep physiology result in nonrestorative sleep, pain, fatigue, cognitive and mood symptoms in patients with fibromyalgia and CFS. Review, Academic

Nairn C, Galbraith DN, Clements GB.	Regional Virus Laboratory, Ruchill Hospital, Glasgow, Scotland.	Comparison of coxsackie B neutralisation and enteroviral PCR in chronic fatigue patients.	949: J Med Virol 1995 Aug;46(4):310-3	Coxsackie B enteroviruses have been implicated repeatedly as agents associated with chronic fatigue syndrome (CFS). The objective of this study was to compare the serological evidence for the presence of Coxsackie B virus neutralising antibody, with the polymerase chain reaction (PCR) detecting a portion of the 5' nontranslated region (NTR) of the enterovirus genome. Serum samples from 100 chronic fatigue patients and from 100 healthy comparison patients were used in this study. In the CFS study group, 42% patients were positive for enteroviral sequences by PCR, compared to only 9% of the comparison group. Using the neutralisation assay, 34% of study patients were positive, compared to 41% of comparison patients. In the study group, 66/100 patient results correlated, i.e., they were either positive/positive or negative/negative for both tests. Of those that did not correlate, the majority were PCR-positive/Coxsackie B antibody-negative (21/34). In the comparison group, 58/100 patient results correlated. Of those that did not, the majority were PCR-negative/Coxsackie B antibody-positive (37/42). The Coxsackie B antibody neutralisation assay was not able to differentiate the CFS study group from the healthy comparison group, and thus the clinical relevance of this assay may be questioned. The PCR assay did differentiate the two groups with significantly more CFS patients having evidence of enterovirus than the comparison group.
Natelson BH, Ellis SP, Braonain PJ, DeLuca J, Tapp WN.	CFS Center, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark 07103.	Frequency of deviant immunological test values in chronic fatigue syndrome patients.	Clin Diagn Lab Immunol 1995 Mar;2(2):238-40	Of 11 immunological tests done on chronic fatigue syndrome patients and on fatigued controls, 3 tests (protein A binding, Raji cell, or C3 or C4 [deviant values in either complement component were counted as positive]) with deviant results discriminated best among the groups. Other tests, including immunoglobulin G subclasses, complement component CH50, interleukin-2, and anticardiolipin antibodies, did not discriminate well among the groups.
Natelson BH, Johnson	Department of	Reducing heterogeneity	916: Clin Infect Dis 1995	Chronic fatigue syndrome (CFS) is a heterogeneous illness characterized by a high

SK, DeLuca J, Sisto S, Ellis SP, Hill N, Bergen MT.	Neurosciences, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark, USA.	in chronic fatigue syndrome: a comparison with depression and multiple sclerosis.	Nov;21(5):1204-10	prevalence of psychiatric problems. We reasoned that we could reduce heterogeneity by excluding patients with psychiatric problems preceding CFS. We compared the functional status, mood, fatigue level, and psychiatric status of this more homogeneous group of CFS patients with the same parameters in patients with mild multiple sclerosis and in patients with major depression or dysthymia. Patients with CFS and those with multiple sclerosis were similar in terms of level of anger, severity of depression, level of anxiety, and frequency of current psychiatric diagnoses. Patients with CFS resembled depressed patients in having impaired vigor and experiencing substantial fatigue and confusion--problems constituting part of the case definition of CFS. The group with CFS was not psychologically vulnerable before the development of this condition and maintained adequate networks of social support despite disabling illness. Stratification to exclude patients with prior psychiatric disease and those with mild CFS allowed us to define a group of patients with CFS who more resembled patients with mild MS than patients with major depression or dysthymia and thus were more likely to have illness with an infectious or immunologic cause. Use of such a stratification strategy should prove important in testing of the viral/immunologic hypothesis of the etiology of CFS.

Patarca R, Nancy G. Klimas Maria N. Garcia, Michael J. Walters, Derek Dombroski, Hector Pons , Mary Ann Fletcher		Dysregulated Expression of Soluble Immune Mediator Receptors in a Subset of Patients with Chronic Fatigue Syndrome: Cross-Sectional Categorization of Patients by Immune Status	Journal of Chronic Fatigue Syndrome 1995: 1(1): 81 - 96	Individuals with chronic fatigue syndrome (CFS) have significantly increased proportions of activated CD8+T cells, decreased natural killer (NK) cell cytotoxic and lymphoproliferative activities, elevated serum levels of tumor necrosis factor (TNF)-α and detectable TNF-β, interleukin (IL)-lβ, and IL-6 mRNA in peripheral blood mononuclear cells (PBMC). We report here that CFS patients as a group also have significantly higher levels, as compared to controls, of soluble TNF receptor type I (sTNF-RI or sCDl20a), sIL-6R (sCD126) and β2-microglobulin (β2-m), but not of IL-1 receptor antagonist (IL-1Ra). Correlative and population distribution studies that included lymphoid phenotypic distributions and function as well as soluble immune mediator expression levels revealed the existence of at least two mainly nonoverlapping immunological categories among CFS patients

				with either: (1) dysregulaled TNF-α/β expression in association with changes in the serum levels of IL-lα, IL-4, sIL-2R and IL-lRa, PBMC-associated expression of IL-1β, IL-6 and TNF-β mRNA, and T cell activation; or, (2) interrelated and dysregulated expression of sTNF-RI, sIL-6R, and β2-m and significantly decreased lymphoproliferative and NK cell cytotoxic activities. This preliminary systematization is of usefulness in the diagnosis, follow-up, and characterization of possible etiological agents for CFS.
Patnaik M, Komaroff AL, Conley E, Ojo-Amaize EA, Peter JB.	Specialty Laboratories, Inc., Santa Monica, California 90404-3900, USA.	Prevalence of IgM antibodies to human herpesvirus 6 early antigen (p41/38) in patients with chronic fatigue syndrome.	919: J Infect Dis 1995 Nov;172(5):1364-7 Erratum in: J Infect Dis 1995 Dec;172(6):1643	To evaluate the association between human herpesvirus 6 (HHV-6) and chronic fatigue syndrome (CFS), 2 geographically separate groups of CFS patients (125 and 29 patients, respectively) and healthy controls (150 and 15 controls, respectively) were compared, using an EIA, for antibodies to HHV-6 early antigen p41/38 (EA). Sixty percent (93/154) of CFS patients were were positive for HHV-6 EA IgM, 40% (61/154) were positive for IgG, and 23% (35/154) were positive for both. A total of 119 (77%) of the CFS patients were positive for HHV-6 EA IgG or IgM (or both); only 12% (20/165) of the controls had IgG or IgM to HHV-6 EA. These data demonstrate that more CFS patients than controls had elevated levels of HHV-6 EA-specific IgM, perhaps indicating active replication of HHV-6 in CFS.
Pelcovitz D, Septimus A, Friedman SB, Krilov LR, Mandel F, Kaplan S.	Department of Psychiatry, North Shore University Hospital, Manhasset, NY 11030, USA.	Psychosocial correlates of chronic fatigue syndrome in adolescent girls.	928: J Dev Behav Pediatr 1995 Oct;16(5):333-8	Behavior problems and family functioning were investigated in a sample of 10 adolescent girls with chronic fatigue syndrome (CFS), 10 matched healthy adolescent girls, and 10 adolescents with childhood cancer in remission. Based on the adolescent girls' reports, the CFS group had significantly higher scores than the cancer and healthy comparison adolescent girls on somatic complaints and also significantly higher scores than the cancer controls on internalizing symptoms and depression. Parent reports resulted in significantly higher scores in the CFS group than the adolescent girls from the healthy comparison groups on internalizing scores and somatic complaints. There were no significant differences on any family variables.
Petrie K, Moss-Morris R, Weinman J.	Department of Psychiatry and Behavioural Science, University of Auckland Medical School, New Zealand.	The impact of catastrophic beliefs on functioning in chronic fatigue syndrome.	J Psychosom Res 1995 Jan;39(1):31-7	This study investigated the association between catastrophic beliefs and disability in the context of Chronic fatigue syndrome (CFS). A sample of 282 CFS sufferers were asked about the consequences of pushing themselves beyond their present physical state. Responses were coded into catastrophic or non-catastrophic categories. While not differing on the length of illness or psychological adjustment, subjects demonstrating catastrophic responses evidenced significantly higher levels of fatigue and were more disabled in terms of their ability to work both in their normal occupation and around the house. Catastrophizers also showed greater disability in terms of their sleep and rest, social communication, and recreational activities. The role of catastrophic beliefs and personal perceptions of CFS in maintaining the illness is discussed.
Plioplys AV, Plioplys S.	Chronic Fatigue Syndrome Center,	Serum levels of carnitine in chronic	Neuropsychobiology 1995;32(3):132-8	Carnitine is essential for mitochondrial energy production. Disturbance in mitochondrial function may contribute to or cause the fatigue seen in chronic

	Mercy Hospital and Medical Center, Chicago, Ill. 60616, USA.	fatigue syndrome: clinical correlates.		fatigue syndrome (CFS) patients. One previous investigation has reported decreased acylcarnitine levels in 38 CFS patients. We investigated 35 CFS patients (27 females and 8 males); our results indicate that CFS patients have statistically significantly lower serum total carnitine, free carnitine and acylcarnitine levels, not only lower acylcarnitine levels as previously reported. We also found a statistically significant correlation between serum levels of total and free carnitine and clinical symptomatology. Higher serum carnitine levels correlated with better functional capacity. These findings may be indicative of mitochondrial dysfunction, which may contribute to or cause symptoms of fatigue in CFS patients.
Plioplys AV, Plioplys S.	Chronic Fatigue Syndrome Center, Mercy Hospital and Medical Center, Chicago, IL 60616, USA.	Electron-microscopic investigation of muscle mitochondria in chronic fatigue syndrome.	Neuropsychobiology 1995;32(4):175-81	Patients with chronic fatigue syndrome (CFS) suffer from disabling physical and mental fatigue. Abnormalities in mitochondrial function can lead to fatigue and weakness. Ultrastructural mitochondrial abnormalities have been reported to be present in CFS patients. We obtained percutaneous needle muscle biopsies from 15 CFS patients and 15 age- and sex-matched controls. We investigated previously reported ultrastructural abnormalites in CFS: subsarcolemmal mitochondrial aggregates, intermyofibrillar mitochondrial aggregates, mitochondrial circumference, area, pleomorphism and the presence of compartmentalization of the inner mitochondrial membrane. All of the steps of tissue processing, electron microscopy and data abstracting and analysis were performed in a totally blinded fashion. All of our data were rigorously quantified. We found no difference in any of these studied parameters between CFS patients and controls. Although there is no ultrastructural mitochondrial abnormality in CFS patients, other lines of evidence suggest the presence of a possible functional mitochondrial abnormality.
Plioplys S, Plioplys AV.	Chronic Fatigue Syndrome Center, Mercy Hospital and Medical Center, Chicago, IL 60616, USA.	Chronic fatigue syndrome (myalgic encephalopathy).	930: South Med J 1995 Oct;88(10):993-1000	Chronic fatigue syndrome is associated with many misconceptions. In this review, we attempt to summarize various pathogenic hypotheses for this disease and discuss new lines of insight into causes and treatments of this baffling and most frustrating condition.
Polich J, Moore AP, Wiederhold MD.	Department of Neuropharmacology, Scripps Research Institute, La Jolla, California 92037, USA.	P300 assessment of chronic fatigue syndrome.	J Clin Neurophysiol 1995 Mar;12(2):186-91	The P3(00) event-related brain potential (ERP) was elicited with an auditory tone-discrimination paradigm in 25 patients diagnosed with chronic fatigue syndrome (CFS) and 25 matched normal control subjects. Target stimulus probability was varied systematically (0.20, 0.50, 0.80) in different task conditions. No differences between the CFS and control subjects were found for either P3 amplitude or latency. No group effects were observed for the N1, P2, and N2 components. Despite the attentional and immediate memory deficits reported in CFS, the P3 ERP from auditory stimuli does not reliably discriminate CFS from matched control subjects.

Telford SR 3rd, Gleit, Fagioli L, Brunet LR, Spielman A.		infection is rarely found in patients with chronic fatigue syndrome.	Feb;20(2):467-8	
Priest RG, Gimbrett R, Roberts M, Steinert J.	Department of Psychiatry, St Mary's Hospital Medical School, Imperial College of Science, Technology and Medicine, University of London, United Kingdom.	Reversible and selective inhibitors of monoamine oxidase A in mental and other disorders.	Acta Psychiatr Scand Suppl 1995;386:40-3	The clinically tested reversible inhibitors of monoamine oxidase A (RIMAs) include brofaromine, moclobemide and toloxatone. Moclobemide has shown unequivocal antidepressant activity against serious depressive illness in 4 placebo-controlled double-blind trials. It has been compared with amitriptyline, imipramine, clomipramine, desipramine, maprotiline, fluoxetine, fluvoxamine, tranylcypromine, toloxatone, mianserin and amineptine in the treatment of depressive disorders. Meta-analysis showed convincing evidence of moclobemide efficacy, comparable with the most potent antidepressants available. The efficacy of moclobemide has been demonstrated in psychotic and non-psychotic depression, in depression with and without melancholia, in endogenous depression (both unipolar and bipolar), in retarded depression and in agitated depression. The efficacy of moclobemide, allied to the unusually benign side effect profile, has led to exploration of its use in other disorders. Two small studies have given encouraging results in the treatment of attention-deficit hyperactivity disorder. Large placebo-controlled studies have shown the activity of moclobemide in the depression that accompanies dementia (such as senile dementia of Alzheimer type). The results also suggested that, in this patient population, cognitive ability improved in parallel. Social phobia has also been shown to improve on treatment with either moclobemide or brofaromine. Clinical trials are in progress on the effect of moclobemide in chronic fatigue syndrome. Moreover, there are encouraging results with the use of brofaromine and moclobemide in panic disorder. Other disorders in which treatment with RIMA is of interest include agoraphobia, bulimia, borderline personality disorder, post-traumatic stress disorder, compulsive hair pulling (trichotillomania), dysmorphophobia, kleptomania as well as various anxiety syndromes.
Ray C, Jefferies S, Weir WR.	Department of Human Sciences, Brunel University, Uxbridge, London.	Coping with chronic fatigue syndrome: illness responses and their relationship with fatigue, functional impairment and emotional status.	936: Psychol Med 1995 Sep;25(5):937-45	The implications of patients' approaches to managing chronic fatigue syndrome were examined in a cross-sectional study. With severity of fatigue controlled, attempting to maintain activity was associated with less functional impairment, while accommodating to the illness was positively related to impairment; behavioural disengagement was related not only to higher levels of impairment but also to greater emotional disturbance. Fatigue itself was positively associated with focusing on symptoms and with behavioural disengagement; it was associated also with illness accommodation, but only for illness of longer duration. The causal direction of relationships between coping and fatigue severity is ambiguous, and a follow-up study will address the effects of coping on changes in the illness over time.
Ray C, Jefferies S, Weir	Department of Human	Life-events and the	910: Br J Med Psychol	Life-events have been implicated in the onset and course of various illnesses. The

WR.	Sciences, Brunel University, Middlesex, UK.	course of chronic fatigue syndrome.	1995 Dec;68 (Pt 4):323-31	present study examined their role in chronic fatigue syndrome, in the context of the ongoing illness. Using the PERI list, events experienced during the past year were elicited in interviews with 130 patients. The analyses were restricted to those events implying moderate or major life change, and separate analyses were carried out for positive and negative events. Positive events were found to be associated with lower scores for fatigue, impairment, anxiety and depression, as assessed at the time of the life-events interview, and these relationships were also significant when prior scores at the beginning of the year were statistically controlled. Negative life-events were associated with higher anxiety, but were unrelated to the other measures. It was concluded that positive life-events and experiences may contribute to the process of recovery in chronic fatigue syndrome, though their occurrence may also be facilitated by a preceding lifting of symptoms.
Reilly PA.	Frimley Park NHS Trust Hospital, Camberley, Surrey, UK.	'Repetitive strain injury': from Australia to the UK.	944: J Psychosom Res 1995 Aug;39(6):783-8	The UK is now experiencing an epidemic of upper limb pain similar to that which affected Australia in the 1980s. The pain is often non-specific, and does not conform to the pattern of various well-recognized rheumatological entities. The syndrome is known by a number of terms, some of which imply an aetiological link to workplace activities unsubstantiated by hard evidence. The syndrome may well be largely psychosocial, and analogous to the chronic fatigue syndrome. It is currently the cause of many contentious and well-publicized medico-legal cases. Possible factors behind the epidemic will be discussed, and an approach to management suggested.

Richardson JR		Disturbance of Hypothalamic Function and Evidence for Persistent Enteroviral Infection in Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 1995: 1(2): 59 - 66	It has been suggested that one of the major effects of persistent virus infections in the production of disorders such as the chronic fatigue syndrome/myalgic encephalomyelitis (CFSFIE) is on the hypothalamus (1). Buspirone, which is one of the anxiolytic drugs of the azapyrone group, causes a release of prolactin by stimulation of serotonin 5-hydroxytryptamine (5-HT) receptors. The buspironeprolactin response was studied in a subgroup of patients with CFS/ME and evidence of persistent enteroviral infection, as shown by the repealed detection of the groupspecific protein of enteroviruses, VPI, in the blood. Family controls who were asymptomatic were studied at the same time. In addition to the response to buspirone, diurnal variations in cortisol and prolactin levels were studied. It was found that the patients with CFS/ME had much greater rises in prolactin levels one hour after buspirone compared to controls. Cortisol levels

				were elevated in the patients, but the rise was not signiftcantly different between the two groups. There was a significant association between the pattern of sleep disturbance, which we speak of as the OWL syndrome, and the ratio of preand post-buspirone prolactin levels. This study shows that there is a hypothalamic disturbance in the patients who also had evidence of enteroviral infection as part of the disorder of CFSME. It represents a quantifiable biochemical alteration to be found in this group of patients

Rowe PC, Bou-Holaigah I, Kan JS, Calkins H.	Department of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD 21287.	Is neurally mediated hypotension an unrecognised cause of chronic fatigue?	Lancet 1995 Mar 11;345(8950):623-4 comment in: Lancet. 1995 Apr 29;345(8957):1112; discussion 1112-3 Lancet. 1995 Apr 29;345(8957):1113	Neurally mediated hypotension is now recognised as a common cause of otherwise unexplained recurrent syncope, but has not been reported in association with chronic fatigue. We describe seven consecutive non-syncopal adolescents with chronic post-exertional fatigue, four of whom satisfied strict criteria for chronic fatigue syndrome. Upright tilt-table testing induced significant hypotension in all seven (median systolic blood pressure 65 mm Hg, range 37-75), consistent with the physiology of neurally mediated hypotension. Four had prompt improvement in their chronic fatigue when treated with atenolol or disopyramide. These observations suggest an overlap in the symptoms of chronic fatigue syndrome and neurally mediated hypotension.
Sairenji T, Yamanishi K, Tachibana Y, Bertoni G, Kurata T.	Department of Pathology, National Institute of Health, Tokyo, Japan.	Antibody responses to Epstein-Barr virus, human herpesvirus 6 and human herpesvirus 7 in patients with	Intervirology 1995;38(5):269-73	To test for an association between chronic fatigue syndrome (CFS) and infections with Epstein-Barr virus (EBV), human herpesvirus 6 (HHV-6) and human herpesvirus 7 (HHV-7), antibodies to these viruses were tested in the serum from three groups of individuals: (1) 10 CFS patients with chronic fatigue beginning with a clinical pattern of acute infectious mononucleosis [IM; true chronic IM

		chronic fatigue syndrome.		(CIM)]; (2) 10 CFS patients whose illness did not start with acute IM (non-CIM), and (3) healthy controls. High EBV antibody titers were demonstrated in most patients. Antibodies to ZEBRA, a product of the immediate early EBV gene BZLF1, were detected in the serum of CFS patients at a higher frequency than in healthy controls. Antibody titers to HHV-6 and HHV-7 were also higher in the patients with CFS than in the controls. These results are consistent with the view that CFS patients may have reactivations of EBV, HHV-6 and HHV-7.
Schaefer KM.	Allentown College of St. Francis de Sales, Center Valley, PA 18034, USA.	Sleep disturbances and fatigue in women with fibromyalgia and chronic fatigue syndrome.	J Obstet Gynecol Neonatal Nurs 1995 Mar-Apr;24(3):229-33	OBJECTIVE: To determine the relationship between sleep disturbances and fatigue in women with fibromyalgia (FM) and those with chronic fatigue syndrome (CFS) and to assess whether any differences existed between the two groups. DESIGN: Descriptive comparative. SETTING: Community program on chronic fatigue syndrome and related disorders. PARTICIPANTS: Sixty-three women who attended the program; 13 had CFS, and 50 had FM. MAIN OUTCOME MEASURES: A moderately strong relationship between fatigue and sleepiness was found ($r = .63$, $p < .01$). Trouble staying asleep was the highest rated sleep disturbance, and fatigue was the most common subjective feeling reported. Women with CFS reported significantly more trouble staying asleep than women with FM, $t(61) = 1.81$, $p < .03$. CONCLUSIONS: Data from this study support that women with FM and CFS encounter problems sleeping. Clinicians are encouraged to assess women with FM and CFS for their quality of sleep rather than amount of sleep. Researchers are encouraged to continue study of sleep disturbances in women with FM and CFS to improve understanding of the disturbances and to test the effectiveness of sleep interventions.
Schlech WF 3rd.	Department of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada.	The practice of infectious diseases in the 1990s: the Canadian experience.	Clin Infect Dis 1995 Feb;20(2):291-5	A survey of the members of the Canadian Infectious Disease Society was carried out to determine the content of an infectious diseases consultative practice in the 1990s. Respondents were asked to identify all new inpatient, outpatient, and telephone consultations during a 1-week period in 1990. Consultations were categorized by the infectious disease syndrome of the patient and by the microorganism that was identified. Bacterial infections were the most common cause of inpatient consultations, while viral infections were more common in outpatients. Consultations for parasitic infections were primarily for Pneumocystis carinii pneumonia related to infection with the human immunodeficiency virus (HIV). "Newer" infectious disease syndromes such as chronic fatigue syndrome, toxic shock syndrome, and Lyme disease were all represented in the responses for the 1-week study period. The significant impact of HIV infection on the overall consultative load suggests that there will be a continuing need for newly trained infectious disease consultants into the 21st century.
Schmaling KB, Jeannie D. DiClementi		Interpersonal Stressors in Chronic Fatigue	Journal of Chronic Fatigue Syndrome 1995:	This paper reports two preliminary studies on interpersonal influences in CFS. The first study explored histories of abuse in patients with CFS and the second

		Syndrome: A Pilot Study	1(3/4): 153 - 158	report assessed fatigue activity level and relationship satisfaction in CFS patients. The results of the first study indicated that the patients with CFS reported high levels of prior abuse compared to prior experiences of healthy controls. In the second study, higher levels of fatigue were moderately correlated with inactivity for CFS individuals in satisfied relationships, but not among patients in dissatisfied relationships. These findings suggested that solicitous partners may be inadvertently reinforcing disability. The results of the two studies support a biopsychosocial model of CFS.

Schweitzer R, Kelly B, Foran A, Terry D, Whiting J.	Queensland University of Technology, Australia.	Quality of life in chronic fatigue syndrome.	917: Soc Sci Med 1995 Nov;41(10):1367-72	Whilst the debilitating fatigue experienced in patients suffering from Chronic Fatigue Syndrome (CFS) results in a subjective marked impairment in functioning, little research has investigated the impact of this disorder on quality of life. Forty-seven subjects with a confirmed diagnosis of CFS and 30 healthy controls were compared using the Sickness Impact Profile (SIP). A subgroup of subjects were interviewed regarding the impact CFS has had on their social and family relationships, work and recreational activities. Results from both the SIP and the interview revealed that CFS subjects had significantly impaired quality of life, especially in areas of social functioning. These findings highlight the importance of addressing the social isolation and loss of role functioning experienced by CFS sufferers.
Secchiero P, Carrigan DR, Asano Y, Benedetti L, Crowley RW, Komaroff AL, Gallo RC, Lusso P.	Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20892.	Detection of human herpesvirus 6 in plasma of children with primary infection and immunosuppressed patients by polymerase chain reaction.	J Infect Dis 1995 Feb;171(2):273-80	A sensitive and specific polymerase chain reaction method for the detection of human herpesvirus 6 (HHV-6) DNA in serum or plasma has been developed. In total, 157 human serum or plasma samples were studied. HHV-6 DNA was detected in 6 (85.7%) of 7 children with exanthem subitum, 3 (23.1%) of 13 bone marrow transplant (BMT) recipients, 4 (22.2%) of 18 human immunodeficiency virus (HIV)-infected patients, 1 (2.6%) of 39 patients with chronic fatigue syndrome, and none of 37 healthy adults. In the HHV-6-positive BMT recipients, HHV-6 plasma DNA was transiently detected during episodes of fever and respiratory infection. In children with exanthem subitum and in 1 HIV-infected patient, the HHV-6 strains were characterized as variant B, whereas variant A was detected in all other patients. Detection of viral DNA in serum or plasma is a marker of active infection that can be used to investigate the role of HHV-6 in human disease.
Shanks MF, Ho-Yen DO.	Royal Cornhill Hospital, Aberdeen.	A clinical study of chronic fatigue syndrome.	973: Br J Psychiatry 1995 Jun;166(6):798-801 comment in: Br J Psychiatry. 1995 Oct;167(4):549-50	BACKGROUND. This study examines the hypothesis that more recently ill patients with chronic fatigue syndrome (CFS) might have different characteristics from more chronic patients in tertiary referral centres. METHOD. Sixty-four patients who fulfilled strict diagnostic criteria for CFS had detailed medical, viral, immunological and psychiatric assessment. Patients were advised to remain

				within their energy limits. Patient and doctor monitored progress using a scoring system. RESULTS. Using the Schedule for Affective Disorders and Schizophrenia, patients were placed into four groups: group A (no psychiatric disorder, 35 patients), group B (psychiatric disorder before onset of CFS, 7 patients), group C (coincident psychiatric disorder and CFS, 11 patients), and group D (psychiatric disorder after onset of CFS, 11 patients). There were no viral or immunological differences between the groups. Patients in groups B, C and D had more severe illness than those in group A ($P < 0.05$), but patients in group A had more muscle pain ($P < 0.05$) than patients in group C. Counselling resulted in 52 patients becoming better; nine remained the same and three became worse. CONCLUSIONS. A lower incidence of psychiatric disorder may characterise patients who are more recently ill, as may the type of associated emotional disorder and better outcome.

Sisto SA, Tapp W,	Neurobehavioral Unit,	Vagal tone is reduced	982: Clin Auton Res	Patients with chronic fatigue syndrome (CFS) often complain of an inability to

Drastal S, Bergen M, DeMasi I, Cordero D, Natelson B.	VA Medical Center, E. Orange, NJ 07018-1095, USA.	during paced breathing in patients with the chronic fatigue syndrome.	1995 Jun;5(3):139-43	maintain activity levels and a variety of autonomic-like symptoms that make everyday activity intolerable at times. The purpose of the study was to determine if there were differences in vagal activity at fixed breathing rates in women with CFS. Twelve women with the diagnosis of CFS between the ages of 32 and 59 years volunteered for the study. Healthy women, who were between the ages of 30 and 49, served as controls. Full signal electrocardiograph and respiratory signals were collected during a paced breathing protocol of three fixed breathing rates (8, 12 and 18 breaths/min) performed in the sitting and standing postures. Vagal activity was analyzed by means of heart rate spectral analysis to determine the subject's response to specific breathing rates and postures. Heart rate variability was used as a non-invasive method of measuring the parasympathetic component of the autonomic nervous system. Using this method, although there was significantly less vagal power in the sitting versus the standing postures for both groups, the overall vagal power was significantly lower ($p < 0.034$) in the CFS group versus healthy controls. Vagal power was also significantly lower ($p < 0.01$ to $p < 0.05$) at all breathing rates in both postures except while standing and breathing at 18 breaths/min. Knowledge of the differences in vagal activity for CFS patients may allow stratification for the analysis of other research variables.
Smets EM, Garssen B, Bonke B, De Haes JC.	University of Amsterdam, Department of Medical Psychology, The Netherlands.	The Multidimensional Fatigue Inventory (MFI) psychometric qualities of an instrument to assess fatigue.	997: J Psychosom Res 1995 Apr;39(3):315-25	The Multidimensional Fatigue Inventory (MFI) is a 20-item self-report instrument designed to measure fatigue. It covers the following dimensions: General Fatigue, Physical Fatigue, Mental Fatigue, Reduced Motivation and Reduced Activity. This new instrument was tested for its psychometric properties in cancer patients receiving radiotherapy, patients with the chronic fatigue syndrome, psychology students, medical students, army recruits and junior physicians. We determined the dimensional structure using confirmatory factor analyses (LISREL's unweighted least squares method). The hypothesized five-factor model appeared to fit the data in all samples tested (AGFIs > 0.93). The instrument was found to have good internal consistency, with an average Cronbach's alpha coefficient of 0.84. Construct validity was established after comparisons between and within groups, assuming differences in fatigue based on differences in circumstances and/or activity level. Convergent validity was investigated by correlating the MFI-scales with a Visual Analogue Scale measuring fatigue ($0.22 < r < 0.78$). Results, by and large, support the validity of the MFI.

Strayer DR, William Carter Kenneth I. Strauss, Isadore Brodsky, Robert Suhadolnik, Dharam Ablashi, Berch Henry , William M. Mitchell , Sheila Bastien , Daniel Peterson		Long Term Improvements in Patients with Chronic Fatigue Syndrome Treated with Ampligen	Journal of Chronic Fatigue Syndrome 1995: 1(1): 35 - 53	Fifteen patients who fit the CDC definition of chronic fatigue syndrome (CFS) and had evidence of severe reduction in performance levels by low Kamofsky performance scores (KPS) of 20-60 were treated with Ampligen. At baseline most patients showed evidence of cerebral dysfunction by neuropsychological testing, were antigen positive by cell culture assay for human herpesvirus-6 (HHV-6), and displayed reduced performance during exercise tolerance testing, as measured by oxygen consumption. These patients represented a subset of CFS patients with especially severe and sustained symptomatology. Following 1248 weeks of Ampligen therapy, sustained improvements were noted in KPS ($p < 0.01$). Cognitive function improved including IQ and memory. Oxygen uptake and treadmill duration during exercise tolerance testing was also improved after 24 weeks of treatment ($p < 0.01$). Reduction in HHV-6 expression as measured by the giant cell assay was significant ($p < 0.001$). Patients continued to show significant improvement late in therapy, taking 8 to 12 weeks as baseline. It was concluded that while receiving Ampligen, the severely afflicted patients studied here derived long-lasting clinical benefit from the Ampligen therapy.
Surawy C, Hackmann A, Hawton K, Sharpe M.	University Department of Psychiatry, Warneford Hospital, Oxford, England.	Chronic fatigue syndrome: a cognitive approach.	980: Behav Res Ther 1995 Jun;33(5):535-44	Observations concerning the characteristics of patients who presented to a medical clinic with a principal complaint of chronic medically unexplained fatigue (Chronic Fatigue Syndrome or CFS) are described, including the cognitions (thoughts and assumptions) elicited from a sample of these patients who were treated using cognitive behavioural therapy. On the basis of these observations a cognitive theory of the aetiology of CFS is proposed. These observations have implications for the treatment of patients with CFS.
Swanink CM, van der Meer JW, Vercoulen JH, Bleijenberg G, Fennis JF, Galama JM.	Department of Medical Microbiology, University Hospital Nijmegen, The Netherlands.	Epstein-Barr virus (EBV) and the chronic fatigue syndrome: normal virus load in blood and normal immunologic reactivity in the EBV regression assay.	992: Clin Infect Dis 1995 May;20(5):1390-2	The etiology of chronic fatigue syndrome (CFS) is unknown. Some patients have high antibody titers to viral capsid antigen (VCA) and early antigen (EA) of Epstein-Barr virus (EBV), suggesting that reactivation of EBV is involved. We investigated virus load (spontaneous transformation) and immunologic regression of EBV-induced transformation in peripheral blood mononuclear cells (PBMCs) from 10 selected patients with CFS who had high antibody titers to VCA and EA. The outcome was compared with that for nine healthy controls and one patient with severe chronic active EBV infection (SCAEBV). There were no significant differences in viral load between patients and healthy controls. Immunologic regression of in vitro-transformed PBMCs was also equally efficient in patients and controls. The SCAEBV-infected patient and two controls, who were all seronegative for EBV, showed impaired regression. In conclusion, we were unable to demonstrate a role for reactivation of EBV in CFS, even in selected patients with high titers of antibody to VCA and EA of EBV.

Swanink CM, Vercoulen JH, Bleijenberg G, Fennis JF, Galama JM, van der Meer JW.	Department of Medical Microbiology, University Hospital, Nijmegen, Netherlands.	Chronic fatigue syndrome: a clinical and laboratory study with a well matched control group.	990: J Intern Med 1995 May;237(5):499-506	OBJECTIVE. To investigate the relation between severity of complaints, laboratory data and psychological parameters in patients with chronic fatigue syndrome (CFS). SUBJECTS. Eighty-eight patients with CFS and 77 healthy controls matched for age, sex and geographical area. METHODS. Patients and controls visited our outpatient clinic for a detailed medical history, physical examination and psychological tests: Checklist Individual Strength (CIS). Beck Depression Inventory (BDI) and Sickness Impact Profile (SIP). Venous blood was drawn for a complete blood cell count, serum chemistry panel, C-reactive protein and serological tests on a panel of infectious agents. RESULTS. All patients fulfilled the criteria for CFS as described by Sharpe et al. (J R Soc Med 1991; 84: 118-21), only 18 patients (20.5%) fulfilled the CDC criteria. The outcome of serum chemistry tests and haematological tests were within the normal range. No significant differences were found in the outcome of serological tests. Compared to controls, significant differences were found in the results on the CIS, the BDI, and the SIP. These results varied with the number of complaints (CDC criteria). When the number of complaints was included as the covariate in the analysis, there were no significant differences on fatigue severity, depression, and functional impairment between patients who fulfilled the CDC criteria and patients who did not. CONCLUSION. It is concluded that the psychological parameters of fatigue severity, depression and functional impairment are related to the clinical severity of the illness. Because the extensive panel of laboratory tests applied in this study did not discriminate between patients and controls, it was not possible to investigate a possible relation between the outcomes of psychological and laboratory testing.
Tedeschi R, Foong YT, Cheng HM, dePaoli P, Lehtinen T, Elfborg T, Dillner J.	Microbiology and Tumor Biology Center, Karolinska Institute, Stockholm, Sweden.	The disease associations of the antibody response against the Epstein-Barr virus transactivator protein ZEBRA can be separated into different epitopes.	983: J Gen Virol 1995 Jun;76 (Pt 6):1393-400	The BamHI-Z-encoded Epstein-Barr virus (EBV) replication activator (ZEBRA) is a key mediator of the switch from latency to productive cycle in EBV virus. Antibodies against ZEBRA are a marker of EBV reactivation and are regularly found among patients with infectious mononucleosis (IM) or nasopharyngeal carcinoma (NPC), but are only rarely found among healthy EBV-seropositive donors. In order to define the serologically reactive epitopes in the ZEBRA protein, we synthesized a set of overlapping peptides and tested them for reactivity with serum samples from EBV-seronegative persons, patients with NPC, IM, chronic fatigue syndrome, lymphoma or from healthy donors. Three major EBV-specific epitopes were found. These epitopes were further defined and optimized using substitution or truncation analogues of the peptides. Reactivity with epitope number 22 was found in 63% of NPC patients' sera, with < 2% of healthy donors' sera being positive. Serological reactivity with epitope number 19 was associated with IM (57% positive, 5% healthy donors positive). Serum

				antibodies against epitope 1 were found among healthy donors, but were significantly elevated among patients with NPC, IM or lymphomas. In conclusion, different serologically reactive epitopes in the ZEBRA protein associate with different EBV-associated diseases.
Trigwell P, Hatcher S, Johnson M, Stanley P, House A.	High Royds Hospital, Menston, Leeds.	"Abnormal" illness behaviour in chronic fatigue syndrome and multiple sclerosis.	961: BMJ 1995 Jul 1;311(6996):15-8 comment in: BMJ. 1995 Oct 21;311(7012):1092-3 BMJ. 1995 Oct 21;311(7012):1093	OBJECTIVE--To investigate the presence of abnormal illness behaviour in patients with a diagnosis of chronic fatigue syndrome. DESIGN--A cross sectional descriptive study using the illness behaviour questionnaire to compare illness behaviour scores and illness behaviour profiles of patients with chronic fatigue syndrome and patients with multiple sclerosis. SETTING--A multidisciplinary fatigue clinic and a teaching hospital neurology outpatient clinic. SUBJECTS--98 patients satisfying the Oxford criteria for chronic fatigue syndrome and 78 patients with a diagnosis of multiple sclerosis. MAIN OUTCOME MEASURE--Responses to the 62 item illness behaviour questionnaire. RESULTS--90 (92%) patients in the chronic fatigue syndrome group and 70 (90%) in the multiple sclerosis group completed the illness behaviour questionnaire. Both groups had significantly high scores on the general hypochondriasis and disease conviction subscales and significantly low scores on the psychological versus somatic concern subscale, as measured in relation to normative data. There were, however, no significant differences in the subscale scores between the two groups and the two groups had identical illness behaviour profiles. CONCLUSION--Scores on the illness behaviour questionnaire cannot be taken as evidence that chronic fatigue syndrome is a variety of abnormal illness behaviour, because the same profile occurs in multiple sclerosis. Neither can they be taken as evidence that chronic fatigue and multiple sclerosis share an aetiology. More needs to be known about the origins of illness beliefs in chronic fatigue syndrome, especially as they are important in determining outcome.
Van Houdenhove B, Onghena P, Neerinckx E, Hellin J.	Department of Psychiatry, Katholieke Universiteit Leuven, Belgium.	Does high 'action-proneness' make people more vulnerable to chronic fatigue syndrome? A controlled psychometric study.	966: J Psychosom Res 1995 Jul;39(5):633-40	Degree of premorbid 'action-proneness' was measured, using a self-administered questionnaire, in 35 patients suffering from chronic fatigue syndrome (CFS), all the members of 'ME'-self help groups and all those meeting CDC-criteria of CFS. The results were compared with those of 30 chronic idiopathic musculoskeletal pain patients, 34 patients with a chronic organic condition, and 34 neurotic patients without primary somatic complaints. Statistical analysis showed that CFS patients described themselves as significantly more 'action-prone' than the last two groups, and to a degree which was comparable with the chronic pain group. The results could not be explained by concomitant depression and are in accordance with anecdotal reports of premorbid hyperactive lifestyle in CFS patients. Further investigations seem worthwhile to test the hypothesis that hyperactivity might be a predisposing factor for chronic illness behaviour in CFS patients.

Wessely S, Chalder T, Hirsch S, Pawlikowska T, Wallace P, Wright DJ.	Department of Psychological Medicine, King's College School of Medicine and Dentistry, London, UK.	Postinfectious fatigue: prospective cohort study in primary care.	986: Lancet 1995 May 27;345(8961):1333-8 comment in: Lancet. 1995 Jul 1;346(8966):47 Lancet. 1995 Jul 1;346(8966):47-8 Lancet. 1995 Jul 1;346(8966):48	The idea that chronic fatigue has an infectious origin has become popular, but the main evidence for such an association has come from retrospective case-control studies, which are subject to ascertainment bias. We report a prospective study of the outcome of clinically diagnosed infections in patients presenting to UK general practitioners. Questionnaires assessing fatigue and psychiatric morbidity were sent to all patients aged 18-45 years in the study practices. The prevalence of chronic fatigue and chronic fatigue syndrome was then ascertained among 1199 people aged 18-45 who presented to the general practitioners with symptomatic infections and in 1167 people who attended the surgeries for other reasons. 84% were followed up at 6 months. 9.9% of cases and 11.7% of controls reported chronic fatigue (odds ratio 1.0 [95% CI 0.6-1.1]). There were no differences in the proportions who met various criteria for chronic fatigue syndrome. No effect of infection was noted when we excluded subjects who reported fatigue or psychological morbidity at the baseline screening. The strongest independent predictors of postinfectious fatigue were fatigue assessed before presentation with clinical infection (3.0 [1.9-4.7]) and psychological distress before presentation (1.8 [1.2-2.9]) and at presentation with the acute infection (1.8 [1.1-2.8]). There was no effect of sex or social class. Our study shows no evidence that common infective episodes in primary care are related to the onset of chronic fatigue or chronic fatigue syndrome.

Westin J, Rodjer S, Turesson I, Cortelezzi A, Hjorth M, Zador G.	Department of Medicine/Haematology, University of Lund, Sweden.	Interferon alfa-2b versus no maintenance therapy during the plateau phase in multiple myeloma: a randomized study. Cooperative Study Group.	Br J Haematol 1995 Mar;89(3):561-8	This clinical trial was designed to investigate if maintenance therapy with alfa-interferon could prolong the plateau phase in patients with multiple myeloma. In addition, the tolerability of interferon treatment and its effect on survival were evaluated. From September 1987 to September 1989 a total of 314 patients were accrued to a multi-institutional randomized clinical trial. All patients entered into the protocol received standard melphalan-prednisone (MP) induction therapy. Response was noted in 184 (59%) and a plateau phase achieved in 155 (49%). From the latter group, 125 eligible patients were randomized to either interferon alfa-2b or no maintenance. The patients were followed for an average of 51 months (minimum 36 months) from the time of randomization. The plateau phase was significantly prolonged in the group of patients treated with interferon (median 13.9 v 5.7 months from the time of randomization; $P < 0.0001$). The interferon therapy was tolerated fairly well, moderate granulocytopenia and a chronic fatigue syndrome being the most frequent side-effects (22% v 18% W.H.O. grade 3 toxicity). The median survival from randomization was almost identical in both groups (36 v 35 months). The study shows that interferon maintenance therapy given to multiple myeloma patients who have achieved a response to initial treatment with MP prolongs the plateau phase duration with tolerable toxicity. The clinical value of this finding should be interpreted with caution, because survival was not prolonged. Further studies are required to clarify the role of interferon in the treatment of multiple myeloma. Multicenter Study Randomized Controlled Trial
Wilson A, Hickie I, Lloyd A, Hadzi-Pavlovic D, Wakefield D.	Department of Psychiatry, Prince Henry Hospital, Little Bay, NSW, Australia.	Cell-mediated immune function and the outcome of chronic fatigue syndrome.	942: Int J Immunopharmacol 1995 Aug;17(8):691-4	This study examined the importance of cell-mediated immunity in determining the long-term outcome of patients diagnosed with chronic fatigue syndrome (CSF). A total of 103 patients (74%) of 139 previously enrolled in one of two treatment trials conducted within a university hospital referral center was reviewed a mean of 3.2 yr after trial entry. Ongoing symptom severity, levels of disability and immunological function were assessed at follow-up. The relationship between immunological function at trial entry and measures of outcome was also evaluated. Sixty-five patients (63%) had improved, while only 6 (6%) reported no current symptoms. Thirty-one subjects (30%) were unable to perform any form of work and 26 (25%) were on a disability benefit directly attributable to CFS. Cell-mediated immune function, as measured at trial entry or follow-up, did not appear to affect outcome. Whilst improvement occurred in the majority of patients with CFS, a substantial proportion (37%) remained

				functionally impaired. Impairment of cell-mediated immunological function measured during the course of the illness may not be an important factor in determining long-term outcome.
Wong MT, Dolan MJ, Lattuada CP Jr, Regnery RL, Garcia ML, Mokulis EC, LaBarre RA, Ascher DP, Delmar JA, Kelly JW, et al.	Department of Infectious Diseases/PSMI, Wilford Hall Medical Center, Lackland Air Force Base, Texas 78236-5300, USA.	Neuroretinitis, aseptic meningitis, and lymphadenitis associated with Bartonella (Rochalimaea) henselae infection in immunocompetent patients and patients infected with human immunodeficiency virus type 1.	945: Clin Infect Dis 1995 Aug;21(2):352-60	Bartonella (Rochalimaea) henselae causes a variety of diseases, including bacillary angiomatosis, peliosis hepatis, lymphadenitis, aseptic meningitis with bacteremia, and cat-scratch disease (CSD). Cases of B. henselae-related disease were collected from September 1991 through November 1993. Patients with suspected CSD, unexplained fever and lymphadenitis, or suspected B. henselae infection who were seen in the Infectious Diseases Clinic at Wilford Hall Medical Center (Lackland Air Force Base, TX) underwent physical and laboratory examinations. In addition to three previously described cases, 23 patients with R. henselae-related infection were identified. The patients included 19 immunocompetent individuals presenting with lymphadenitis (11), stellate neuroretinitis (5), Parinaud's oculoglandular syndrome with retinitis (1), chronic fatigue syndrome-like disease (1), and microbiologically proven adenitis without the presence of immunofluorescent antibodies to B. henselae (1) and four patients infected with human immunodeficiency virus type 1 presenting with isolated lymphadenitis (1), diffuse upper-extremity adenitis (1), neuroretinitis (1), and aseptic meningitis (1). A couple with neuroretinitis and their pet cat, a persistently fatigued patient, and a patient with Parinaud's oculoglandular syndrome were shown to have bacteremia. Tissue cultures were positive for B. henselae in three recent cases of adenitis. Twenty-two patients were exposed to cats. This series further demonstrates the similarities between B. henselae-related diseases and CSD and identifies several new syndromes due to B. henselae.
Woodward RV, Broom DH, Legge DG.	National Centre for Epidemiology and Population Health, Australian National University, Canberra.	Diagnosis in chronic illness: disabling or enabling--the case of chronic fatigue syndrome.	978: J R Soc Med 1995 Jun;88(6):325-9 comment in: J R Soc Med. 1995 Dec;88(12):723	This paper examines doctors' and patients' views on the consequences of an increasingly common symptomatic diagnosis, chronic fatigue syndrome (CFS). Two studies were conducted: the first comprised interviews with 20 general practitioners; the second was a longitudinal study, comprising three interviews over a period of 2 years with 50 people diagnosed with CFS. Contrasts were apparent between doctors' practical and ethical concerns about articulating a diagnosis of CFS and patients' experiences with and without such a diagnosis. Seventy per cent of the doctors were reluctant to articulate a diagnosis of CFS. They felt constrained by the scientific uncertainty regarding its aetiology and by a concern that diagnosis might become a disabling self-fulfilling prophecy. Patients, by contrast, highlighted the enabling aspects of a singular coherent diagnosis and emphasized the negative effects of having no explanation for their problems.

Yatham LN, Morehouse RL, Chisholm BT, Haase DA, MacDonald DD, Marrie TJ.	Dalhousie University, Nova Scotia Hospital, Dartmouth.	Neuroendocrine assessment of serotonin (5-HT) function in chronic fatigue syndrome.	Can J Psychiatry 1995 Mar;40(2):93-6 comment in: Can J Psychiatry. 1996 Mar;41(2):129-31	Prolactin and cortisol responses to dl-fenfluramine challenge were examined in 11 patients with chronic fatigue syndrome and in 11 healthy controls who were age and gender matched. After obtaining two baseline samples, each subject was given 60 mg of dl-fenfluramine orally and further blood samples were drawn hourly during the following five hours in order to measure prolactin and cortisol levels. There was no difference in either baseline or fenfluramine-induced hormonal responses between patients with chronic fatigue syndrome and controls. There was also no correlation between depression scores on HAM-D and hormonal responses in patients with chronic fatigue syndrome. The findings of this study do not support a role for 5-HT in chronic fatigue syndrome.
Zannolli R, Morgese G.	Paediatric Clinic, Chieti University, Italy.	New pathogens, and diseases old and new. I) Afipia felis and Rochalimaea. II) Parvovirus B 19. III) herpesvirus 6.	909: Panminerva Med 1995 Dec;37(4):238-47	The paper describes events that in the last fifteen years, have led to the identification of the aetiological agents of three widely known diseases: cat scratch disease, erythema infectiosum and exanthem subitum. The particular features of Afipia felis and Rochalimaea, Parvovirus B 19 and Herpesvirus 6 are presented. The paternity of new diseases (i.e. bacillary angiomatosis, bacillary peliosis hepatitis, LES-like syndrome, chronic fatigue syndrome, petechial glove and sock syndrome, etc.) has also been attributed to some of these pathogens as has the paternity of some older ones (i.e. aplastic crisis, erythroblastosis fetalis, trench fever, hepatitis, opportunistic infection, etc.). It has been argued that the same pathogen can cause different diseases depending on the immunogenic state of the subject. To date, persisting difficulties in isolating the pathogen or differentiating between latent or active infection, still in some cases raises doubts concerning the attribution of the disease to a specific agent. New immunological or molecular techniques, allowing the direct detection of in vivo replication, are still needed in order to establish a sure connection between some of these agents and some of these diseases. Progress here will both give more accurate data about the epidemiology of some diseases and allow us to apply more appropriate treatment and prevention techniques. Review, Academic

Ablashi DV, Berneman ZN, Kramarsky B, Asano Y, Choudhury S, Pearson GR.	Georgetown University School of Medicine, Washington, DC 20007.	Human herpesvirus-7 (HHV-7).	In Vivo 1994 Jul-Aug;8(4):549-54	HHV-7 first isolated in 1990 from a healthy individual, is a ubiquitous agent. The second independent isolation of HHV-7 from a chronic fatigue syndrome patient was reported in 1992. The seroepidemiology of HHV-7 suggested that its prevalence rate in the U.S.A. population is > 85%; however, in Japan a low prevalence rate has been reported. HHV-7 can be more readily isolated from the saliva than HHV-6. The primary infection of HHV-7 appears later in life than HHV-6. No disease has been reported that is etiologically linked to HHV-7. HHV-7 is more closely related to HHV-6 and the human cytomegalovirus than other members of the human herpesvirus family.

Agut H, Aubin JT.	Laboratoire de virologie, CNRS EP 57, CERVI, hopital Pitie-Salpetriere, Paris.	[A new virus: the human herpesvirus 6].[article in French]	Rev Prat 1994 Apr 1;44(7):871-4	Human herpesvirus 6 (HHV-6) was discovered in 1986. This novel virus is genetically related to cytomegalovirus. HHV-6 mainly infects T lymphocytes but its tropism appears to be much wider and probably involves some epithelial cells. Two HHV-6 variants, designated as A and B, can be distinguished by genetical and immunological analysis. HHV-6 infection is ubiquitous and widespread; it occurs most often during infancy and it is life-long. During primary infection, HHV-6 is the causative agent of exanthem subitum and fever episodes without rash in infants. HHV-6 is suspected to be the causative agent of opportunistic infections such as pneumonitis and retinitis in immunocompromised subjects. Its role in human immunodeficiency virus infection, lymphomas and chronic fatigue syndrome is controversial. In vitro, HHV-6 is sensitive to ganciclovir and foscarnet.
Altura BT, Burack JL, Cracco RQ, Galland L, Handwerker SM, Markell MS, Mauskop A, Memon ZS, Resnick LM, Zisbrod Z, et al.	Department of Physiology, State University of New York, Health Science Center at Brooklyn 11203.	Clinical studies with the NOVA ISE for IMg2+.	Scand J Clin Lab Invest Suppl 1994;217:53-67	The Nova ISE for IMg2+ was utilized to examine IMg2+ in plasma and serum of patients with a variety of pathophysiologic and disease syndromes (e.g., long-term renal transplants [LTRT], during and before cardiac surgery, migraine headaches, head trauma, pregnancy, chronic fatigue syndrome [CFS], non-insulin dependent diabetes mellitus [NIDDM], asthma and after excessive dietary intake of Mg). The results indicate that LTRT treated with cyclosporin A, migraine, head trauma, pregnancy, NIDDM, diseased pregnant, and asthmatic patients all on the average, exhibit significant depression in IMg2+ but not total Mg (TMg). Patients with CFS failed to exhibit changes in serum IMg2+ or TMg levels. Increased

				dietary load of Mg, for only 6 days, resulted in significant elevations of serum IMg2+ but not TMg. Correlations between the clinical course of several of these syndromes and the fall in IMg2+ were found. The Ca2+/Mg2+ ratio appears to be an important guide for signs of peripheral vasoconstriction and or spasm and possibly enhanced atherogenesis. Overall, the data point to important uses for ISE's for IMg2+ in the diagnosis and treatment of disease states.
Ambrogetti A, Olson LG.	Sleep Disorders Centre, John Hunter Hospital, New Lambton, NSW.	Consideration of narcolepsy in the differential diagnosis of chronic fatigue syndrome.	Med J Aust 1994 Apr 4;160(7):426-9	OBJECTIVE: To justify the inclusion of narcolepsy in the differential diagnosis of patients with chronic fatigue. CLINICAL FEATURES: We report three patients aged 17 (two women and one man) and one woman aged 45 who had been diagnosed as having chronic fatigue syndrome (CFS). They had no psychiatric illness. Their main problem was severe daytime sleepiness, presenting as "tiredness and fatigue". The history, sleep study and multiple sleep latency test suggested a diagnosis of narcolepsy. INTERVENTION: Treatment with methylphenidate resulted in complete resolution of symptoms in two patients and significant improvement in the other two. CONCLUSIONS: The differential diagnosis of CFS requires the exclusion of other conditions. If daytime sleepiness is a major complaint, other symptoms of narcolepsy should be sought and the diagnosis confirmed with sleep study and a multiple sleep latency test.
Anand AC, Kumar R, Rao MK, Dham SK.	AFMC, Pune.	Low grade pyrexia: is it chronic fatigue syndrome?	J Assoc Physicians India 1994 Aug;42(8):606-8 comment in: J Assoc Physicians India. 1995 Oct;43(10):725-6	Eighty seven consecutive patients presenting with prolonged low grade pyrexia (99 degrees-101 +/- F) during 1984-93 were followed up for a mean duration of 2.9 years. Mean age was 37.55 years (SD + 10.16) and 66 (75.8%) were females. Onset of pyrexia was acute in 57 patients and was associated with chilly sensation (42), Fatigue (69), Arthralgias (61), myalgias (55) and several other non specific symptoms. Clinical examination showed paucity of physical signs with 7 patients showing tender lymphadenopathy, 7 showing splenomegaly, 5 hepatomegaly, and 1 phylctenular conjunctivitis. Psychiatric examination was within normal limits. Extensive investigations for any viral or other infection, autoimmune disorder or malignancy were unrewarding. Patients were followed up for an average of 2.9 (2 to 5 years). Thirteen patients had become asymptomatic within one year of onset of symptoms, 38 by two years and 45 by the end of three years. This syndrome may be a variant of chronic fatigue syndrome.

Antoni MH, Brickman A, Lutgendorf S, Klimas N, Imia-Fins A, Ironson G, Quillian R, Miguez	Department of Psychology, University of Miami, Coral Gables, Florida 33124.	Psychosocial correlates of illness burden in chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S73-8	We related reported physical symptoms, cognitive appraisals (e.g., negative style of thinking), and coping strategies (e.g., denial/disengagement strategies) with illness burden across several functional domains separately in subsets of chronic fatigue syndrome (CFS) patients with (n = 26) and without (n = 39) concurrently

MJ, van Riel F, Morgan R, et al.				diagnosed major depressive disorder (MDD). In regard to cognitive appraisal measures, automatic thoughts and dysfunctional attitudes were strongly associated with a higher illness burden, as indicated in sickness impact profile (SIP) scores. Active-involvement coping strategies measured on COPE scales (active coping, planning, and positive reinterpretation and growth) were not associated with SIP scores, while other coping strategies (mental disengagement, behavioral disengagement, and denial) were positively correlated with psychosocial and physical SIP scales, especially those pertaining to interpersonal life-style arenas. After we accounted for the number of different CFS-specific physical complaints reported and DSM-III-R depression diagnosis status, cognitive appraisals and coping strategies predicted a substantial proportion of the variance in the severity of illness burden. For the most part, the magnitude of these relationships between our predictor model variables and illness burden severity was similar in the MDD and non-MDD subgroups.
Arber M, Macintyre A.		Chronic fatigue syndrome or myalgic encephalitis.	Lancet 1994 Jan 22;343(8891):242-3 comment on: Lancet. 1993 Nov 13;342(8881):1247-8	
Artsimovich NG, Chugunov VS, Kornev AV, Ivanova TM, Chugunov AV, Oprishchenko MA.		[The chronic fatigue syndrome].[article in Russian]	Zh Nevropatol Psikhiatr Im S S Korsakova 1994;94(5):47-50	CFIDS (chronic fatigue and immune disfunction syndrome) is also known as CFS (chronic fatigue syndrome), CEBV (chronic Epstein-Barr virus), M.E. (myalgic encephalomyelitis), yuppie flu and by other names. It is a complex illness characterized by incapacitating fatigue (experienced as exhaustion and extremely poor stamina), neurological problems and a constellation of symptoms that can resemble many disorders, including; mononucleosis, multiple sclerosis, fibromyalgia, AIDS-related complex (ARC) and autoimmune diseases such as lupus. These symptoms tend to wax and wane, but any often severely debilitating and may last for many months or years. All sections of the population (including children) are at risk, but women under 45 seem to be most susceptible. The investigators suggest that CFIDS results from dysfunction of the immune system. The exact nature of this dysfunction is not yet well defined, but it can generally be viewed as an unregulated or overactive state which is responsible for most of the symptoms. There is also evidence of some immune suppression in CFIDS. None of the treatments is consistently satisfactory, but some may be helpful: psychotherapy, physiotherapy, exercise programs, acupunctures, small doses of antidepressants, etc.
Barker E, Fujimura SF, Fadem MB, Landay AL, Levy JA.	Department of Medicine, University of California, San Francisco 94143-0128.	Immunologic abnormalities associated with chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S136-41	Several aspects of cellular immunity in patients with clinically defined chronic fatigue syndrome (CFS) were evaluated and compared with those in healthy individuals. Flow cytometric analyses revealed normal expression of total T (CD3+), B (CD19+), and NK (natural killer) (CD16+, CD56+) markers on the surface

				of peripheral blood mononuclear cells (PMC) from patients with CFS. However, compared with those of healthy individuals, patients' CD8+ T cells expressed reduced levels of CD11b and expressed the activation markers CD38 and HLA-DR at elevated levels. In many of the individuals in whom expression of CD11b was reduced the expression of CD28 was increased. These findings indicate expansion of a population of activated CD8+ cytotoxic T lymphocytes. A marked decrease in NK cell activity was found in almost all patients with CFS, as compared with that in healthy individuals. No substantial abnormalities in monocyte activity or T cell proliferation were observed. The results of this study suggest that immune cell phenotype changes and NK cell dysfunction are common manifestations of CFS.
Bates DW, Buchwald D, Lee J, Kith P, Doolittle TH, Umali P, Komaroff AL.	Department of Medicine, Brigham and Women's Hospital, Boston, Massachusetts 02115.	A comparison of case definitions of chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S11-5	We compared three case definitions of chronic fatigue syndrome (CFS) applied to patients followed in CFS clinics at two institutions. All patients had debilitating fatigue without apparent etiology; patients with medical conditions associated with chronic fatigue and with major psychiatric disorders were stratified and presented separately. Patients were classified according to whether they met case definitions developed by a Centers for Disease Control and Prevention (CDC) Working Group, a British group, or an Australian group. When findings for 805 patients followed at the two clinics were combined, 61% met the CDC criteria, 55% met the British criteria, and 56% met the Australian criteria; these proportions were relatively similar at both sites. In addition, similar laboratory abnormalities were found for all case groups and for fatigued patients who met none of the three case definitions. These data suggest that more inclusive case definitions may be superior.

Bell DS, Bell KM, Cheney PR.	Department of Pediatrics, Cambridge Hospital, Massachusetts 02139.	Primary juvenile fibromyalgia syndrome and chronic fatigue syndrome in adolescents.	Clin Infect Dis 1994 Jan;18 Suppl 1:S21-3	Chronic fatigue syndrome (CFS) and primary juvenile fibromyalgia syndrome (PJFS) are illnesses with a similar pattern of symptoms of unknown etiology. Twenty-seven children for whom CFS was diagnosed were evaluated for fibromyalgia by the presence of widespread pain and multiple tender points. Eight children (29.6%) fulfilled criteria for fibromyalgia. Those children who met fibromyalgia criteria had a statistically greater degree of subjective muscle pain, sleep disturbance, and neurological symptoms than did those who did not meet the fibromyalgia criteria. There was no statistical difference between groups in degree of fatigue, headache, sore throat, abdominal pain, depression, lymph node pain, concentration difficulty, eye pain, and joint pain. CFS in children and PJFS appear to be overlapping clinical entities and may be indistinguishable by current diagnostic criteria.
Bell DS.	Harvard Medical School, Boston, Massachusetts.	Chronic fatigue syndrome update.	Postgrad Med 1994 Nov 1;96(6):73-6, 79-81	Neither Epstein-Barr virus nor human herpesvirus 6 appears to play a causative role in chronic fatigue syndrome. The possibility that a novel human retrovirus

		Findings now point to CNS involvement.		may be present in patients with the syndrome needs further study. A number of abnormalities found in patients with chronic fatigue syndrome point to central nervous system (CNS) involvement. These include immunologic abnormalities, indications of pituitary and hypothalamic involvement, abnormal basal plasma levels of certain neurotransmitter metabolites, and cerebral perfusion abnormalities. The symptom pattern of chronic fatigue syndrome may eventually be explainable in terms of CNS dysfunction.

Bertolin Guillen JM, Bedate Villar J.	Centro de Salud Mental, Diputacion Provincial-Servicio Valenciano de Salud.	[Therapeutic guidelines in chronic fatigue syndrome].[article in Spanish]	Actas Luso Esp Neurol Psiquiatr Cienc Afines 1994 May-Jun;22(3):127-30	The treatment of CFS is not definitive up till now and it is limited both by ignorance of its causes and by different applicable operative case definitions. It has been etiopathologically related to infectious agents, neuromuscular illnesses, neuro-endocrinous-immunologic alterations and to different psychiatric disorders, particularly depressive disorders. Consequently, a great variety of therapeutic strategies have been tried, most of them with insufficient results. Among the medicamentous ones: immunity activator agents such as recombinant interleukin-2, nonspecific immunitary modulators such as seric gamma globulin, antivirus drugs such as acyclovir, muscular relaxants such as ciclobenzaprine, H2 receptor blockers and steroid and nonsteroid anti-inflammatory drugs such as ibuprofen, naproxen and fulbiprofen. Better results seem to have been obtained with antidepressants, and amfebutamone and serotonin-reuptake selective inhibitors are specially promising. Among the nonmedicamentous strategies, cognitive behavioural treatment can be effective and the so called "psychiatric management of the patient with CFS" has been proposed as a global, pragmatic, individualized, comprehensive approach which must be completed with other interdisciplinary interventions on the patient and his environment.

Chalder T, Butler S, Wessely S.	London, UK.	syndrome: a follow up study.	Psychiatry 1994 May;57(5):617-21 comment in: J Neurol Neurosurg Psychiatry. 1995 Jun;58(6):764-5	treatment four years previously were followed up. Twenty-nine patients were interviewed, three patients refused an interview, and information on the remaining 14 was obtained from their general practitioners. All the instruments used at interview had been used in the initial study. The long-term prognosis for patients with chronic fatigue syndrome who have initially responded to treatment is good. Spontaneous recovery in those who declined or who did not benefit from treatment is unlikely. Patients who continue to fulfil the criteria for chronic fatigue syndrome four years after they were initially diagnosed are likely to have had more somatic disorders, to have been more fatigued, and to have had a previous psychiatric history when they were initially assessed.
Branco JC, Tavares V, Abreu I, Humbel RL.	Unidade de Reumatologia, Hospital de Egas Moniz, Lisboa.	[Viral infection and fibromyalgia].[article in Portuguese]	Acta Med Port 1994 Jun;7(6):337-41	Fibromyalgia (FM) is a very frequent syndrome of unknown cause, characterized by generalized pain, fatigue and a number of tender points to palpation. Among the several etiopathogenic hypotheses discussed, the association of FM with some viral infections has been the object of multiple studies due to its relation and similarity with the chronic fatigue syndrome, acknowledges as being related, although not exclusively, with the chronic infection by the Epstein-Barr virus. Many individual descriptions of association between infection with the human parvovirus B19 and FM led us to carry out this study, comparing the serology for that virus in 52 patients with FM and 39 healthy controls. The titers of specific IgG anti-parvovirus B19 antibodies, indicating previous infection with that virus, were determined in all 91 individuals through ELISA method and at the same laboratory. Results revealed, though not significantly, a greater prevalence of positive titers, of which the mean was also higher, in patients than in controls. When comparing the women from both groups, this tendency was even less perceptible. These data imply that there is no etiologic association between infection with the human parvovirus B19 and FM.
Briggs NC, Levine PH.	Viral Epidemiology Branch, NCI/NIH, Bethesda, Maryland 20892.	A comparative review of systemic and neurological symptomatology in 12 outbreaks collectively described as chronic fatigue syndrome, epidemic neuromyasthenia, and myalgic encephalomyelitis.	Clin Infect Dis 1994 Jan;18 Suppl 1:S32-42	Outbreaks of illnesses of unknown etiology typified by a chronic relapsing course of constitutional symptoms and nervous system involvement have collectively been referred to as chronic fatigue syndrome, epidemic neuromyasthenia, and myalgic encephalomyelitis. To examine heterogeneity of clinical presentation, a comparative review was undertaken for 12 well-documented outbreaks reported since 1934. A systemic syndrome characterized by excessive fatigue, myalgias, headache, low-grade fever, and other constitutional symptoms was common to cases in all outbreaks. However, marked heterogeneity in the range of neurological features was apparent. On the basis of predominant neurological manifestations, outbreaks could be grouped into four levels of increasing neurological involvement: affective neuropsychological changes (level I); prominent cutaneous sensory symptoms with both affective and cognitive neuropsychological changes (level II); marked objective paresis with cutaneous sensory as well as affective and cognitive neuropsychological changes (level III);

				and cutaneous sensory, affective and cognitive neuropsychological, posterior column, cranial nerve, and mixed upper and lower motor neuron changes (level IV). Groups with the most prominent objective neurological findings (levels III and IV) comprised exclusively outbreaks reported between the 1930s and 1950s. All but one outbreak in groups with less prominent neurological findings (levels I and II) were reported between the 1960s and 1980s; a range of neurological features was observed for these groups. Because a complete neurological examination is not emphasized as part of the diagnostic workup in current outbreaks, it is possible that less obvious neurological findings may be overlooked. Careful evaluation of neurological features in epidemic and endemic cases of what is now called chronic fatigue syndrome may be one approach to distinguishing subtypes of what has been described in the past as a nosological entity. Review Review, Tutorial

Buchwald D, Garrity D.	Department of Medicine, Harborview Medical Center, Seattle.	Comparison of patients with chronic fatigue syndrome, fibromyalgia, and multiple chemical sensitivities.	Arch Intern Med 1994 Sep 26;154(18):2049-53 comment in: Arch Intern Med. 1995 Sep 25;155(17):1913	BACKGROUND: Chronic fatigue syndrome (CFS), fibromyalgia (FM), and multiple chemical sensitivities (MCS) are conditions associated with fatigue and a variety of other symptoms that appear to share many clinical and demographic features. Our objectives were to describe the similarities and differences among patients with CFS, FM, and MCS. Additional objectives were to determine how frequently patients with MCS and FM met the criteria for CFS and if they differed in their health locus of control. METHODS: Demographic, clinical, and psychosocial measures were prospectively collected in 90 patients, 30 each with CFS, FM, and MCS. Patients were recruited from a university-based referral clinic devoted to the evaluation and treatment of chronic fatigue and three private practices. Variables included demographic features, symptoms characteristic of each condition, psychological complaints, a measure of health locus of control, and information on health care use. RESULTS: Overall, the three patient groups were remarkably similar in demographic characteristics and the presence of specific symptoms. Patients with CFS and FM frequently reported symptoms compatible with MCS. Likewise, 70% of patients with FM and 30% of those with MCS met the criteria for CFS. Health care use was substantial among patients with CFS, FM, and MCS, with an average of 22.1, 39.7, and 23.3 visits, respectively, to a medical provider during the prior year. Health locus of control did not differ among the three populations. CONCLUSIONS: In general, demographic and clinical factors and health locus of control do not clearly distinguish patients with CFS, FM, and

				MCS. Symptoms typical of each disorder are prevalent in the other two conditions.
Buchwald D, Pascualy R, Bombardier C, Kith P.	Department of Medicine, University of Washington, Seattle.	Sleep disorders in patients with chronic fatigue.	Clin Infect Dis 1994 Jan;18 Suppl 1:S68-72	This prospective, cohort study examined the prevalence of sleep disorders among highly selected patients with chronic fatigue. On the basis of responses suggestive of sleep pathology on a screening questionnaire, 59 patients from a university-based clinic for chronic fatigue who had undergone a medical and psychiatric evaluation underwent polysomnography. Criteria for chronic fatigue syndrome (CFS) were met by 64% of patients and those for a current psychiatric disorder were met by 41%. Overall, 41% of patients had abnormal results for a multiple sleep latency test and 81% had at least one sleep disorder, most frequently sleep apnea (44%) and idiopathic hypersomnia (12%). In comparing patients who did and did not meet CFS criteria, no significant differences were found in individual sleep symptoms or sleep disorders. Likewise, symptoms and sleep disorders were unrelated to psychiatric diagnoses. In conclusion, chronically fatigued patients with suggestive symptoms may have potentially treatable coexisting sleep disorders that are not associated with meeting criteria for CFS or a current psychiatric disorder.
Buchwald D, Pearlman T, Kith P, Schmaling K.	Department of Medicine, University of Washington, Seattle.	Gender differences in patients with chronic fatigue syndrome.	J Gen Intern Med 1994 Jul;9(7):397-401	OBJECTIVE: To determine whether there are differences between men and women patients who have chronic fatigue syndrome (CFS) and, if so, to ascertain whether a gender-related pattern exists. DESIGN: A descriptive study of demographic, clinical, and psychosocial measures, the results of which were prospectively collected for patients who had CFS. SETTING: A university-based referral clinic devoted to the evaluation and management of chronic fatigue. PATIENTS: 348 CFS patients who had undergone complete medical evaluations. MEASURES: Clinical variables included symptoms, physical examination findings, and laboratory results. Psychosocial assessment consisted of a structured psychiatric interview, the Medical Outcomes Study Short-form General Health Survey to assess functional status, the General Health Questionnaire to ascertain psychological distress, the Multidimensional Health Locus of Control, and measures of attribution, social support, and coping. MAIN RESULTS: Overall, few gender-related differences were identified. Women had a higher frequency of tender or enlarged lymph nodes (60% versus 33%, p < or = 0.01) and fibromyalgia (36% versus 12%, p < or = 0.001) and lower scores on the physical functioning subscale of the Medical Outcomes Study Short-form General Health Survey (37.6 versus 52.2, p < 0.01); men more often had pharyngeal inflammation (42% versus 22%, p < or = 0.001) and reported a higher lifetime prevalence of alcoholism (20% versus 9%, p < or = 0.01). CONCLUSIONS: In general, demographic, clinical, and psychosocial factors do not distinguish men from women CFS patients.
Caffery BE, Josephson JE, Samek MJ.		The ocular signs and symptoms of chronic	J Am Optom Assoc 1994 Mar;65(3):187-91	BACKGROUND: Chronic Fatigue syndrome (CFS) is a relatively newly defined clinical entity that affects multiple systems including the ocular system. These

		fatigue syndrome.		effects have not been well documented. METHODS: 25 consecutive CFS patients were evaluated and the ocular signs and symptoms were described. RESULTS: Significant ocular symptoms were present in all 25 patients. The most common clinical findings were abnormalities of the preocular tear film and ocular surface (19 patients) and reduced accommodation for age (18 patients). CONCLUSIONS: CFS affects the ocular system in many ways. Eye care practitioners should pay particular attention to accommodative needs, ocular surface disease and tear film dysfunction when examining these patients. Further research into the pathophysiology of these ocular findings may lead to a better understanding of the pathophysiology of CFS.
Calabrese LH, Davis ME, Wilke WS.	Department of Rheumatic and Immunologic Disease, Cleveland Clinic Foundation, Ohio 44195-5028.	Chronic fatigue syndrome and a disorder resembling Sjogren's syndrome: preliminary report.	Clin Infect Dis 1994 Jan;18 Suppl 1:S28-31	Chronic fatigue syndrome (CFS), as currently described in the working criteria proposed by the Centers for Disease Control and Prevention (Atlanta), may be associated with multiple, distinct, and possibly unique clinical and/or etiopathogenic subsets. Sjogren's syndrome (SS) is a disease of unknown etiology that is characterized by dryness of the mucous membranes and a variety of autoimmune phenomena and conditions. Subjective manifestations of SS such as neurocognitive dysfunction and fatigue have been stressed by some observers. We have detected a large number of patients with unrecognized SS-like illness in a clinical specializing in CFS and believe the relationship to be more than casual. From January 1991 through April 1992, 172 patients were evaluated for CFS; the SS cohort consisted of 27 females (mean age, 41.9 years). Sixteen of these patients had previously been found to have CFS by a physician, and 11 were self-referred. All patients complained of severe, dominating, chronic fatigue. Complaints of myalgia were prominent; 20 of 27 patients met the criteria for fibromyalgia. Neurocognitive complaints and/or a history of neuropsychiatric disease was frequent. Results of Schirmer's test were abnormal for 16 of 27, and results of minor salivary-gland biopsy were abnormal for 20 of 25. Antibodies to nuclear antigen were present in 16 of 27, but anti-Ro was present in only 1 of 21. In the SS group, 13 of 27 patients met eight or more CDC minor criteria for CFS, and 18 of 27 met six or more of the criteria.(ABSTRACT TRUNCATED AT 250 WORDS)
Carver LA, Connallon PF, Flanigan SJ, Crossley-Miller MK.	159th MASH, Louisiana Army National Guard, Jackson Barracks, New Orleans 70146.	Epstein-Barr virus infection in Desert Storm reservists.	Mil Med 1994 Aug;159(8):580-2	Approximately 150 U.S. Army reservists from Indiana reported symptoms consistent with chronic fatigue syndrome after returning stateside from the tour of duty in Saudi Arabia. A psychiatric team confirmed the diagnosis, evaluated possible etiology, and treated the service members when appropriate. Those available service members who met the study's diagnostic criteria for chronic fatigue syndrome (n = 37) received an Epstein-Barr virus panel. Seventy-three percent of these selected service members were positive either for an acute or reactivated Epstein-Barr viral infection. These data suggest that service members who suffer from chronic fatigue syndrome may have their symptoms increased

				and prolonged by secondary viral infections.
Chester AC, Levine PH.	Georgetown University Medical Center, Washington, D.C.	Concurrent sick building syndrome and chronic fatigue syndrome: epidemic neuromyasthenia revisited.	Clin Infect Dis 1994 Jan;18 Suppl 1:S43-8	Sick building syndrome (SBS) is usually characterized by upper respiratory complaints, headache, and mild fatigue. Chronic fatigue syndrome (CFS) is an illness with defined criteria including extreme fatigue, sore throat, headache, and neurological symptoms. We investigated three apparent outbreaks of SBS and observed another more serious illness (or illnesses), characterized predominantly by severe fatigue, that was noted by 9 (90%) of the 10 teachers who frequently used a single conference room at a high school in Truckee, California; 5 (23%) of the 22 responding teachers in the J wing of a high school in Elk Grove, California; and 9 (10%) of the 93 responding workers from an office building in Washington, D.C. In those individuals with severe fatigue, symptoms of mucous membrane irritation that are characteristic of SBS were noted but also noted were neurological complaints not typical of SBS but quite characteristic of CFS. We conclude that CFS is often associated with SBS.

Conti F, Priori R, De Petrillo G, Rusconi AC, Arpino C, Valesini G.	Istituto di Clinica Medica I, Universita degli Studi La Sapienza di Roma.	Prevalence of chronic fatigue syndrome in Italian patients with persistent fatigue.	Ann Ital Med Int 1994 Oct-Dec;9(4):219-22	Our study was carried out to determine the prevalence of chronic fatigue syndrome (CFS) within a selected population of patients suffering from persistent fatigue. We studied subjects with recurrent or persistent fatigue lasting 6 months and fulfilling at least four minor Center for Disease Control (CDC) criteria for the diagnosis of CFS. Evaluation included both clinical examination and laboratory testing. All subjects filled out a questionnaire specifically designed to gain information about the length and severity of symptoms, and patients with a previously diagnosed illness associated with fatigue were excluded. The study was carried out at the Fatigue Clinic of an internal medicine unit (Clinica Medica I) of the University of Rome "La Sapienza". Sixty-three subjects, residents of the Lazio region (central Italy), completed the diagnostic assessment. Alternative diagnoses were established in 37 (59%) of the 63 patients. A diagnosis of CFS based on the CDC criteria was established in only 6 cases. In 2 subjects, CFS had appeared following infectious mononucleosis, and no definitive diagnosis could

				be formulated for 18 patients. In Italy, CFS seems to be an infrequent cause of severe and persistent fatigue in a selected population. Numerous morbid conditions may be responsible for a clinical picture closely resembling CFS. We recommend that patients suffering from fatigue be thoroughly evaluated.

Dantzer R.	INRA-INSERM U 176, Bordeaux.	[Current studies on the neurobiology of chronic fatigue syndrome].[article in French]	Encephale 1994 Nov;20 Spec No 3:597-602	Cytokines are soluble mediators which are released by activated immune cells during infection and inflammation. The possibility that fatigue is mediated by the effects of cytokines on the central nervous system is supported by several converging lines of evidence: 1) infusions of cytokines to immunocompromised patients induce flu-like symptoms including fatigue and malaise; 2) peripheral and central injection of cytokines to laboratory rodents induce sickness behaviour; 3) symptoms of sickness behaviour occurring during experimental infections can be abrogated by administration of anti-cytokine treatments; 4) although many pitfalls in the detection of cytokines still exist, patients afflicted with the chronic fatigue syndrome have been found in some studies to display instances of excessive production of cytokines. Experimental studies have confirmed that cytokines are interpreted by the brain as internal signals for sickness. Furthermore, there is evidence that sickness is a motivation which reorganizes the organism's priorities in face of this particular threat which is represented by infectious pathogens. The elucidation of the mechanisms that are involved in these effects and in particular, the role of the cytokines which are produced in the brain in response to peripheral immune stimuli and to stressors, should give new insight on the way sickness and recovery processes are organized in the brain.

Eicosanoids and essential fatty acid modulation in chronic disease and the chronic fatigue syndrome.	Gray JB, Martinovic AM.	Erratum in: Med Hypotheses 1995 Aug;45(2):219	Med Hypotheses 1994 Jul;43(1):31-42	Abnormalities of Essential Fatty Acid (EFA) incorporation into phospholipid are found in chronic diseases. More recently changes in circulating EFA metabolites (EFAM) together with EFAM hypo-responsiveness of immune cells and EFAM production from cells have been found associated with disease. We hypothesize that changes in ratio of EFAMs are the normal physiological responses to stressors, but when stressors are excessive or prolonged, EFAM systems may become unpredictably hypo-responsive owing to factors such as receptor down regulation and substrate depletion. In time, many homeostatic system become deranged and held in that state by minor stressors. Literature review of chronic fatigue syndrome (CFS) shows hyper and hypo-responsiveness in immune function, several Hypothalamo-Pituitary (HP) axes and sympathetic nervous system, all relatable to dysfunctional changes in EFA metabolism. For the first time, we explain chronic immune system activation and hypo-responsive immune function in CFS; through EFAMs. Dietary EFA modulation (DEFA) can alter ratios of both membrane EFAs and produced EFAMs, and if maintained can restore hypo-responsive function. We discuss dietary strategies and relevance in CFS, and a case series of CFS patients applying DEFA with other titrated published managements which saw 90% gaining improvement within 3 months and more than 2/3 fit for full time duties. This hypothesis and DEFA may have relevance in other chronic conditions. Review, Academic
Fenske TK, Davis P, Aaron SL.	Department of Medicine, University of Alberta, Edmonton, Canada.	Human adjuvant disease revisited: a review of eleven post-augmentation mammoplasty patients.	Clin Exp Rheumatol 1994 Sep-Oct;12(5):477-81	OBJECTIVES: We have reviewed 11 women post-augmentation mammoplasty who were referred to our clinic with diffuse rheumatic complaints. All patients had undergone mammoplasty with silicone gel-filled implants prior to the onset of their locomotor symptoms (mean latency time 7.8 years). One physician interviewed and examined each of these patients following a standardized format for clinical retrieval. RESULTS: Of the patients reviewed, 6 patients had clinical fibromyalgia based on the ACR criteria, and the remaining 5 patients had symptoms consistent with the "chronic fatigue syndrome." None of our patients were found to have evidence of a defined connective tissue disease. Antinuclear

				antibodies were detected in 4 (36%) patients and low level titres of extractable nuclear antigens in only 2 (18%). CONCLUSIONS: Previously a causal relationship between the use of silicone gel-filled breast implants and the subsequent development of symptoms referred to as human adjuvant disease (HAD) has been proposed. On the basis of currently accepted criteria we have preferred to diagnose our post-mammoplasty patients without specific connective tissue disease, as having chronic fatigue syndrome (CFS), or when tender points are present, as having fibromyalgia (FMS), rather than implying that such cases represent a separate and unique rheumatological disease entity. In the light of our current understanding of CFS and FMS, a relationship between them and the previous silicone mammoplasty seems possible.
Fiedler N, Kipen H, Deluca J, Kelly-McNeil K, Natelson B.	UMDNJ-Robert Wood Johnson Medical School, Environmental and Occupational Health Sciences Institute, Piscataway 08855, USA.	Neuropsychology and psychology of MCS.	Toxicol Ind Health 1994 Jul-Oct;10(4-5):545-54	Neurological symptoms are frequently reported by patients with multiple chemical sensitivities (MCS). Methods to compare the psychiatric, personality, and neuropsychological function of patients with MCS, chronic fatigue syndrome (CFS), and normal controls are described. Increased rates of Axis I psychiatric diagnoses are observed in the literature for MCS and CFS subjects relative to controls. Findings on the MMPI-2 and the Toronto Alexithymia Scale reveal profiles consistent with the tendency to report somatic rather than emotional symptoms in response to stress. However, many of the reported somatic symptoms also coincide with those found in neurologic disorders. The overall neuropsychological profile for MCS subjects does not reflect cognitive impairment. Relative to normal controls, the only difference in neuropsychological performance observed is reduced recognition of nontarget designs on a visual memory task. More fruitful areas for future psychological research will include measurement of the interaction between behavioral response styles and attentional processes in cognition, as well as observations under controlled challenge conditions.
Fox DS.		Chronic fatigue syndrome: a review and practical guide.	J Am Acad Nurse Pract 1994 Dec;6(12):565-70	Diagnosis and management of chronic fatigue syndrome (CFS) is a difficult challenge for nurse practitioners. The syndrome is widespread, poorly-defined, and problematic. Despite extensive etiologic research, no cause has been identified. Each case should be carefully evaluated for possible organic, psychiatric, and other factors reported as potential causes. Clinical manifestations, possible causes, and options for management are reviewed.
Friedberg F, Krupp LB.	Department of Psychiatry, State University of New York at Stony Brook.	A comparison of cognitive behavioral treatment for chronic fatigue syndrome and primary depression.	Clin Infect Dis 1994 Jan;18 Suppl 1:S105-10 comment in: Clin Infect Dis. 1995 Mar;20(3):717-8	To evaluate the effect of cognitive behavioral intervention on chronic fatigue syndrome (CFS), we studied three patient groups: a CFS-treatment group (n = 22), a primary depression-treatment group (n = 20), and a no-treatment control group of subjects with CFS (n = 22). For the CFS-treatment group, a trend toward reduced depression-symptom scores was noted, but there were no significant changes in stress-related symptoms or fatigue severity. For the most depressed treated subjects with CFS, significant score reductions were observed in

				measures of depression, stress, fatigue severity, and fatigue-related thinking. In the depression group, significant reductions in depression, stress, and fatigue severity scores were found. No significant changes in any measure were observed in the CFS control group. A new fatigue-related cognitions scale, developed to assess cognitive and emotional reactions to fatigue, showed a significant reduction in such reactions in the CFS-treatment group, a finding suggesting that depression in this group was mediated by maladaptive thinking. The results suggest that a subset of CFS patients with cognition-related depressive symptomatology may respond to short-term behavioral intervention.

Gow JW, Behan WM, Simpson K, McGarry F, Keir S, Behan PO.	Department of Neurology, University of Glasgow, Scotland,	Studies on enterovirus in patients with chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S126-9	A large study on 121 patients with the chronic fatigue syndrome (CFS) that examined muscle biopsy samples for enterovirus by means of polymerase chain reaction analysis was carried out. The results were compared with those

	United Kingdom.			obtained from 101 muscle biopsy specimens from patients with a variety of other neuromuscular disorders (OND), including neurogenic atrophies, dystrophies, and mitochondrial, metabolic, and endocrine myopathies. Thirty-two (26.4%) of the biopsy specimens from the group of patients with CFS were positive, compared with 20 (19.8%) from the group of patients with OND, a difference that was not significant. This finding is in contrast to those of our previous smaller study in which significantly more patients with CFS than control subjects (53% [32 of 60] vs. 15% [6 of 41]) had enterovirus RNA sequences in their muscle. It was concluded that it is unlikely that persistent enterovirus infection plays a pathogenetic role in CFS, although an effect in initiating the disease process cannot be excluded.

Lack of evidence for infection with known human and animal retroviruses in patients with chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S121-5	We investigated 21 patients with chronic fatigue syndrome who were identified through the surveillance system of the Centers for Disease Control and Prevention (CDC) in Atlanta for the presence of several human and animal retroviruses. In addition, we evaluated 21 CDC employee controls matched with the patients for age (+/- 5 years), gender, and race. The viruses tested included human T-lymphotropic viruses types I and II; human spuma retrovirus; simian T-lymphotropic virus type I; simian retroviruses types 1, 2, and 3; bovine leukemia virus; feline leukemia virus; and gibbon ape leukemia virus. Samples of peripheral blood lymphocytes and leukocytes from patients and controls were analyzed in a blinded fashion for retroviral sequences; polymerase chain reaction (PCR) amplification assays and Southern blot hybridization to 32P-labeled internal oligoprobes were used. All PCR assays were optimized for maximal sensitivity on respective infected cell lines or plasmids, and sensitivity controls were included in each experiment. All samples from patients and controls were negative for the tested retroviral sequences. Our data indicate that none of these retroviruses plays an etiologic role or is a cofactor in the chronic fatigue syndrome illnesses of our study population.
Hilgers A, Frank J.	Institut fur angewandte Immunologie und Umweltmedizin, Dusseldorf.	[Chronic fatigue syndrome: immune dysfunction, role of pathogens and toxic agents and neurological and cardial	Wien Med Wochenschr 1994;144(16):399-406	375 patients with chronic fatigue syndrome (CFS) were examined using a standardized questionnaire and subsequent interview on 11 risk factors and 45 symptoms. Additionally immunologic, serologic, toxicologic, neuroradiologic, neurophysiologic and cardiologic investigations were performed. Immunologic tests showed cellular immunodeficiences particularly in functional regard (pathological lymphocyte stimulation in 50% of the patients, disorders of

		changes].[article in German]		granulocyte function in 44%). Furthermore variable deviations were found in the lymphocyte subpopulations (CD3, CD4, CD8, CD19, DR, Leu 11 + 19). In the humoral part tendencies to low IgG-3- and IgG-1-subclass-levels occurred (59% respectively 11% of the patients) also as decreases in complement system (CH50, C3, C4, C1-esterase-inhibitor). In the group of activation markers and cytokines 42% of the investigated patients had circulating immune complexes (CIC), 47% increases of tumor-necrosis-factor (TNF-a) and 21% increases of soluble interleukin-2-receptor (IL-2-R). The increased occurrence of autoantibodies in the CFS-patients (specially antinuclear anti-bodies [ANA], microsomal thyroid antibodies) suggest, that CFS is associated with or the beginning of manifest autoimmune disease. Under the pathogens 78% of the patients had a striking serological constellation of Epstein-Barr-Virus (EBV-EA positive, low EBNA-titers), in the HHV-6-Virus 47% showed increased antibody-titers. Tests on further herpes viruses and on Borreliae, Chlamydiae, Candida and Amoebae were positive in 8 to 36% of the examined patients. Furthermore there were found variable deficits of vitamins and trace elements also as hormonal disturbances.(ABSTRACT TRUNCATED AT 250 WORDS)
Hinds G, Bell NP, McMaster D, McCluskey DR.	Department of Medicine, Queen's University of Belfast, Northern Ireland, UK.	Normal red cell magnesium concentrations and magnesium loading tests in patients with chronic fatigue syndrome.	Ann Clin Biochem 1994 Sep;31 (Pt 5):459-61	Red blood cell magnesium concentrations were measured in samples from 89 patients who fulfilled the diagnostic criteria for chronic fatigue syndrome and the results compared to those found in an age and sex matched group selected from the normal population. No significant difference was found. Six patients were further investigated using a magnesium loading test to determine if there was any evidence of magnesium deficiency associated with this disorder. None was found. There is therefore no indication for the use of magnesium therapy in the management of this condition.

Jefferies WM.	Case-Western Reserve University School of Medicine, Cleveland, Ohio.	Mild adrenocortical deficiency, chronic allergies, autoimmune disorders and the chronic fatigue syndrome: a continuation of the cortisone story.	Med Hypotheses 1994 Mar;42(3):183-9	The possibility that patients with disorders that improve with administration of large, pharmacologic dosages of glucocorticoids, such as chronic allergies and autoimmune disorders, might have mild deficiency of cortisol production or utilization has received little attention. Yet evidence that patients with rheumatoid arthritis improved with small, physiologic dosages of cortisol or cortisone acetate was reported over 25 years ago, and that patients with chronic allergic disorders or unexplained chronic fatigue also improved with administration of such small dosages was reported over 15 years ago, suggesting that these disorders might be associated with mild adrenocortical deficiency. The apparent reasons for the failure of these reports to be confirmed or mentioned in medical textbooks and the facts needed to restore perspective are reviewed, and the need for further studies of the possible relationship of a mild deficiency of the production or utilization of cortisol and possibly other normal adrenocortical hormones to the development of these disorders is discussed.
Johnson SK, DeLuca J, Fiedler N, Natelson BH.	Department of Physical Medicine, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark.	Cognitive functioning of patients with chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S84-5	Neuropsychological problems are a distressing and frequent component of the symptom complex associated with chronic fatigue syndrome. Objective assessment of these difficulties is essential to understanding the nature of this illness. Results of the studies discussed in this paper suggest that impaired information processing, rather than primary memory dysfunction, may be at the root of the cognitive problems that afflict so many patients with CFS.

Chronic pain syndrome and myofascial pain	Arch Phys Med Rehabil 1994 May;75(5 Spec No):S9-14.	This article highlights chronic pain syndrome and myofascial pain. It is part of the chapter on pain rehabilitation in the Self-Directed Medical Knowledge Program for practitioners and trainees in physical medicine and rehabilitation. This article discusses behavioral maladaptations to chronic pain which lead to global physical, psychologic, social, and vocational impairments--the chronic pain syndrome. The spectrum of myofascial pain syndromes, contributing factors, and interventions are detailed. New advances that are covered in this section include controversies in long-term use of opioids and muscle relaxants; differentiating fibromyalgia, myofascial pain syndromes, and chronic fatigue syndrome; pathophysiology of myofascial pain; and beneficial treatments.

Krueger GR, Klueppelberg U, Hoffmann A, Ablashi DV.	Immunopathology Section, University of Cologne, Germany.	Clinical correlates of infection with human herpesvirus-6.	In Vivo 1994 Jul-Aug;8(4):457-85	Human herpesvirus-6 is a lymphotropic virus which infects susceptible individuals during the first year of life and usually causes life-long latency. In a variable percentage primary infections are followed by a short acute disease, exanthema subitum. Older individuals may suffer from infectious mononucleosis-like illnesses or from Kikuchi-Fujimoto's disease. In addition, there is a fairly wide spectrum of lymphoid and hematopoietic diseases or autoimmune disorders, which are associated with elevated titers of HHV-6 antibody, and from which replicating virus may be isolated. Such diseases include atypical polyclonal lymphoproliferation, Hodgkin's disease, chronic fatigue syndrome and systemic lupus erythematosus. The present article reviews the current knowledge of such associations. Review, Academic
Krupp LB, Sliwinski M, Masur DM, Friedberg F, Coyle PK.	Department of Neurology, State University of New York-Stony Brook.	Cognitive functioning and depression in patients with chronic fatigue syndrome and multiple sclerosis.	Arch Neurol 1994 Jul;51(7):705-10	OBJECTIVE: To assess cognitive function in patients with chronic fatigue syndrome (CFS) and multiple sclerosis (MS) and to evaluate the role of depressive symptoms in cognitive performance. DESIGN: Case-control. All subjects were given a neuropsychological battery, self-report measures of depression and fatigue, and a global cognitive impairment rating by a neuropsychologist "blinded" to clinical diagnosis. Patients with MS and CFS were additionally evaluated with a Structured Clinical Interview for DSM-III-R (Diagnostic and Statistical Manual of Mental Disorders, Revised Third Edition) disorders. SETTING:

				Institutional and private neurological practices and the community at large. PATIENTS: Twenty patients with CFS diagnosed in accord with the Centers for Disease Control and Prevention-revised criteria who had cognitive complaints; 20 patients with clinically definite MS who were ambulatory and were matched for fatigue severity, age, and education to CFS subjects; and 20 age- and education-matched healthy controls. RESULTS: Patients with CFS had significantly elevated depression symptoms compared with patients with MS and healthy controls (P < .001) and had a greater lifetime prevalence of depression and dysthymia compared with MS subjects. Patients with CFS, relative to controls, performed more poorly on the Digit Symbol subtest (P = .023) and showed a trend for poorer performance on logical memory (P = .087). Patients with MS compared with controls had more widespread differences of greater magnitude on the Digit Span (P < .004) and Digit Symbol (P < .001), Trail Making parts A (P = .022) and B (P = .037), and Controlled Oral Word Association (P = .043) tests. Patients with MS also showed a trend of poorer performance on the Booklet Category Test (P = .089). When patients with CFS and MS were directly compared, MS subjects had lower scores on all measures, but the differences reached significance only for the Digit Span measure of attention (P = .035). CONCLUSIONS: Patients with CFS compared with MS have more depressive symptoms but less cognitive impairment. Relative to controls, a subset of CFS subjects did poorly on tests of visuomotor search and on the logical memory measure of the Wechsler Memory Scale-revised. Poor performance of logical memory in CFS appears to be related to depression, while visuomotor deficits in CFS are unrelated. Cognitive deficits in patients with MS are more widespread compared with those in patients with CFS and are independent of depressive symptoms.
Kuratsune H, Yamaguti K, Takahashi M, Misaki H, Tagawa S, Kitani T.	Osaka University Medical School, Japan.	Acylcarnitine deficiency in chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S62-7	One of the characteristic complaints of patients with chronic fatigue syndrome (CFS) is the skeletal muscle-related symptom. However, the abnormalities in the skeletal muscle that explain the symptom are not clear. Herein, we show that our patients with CFS had a deficiency of serum acylcarnitine. As carnitine has an important role in energy production and modulation of the intramitochondrial coenzyme A (CoA)/acyl-CoA ratio in the skeletal muscle, this deficiency might induce an energy deficit and/or abnormality of the intramitochondrial condition in the skeletal muscle, thus resulting in general fatigue, myalgia, muscle weakness, and postexertional malaise in patients with CFS. Furthermore, the concentration of serum acylcarnitine in patients with CFS tended to increase to the normal level with the recovery of general fatigue. Therefore, the measurement of acylcarnitine would be a useful tool for the diagnosis and assessment of the degree of clinical manifestation in patients with CFS.

Clin Lab Sci 1994 Sep-Oct;7(5):279-82	OBJECTIVE: To review the literature and current research about the causes of chronic fatigue syndrome (CFS). DATA SOURCES: Recent research articles about CFS and data gathered by the author. STUDY SELECTION: Performed by the author. DATA EXTRACTION: Performed by the author. DATA SYNTHESIS: Chronic fatigue syndrome (CFS) is a disease of pain, excessive fatigue after minor exertion, cognitive difficulties, and other symptoms-all occurring in cycles. While its etiology is unclear, CFS is associated with abnormal results of immune system tests. There is no specific marker for the illness. Treatment is symptomatic, and the long-term outlook for recovery is good. CONCLUSION: A rational, symptomatic approach to treating CFS patients can be made using the model developed at the author's institution. Research into the causes of CFS must continue.

Levine PH, Atherton M, Fears T, Hoover R.	Viral Epidemiology Branch, National Cancer Institute, Bethesda, Maryland 20892.	An approach to studies of cancer subsequent to clusters of chronic fatigue syndrome: use of data from the Nevada State Cancer Registry.	Clin Infect Dis 1994 Jan;18 Suppl 1:S49-53	Chronic fatigue syndrome (CFS) has been increasingly associated with immune dysregulation, including depressed natural killer cell activity; this phenomenon is associated with increased susceptibility to cancer. Although anecdotal reports have suggested an association between CFS and cancer, particularly non-Hodgkin's lymphoma and brain cancer, there has been no a priori justification for evaluating such an association and no consideration of relevant parameters, such as length of latent period vs. tumor type. We reviewed data from the Nevada State Cancer Registry subsequent to a reported outbreak of a CFS-like illness in Nevada that occurred during 1984-1986. We concentrated on non-Hodgkin's lymphoma and brain/CNS tumors, with particular emphasis on persons 15-34 and 35-54 years of age. An upward trend in the incidence of brain/CNS tumors, which could be related to a national upward trend for this disease, was noted. No consistent trends were noted for non-Hodgkin's lymphoma. Because of the difficulties inherent in studies of cancer subsequent to various exposures, we evaluated the methodology for determining an association between outbreaks of CFS-like disease and cancer. We propose several approaches that should be considered in future studies for investigation of possible associations between CFS and cancer, including expected latent periods for specific tumors.
Levine PH.	Viral Epidemiology Branch, National Cancer Institute, Bethesda, Maryland 20892.	Epidemiology of chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S57-60	
Levine PH.	Viral Epidemiology Branch, National Cancer Institute, Bethesda, Maryland 20892.	Epidemic neuromyasthenia and chronic fatigue syndrome: epidemiological importance of a cluster definition.	Clin Infect Dis 1994 Jan;18 Suppl 1:S16-20	Outbreaks of illness variously identified by a number of terms, including epidemic neuromyasthenia, myalgic encephalomyelitis, Iceland disease, and atypical poliomyelitis, have been reported from many countries during the past 45 years. Since the first well-described outbreak occurring in 1934, > 60 outbreaks have been reported, but few of these have been described in considerable detail. These outbreaks are usually cited in historical reports of chronic fatigue syndrome (CFS) since each of these outbreaks appears to contain a number of cases meeting the current case definition of CFS. There has been inadequate attention given to the fact that epidemic neuromyasthenia and related clusters characterized by various complaints, including fatigue, do not have an accepted epidemiological or clinical definition, and only rarely have descriptions of these clusters included a specific case definition. When such case definitions have been applied, the occurrence of cases meeting the current case definition for CFS appears to be both variable and infrequent. This report utilizes examples of several well-documented outbreaks to emphasize specific aspects that should be considered in the investigation of future clusters.
Levy JA.	Department of Medicine, University of	Viral studies of chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S117-20	Chronic fatigue syndrome (CFS) has many characteristics suggesting persistent fatigue following a viral illness. At least nine different RNA and DNA viruses have

	California School of Medicine, San Francisco.			been considered to be associated with this disease, but none of these viruses has been found to be the etiologic agent. Immunologic studies have demonstrated activated CD8+ cells and reduced function of natural killer cells suggesting a host response to an infection that has led to persistent immune disorders. Some of the symptoms of CFS may be due to cytokines produced by this hyperactive immune response to a virus that is still present in the host or that has been eliminate but leaves abnormal immunologic sequelae. These possibilities offer directions for future studies of CFS and therapeutic approaches to this condition.
Lewis S, Cooper CL, Bennett D.	Department of Psychology and Speech Pathology, Manchester Metropolitan University.	Psychosocial factors and chronic fatigue syndrome.	Psychol Med 1994 Aug;24(3):661-71	This study investigated the number and severity of life events, Type A behaviour, coping strategies and social support differences between chronic fatigue and irritable bowel syndrome patients prior to illness and between these groups and healthy controls. Although few differences were found between the groups for life events, a number of interesting results emerged with regard to different aspects of Type A behaviour, various coping strategies and social support. These findings are discussed with respect to existing research in the field.
Lloyd A, Gandevia S, Brockman A, Hales J, Wakefield D.	Department of Infectious Diseases, Prince Henry Hospital, Little Bay, New South Wales, Australia.	Cytokine production and fatigue in patients with chronic fatigue syndrome and healthy control subjects in response to exercise.	Clin Infect Dis 1994 Jan;18 Suppl 1:S142-6	We have studied the relationship between the cytokine production induced in vivo by prolonged isometric exercise and the symptom complex marked by fatigue in patients with chronic fatigue syndrome (CFS). Twelve male patients and 13 matched male control subjects undertook an isometric hand-grip exercise protocol utilizing dynamometers. Subjects undertook 30 minutes of exercise, for which the target force was set at 40% of the maximal voluntary contraction and the duty cycle was 50%. Prior to, during, and for 24 hours following the exercise, blood samples were collected and assayed for the presence of cytokines, including interferon-gamma and interferon-alpha, interleukin-1 beta, and tumor necrosis factor-alpha. At those times subjects also completed the Profile of Mood States (POMS) questionnaire, which served as a measure of changes in subjective fatigue. No significant alteration in the level of any of the cytokines in the plasma of patients or control subjects was detected before, during, or after exercise. Surprisingly, the patients' levels of fatigue, depression, and confusion, as measured by the POMS, decreased in response to the exercise. These data do not confirm the presence of an immunologic process correlating with the exacerbation of fatigue after exercise experienced by patients with CFS. Limitations in the study design and in the sensitivity of the cytokine assays may have affected our results.

Manian FA.	Division of Infectious Diseases, St. John's Mercy Medical Center, St. Louis, Missouri.	Simultaneous measurement of antibodies to Epstein-Barr virus, human herpesvirus 6, herpes simplex virus types 1 and 2, and 14 enteroviruses in chronic fatigue syndrome: is there evidence of activation of a nonspecific polyclonal immune response?	Clin Infect Dis 1994 Sep;19(3):448-53 comment in: Clin Infect Dis. 1995 Sep;21(3):708-9	As a test of the hypothesis that elevated titers of viral antibodies in patients with chronic fatigue syndrome (CFS) are due to a nonspecific polyclonal immune response, antibodies to Epstein-Barr virus (EBV), human herpesvirus 6 (HHV-6), and 14 enteroviruses in 20 patients with CFS and 20 age- and gender-matched controls were simultaneously measured. Similarly, titers of IgG to herpes simplex virus (HSV) types 1 and 2 were measured in 18 of these cases and in the respective controls. IgG to EBV viral capsid antigen (VCA) was present at titers > or = 1:320 in 55% of cases vs. 15% of controls (P = .02). The geometric mean titers of early antigen antibody to EBV, HHV-6 IgG, and HSV-1 and HSV-2 IgG were not significantly different among cases and controls. Of the 14 enteroviral antibodies tested for, only those to coxsackieviruses B1 and B4 were present at significant titers (> or = 1:8) in cases vs. controls (P = .02 and P = .001, respectively). Of the cases, 19 (95%) had either an EBV VCA IgG titer > or = 1:320 or a coxsackievirus B1 or B4 antibody titer > or = 1:8, a percentage significantly higher than that of controls (40%; P = .0004). Titers of EBV VCA IgG and coxsackievirus B1 and B4 antibodies were simultaneously elevated in only 20% of cases. There was no correlation between elevated titers of EBV VCA IgG and IgG to HHV-6, HSV-1, and HSV-2 or antibody to coxsackieviruses B1 and B4 in the cases. The prevalence of reported allergies to medications or other substances was identical in both groups (60%). These findings suggest that in the majority of cases of CFS, elevation of viral antibody titers is not due to a nonspecific polyclonal immune

				response.
Mann AH, Mc Donald E, Cope H, Pelosi A, David A.	Section of Epidemiology & General Practice, Institute of Psychiatry, London, United Kingdom.	[Epidemiologic study of chronic fatigue in primary care (general practice)].[article in French]	Encephale 1994 Nov;20 Spec No 3:575-9	The results of a cross sectional study of fatigue in two large samples of patients attending primary care physicians are reported. The level of complaint of fatigue was higher in the prospective sample, which consisted of patients who had been diagnosed as suffering from a viral infection six months earlier. Duration and frequency of experience of fatigue correlated with severity in both samples. Severity, duration and frequency were continuously distributed in these populations. Attribution of fatigue in these two samples was mixed: social stresses, current physical illness and psychological problems all being offered as explanations. 11% of the cross sectional sample and 17% of the prospective sample met study operational criteria for a possible chronic fatigue state. These patients were assessed in greater detail. The majority had a diagnosable psychiatric disorder, predominantly depression. Physical illnesses were not adequate to explain these fatigue states. These studies in primary care do not support a clinical entity of a "chronic fatigue syndrome". Some patients in primary care settings have complaints of fatigue that are both disabling and long lasting, but they do not form a distinct group although the majority are likely however to be suffering from a concurrent psychiatric disorder. In contrast to similar patients with chronic fatigue syndromes attending hospital clinics, primary care patients with complaints of fatigue are much more varied in their ideas of causation with considerable less evidence of disease conviction.
Mant D.	University of Southhampton, UK.	Chronic fatigue syndrome.	Lancet 1994 Sep 24;344(8926):834-5 comment on: Lancet. 1994 Sep 24;344(8926):864-8	
Manu P, Lane TJ, Matthews DA, Castriotta RJ, Watson RK, Abeles M.	Department of Medicine, University of Connecticut School of Medicine, Farmington.	Alpha-delta sleep in patients with a chief complaint of chronic fatigue.	South Med J 1994 Apr;87(4):465-70 comment in: South Med J. 1994 Dec;87(12):1289-90	Our prospective, standardized cohort study was designed to assess the presence of alpha wave intrusions during non-rapid eye movement sleep (alpha-delta sleep) and its relationship to fibromyalgia, major depression, and chronic fatigue syndrome (CFS) in patients with a chief complaint of chronic fatigue. The study group comprised 30 consecutive patients seen at a university hospital referral clinic for evaluation of chronic fatigue. All patients had nocturnal polysomnography, dolorimetric tender point assessment for fibromyalgia, a comprehensive history, physical, and laboratory evaluation, and a structured psychiatric interview. Alpha-delta sleep was identified in 8 of the 30 patients (26%), major depression in 20 (67%), CFS in 15 (50%), and fibromyalgia in 4 (13%). Ten of the 30 patients (33%) had a primary sleep disorder (sleep apnea, periodic limb movements, or narcolepsy). Alpha-delta sleep was not significantly correlated with fibromyalgia, CFS, major depression, or primary sleep disorders, but was significantly more common among patients who had chronic fatigue

				without major depression. We conclude that primary sleep disorders are relatively common among patients with chronic fatigue and must be diligently sought and treated. Alpha-delta sleep is not a marker of fibromyalgia or CFS, but may contribute to the illness of nondepressed patients with these conditions.
Martin WJ, Zeng LC, Ahmed K, Roy M.	Department of Pathology, USC School of Medicine, Los Angeles 90033.	Cytomegalovirus-related sequence in an atypical cytopathic virus repeatedly isolated from a patient with chronic fatigue syndrome.	Am J Pathol 1994 Aug;145(2):440-51	An atypical virus, cytopathic for human and animal fibroblasts, was repeatedly cultured from a patient with chronic fatigue syndrome. Viral particles, suggestive of cytomegalovirus (CMV) were seen by electron microscopy. Infected cells did not, however, stain with antisera specific for CMV, herpes, simplex virus, or human herpes-virus-6. Polymerase chain reaction (PCR) assays for these viruses were also negative. Two distinct products of approximately 1.5 kilobase pairs were amplified from virally infected cells using the human T lymphotropic virus-II tax gene reactive primer, SK44, in low stringency PCR. Sequencing of one of the amplified products showed a region of highly significant partial homology with the UL34 gene of CMV. The sequence of the other PCR product did not correspond with CMV or any other virus. DNA was extracted from the material pelleted by ultracentrifugation of filtered culture supernatants. It migrated in agarose gels as a single band of approximately 20 kpb. The banded DNA was digested with EcoRI and cloned. A 2.2 kbp plasmid containing the CMV-related sequence identified within the PCR product was recovered. Sequencing of this plasmid extended the region of partial sequence homology with CMV to include a portion of the UL35 gene of CMV. Initial sequencing of additional plasmids has confirmed the partial relatedness to CMV. The data indicate a novel type of CMV-related "stealth" virus that is able to establish a clinically persistent human infection.
Martin WJ.	University of Southern California School of Medicine, Los Angeles 90033, USA.	Stealth viruses as neuropathogens.	CAP Today 1994 Oct;8(10):67-70	Neuropsychiatric diseases viewed as multifaceted expression of a dysfunctional brain in which atypical responses are evoked by various sensory inputs. Disease entities have traditionally been classified according to the predominant manifestation ( ) without regard to the overlapping features of many of the diseases (+/-). Thus, mild to moderate pain, mood, cognitive, and neurosomatic symptoms are frequently present in chronic fatigue syndrome (CFS) patients. Fibromyalgia syndrome (FMS) is listed as an example of a predominantly chronic pain syndrome. Affect (mood) disorders include depression (Depress.), anxiety, panic reactions, blunted affect, mania, etc. Schizophrenia (Schizo.) is listed as an example of a major cognitive psychosis. Autism as well as various forms of dementia would be included in this category. Irritable bowel syndrome (IBS) is an example of a neurosomatic disease.
Masuda A, Nozoe SI, Matsuyama T, Tanaka H.	First Department of Internal Medicine, Faculty of Medicine, Kagoshima University,	Psychobehavioral and immunological characteristics of adult people with chronic	Psychosom Med 1994 Nov-Dec;56(6):512-8	The psychobehavioral responses and cellular immune function were investigated in healthy people (control, N = 21), adult people with chronic fatigue (fatigue-non-CFS group, N = 24), and patients with chronic fatigue syndrome (CFS, N = 10). Based on psychobehavioral responses, the fatigue-non-CFS group had low

	Japan.	fatigue and patients with chronic fatigue syndrome.		general activity levels ($p < .05$) and slightly depressive tendencies ($p < .01$) compared with the control. They had many life event stresses ($p < .05$) and sleep disturbances ($p < .01$), and they could not cope appropriately with stresses. The fatigue-non-CFS group also showed significantly lower natural killer (NK) cell activity ($p < .01$) and decreased numbers of CD16+ and CD56+ cells ($p < .05$). Compared with the fatigue-non-CFS group, patients with CFS had higher degrees of physical fatigue ($p < .01$) and more life event stresses ($p < .05$). They had lower general activity levels and social introversion. They were also in a depressive state. NK cell activity and the numbers of CD16+ and CD56+ cells were significantly reduced in patients with CFS ($p < .01$). These findings suggest that adult people with chronic fatigue may be in an intermediate state between the healthy control and patients with CFS in terms of psychobehavioral responses and low NK cell activity. We observed three cases in such an intermediate state in whom CFS subsequently developed. Randomized Controlled Trial

Matsuno T, Hikita K, Matsuo T.	Department of Neuropsychiatry, Faculty of Medicine, Kyushu University.	[Chronic fatigue syndrome and psychiatric diseases].[article in Japanese]	Nippon Rinsho 1994 May;52(5):1339-44	The chronic fatigue syndrome consists of a combination of non-specific symptoms. Some believe that the CFS is subcategory of major depression, because the symptoms are similar to those of major depression. We believe that the CFS is quite different from major depression or neurotic depression, since the CFS has no lack of initiative and effort, no inhibition which is seen in endogenous depression, and sharp fluctuations in general fatigue, anxiety, and various persisting somatic symptoms, such as, malaise and mild fever. CFS seems to be similar to the neurasthenia. It is harmful, at least, in aetiology and treatment, to neglect the diagnosis of the CFS.

	Administration, Philadelphia, PA 19122.	literature in the social work journals, 1985-1992.		articles. Over half addressed issues of reproduction and sexuality including pregnancy, family planning, abortion, substance abuse in pregnancy, and fetal protection policies. Remaining articles addressed medical diagnoses; including AIDS/HIV/STDs, cancer, illnesses associated with aging, PMS, Turner's Syndrome, and chronic fatigue syndrome. Foci, methodologies, and recommendations are discussed and the authors critically analyze the articles' reflections of the status of women's health as a social work concern.
Moutschen M, Triffaux JM, Demonty J, Legros JJ, Lefebvre PJ.	Department of Internal Medicine, CHU Sart-Tilman, Liege, Belgium.	Pathogenic tracks in fatigue syndromes.	Acta Clin Belg 1994;49(6):274-89	This review analyses the recent literature devoted to two related fatigue syndromes: chronic fatigue syndrome (CFS) and acute onset postviral fatigue syndrome (PVFS). The articles are grouped into five pathogenic tracks: infectious agents, immune system, skeletic muscle, hypothalamo-pituitary-adrenal (HPA) axis and psychiatric factors. Although a particular infectious agent is unlikely to be responsible for all CFS cases, evidence is shown that host-parasite relationships are modified in a large proportion of patients with chronic fatigue. Antibody titres against infectious agents are often elevated and replication of several viruses could be increased. Chronic activation of the immune system is also observed and could be due to the reactivation of persistent or latent infectious agents such as herpes viruses (i.e. HHV-6) or enteroviruses. It could also be favorised by an impaired negative feedback of the HPA axis on the immune system. A model is proposed where the abnormalities of the HPA axis are primary events and are mainly responsible for a chronic activation of the immune system which in turn induces an increased replication of several viruses under the control of cellular transcription factors. These replicating viruses together with cytokines such as TNF-alpha would secondarily induce functional disorders of muscle and several aspects of asthenia itself.
Natelson BH, Ye N, Moul DE, Jenkins FJ, Oren DA, Tapp WN, Cheng YC.	Chronic Fatigue Syndrome Center, UMDNJ-New Jersey Medical School, Newark.	High titers of anti-Epstein-Barr virus DNA polymerase are found in patients with severe fatiguing illness.	J Med Virol 1994 Jan;42(1):42-6	Forty-one patients with chronic fatigue syndrome (CFS), 76 healthy controls matched with the patient group for age range, sex, race, and socioeconomic class, and 22 symptomatic patients with seasonal affective disorder (SAD) had serum sampled for antibodies against 2 Epstein-Barr virus (EBV) replicating enzymes. Abnormal titers of antibodies were found twice as often in CFS patients as controls (34.1% vs. 17.1%), with SAD patients having an intermediate frequency (27.3%). Stratifying for disease severity sharpened the differences considerably, with the sicker CFS and SAD patients having 52% and 50% abnormal tests, respectively; more mildly afflicted CFS and SAD patients had a frequency of abnormal tests in the normal range. Antibodies to EBV DNA polymerase (DNAP) were the more sensitive of the two tests in that they were positive in all cases but one. These findings suggest that antibodies against EBV DNAP may be a useful marker in delineating a subset of patients with severe fatiguing illness for appropriate treatment trials and for monitoring their outcomes.

	Studies Program, California Department of Health Services, Albany 94706.	thoughts on the potential contribution of epidemiology to the question of multiple chemical sensitivity.	1994;22(3-4):271-8	as AIDS, Chronic Fatigue Syndrome, and Psychiatric Disease. Is Multiple Chemical Sensitivity a new environmental disease or another in the parade of psychosomatic syndromes which have come and gone in history. It is proposed that epidemiology can: (1) Describe quantitatively the relative frequency of presenting symptoms and natural history. (2) Work with experimental psychologists to develop double-blind protocols for the "environmental unit" where chemical challenges are said to reveal chemical etiology. (3) Develop an epidemiological definition in a clinical series. (4) Develop an epidemiological definition in cohorts recently exposed to chemicals. (5) Apply the epidemiological definitions in descriptive studies and around hazardous waste sites.
Nixon PG.	Charing Cross Hospital, London, England.	Effort syndrome: hyperventilation and reduction of anaerobic threshold.	Biofeedback Self Regul 1994 Jun;19(2):155-69	Effort syndrome is an entity in danger of being subsumed into "chronic fatigue syndrome" and lost to sight. Its distinctive feature is the reduction of the anaerobic threshold for work by depletion of the body's alkaline buffering systems through hyperventilation. This article describes the history and clinical features of effort syndrome and reports a study in which capnography is used to identify the anaerobic threshold by registering the respiratory response to the onset of metabolic acidosis. The patients' thresholds are low, and provide a goal for rehabilitation. In other forms of chronic fatigue syndrome, the pathogenesis and logic of therapy are unclear.
Packer TL, Sauriol A, Brouwer B.	Division of Occupational Therapy, School of Rehabilitation Therapy, Queen's University, Kingston, Ontario, Canada.	Fatigue secondary to chronic illness: postpolio syndrome, chronic fatigue syndrome, and multiple sclerosis.	Arch Phys Med Rehabil 1994 Oct;75(10):1122-6	Estimates of the percentage of patients with postpolio syndrome, chronic fatigue syndrome, and multiple sclerosis who experience fatigue range from approximately 75% to 100%. In this study we describe the severity of fatigue and its impact on subjects with these three diagnoses. The Fatigue Severity Scale, the Human Activity Profile, and the Nottingham Health Profile were used to measure fatigue, activity, and health status respectively of each diagnostic group as well as a control group. Using a Kruskal-Wallis one-way analysis of variance followed by a Bonferroni-adjusted Mann Whitney U test all diagnostic groups reported significantly higher levels ($p = .0000$ to $p = .002$) of fatigue and lower perceived health status than the control group. Subjects with chronic fatigue and multiple sclerosis also had significantly reduced activity levels ($p = .002$ to $p = .01$) compared with the control group. Further attention should be directed toward understanding the relationship between fatigue and ability to engage in activities as well as strategies for remediation and/or compensation of the fatigue.
Pagani M, Lucini D, Mela GS, Langewitz W, Malliani A.	Centro Ricerche Cardiovascolari, CNR, Ospedale L Sacco, University of Milano, Italy.	Sympathetic overactivity in subjects complaining of unexplained fatigue.	Clin Sci (Colch) 1994 Dec;87(6):655-61	1. Theoretical and practical considerations suggest that in subjects complaining of fatigue, in the absence of evident organ dysfunction, an alteration in the autonomic nervous system might be present as a functional correlate. 2. Autoregressive spectral analysis of R-R interval variability from a surface ECG, was used in healthy control subjects (n = 24, age 45 +/- 4 years) and in subjects complaining of unexplained fatigue (n = 53, age 46 +/- 9 years) to obtain quantitative indices of the state of the sympathovagal balance, both at rest and

				during a mental stimulus (mental arithmetic), capable of enhancing sympathetic drive. Sympathetic and vagal modulations were inferred from the normalized powers of the low frequency and high frequency spectral components respectively. 3. We observed in patients, at rest, a prevailing low frequency component of R-R variability (patients low frequency = 73 +/- 11, control subjects 51 +/- 10 normalized units, P < 0.05). The responsiveness to mental arithmetic was reduced in patients as compared with controls. Systolic blood pressure variability did not differ. This suggested a selective imbalance in autonomic control of the sinoatrial node, characterized by sympathetic predominance as well as by vagal withdrawal, at rest. 4. The possibility of discriminating patients from control subjects on the basis of simple non-invasive functional markers might provide a better understanding of the mechanisms, clinical evolution and outcome of conditions such as the chronic fatigue syndrome, which lack ordinary evidence of disease, but comprise, as physiopathological correlate, a quantitative alteration of autonomic control.
Patarca R, Klimas NG, Lugtendorf S, Antoni M, Fletcher MA.	E. M. Papper Laboratory of Clinical Immunology, University of Miami School of Medicine, Florida.	Dysregulated expression of tumor necrosis factor in chronic fatigue syndrome: interrelations with cellular sources and patterns of soluble immune mediator expression.	Clin Infect Dis 1994 Jan;18 Suppl 1:S147-53	Among a group of 70 individuals who met the criteria established by the Centers for Disease Control and Prevention (Atlanta) for chronic fatigue syndrome (CFS), 12%-28% had serum levels exceeding 95% of control values for tumor necrosis factor (TNF) alpha, TNF-beta, interleukin (IL) 1 alpha, IL-2, soluble IL-2 receptor (sIL-2R), or neopterin; overall, 60% of patients had elevated levels of one or more of the nine soluble immune mediators tested. Nevertheless, only the distributions for circulating levels of TNF-alpha and TNF-beta differed significantly in the two populations. In patients with CFS--but not in controls--serum levels of TNF-alpha, IL-1 alpha, IL-4, and sIL-2R correlated significantly with one another and (in the 10 cases analyzed) with relative amounts (as compared to beta-globin or beta-actin) of the only mRNAs detectable by reverse transcriptase-coupled polymerase chain reaction in peripheral-blood mononuclear cells: TNF-beta, unspliced and spliced; IL-1 beta, lymphocyte fraction; and IL-6 (in order of appearance). These findings point to polycellular activation and may be relevant to the etiology and nosology of CFS.
Pawlikowska T, Chalder T, Hirsch SR, Wallace P, Wright DJ, Wessely SC.	Department of General Practice, St Mary's Hospital Medical School, London.	Population based study of fatigue and psychological distress.	BMJ 1994 Mar 19;308(6931):763-6 comment in: BMJ. 1995 Jul 29;311(7000):329 BMJ. 2000 Feb 19;320(7233):515-6 BMJ. 2000 May 13;320(7245):1343	OBJECTIVES--To determine the prevalence of fatigue in the general population and the factors associated with fatigue. DESIGN--Postal survey. SETTING--Six general practices in southern England. SUBJECTS--31,651 men and women aged 18-45 years registered with the practices. MAIN OUTCOME MEASURES--Responses to the 12 item general health questionnaire and a fatigue questionnaire which included self reported measures of duration, severity, and causes of fatigue. RESULTS--15,283 valid questionnaires were returned, giving a response rate of 48.3%, (64% after adjustment for inaccuracies in the practice registers). 2798 (18.3%) of respondents reported substantial fatigue lasting six months or longer. Fatigue and psychological morbidity were moderately

				correlated (r = 0.62). Women were more likely to complain of fatigue than men, even after adjustment for psychological distress. The commonest cited reasons for fatigue were psychosocial (40% of patients). Of 2798 patients with excessive tiredness, only 38 (1.4%) attributed this to the chronic fatigue syndrome. CONCLUSION--Fatigue is distributed as a continuous variable in the community and is closely associated with psychological morbidity.
Peterson PK, Sirr SA, Grammith FC, Schenck CH, Pheley AM, Hu S, Chao CC.	Department of Medicine, Hennepin County Medical Center, Minneapolis, MN 54415, USA.	Effects of mild exercise on cytokines and cerebral blood flow in chronic fatigue syndrome patients.	Clin Diagn Lab Immunol 1994 Mar;1(2):222-6	Chronic fatigue syndrome (CFS) is an idiopathic disorder characterized by fatigue that is markedly exacerbated by physical exertion. In the present study, we tested the hypothesis that mild exercise (walking 1 mph [1 mile = 1.609 km] for 30 min) would provoke serum cytokine and cerebral blood flow abnormalities of potential pathogenic importance in CFS. Interleukin-1 beta, interleukin-6, and tumor necrosis factor alpha were nondetectable in sera of CFS patients (n = 10) and healthy control subjects (n = 10) pre- and postexercise. At rest, serum transforming growth factor beta (TGF-beta) levels were elevated in the CFS group compared with the control group (287 +/- 18 versus 115 +/- 5 pg/ml, respectively; P < 0.01). Serum TGF-beta and cerebral blood flow abnormalities, detected by single-photon emission-computed tomographic scanning, were accentuated postexercise in the CFS group. Although these findings were not significantly different from those in the control group, the effect of exercise on serum TGF-beta and cerebral blood flow appeared magnified in the CFS patients. Results of this study encourage future research on the interaction of physical exertion, serum cytokines, and cerebral blood flow in CFS that will adopt a more rigorous exercise program than the one used in this study.
Pichot P.		[Neurasthenia, yesterday and today].[article in French]	Encephale 1994 Nov;20 Spec No 3:545-9	Neurasthenia was described and explained in very mechanistic terms, at the end of the 19th century, by G.M. Beard to account for physical and mental exhaustion and for varied somatic troubles imputed to failure of too much solicited nervous resources. This concept was then universally adopted and gave rise to diverse interpretations, among which was the Freud's one. Later, in Occident, came a deterioration, the diagnostic of neurasthenia giving way to those of anxious or affective disorders. In the same time, at least for ideological and cultural reasons, the concept remained lively in Russia and in Asia. During the last decade the western psychiatry has been led to accept that there are clinical situations focussed on fatigue and fatigability, even if it coined for them new terminologies (post-infectious fatigue, chronic fatigue syndrome, etc.) and while DSMs keep on ignoring neurasthenia, the ICD 10 gives it an important place.

Rasmussen AK, Andersen V, Nielsen H, Wiik A.	Medicinsk afdeling TTA, Rigshospitalet, Kobenhavn.	[Chronic fatigue syndrome--a defined unity]?[article in Danish]	Ugeskr Laeger 1994 Nov 14;156(46):6832-6 comment in: Ugeskr Laeger. 1995 Feb 6;157(6):756-7 Ugeskr Laeger. 1995 Feb 6;157(6):757	Chronic fatigue syndrome (CFS) is characterized by a sudden onset of an influenza-like illness followed by marked chronic fatigue and abnormal exercise-induced exhaustion. The precise pathogenesis of this disorder is unknown, but viral infection triggering immune imbalance has been suggested. The literature on CFS is reviewed. We find no consistent support for chronic viral infection or immunological dysfunction. The data in the published studies are rather conflicting, and further research in order to identify parameters that differentiate CFS from other disorders is necessary.
Rasmussen AK, Nielsen H, Andersen V, Barington T, Bendtzen K, Hansen MB, Nielsen L, Pedersen BK, Wiik A.	Medicinsk afdeling TTA og infektionsmedicinsk afdeling M, Rigshospitalet, Kobenhavn.	[Chronic fatigue syndrome--a controlled cross-sectional study].[article in Danish]	Ugeskr Laeger 1994 Nov 14;156(46):6836-40 comment in: Ugeskr Laeger. 1995 Feb 6;157(6):756-7	Twenty-one patients fulfilling the Center for Disease Control criteria for chronic fatigue syndrome (CFS) were examined in a controlled study. Viral antibodies and tests evaluating the immune system were investigated in the patients and in a control group of 21 sex- and age-matched individuals. Production in vitro of the predominantly T-cell-derived cytokines interleukin-2 and interferon-gamma was significantly higher in patients with CFS compared the control group. Furthermore, the serum concentrations of IgA and IgE were significantly lower in patients with CFS; however, the values were within the normal reference range. All other variables were similar in the two groups. This study does not suggest a clearly disordered immune system or a chronic viral infection as a major pathogenetic factor in CFS. Longitudinal studies of immunological and virological parameters in CFS are warranted as are studies on patients that are severely handicapped.
Rasmussen AK, Nielsen H, Andersen V, Barington T, Bendtzen K, Hansen MB, Nielsen L, Pedersen BK, Wiik A.	Medical Department TTA M. Rigshospitalet, Copenhagen, Denmark.	Chronic fatigue syndrome--a controlled cross sectional study.	J Rheumatol 1994 Aug;21(8):1527-31	OBJECTIVE. To look for signs of immunodeficiencies and/or longstanding infections underlying chronic fatigue syndrome (CFS). METHODS. Twenty-one patients fulfilling the Centers for Disease Control criteria for CFS were compared to 21 age and sex matched controls. A number of viral antibodies as well as the following tests evaluating the immune system were studied: autoantibody profile, cell surface markers on isolated blood mononuclear cells, cytokine production, lymphocyte proliferative responses, natural killer cell activity and

				quantitation of immunoglobulin secreting cells. RESULTS. Production in vitro of the predominantly T cell derived cytokines interleukin 2 and interferon gamma was significantly higher in patients with CFS compared to the control group. Furthermore, the serum concentrations of IgA and IgE were lower in patients with CFS; however, this difference was caused by a larger number with values of IgA and IgE above the upper limit of the normal range among the controls than among the patients with CFS. All other variables were similar in the 2 groups. CONCLUSION. A pathogenically significant imbalance of the immune system in patients with CFS cannot be excluded. However, evidence of a causal link between abnormal immunity and CFS was not obtained.
Rebora A, Drago F.	Department of Dermatology, University of Genoa, Italy.	Chronic fatigue syndrome: a novel disorder with cutaneous manifestations.	Dermatology 1994;188(1):3-5	Persistent and disabling fatigue associated with low-grade fever and other constitutional symptoms, without any known disorder that accounts for it, is recognized as chronic fatigue syndrome (CFS). Skin lesions occur in 10-35% of patients, but their description is inaccurate. Recurrent aphthous stomatitis or persistent Epstein-Barr virus (EBV)-related erythema multiforme have also been reported. Patients may be diagnosed as having CFS only when they fulfill at least 2 major and 8 minor criteria. Major criteria are the presence of debilitating fatigue persisting or recurring for at least 6 months and the absence of any other medical disorder that may explain it. Although different viral or nonviral etiologies have been documented, evidence implicating EBV is gaining support.

Richman JA, Flaherty JA, Rospenda KM.	Department of Psychiatry, University of Illinois at Chicago 60612.	Chronic fatigue syndrome: have flawed assumptions been derived from treatment-based studies?	Am J Public Health 1994 Feb;84(2):282-4	Chronic fatigue syndrome is a disabling disorder that has been studied primarily in clinical settings. In the absence of an adequate epidemiological database, cultural stereotypes have influenced the characterization of chronic fatigue syndrome as "the yuppie flu," similar to the 19th century characterization of neurasthenia as a disease of the affluent. The limited epidemiological data available and the overall medical-sociological literature call this assumption into question. Only a community "true" prevalence study that is unbiased by help seeking and access to health care can provide an accurate assessment of the risk factors for and the public health ramifications of this disease.
Roberts L, Byrne E.	Department of Neurology, St Vincent's Hospital, Fitzroy, Melbourne, Australia.	Single fibre EMG studies in chronic fatigue syndrome: a reappraisal.	J Neurol Neurosurg Psychiatry 1994 Mar;57(3):375-6 comment in: J Neurol Neurosurg Psychiatry.	Single fibre EMG studies were carried out on the right extensor digitorum communis muscle in 30 subjects with chronic fatigue syndrome and in 30 age and sex matched controls. Abnormal jitter was seen in five patients with chronic fatigue syndrome. Slight but significant differences between the mean consecutive differences in the remainder of the chronic fatigue subjects and the

			1994 Sep;57(9):1157	control subjects were recorded. Overall the differences were so minor that it seems unlikely that a disturbance of neuromuscular function as reflected by jitter measurement has a pathogenetic role. It is suggested that the increased jitter seen may be explained by the effects of the variability of motor unit firing rates on the myogenic component of the jitter.

Saisch SG, Deale A, Gardner WN, Wessely S.	Department of Thoracic Medicine, Kings College School of Medicine and Dentistry, London, UK.	Hyperventilation and chronic fatigue syndrome.	Q J Med 1994 Jan;87(1):63-7 comment in: Q J Med. 1994 Jun;87(6):373-4	We studied the link between chronic fatigue syndrome (CFS) and hyperventilation in 31 consecutive attenders at a chronic fatigue clinic (19 females, 12 males) who fulfilled criteria for CFS based on both Oxford and Joint CDC/NIH criteria. All experienced profound fatigue and fatigability associated with minimal exertion, in 66% developing after an infective episode. Alternative causes of fatigue were excluded. Hyperventilation was studied during a 43-min protocol in which end-tidal PCO2 (PETCO2) was measured non-invasively by capnograph or mass spectrometer via a fine catheter taped in a nostril at rest, during and after exercise (10-50 W) and for 10 min during recovery from voluntary overbreathing to approximately 2.7 kPa (20 mmHg). PETCO2 < 4 kPa (30 mmHg) at rest, during or after exercise, or at 5 min after the end of voluntary overbreathing, suggested either hyperventilation or a tendency to hyperventilate. Most patients were able voluntarily to overbreathe, but not all were able to exercise. Twenty-two patients (71%) had no evidence of hyperventilation during any aspect of the test. Only four patients had unequivocal hyperventilation, in one associated with asthma and in three with panic. Only one patient with severe functional disability and agoraphobia had hyperventilation with no other obvious cause. A further five patients had borderline hyperventilation, in which PETCO2 was < 4 kPa (30 mmHg) for no more than 2 min, when we would have expected it to be normal. There was no association between level of functional impairment and degree of hyperventilation. There is only a weak association between hyperventilation and chronic fatigue syndrome.(ABSTRACT TRUNCATED AT 250 WORDS)
Schmaling KB, DiClementi JD, Cullum CM, Jones JF.	Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle 98105.	Cognitive functioning in chronic fatigue syndrome and depression: a preliminary comparison.	Psychosom Med 1994 Sep-Oct;56(5):383-8	This study used a brief battery of neuropsychological measures to examine the performance of patients with chronic fatigue syndrome (CFS) (N = 16) and patients in a major depressive episode (N = 23). The overall neuropsychological performance of the CFS group was not significantly different from depressed patients, and both groups scored within normal limits on most measures. Variability of neuropsychologic performance was in general unrelated to level of depressive symptoms. The results are discussed in terms of the validity of the cognitive criterion for the CFS diagnosis. Subjective complaints of cognitive

				dysfunction by CFS patients in light of the lack of objective evidence for the same are considered in terms of a somatic vigilance hypothesis.

Schwartz RB, Garada BM, Komaroff AL, Tice HM, Gleit M, Jolesz FA, Holman BL.	Department of Radiology, Brigham and Women's Hospital, Boston, MA 02115.	Detection of intracranial abnormalities in patients with chronic fatigue syndrome: comparison of MR imaging and SPECT.	AJR Am J Roentgenol 1994 Apr;162(4):935-41	OBJECTIVE. Chronic fatigue syndrome is a recently characterized condition of unknown origin that is manifested by fatigue, flulike complaints, and neurologic signs and symptoms, including persistent headache, impaired cognitive abilities, mood disorders, and sensorimotor disturbances. This syndrome can be difficult to diagnose clinically or by standard neuroradiologic tests. We performed MR imaging and single-photon emission computed tomography (SPECT) in patients with chronic fatigue syndrome to compare the usefulness of functional and anatomic imaging in the detection of intracranial abnormalities. SUBJECTS AND METHODS. Sixteen patients who fulfilled the Centers for Disease Control, British, and/or Australian criteria for chronic fatigue syndrome had MR and SPECT examinations within a 10-week period. Axial MR and SPECT scans were analyzed as to the number and location of focal abnormalities by using analysis of variance with the Student-Newman-Keuls option. MR imaging findings in patients with chronic fatigue syndrome were compared with those in 15 age-matched control subjects, and SPECT findings in the patients with chronic fatigue syndrome were compared with those in 14 age-matched control subjects by using Fisher's exact test. The findings on MR and SPECT scans in the same patients were compared by using the Wilcoxon matched-pairs signed-ranks test. RESULTS. MR abnormalities consisted of foci of T2-bright signal in the periventricular and subcortical white matter and in the centrum semiovale; there were 2.06 foci per patient, vs 0.80 foci per control subject. MR abnormalities were present in eight (50%) of 16 patients, compared with three (20%) of 15 age-matched control subjects. Neither of these differences reached significance, although the power of the study to detect differences between groups was small. Patients with chronic fatigue syndrome had significantly more defects throughout the cerebral cortex on SPECT scans than did normal subjects (7.31 vs 0.43 defects per subject, $p < .001$). SPECT abnormalities were present in 13 (81%) of 16 patients, vs three (21%) of 14 control subjects ($p < .01$). SPECT scans showed significantly more abnormalities than did MR scans in patients with chronic fatigue syndrome ($p < .025$). In the few patients who had repeat SPECT and MR studies, the number of SPECT

				abnormalities appeared to correlate with clinical status, whereas MR changes were irreversible. CONCLUSION. SPECT abnormalities occur more frequently and in greater numbers than MR abnormalities do in patients with chronic fatigue syndrome. SPECT may prove to be useful in following the clinical progress of patients with this syndrome.
Schwartz RB, Komaroff AL, Garada BM, Gleit M, Doolittle TH, Bates DW, Vasile RG, Holman BL.	Department of Radiology, Brigham and Women's Hospital, Boston, MA 02215.	SPECT imaging of the brain: comparison of findings in patients with chronic fatigue syndrome, AIDS dementia complex, and major unipolar depression.	AJR Am J Roentgenol 1994 Apr;162(4):943-51	OBJECTIVE. Chronic fatigue syndrome is an illness of unknown origin that begins abruptly with a flulike state and has symptoms suggesting both a chronic viral encephalitis and an affective disorder. We compared single-photon emission computed tomography (SPECT) scans of patients with chronic fatigue syndrome with those of patients with AIDS dementia complex and unipolar depression. SUBJECTS AND METHODS. We used 99mTc-hexamethylpropyleneamine oxime to examine 45 patients with chronic fatigue syndrome, 27 patients with AIDS dementia complex, and 14 patients with major unipolar depression. Scans of 38 healthy persons were used as controls. Comparison of regional defects between groups, as well as midcerebral uptake indexes (an objective measure of global radionuclide uptake), was performed by using analysis of variance with the Student-Newman-Keuls option. Correlation between the number of regional defects and the midcerebral uptake index was determined by using the Spearman rank-correlation test. RESULTS. Patients with AIDS dementia complex had the largest number of defects (9.15 per patient) and healthy patients had the fewest defects (1.66 per patient). Patients with chronic fatigue syndrome and depression had similar numbers of defects per patient (6.53 and 6.43, respectively). In all groups, defects were located predominantly in the frontal and temporal lobes. The midcerebral uptake index was found to be significantly lower ($p < .002$) in the patients with chronic fatigue syndrome (.667) and patients with AIDS dementia complex (.650) than in patients with major depression (.731) or healthy control subjects (.716). Also, a significant negative correlation was found between the number of defects and midcerebral uptake index in patients with chronic fatigue syndrome and AIDS dementia complex, but not in depressed patients or control subjects. CONCLUSION. These findings are consistent with the hypothesis that chronic fatigue syndrome may be due to a chronic viral encephalitis; clinical similarities between chronic fatigue syndrome and depression may be due to a similar distribution and number of defects in the two disorders.
Schweitzer R, Robertson DL, Kelly B, Whiting J.	Department of Psychology, University of Queensland, Australia.	Illness behaviour of patients with chronic fatigue syndrome.	J Psychosom Res 1994 Jan;38(1):41-9	The study examines the illness behaviour of patients with Chronic Fatigue Syndrome (CFS). The Illness Behaviour Questionnaire (IBQ), the twenty-eight version of the General Health Questionnaire (GHQ-28), and the Beck Depression Inventory (BDI) were administered to forty patients with a diagnosis of CFS. The results revealed that CFS patients in comparison with general practice patients, scored significantly higher on the IBQ sub-scales of General Hypochonriasis,

				t(188) = 5.2, p < 0.001 and Disease Conviction, t(188) = 13.28, p < 0.001 but lower on the Psychological/Somatic sub-scale, t(188) = -5.88, p < 0.001. The CFS and psychiatric patients did not differ significantly on the general hypochondriasis sub-scale. Results of the GHQ-28 revealed 66.7% of the CFS patients scored above the cut-off for psychiatric morbidity. In comparison to a previous study of CFS patients [1], the current findings indicate a significantly higher score on general hypochondriasis. The implications of these findings are discussed.
Secchiero P, Berneman ZN, Gallo RC, Lusso P.	Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20892.	Biological and molecular characteristics of human herpesvirus 7: in vitro growth optimization and development of a syncytia inhibition test.	Virology 1994 Jul;202(1):506-12	Two isolates of human herpesvirus 7 (HHV-7) were recovered from phytohemagglutinin-activated peripheral blood mononuclear cells of a patient with chronic fatigue syndrome and of a healthy blood donor. A genetic polymorphism between the two isolates was detected by Southern blot analysis using a novel HHV-7 genomic clone (pVL8) as a probe. We developed optimized conditions for the in vitro propagation of HHV-7 by using enriched populations of activated CD4+ T lymphocytes derived from normal peripheral blood, resulting in the production of high-titered extracellular virus (> 10(6) cell culture infectious doses/ml). Bona fide syncytia formation was documented both in normal CD4+ T lymphocytes and in the Sup-T1 CD4+ T-cell line following infection with high-titered HHV-7. To identify neutralizing antibodies to HHV-7, a syncytia-inhibition test was developed. Variable titers of syncytia-neutralizing antibodies were detected in all the human sera tested, thus confirming the high prevalence of HHV-7 in the human population.

Steere AC.	Division of Rheumatology/Immunology, Tufts University School of Medicine, New England Medical Center, Boston, MA 02111.	Lyme disease: a growing threat to urban populations.	Proc Natl Acad Sci U S A 1994 Mar 29;91(7):2378-83	Lyme disease or Lyme borreliosis, which is caused by three groups of the spirochete Borrelia burgdorferi, is transmitted in North America, Europe, and Asia by ticks of the Ixodes ricinus complex. The primary areas around the world that are now affected by Lyme disease are near the terminal moraine of the glaciers 15,000 years ago. The emergence of Lyme disease in the United States in this century is thought to have occurred because of ecological conditions favorable for deer. From 1982 through 1991, 40,195 cases occurring in 47 states were reported to the Centers for Disease Control, but enzootic cycles of B. burgdorferi have been identified in only 19 states. During the last several decades, the

				disease has spread to new areas and has caused focal outbreaks, including locations near Boston, New York, and Philadelphia. Lyme disease is like syphilis in its multisystem involvement, occurrence in stages, and mimicry of other diseases. Diagnosis of late neurologic abnormalities of the disorder has created the most difficulty. A recent phenomenon is that a number of poorly understood conditions, such as chronic fatigue syndrome or fibromyalgia, are misdiagnosed as "chronic Lyme disease." Part of the reason for misdiagnosis is due to problems associated with diagnostic tests. The various manifestations of Lyme disease can usually be treated successfully with oral doxycycline or amoxicillin, except for objective neurologic manifestations, which seem to require intravenous therapy. Vector control of thick-borne diseases has been difficult and, therefore, reduction of the risk of infection has been limited primarily to personal protection measures.
Sternon J, Decaux G, Hoffmann G.	Service de Medecine Interne, Hopital Erasme.	[Chronic fatigue syndrome].[article in French]	Rev Med Brux 1994 Sep-Oct;15(5):311-5	The major and minor diagnostic criteria of the chronic fatigue syndrome are described. The stages of the differential diagnosis, the diagnostic strategies and the controversies, while insisting on certain sleeping disorders are discussed. The cause of the syndrome may be a viral infection, and an anxious-depressive state may increase somatic complaints. Patients with chronic fatigue syndrome did not demonstrate a specific response to therapy. Spontaneous remission after a few years is a typical feature of this syndrome.
Straus SE, Komaroff AL, Wedner HJ.	Laboratory of Clinical Investigation, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD 20892.	Chronic fatigue syndrome: point and counterpoint.	J Infect Dis 1994 Jul;170(1):1-6	Two clinical investigators with divergent views on chronic fatigue syndrome (CFS) were invited to debate their positions at the 1993 annual meeting of The Infectious Disease Society of America. Major points of the discourse focused on the value of the US Centers for Disease Control and Prevention case definition of CFS, the potential roles of infectious and allergic problems in the syndrome, the confounding problem of concurrent psychiatric problems, and the utility of diagnostic tests.
Strayer DR, Carter WA, Brodsky I, Cheney P, Peterson D, Salvato P, Thompson C, Loveless M, Shapiro DE, Elsasser W, et al.	School of Medicine, Hahnemann University, Philadelphia, Pennsylvania 19102.	A controlled clinical trial with a specifically configured RNA drug, poly(I).poly(C12U), in chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S88-95	Chronic fatigue syndrome (CFS) is a physically debilitating illness associated with immunologic abnormalities, viral reactivation, and impairment of cognition. In a randomized, multicenter, placebo-controlled, double-blind study of 92 patients meeting the CFS case definition of the Centers for Disease Control and Prevention, the response of several laboratory and clinical variables to an antiviral and immunomodulatory drug, poly(I).poly(C12U), was determined. Measures of clinical response included Karnofsky performance score, a cognition scale derived from a self-administered instrument assessing symptomatology (SCL-90-R), an activities of daily living scale, and exercise treadmill performance. After 24 weeks, patients receiving poly(I).poly(C12U) had higher scores for both global performance and perceived cognition than did patients receiving placebo. In particular, patients given poly(I).poly(C12U) had increased Karnofsky performance scores ($P < .03$), exhibited a greater ability to do work during

				exercise treadmill testing (P = .01), displayed an enhanced capacity to perform the activities of daily living (P < .04), had a reduced cognitive deficit (P = .05), and required less use of other medications (P < .05). Multicenter Study Randomized Controlled Trial
Suhadolnik RJ, Reichenbach NL, Hitzges P, Adelson ME, Peterson DL, Cheney P, Salvato P, Thompson C, Loveless M, Muller WE, et al.	Department of Biochemistry, Temple University School of Medicine, Philadelphia, Pennsylvania 19140.	Changes in the 2-5A synthetase/RNase L antiviral pathway in a controlled clinical trial with poly(I)-poly(C12U) in chronic fatigue syndrome.	In Vivo 1994 Jul-Aug;8(4):599-604	Latent 2', 5'-oligoadenylate (2-5A) synthetase activity, bioactive 2-5A and RNase L activity were measured in extracts of peripheral blood mononuclear cells (PMBC) before and during a randomized, multicenter, placebo-controlled, double-blind study of poly(I)-poly(C12U) in individuals with chronic fatigue syndrome (CFS) as defined by the Centers for Disease Control and Prevention. The mean values for bioactive 2-5A and RNase L activity were significantly elevated at baseline compared to controls (p < .0001 and p = .001, respectively). In individuals that presented with elevated RNase L activity at baseline, therapy with poly(I)-poly(C12U) resulted in a significant decrease in both bioactive 2-5A and RNase L activity (p = .09 and p = .005, respectively). Decrease in RNase L activity in individuals treated with poly(I)-poly(C12U) correlated with cognitive improvement (p = .007). Poly(I)-poly(C12U) therapy resulted in a significant decrease in bioactive 2-5A and RNase L activity in agreement with clinical and neuropsychological improvements (Strayer DR, et al., Clin. Infectious Dis. 18:588-595, 1994). The results described show that poly(I)-poly(C12U) is a biologically active drug in CFS. Multicenter Study Randomized Controlled Trial
Suhadolnik RJ, Reichenbach NL, Hitzges P, Sobol RW, Peterson DL, Henry B, Ablashi DV, Muller WE, Schroder HC, Carter WA, et al.	Department of Biochemistry, Temple University School of Medicine, Philadelphia, Pennsylvania 19140.	Upregulation of the 2-5A synthetase/RNase L antiviral pathway associated with chronic fatigue syndrome.	Clin Infect Dis 1994 Jan;18 Suppl 1:S96-104	Levels of 2',5'-oligoadenylate (2-5A) synthetase, bioactive 2-5A, and RNase L were measured in extracts of peripheral blood mononuclear cells (PBMCs) from 15 individuals with chronic fatigue syndrome (CFS) before and during therapy with the biological response modifier poly(I).poly(C12U) and were compared with levels in healthy controls. Patients differed significantly from controls in having a lower mean basal level of latent 2-5A synthetase (P < .0001), a higher pretreatment level of bioactive 2-5A (P = .002), and a higher level of pretherapy RNase L activity (P < .0001). PBMC extracts from 10 persons with CFS had a mean basal level of activated 2-5A synthetase higher than the corresponding control value (P = .009). All seven pretherapy PBMC extracts tested were positive for the replication of human herpesvirus 6 (HHV-6). Therapy with poly(I).poly(C12U) resulted in a significant decrease in HHV-6 activity (P < .01) and in downregulation of the 2-5A synthetase/RNase L pathway in temporal association with clinical and neuropsychological improvement. The upregulated 2-5A pathway in CFS before therapy is consistent with an activated immune state and a role for persistent viral infection in the pathogenesis of CFS. The response to therapy suggests direct or indirect antiviral activity of poly(I).poly(C12U) in this situation.
Swanink CM, Melchers WJ, van der Meer JW,	Department of Medical Microbiology, University	Enteroviruses and the chronic fatigue	Clin Infect Dis 1994 Nov;19(5):860-4	The possible role of enteroviral persistence in the etiology of the chronic fatigue syndrome (CFS) was investigated by serological testing, VP-1 antigen testing, and

Vercoulen JH, Bleijenberg G, Fennis JF, Galama JM.	Hospital Nijmegen, The Netherlands.	syndrome.		polymerase chain reaction (PCR) analysis of stool specimens as well as by viral cultures of stool--both direct and after acid treatment. No differences between 76 patients with disabling unexplained fatigue and 76 matched controls were found by serological or antigen testing. Furthermore, no enteroviruses were isolated from any stool culture. Enterovirus was detected by PCR in one stool specimen from a patient with CFS but was not detectable in a second sample obtained from the same patient 3 months later. All stool specimens from controls were PCR-negative. These results argue against the hypothesis that enteroviruses persist in patients with CFS and that their persistence plays a role in the pathogenesis of this syndrome.

Taerk G, Gnam W.	Department of Psychiatry, Toronto Hospital, Ontario, Canada.	A psychodynamic view of the chronic fatigue syndrome. The role of object relations in etiology and treatment.	Gen Hosp Psychiatry 1994 Sep;16(5):319-25 comment in: Gen Hosp Psychiatry. 1998 Nov;20(6):382-4	The chronic fatigue syndrome (CFS) is a constellation of physical and psychological symptoms including incapacitating fatigue associated with a marked reduction in activity. Although the etiology of CFS is unclear, reports in the literature suggest the presence of both physical and psychological dysfunction in this patient population. These findings have led to a debate between those who consider CFS to be primarily organic in origin and those who view CFS as a primary psychiatric disorder characterized by somatic preoccupations. This debate led the authors to develop a working model for CFS designed to integrate the psychological and physiological findings, based on the hypothesis that early object relations have an etiologic relationship to CFS. This hypothesis then formed the rationale for a psychoanalytic treatment approach which will be described. There are no published case reports describing psychoanalytic psychotherapy as a primary treatment modality for this patient population. The current paper attempts to fill a void. Two case reports of long-term (> 18 months), intensive (2-3 times per week) psychoanalytic psychotherapy with CFS patients referred by infectious disease specialists at a university teaching hospital will be presented. The following aspects of the treatment will be highlighted: 1) the unique opportunity afforded by this treatment to view the nature of CFS, namely, the intimate relationship over time of fatigue symptoms to disturbances in object relationships, particularly within the transference; (2) the improvement in symptoms when this relationship is seen and understood by the patient; (3) the importance of the patient-therapist bond as a facilitating medium for clinical improvement; (4) the challenges involved in treating CFS patients with psychotherapy.

Tirdei G, Ruta SM, Popescu AE.	Institut de Virologie, Stefan S. Nicolau, Bucarest, Roumanie.	[Human herpesvirus 6. General overview].[article in French]	Rev Roum Virol 1994 Jan-Jun;45(1-2):83-95	Human herpesvirus 6 (HHV6) was first isolated in 1985 and included in the Herpesviridae family and the beta-herpes virinae subfamily, mainly due to its genomic similarities to the human cytomegalic virus (HCMV). HHV6 is largely disseminated in the population. The contamination takes place very early, most frequently before the age of three. In some very rare cases, a benign illness is produced, known since 1911 as Roseolum infantum or Exanthemum subitum. Seroepidemiological surveys showed that anti-HHV6 IgG antibodies were present in more than 60% of the adult population. By now, there are good information about in vitro cultivability of the virus, viral genome and proteins, epidemiology of the infection and etiopathogenic relation between virus and Exanthemum subitum. Relations between virus and lymphoproliferative diseases, some auto-immune diseases, chronic fatigue syndrome and some other diseases are less clear. Relation between this virus and HIV-infection is another problem requiring more research.
Tirelli U, Marotta G, Improta S, Pinto A.	CFS Unit, Division of Medical Oncology and AIDS, Centro di Riferimento Oncologico (CRO), Aviano, Italy.	Immunological abnormalities in patients with chronic fatigue syndrome.	Scand J Immunol 1994 Dec;40(6):601-8	Between January 1991 and January 1993, 265 patients who fulfilled the CDC criteria of the working case definition of Chronic Fatigue Syndrome (CFS) have been observed at our Institution and submitted for clinical and laboratory evaluation. One hundred and sixty-three patients were females and 102 males, the median age was 35 years (range 4-55 years); all patients reported profound and prolonged fatigue, lasting for a median of 3 years (range 6 months-10 years), preceded or accompanied at appearance by fever in 185 cases, and neuropsychologic problems including inability to concentrate, difficulty in thinking, confusion, irritability, forgetfulness, and depression. The fatigue was so severe that it required 102 patients to stop their working activities for a period of time ranging from 3 months to 2 years (range 7 months). In 40 consecutive patients a comprehensive immunologic testing by single and two-colour flow cytometry was performed and results compared with a group of 35 healthy, age- and sex-matched controls. Whilst no significant differences were found in the absolute numbers of circulating total T cells (CD3+) and of total helper/inducer (CD4+) or suppressor/cytotoxic (CD8+) T cells, an evident reduction in CD3-/CD16+ and CD57+/CD56+ NK lymphocytes along with an expansion of the CD8+/CD56+ and CD16-/CD56+ NK subsets, were found in the CFS group. In addition, CD56+ NK cells from CFS subjects were found to express an increased amount of cell adhesion molecules (CD11b, CD11c, CD54) and activation antigens (CD38). Both the percentage and absolute numbers of CD4+ T cells bearing the CD45RA antigen appeared significantly reduced in CFS patients, and CD4+ T

				lymphocytes from CFS subjects displayed an increased expression of the intercellular adhesion molecule-1 (ICAM-1/CD54). Finally, the total numbers of circulating (CD19+) B lymphocytes, were significantly higher in CFS cases than in controls, and in 11 out of 30 CFS patients the increase in circulating B cells was sustained by the expansion of the CD5+/CD19+ subset of B lymphocytes. We conclude that CFS is a syndrome not previously described in Italy, with already known clinical characteristics and appears to be associated with several immunologic abnormalities, including those reported previously in cohort of patients from different countries. We also show for the first time that CD56- NK cell subsets from CFS patients display an abnormally increased expression of cell adhesion molecules and activation markers.
Trevor A.		Chronic fatigue syndrome: what's in a name?	Can Fam Physician 1994 Jun;40:1088-9 comment on: Can Fam Physician. 1993 Dec;39:2586-92, 2595-7

Vercoulen JH, Swanink CM, Fennis JF, Galama JM, van der Meer JW, Bleijenberg G.	Department of Medical Psychology, University Hospital, Nijmegen, The Netherlands.	Dimensional assessment of chronic fatigue syndrome.	J Psychosom Res 1994 Jul;38(5):383-92	The absence of laboratory tests and clear criteria to identify homogeneous (sub)groups in patients presenting with unexplained fatigue, and to assess clinical status and disability in these patients, calls for further assessment methods. In the present study, a multi-dimensional approach to the assessment of chronic fatigue syndrome (CFS) is evaluated. Two-hundred and ninety-eight patients with

				CFS completed a set of postal questionnaires that assessed the behavioural, emotional, social, and cognitive aspects of CFS. By means of statistical analyses nine relatively independent dimensions of CFS were identified along which CFS-assessment and CFS-research can be directed. These dimensions were named: psychological well-being, functional impairment in daily life, sleep disturbances, avoidance of physical activity, neuropsychological impairment, causal attributions related to the complaints, social functioning, self-efficacy expectations, and subjective experience of the personal situation. A description of the study sample on these dimensions is presented.
Wassif WS, Sherman D, Salisbury JR, Peters TJ.	Department of Clinical Biochemistry, Kings College School of Medicine and Dentistry, London, UK.	Use of dynamic tests of muscle function and histomorphometry of quadriceps muscle biopsies in the investigation of patients with chronic alcohol misuse and chronic fatigue syndrome.	Ann Clin Biochem 1994 Sep;31 (Pt 5):462-8	Ischaemic lactate/ammonia tests, serum carnosinase and creatine kinase assays and percutaneous needle muscle biopsies were performed on 10 patients with chronic fatigue syndrome (CFS), and 10 with chronic alcohol misuse complaining of muscular symptoms. Basal serum lactate levels were significantly elevated in the alcohol misusers compared to the CFS patients, but all were within the reference range. Lactate profiles after ischaemic forearm exercise did not differ significantly for the two patient groups. In one patient previously diagnosed as having CFS, myoadenylate deaminase deficiency was identified on the basis of a flat ammonia response to ischaemia and absent muscle adenosine monophosphate deaminase activity. In addition, two further patients in the CFS group were subsequently shown to have other disorders: one had polymyositis and one had myopathy with mild type II fibre atrophy of unknown cause. Histomorphometric examination of muscle needle biopsy in the alcohol misusers showed features of chronic alcohol-induced skeletal myopathy in six patients and polymyositis in one patient. Type II fibre atrophy factors were significantly elevated in the alcohol group but were within the reference range in CFS patients. Dynamic tests of muscle function and muscle histology are valuable tools in excluding alternative pathology in CFS, whereas muscle histomorphometry is of the greatest value in the diagnosis of chronic alcoholic myopathy.
Wessely S.	Academic Dpt of Psychologic, King's College Hospital, London, United Kingdom.	[Chronic fatigue syndrome. Clinical, social psychological problems and management].[article in French]	Encephale 1994 Nov;20 Spec No 3:581-95	Fatigue chronic syndrome (SFC) is the heir-at-law of neurasthenia. Both are seen like physical diseases and share certain therapeutic measures, such as sleep; they have the same symbolic function and enable patients as well as doctors reluctant to psychological dimensions of pathology, to get and express sympathy and attention. A strong controversy developed these last years concerning the SFC physiopathology particularly concerning the responsibility of viral infectious agents or psychiatric troubles. The SFC fatigue is unlikely hysterical or neuromuscular but it probably depends on several associated factors; cerebral neurobiochemistry anomalies (possibly induced by an infection or immune reactions), effort perception trouble, affective trouble, lack of physical activity. The handicap seems to be worse on account of unsuitable care and inefficacious

				treatment. Especially sleep, which is often beneficial in a short term, is source of ulterior chronicisation. Antidepressants are the only justified pharmacological treatment for SFC at the moment. Referring to the existence and the nature of cognitive distortions, the author suggests a cognitivo-behavioural therapy, whose aim is a progressive activity resumption.
Wilborn F, Schmidt CA, Brinkmann V, Jendroska K, Oettle H, Siegert W.	Universitatsklinikum Rudolf Virchow, Innere Medizin und Poliklinik mit Schwerpunkt Hamatologie und Onkologie, Berlin, Germany.	A potential role for human herpesvirus type 6 in nervous system disease.	J Neuroimmunol 1994 Jan;49(1-2):213-4	Human herpesvirus type 6 (HHV-6) is a new representative of the herpesvirus family which was associated with a spectrum of diseases, including myalgic encephalitis, meningitis and the chronic fatigue syndrome. We set out to study the potential role of HHV-6 in multiple sclerosis (MS) (n = 21), facial palsy (FP) (n = 19) and Guillain-Barre-syndrome (GBS) (n = 7). Results were compared with a control group (CG) (n = 16). We analyzed paired samples of serum and cerebrospinal fluid (CSF) with the polymerase chain reaction (PCR) for the presence of HHV-6 DNA. The studies were complemented by ELISA determination of serum antibodies against HHV-6. In the MS group we detected HHV-6 DNA in the CSF from three of 21 (14.3%) patients but not in the corresponding serum samples. In FP, GBS and controls CSF and serum PCRs were negative in all cases. HHV-6 serum antibody titers were significantly higher in MS compared with FP, GBS and controls. These findings suggest that HHV-6 may play a role in MS.
Wilson A, Hickie I, Lloyd A, Hadzi-Pavlovic D, Boughton C, Dwyer J, Wakefield D.	Department of Psychiatry, Prince Henry Hospital, Little Bay, NSW, Australia.	Longitudinal study of outcome of chronic fatigue syndrome.	BMJ 1994 Mar 19;308(6931):756-9 comment in: BMJ. 1994 May 14;308(6939):1297 BMJ. 1994 May 14;308(6939):1297-8 BMJ. 1994 May 14;308(6939):1299	OBJECTIVE--To examine the predictors of long term outcome for patients with the chronic fatigue syndrome. DESIGN--Cohort study. SUBJECTS--139 subjects previously enrolled in two treatment trials; 103 (74%) were reassessed a mean of 3.2 years after start of the trials. SETTING--University hospital referral centre. MAIN OUTCOME MEASURES--Age at onset, duration of illness, psychological and immunological status at initial assessment. Ongoing symptom severity, levels of disability, and immunological function at follow up. RESULTS--65 subjects had improved but only six reported no current symptoms. An alternative medical diagnosis had been made in two and psychiatric illness diagnosed in 20. The assignment of a primary psychiatric diagnosis at follow up and the strength of the belief that a physical disease process explained all symptoms at entry to the trials both predicted poor outcome. Age at onset of illness, duration of illness, neuroticism, premorbid psychiatric diagnoses, and cell mediated immune function did not predict outcome. CONCLUSION--Though most patients with the chronic fatigue syndrome improve, a substantial proportion remain functionally impaired. Psychological factors such as illness attitudes and coping style seem more important predictors of long term outcome than immunological or demographic variables.
Wilson A, Hickie I, Lloyd A, Wakefield D.	Department of Psychiatry, Prince Henry Hospital, Little Bay NSW, Australia.	The treatment of chronic fatigue syndrome: science and speculation.	Am J Med 1994 Jun;96(6):544-50	The chronic fatigue syndrome (CFS) is a heterogeneous disorder characterized by fatigue, neuropsychiatric symptoms, and various other somatic complaints. Treatment studies to date reflect both the diversity of medical disciplines involved in the management of patients with CFS and the multiple

				pathophysiologic mechanisms proposed. There have been few attempts to study integrated treatment programs, and although several controlled studies have been reported, no treatment has been shown clearly to result in long-term benefit in the majority of patients. Good clinical care integrating medical and psychologic concepts, together with symptomatic management, may prevent significant secondary impairment in the majority of patients. Future treatment studies should examine differential response rates for possible subtypes of the disorder (eg, documented viral onset, concurrent clinical depression), evaluate the extent of any synergistic effects between therapies (ie, medical and psychologic), and employ a wide range of biologic and psychologic parameters as markers of treatment response.
Yalcin S, Kuratsune H, Yamaguchi K, Kitani T, Yamanishi K.	Department of Virology, Osaka University Medical School, Japan.	Prevalence of human herpesvirus 6 variants A and B in patients with chronic fatigue syndrome.	Microbiol Immunol 1994;38(7):587-90	Peripheral blood mononuclear cells collected from 13 patients with chronic fatigue syndrome and 13 healthy controls were analyzed for the presence of human herpesvirus 6 (HHV-6) DNA by variant-specific polymerase chain reaction and dot blot hybridization. HHV-6 DNA was detected in 7 of 13 (53%) patients, and of those 7 patients, 4 were positive for HHV-6 variant A DNA and 3 were for variant B. No HHV-6 DNA was detected in the controls. Serum antibody titers to the late antigen and antibody prevalence to the early antigen of HHV-6 were significantly higher in the patient group. These results suggest active replication of HHV-6 in patients with chronic fatigue syndrome.

Zubieta JK, Engleberg NC, Yargic LI, Pande AC, Demitrack MA.	Department of Psychiatry, University of Michigan Medical Center, Ann Arbor 48109-0116.	Seasonal symptom variation in patients with chronic fatigue: comparison with major mood disorders.	J Psychiatr Res 1994 Jan-Feb;28(1):13-22	The psychobiology of idiopathic fatigue has received renewed interest in the medical literature in recent years. In order to examine the relation between chronic, idiopathic fatigue and specific subtypes of depressive illness, we characterized the pattern and severity of seasonal symptom variation in 73 patients with chronic, idiopathic fatigue, compared to patients with major depression (n = 55), atypical depression (n = 35), and seasonal affective disorder (n = 16) Fifty of the fatigued subjects also met the specific Centers for Disease Control and Prevention case criteria for chronic fatigue syndrome, though this definition was unable to discriminate a distinct subgroup of patients, based on their seasonality scores alone. As a group, the fatigued subjects reported the lowest levels of symptom seasonality of any of the study groups. Further, even in those fatigued subjects with scores in the range of those seen in patients with seasonal affective disorder, seasonality was not reported to be a subjectively distressing problem. These findings lend support to the idea that although chronic fatigue shares some clinical features with certain mood disorders, they are not the same illnesses. These data are also consistent with the emerging view that chronic fatigue represents a heterogeneously determined clinical condition.

Abbey SE.	Department of Psychiatry, Toronto Hospital, Ontario, Canada.	Somatization, illness attribution and the sociocultural psychiatry of chronic fatigue syndrome.	Ciba Found Symp 1993;173:238-52; discussion 252-61	In addition to epidemiological and neurobiological perspectives on the relationship between chronic fatigue syndrome (CFS) and psychiatric disorders there has been increasing interest in the role of cognitive-behavioural, psychological, psychodynamic and social factors in the psychiatric aspects of this syndrome. These factors may be important in the initiation and/or maintenance of CFS and play important roles in the misdiagnosis of primary psychopathology as CFS. They may be important targets for intervention and treatment. This paper examines the relevance of the following issues for better understanding the relationship between CFS and the results of psychiatric studies: (1) the concepts of somatization and abnormal illness behaviour; (2) the role of patients' illness attributions; (3) psychological and psychodynamic constructs such as depressive vulnerability occurring in individuals dependent upon achievement for the maintenance of self-esteem and euthymic mood, perfectionism, and helplessness; (4) the role of personality characteristics and styles; (5) the potential iatrogenic role of the health care system in producing disability in individuals with a diagnosis of CFS; (6) the role of the media and other sociocultural forces in the patient's choice of the CFS label; and (7) the impact of the CFS label on the patient. The importance of differentiating between initiating and maintaining or perpetuating factors is emphasized.
Anon		Inability of retroviral tests to identify persons with chronic fatigue syndrome, 1992.	MMWR Morb Mortal Wkly Rep 1993 Mar 19;42(10):183, 189-90	Chronic fatigue syndrome (CFS) is characterized by prolonged, debilitating fatigue. Although the cause of CFS unknown, CDC and researchers in other organizations have been investigating whether infection with a previously unidentified retrovirus might be an etiologic factor. Based on reports suggesting that retroviral infection with a human T-lymphotropic virus type 2 (HTLV-II)-like retrovirus or a spumavirus might be associated with CFS, some research and commercial laboratories developed assays to test specimens from persons with CFS. Even though the hypothesized association between infection with retroviruses and CFS has not been confirmed, these tests are used commonly to evaluate patients with CFS. This report summarizes the findings of a controlled, blinded study conducted in 1992 to determine whether three retroviral tests can distinguish serologically between patients with CFS (i.e., case-patients) and healthy controls.

Barnes PR, Taylor DJ, Kemp GJ, Radda GK.	MRC Biochemical and Clinical Magnetic Resonance Unit, John Radcliffe Hospital, Oxford, UK.	Skeletal muscle bioenergetics in the chronic fatigue syndrome.	J Neurol Neurosurg Psychiatry 1993 Jun;56(6):679-83	Skeletal muscle bioenergetics and control of intracellular pH have been investigated in 46 patients with chronic fatigue syndrome by phosphorus magnetic resonance spectroscopy. The results have been compared with those from healthy controls and from a group of patients with mitochondrial cytopathies affecting skeletal muscle. No consistent abnormalities of glycolysis, mitochondrial metabolism or pH regulation were identified in the group when taken as a whole, although in 12 of the 46 patients the relationship between pH and phosphocreatine utilisation during exercise fell outside the normal range. Of these, 6 patients showed increased acidification relative to phosphocreatine depletion while 6 showed reduced acidification. These findings do not support the hypothesis that any specific metabolic abnormality underlies fatigue in this syndrome although abnormalities may be present in a minority of patients.
Bates DW, Schmitt W, Buchwald D, Ware NC, Lee J, Thoyer E, Kornish RJ, Komaroff AL.	Department of Medicine, Brigham and Women's Hospital, Boston, Mass.	Prevalence of fatigue and chronic fatigue syndrome in a primary care practice.	Arch Intern Med 1993 Dec 27;153(24):2759-65	BACKGROUND: Our goals were to determine the prevalence of unusual, debilitating fatigue and the frequency with which it was associated with the chronic fatigue syndrome (CFS) or other physical or psychological illness in an outpatient clinic population. METHODS: We prospectively evaluated a cohort of 1000 consecutive patients in a primary care clinic in an urban, hospital-based general medicine practice. The study protocol included a detailed history, physical examination, and laboratory and psychiatric testing. RESULTS: Five patients who came because of CFS studies were excluded. Of the remaining 995, 323 reported fatigue, and 271 (27%) complained of at least 6 months of unusual fatigue that interfered with their daily lives. Of the 271, self-report or record review revealed a medical or psychiatric condition that could have explained the fatigue in 186 (69%). Thus, 85 (8.5%) of 995 patients had a debilitating fatigue of at least 6 months' duration, without apparent cause. Of these patients, 48 refused further evaluation, and 11 were unavailable for follow-up; 26 completed the protocol. Three of the 26 were hypothyroid, and one had a major psychiatric disorder. Of the remaining 22 patients, three met Centers for Disease Control and Prevention criteria for CFS, four met British criteria, and 10 met the Australian case definition. The point prevalences of CFS were thus 0.3% (95% confidence interval [CI], 0% to 0.6%), 0.4% (95% CI, 0% to 0.8%), and 1.0% (95% CI, 0.4% to 1.6%) using the Centers for Disease Control and Prevention, British, and Australian case definitions, respectively. These estimates were conservative, because they assumed that none of the patients who refused evaluation or were unavailable for follow-up would meet criteria for CFS. CONCLUSIONS: While chronic, debilitating fatigue is common in medical outpatients, CFS is relatively uncommon. Prevalence depends substantially on the case definition used.

Bentall RP, Wood GC, Marrinan T, Deans C, Edwards RH.	Department of Clinical Psychology, University of Liverpool, UK.	A brief mental fatigue questionnaire.	Br J Clin Psychol 1993 Sep;32 (Pt 3):375-9	A brief mental fatigue questionnaire was administered to normal subjects and muscle-diseased, Chronic Fatigue Syndrome (CFS), recovered CFS and depressed patients. The questionnaire was found to have excellent internal consistency and discriminated effectively between CFS and depressed patients on the one hand and recovered CFS, normal and muscle-diseased patients on the other. However, the scale failed to discriminate between CFS and depressed subjects, who were found to experience qualitatively and quantitatively similar mental fatigue symptoms.

Bialyszewski A.	IV Kliniki Psychiatrycznej Instytutu Psychiatrii i Neurologii, Warszawie.	[The chronic fatigue syndrome].[article in Polish]	Psychiatr Pol 1993 Nov-Dec;27(6):601-11	The chronic fatigue syndrome (CFS) including myalgic encephalomyelitis and the postviral syndrome is a term used today to describe a not fully recognized disease characterized primarily by chronic or recurrent debilitating fatigue and various combinations of neuromuscular and neuropsychological symptoms. The term CFS has been introduced and defined by the Centers for Disease Control (CDC) in Atlanta. Fatigue is one of the most common symptoms in medicine, but CFS as defined by CDC has appeared to be quite rare in the general population. Researchers have suggested that the syndrome is a heterogenous immunologic disorder that follows viral infection, but despite numerous studies on the subject the etiologic factor of the syndrome is unknown. CFS is a controversial diagnosis. In a very high percentage of patients with the CFS depression, phobias or anxiety disorders have frequently preceded the onset of the chronic fatigue. There are many overlapping symptoms between CFS and major depression. Some clinicians suggest that it is not obvious that CFS can be distinguished from neurasthenia.
Blondel-Hill E, Shafran SD.	Department of Medicine, University of Alberta, University of Alberta Hospitals, Walter Mackenzie Health Sciences Centre, Edmonton, Canada.	Treatment of the chronic fatigue syndrome. A review and practical guide.	Drugs 1993 Oct;46(4):639-51	The chronic fatigue syndrome (CFS) was formally defined in 1988 to describe a syndrome of severe and disabling fatigue of uncertain aetiology associated with a variable number of somatic and/or psychological symptoms. CFS has been reported in most industrialised countries and is most prevalent in women aged between 20 and 50 years. Despite occasional claims to the contrary, the aetiology of CFS remains elusive. Although abnormalities in tests of immune function and cerebral imaging have been described in variable numbers of CFS patients, such findings have been inconsistent and cannot be relied upon, either to establish or exclude the diagnosis. Thus, diagnosis rests on fulfillment of the Centers for

				Disease Control case definition which was revised in 1992. This case definition remains somewhat controversial, largely due to its subjectiveness. The mainstay of treatment is establishing the diagnosis and educating the patient about the illness. An empathetic clinician can stop further consultations elsewhere ('doctor shopping') and subsequent excessive investigations, which frequently occur in such patients. Most patients should undertake a trial of antidepressant therapy, even if major depression is not present. The choice of antidepressant drug should tailor the tolerability profile to relief of particular CFS symptoms, such as insomnia or hypersomnia. Failure to improve within 12 weeks warrants an alternative antidepressant agent of another class. Many other drugs have been reported anecdotally to be beneficial, but no therapy has been demonstrated to be reproducibly useful in double-blind, placebo-controlled clinical trials with an adequate duration of follow-up.

Bowles NE, Bayston TA, Zhang HY, Doyle D, Lane RJ, Cunningham L, Archard LC.	Department of Biochemistry, Charing Cross and Westminster Medical School, London, England.	Persistence of enterovirus RNA in muscle biopsy samples suggests that some cases of chronic fatigue syndrome result from a previous, inflammatory viral myopathy.	J Med 1993;24(2-3):145-60	Molecular hybridization using an enterovirus group specific probe detected virus RNA in muscle biopsy samples from 25 of 96 cases of inflammatory muscle disease and similarly from 41 of 158 cases of postviral fatigue syndrome (PFS). Enterovirus RNA was detected in only two of 152 samples of control muscle. The inflammatory myopathy group comprised patients with polymyositis (PM), juvenile dermatomyositis (JDM) or adult dermatomyositis (DM), and all showed the presence of an inflammatory infiltrate and fiber necrosis on histological examination of a muscle biopsy sample. In contrast, muscle samples from the PFS group were histologically normal except for non-specific changes such as occasional single fiber atrophy. By analogy with enteroviral myocarditis, which can progress to a post-inflammatory disease with persistence of virus in myocardium and disposes to the rapid development of dilated cardiomyopathy, we propose that PFS syndrome may be a sequela of a previous inflammatory viral myopathy.

Burdge DR, O'Hanlon DP.	Department of Medicine, University of British Columbia, Vancouver, Canada.	Experience at a referral center for patients with suspected Lyme disease in an area of nonendemicity: first 65 patients.	Clin Infect Dis 1993 Apr;16(4):558-60	A multidisciplinary referral center was established at a university hospital for prospectively assessing patients with possible Lyme disease. Borrelia burgdorferi is not known to be endemic in this region, but considerable anxiety about Lyme disease has developed among the general public. Sixty-five patients were referred for suspected Lyme borreliosis. Detailed histories were obtained and physical examinations were performed; patients were investigated aggressively in accordance with their symptom complexes. Strict diagnostic criteria consistent with published standards were applied. Only two of the 65 patients were judged to have probable Lyme disease. Definite major alternate diagnoses were made for 50 patients (77%); firm medical diagnoses (11 dermatologic, 9 rheumatologic, 9 infectious disease, 6 gastrointestinal, 4 neurological, and 2 miscellaneous) were made for 41 patients (63%); and major psychiatric diagnoses were made for 9 patients (14%). Probable diagnoses of chronic fatigue syndrome and fibromyalgia were made for 11 patients (17%). The conditions of four patients (6%) were undiagnosed. A referral center for patients with suspected Lyme disease can be useful even in an area of nonendemicity, and careful clinical assessment will reveal treatable alternate diagnoses for many patients with suspected Lyme disease.
Cathebras P, Bouchou K, Charmion S, Rousset H.	Service de Medecine Interne, Hopital Nord, Saint-Etienne.	[Chronic fatigue syndrome: a critical review].[article in French]	Rev Med Interne 1993 Apr;14(4):233-42	The term "chronic fatigue syndrome" (CFS) applies to a condition of unknown aetiology characterized clinically by an association of subjective symptoms, the most constant being an invalidating tiredness. The diagnostic criteria in current use do not permit to isolate an homogeneous subgroup among patients consulting for chronic asthenia. In the present state of research no infectious or immunological cause has been demonstrated conclusively, although a persistent enterovirus or herpesvirus type 6 infection or a state of chronic immune activation seem to play a role in some cases. Patients who fulfill the criteria of CFS present with psychiatric overmorbidity, essentially depressive, and in 50% of the cases with the mental disorders preceding CFS. The various theoretical models linking CFS to psychopathology are discussed, and finally the syndrome is regarded as a social construction reproducing or renovating the neurasthenia of the late 19th century. There is no specific treatment of CFS, but antidepressants, cognitive-behavioural therapy and perhaps certain immuno-modulators can be useful. The future lines of research should endeavour to isolate a subgroup of patients with prolonged asthenia after a recognized episode of infection and to identify the immunological, psychological and behavioral characteristics of this particular group as well as their reciprocal interactions. Chester AC.		Hypothesis: the nasal fatigue reflex.	Integr Physiol Behav Sci 1993 Jan-Mar;28(1):76-83	Natural selection results in adaptations. I suggest that unexplained fatigue may be an adaptive response to nasal impairment. For macrosmatic animals, intact olfaction is necessary to detect predators. In such animals, any reflex (e.g., fatigue) triggered by nasal dysfunction that limited exposure would offer great survival advantage. The "fatigued" animal would remain in its protected environment, unexposed to hungry carnivores, while the nose healed. In humans, clinical syndromes associated with unexplained fatigue (chronic fatigue syndrome, tension fatigue syndrome, allergic fatigue, neurasthenia, etc.) are characterized by symptoms that, in part, are nasal in origin. The older medical literature does describe the resolution of fatigue in neurasthenia after nasal treatments. Nasal reflexes in animals do cause significant systemic effects, including an inhibition of muscle action potentials that is, perhaps, analogous to the "heavy-limbed" sensation of those with fatigue. Furthermore, reflexes similar to the one proposed do exist in humans: the diving reflex presumably served our amphibian ancestors well as an oxygen conserving technique with submersion, but serves no known useful function now. Other human nasopharyngeal reflexes with profound cardiovascular and systemic effects are well described but only occasionally studied. The proposed nasal fatigue reflex should be examined as a possible ancient adaptive response to nasal malfunction.

Dechene L.	Fitchburg State College, Fitchburg, Massachusetts 01420.	Chronic fatigue syndrome: influence of histamine, hormones and electrolytes.	Med Hypotheses 1993 Jan;40(1):55-60	The chronic fatigue syndrome is poorly understood. We believe the underlying causes in many atopics and women are a persistent infection and hypersensitivity to the immune-suppressive effects of histamine and certain pathogens. We believe much to the symptomatology can be explained by all four types of hypersensitivity (Gell and Coombs classification) in reaction to a pathogen, electrolyte disturbances which include sometimes permanent changes in cell membranes' ability to pass electrolytes, sometimes permanent biochemical

				changes in mitochondrial function, and disturbances of insulin and T3-thyroid hormone functions. We also explain in detail what 'fatigue' means for these patients. We present evidence from the medical literature for the plausibility of our hypotheses.

DeLuca J, Johnson SK, Natelson BH.	Department of Physical Medicine and Rehabilitation, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark.	Information processing efficiency in chronic fatigue syndrome and multiple sclerosis.	Arch Neurol 1993 Mar;50(3):301-4	OBJECTIVE--To compare the cognitive performance of subjects with chronic fatigue syndrome (CFS), multiple sclerosis (MS), and healthy controls. All subjects were matched for age, education, and verbal intelligence, as previous neuropsychological studies of CFS had not used appropriate control groups. DESIGN--Case-control design. All subjects were given a neuropsychological battery and the test scores were compared among the groups. SETTING--Subjects with CFS and subjects with MS were recruited from private and institutional practice and from the community. Healthy subjects were recruited from the community. PATIENTS/OTHER PARTICIPANTS--Twelve subjects (all female) with CFS participated in the study. Chronic fatigue syndrome was diagnosed in these patients in accordance with the requirements outlined by the Centers for Disease Control as modified subsequently to not exclude patients with concurrent depression and/or anxiety. All subjects with CFS were referred for a neuropsychological examination to assess persistent cognitive complaints. Eleven subjects (10 female, one male) with the diagnosis of clinically stable MS were chosen from clinics and the community because of complaints of mild to moderate cognitive impairment. The subjects with MS and 11 healthy volunteers (10 female, one male) were matched to the group with CFS by age, education, and estimated verbal intelligence (based on the Vocabulary subtest of the Wechsler Adult Intelligence Scale-Revised). The subjects with MS had a mean Kurtzke Expanded Disability Status Scale score of 4.95 (SD, 1.95; range, 2.0 to 7.5). As a result of the matching procedure, there were no differences among the three groups in age ($F[2,31] = 0.32$), education ($F[2,31] = 0.80$), and verbal intelligence ($F[2,31] = 0.31$). INTERVENTIONS--None. MAIN OUTCOME MEASURES--These measures included the Beck Depression Inventory (BDI), the Paced Auditory Serial Addition Test (PASAT), Digit Span Test, and the Similarities Test of Verbal Abstract Reasoning. RESULTS--The mean number of correctly identified responses collapsed across the four PASAT trials was significantly different across groups ($F[2,31] = 4.03$; $P < .05$). While the CFS and MS groups did not differ from each other, subjects with CFS (SEM, 124.2 +/- 6.4) and subjects

				with MS (SEM, 112.9 +/- 10.9) scored significantly below controls (SEM, 146.4 +/- 6.4) (Fisher's Protected Least Significant Difference test; P < .05). There were significant differences among the three groups on mean Digit Span Test performance (F[2,31] = 5.5; P < .01). While the CFS and MS group did not differ significantly from each other, only the CFS group was significantly lower than control (Fisher's Protected Least Significant Difference test; P < .05). Mean performance on the Similarities test did not differ among the three groups (F = 0.58). In addition, there were significant differences among the three groups in mean BDI scores (F[2,31] = 7.6; P < .01). The CFS and MS groups did not differ significantly from each other, and both groups showed a statistically significantly elevated mean BDI score relative to the control group (Fisher's Protected Least Significant Difference test; P < .05). No significant correlations were found between BDI scores and PASAT total scores (CFS, r = -.21; MS, r = .13; control, r = .27), or between BDI and Digit Span Test (CFS, r = -.32; MS, r = -.40; control, r = -.19). Results of the PASAT and Digit Span Test were significantly correlated in the CFS group (r = .71; P < .01), but not in the MS (r = .06) or control groups (r = .49). CONCLUSIONS--These results indicate that subjects with CSF and subjects with MS show significant impairment on a test of complex concentration when compared with appropriate controls. The data suggest that subjects with CFS and subjects with MS have difficulty on tasks that require the simultaneous processing of complex cognitive information. Selective impairment in information processing efficiency may lie at the
Denz-Penhey H, Murdoch JC.	Department of General Practice, University of Otago Medical School, Dunedin.	General practitioners acceptance of the validity of chronic fatigue syndrome as a diagnosis.	N Z Med J 1993 Apr 14;106(953):122-4	AIM. To identify whether general practitioners accept the validity of a diagnosis of chronic fatigue syndrome (CFS). METHOD. An anonymous questionnaire was sent out to 98 general practitioners in Otago. RESULTS. The clinical validity of chronic fatigue syndrome was accepted by 74 (90%); 57 believed they had sufficient knowledge about the condition to make a differential diagnosis; 72 indicated they had had patients with chronic fatigue syndrome in the past; 62 currently had patients; there is a minimum prevalence rate of 167/100,000 in the general practice population; 83 replies were received. CONCLUSION. The 90% acceptance rate of chronic fatigue syndrome as a clinically valid diagnosis suggests that amongst the Otago general practitioners the controversy had receded. The low numbers suggest that they are on the conservative end of the diagnostic spectrum.
Denz-Penhey H, Murdoch JC.	Department of General Practice, Otago Medical School, Dunedin, New Zealand.	Service delivery for people with chronic fatigue syndrome: a pilot action research study.	Fam Pract 1993 Mar;10(1):14-8	Chronic fatigue syndrome (CFS) is a symptom complex which while mild in some cases is severely debilitating in others. Long-term ill health leads to greater use of resources but in the case of long-term CFS the anecdotal evidence suggested a low compliance with the available options and a high level of both patient and general practitioner dissatisfaction. This pilot study sought through repeated action research cycles to start to identify culturally and contextually sensitive

				forms of language and models for service delivery suitable for people with CFS in a general practice setting. It worked through a number of action research cycles, to initiate the identification of conceptual models acceptable to both doctors and to patients suffering from CFS, self-management options which encouraged the body's ability to heal itself and services and delivery mechanisms which met patient needs within health provider options.
Edwards RH, Gibson H, Clague JE, Helliwell T.	Department of Medicine, University of Liverpool, UK.	Muscle histopathology and physiology in chronic fatigue syndrome.	Ciba Found Symp 1993;173:102-17; discussion 117-31	Chronic fatigue syndrome (CFS) is characterized by fatigue at rest which is made worse by exercise. Previous biopsy studies on small numbers of CFS patients have shown a range of morphological changes to which have been attributed fatigue and myalgia. We have now studied 108 patients with CFS or muscle pain and 22 normal volunteers by light and electron microscopy. There was no consistent correlation between symptoms and changes in fibre type prevalence, fibre size, degenerative or regenerative features, glycogen depletion, or mitochondrial abnormalities. Physiological contractile properties of quadriceps (maximal isometric force generation, frequency: force characteristics and relaxation rate) were also examined before and for up to 48 hours after a symptom-limited incremental cycle ergometer exercise test in 12 CFS patients and 12 normal volunteers. Voluntary and stimulated force characteristics were normal at rest and during recovery. Exercise duration was similar in the two groups although CFS patients had higher perceived exertion scores in relation to heart rate during exercise, indicating a reduced effort sensation threshold. On physiological and pathological grounds it is clear that CFS is not a myopathy. Psychological/psychiatric factors appear to be of greater importance in this condition.
Fohlman J, Friman G.	Department of Infectious Diseases, University Hospital of Uppsala, Sweden.	Is juvenile diabetes a viral disease?	Ann Med 1993 Dec;25(6):569-74	The purpose of this review is to discuss recent literature data concerning the etiology and pathobiology in insulin-dependent diabetes mellitus as well as present our own experience from all children up to 15 years of age in Uppsala County, Sweden presenting with juvenile (type I) diabetes since 1976. Chronic enterovirosis is an emerging concept in apparently immunologically competent patients. By means of new serological and DNA-based methods, a persistent enteroviral (Coxsackie virus A, B and ECHO virus) infection can sometimes be demonstrated after an acute primary infection, which is often subclinical. There are several indications that these viruses can contribute to the development of illnesses with a pathogenesis as yet not fully understood, e.g. dilated cardiomyopathy, type I diabetes, and possibly some cases of the so-called chronic fatigue syndrome. In type I diabetes, many pieces of evidence including epidemiology, genetic analysis of the host susceptibility genes, cytokine analysis and new seriological evaluation suggest an infection to be the starting point for the beta cell destruction. These etiological agents most likely belong to the enteroviral group of picornaviruses. Later events may well involve all parts of the

				immune system launching a selective autoimmune 'suicidal attack' on the cells necessary for glucose homeostasis.
Folks TM, Heneine W, Khan A, Woods T, Chapman L, Schonberger L.	Division of Viral and Rickettsial Diseases, Centers for Disease Control, Atlanta, GA 30333.	Investigation of retroviral involvement in chronic fatigue syndrome.	Ciba Found Symp 1993;173:160-6; discussion 166-75	Within the last few years significant efforts have been made to identify objective reliable diagnostic markers from individuals with chronic fatigue syndrome (CFS). We report the absence of a previously described retroviral marker (HTLV-II gag) in a blinded study of CFS cases. Even with excellent reproducible sensitivities, this marker failed in repeated attempts to distinguish cases from controls. In addition, four other retroviruses (simian T cell leukaemia virus, human spumavirus, bovine leukaemia virus and simian retrovirus) were examined for their presence in these CFS cases and found to be absent. Our findings suggest that these agents, at least as markers, are non-distinguishing for CFS and that other factors may be confounding the resolution of an aetiology to this syndrome.
Fucikova T, Petanova J.	Oddeleni klinicke imunologie 1. Lekarske fakulty Univerzity Karlovy, Praha.	[Chronic fatigue syndrome].[article in Czech]	Vnitr Lek 1993 Oct;39(10):995-1002	The authors followed up for a period of 1-14 years 52 patients with CFS who met the criteria outlined by Holmes. The group comprised 10 men and 42 women. In 15% of these patients after a mean period of 5.5 years thyroiditis was diagnosed. Complete recovery was recorded in 20%, improvement in 32% of the patients, on average after 7 years. In the course of treatment mainly immunomodulating preparations were used. Indication of these drugs was individual based on immunological examinations. The success was only partial. The clinical condition of the patients did not correlate with serological findings of IgM, IgA and IgG antibodies against VCA nor with antibodies against EA of the EBV virus.
Gibson H, Carroll N, Clague JE, Edwards RH.	Department of Medicine, University of Liverpool, UK.	Exercise performance and fatiguability in patients with chronic fatigue syndrome.	J Neurol Neurosurg Psychiatry 1993 Sep;56(9):993-8 comment in: J Neurol Neurosurg Psychiatry. 1994 May;57(5):662-3	To examine the role of delay in recovery of peripheral muscle function following exercise in the fatigue experienced by patients with the chronic fatigue syndrome (CFS) and to examine the influence of effort perception in limiting exercise performance in these patients, a study was carried out on a group of twelve patients with chronic fatigue syndrome and 12 sex and age-matched sedentary control subjects. Symptom limited incremental cycle exercise tests including measurements of perceived exertion were performed followed by examination of the contractile properties of the quadriceps muscle group for up to 48 hours. Muscle function was assessed by percutaneous electrical stimulation and maximum voluntary contractions. Muscle function at rest and during recovery was normal in CFS patients as assessed by maximum isometric voluntary contraction, 20:50 Hz tetanic force ratio and maximum relaxation rate. Exercise duration and the relationship between heart rate and work rate during exercise were similar in both groups. CFS patients had higher perceived exertion scores in relation to heart rate during exercise representing a reduced effort sensation threshold of 3.2 units on an unmodified Borg scale in CFS patients. Patients with chronic fatigue syndrome show normal muscle physiology before and after exercise. Raised perceived exertion scores during exercise suggest that central factors are limiting exercise capacity in these patients.

Goldenberg DL.	Newton-Wellesley Hospital, Massachusetts.	Fibromyalgia, chronic fatigue syndrome, and myofascial pain syndrome.	Curr Opin Rheumatol 1993 Mar;5(2):199-208	Operational diagnostic criteria for fibromyalgia were applied to most clinical studies during the past year. Similar diagnostic criteria for chronic fatigue syndrome are being revised, but criteria for myofascial pain have not been agreed on or tested. Intense research efforts focused on the role of neurohormones and the hypothalamic-pituitary-adrenal axis in fibromyalgia and chronic fatigue syndrome over the past year.
Goodnick PJ, Sandoval R.	Department of Psychiatry, University of Miami, FL 33136.	Psychotropic treatment of chronic fatigue syndrome and related disorders.	J Clin Psychiatry 1993 Jan;54(1):13-20	BACKGROUND: Chronic fatigue syndrome (CFS) and fibromyalgia frequently are associated with symptoms of major depression. For this reason, antidepressants have been used in treatment of these disorders; however, little direction has been provided into this application in psychopharmacology. METHOD: First, nine studies were reviewed regarding the relationship of the symptoms of fatigue and depression. Next, 23 reports (12 double-blind studies, 7 open studies, and 4 case reports) were reviewed for the effectiveness of therapy as assessed by global response and improvement of both depression and pain. Studies were differentiated by type of controls, as well as by alleged mechanism of action of the pharmacologic agent. RESULTS: Disturbances in brain neurochemistry shared by CFS and major depression may serve as a basis for the effectiveness of some antidepressants in CFS. Response to some antidepressants in patients with CFS or fibromyalgia may occur at doses lower than those used in major depression, e.g., amitriptyline 25-75 mg/day. We further found that the more serotonergic treatments (e.g., clomipramine) were more successful in alleviating pain than depression, whereas catecholaminergic agents (e.g., maprotiline, bupropion) seemed particularly effective for symptoms of associated depression. CONCLUSION: To maximize response of the physiologic and psychological consequences of the disorder, more investigation is needed to replicate the apparent findings that relate the neurochemical impairment underlying CFS and fibromyalgia to the type of antidepressant mechanism.
Grafman J, Schwartz V, Dale JK, Scheffers M, Houser C, Straus SE.	Cognitive Neuroscience Section, NINDS, NIH, Bethesda, MD 20892.	Analysis of neuropsychological functioning in patients with chronic fatigue syndrome.	J Neurol Neurosurg Psychiatry 1993 Jun;56(6):684-9	Memory impairment dominates the cognitive complaints of patients with chronic fatigue syndrome (CFS). Twenty CFS patients were available for studies with a clinical and experimental battery composed of memory and cognitive tests. The results on objective testing indicated that the CFS patients had some mild memory impairment, but only on tasks requiring conceptually driven encoding and retrieval processes. There were no associations between the nature of the precipitating illness, self ratings of fatigue, physical findings, or laboratory determination and objective memory performance or self report of memory functioning. These generally negative results indicate that memory impairment in CFS patients is typically mild and involves memory processes that participate in conceptualising information.
Gunn WJ, Connell DB, Randall B.	Division of Viral and Rickettsial Diseases,	Epidemiology of chronic fatigue syndrome: the	Ciba Found Symp 1993;173:83-93;	The US Centers for Disease Control initiated physician-based chronic fatigue syndrome (CFS) surveillance systems in four cities in September 1989 to

	Centers for Disease Control, Atlanta, GA 30333.	Centers for Disease Control Study.	discussion 93-101	determine the prevalence, incidence, course and impact of the illness. The participating physicians have referred to our surveillance system 590 patients who were ill during the first two years of surveillance with severe, debilitating, unexplained fatigue for at least the preceding six months. Referred patients were screened for psychiatric disorders preceding, concurrent with, and subsequent to the onset of their fatigue by specially trained nurses using a modified Diagnostic Interview Schedule. Complete health histories were obtained by interview and review of medical records and a basic panel of standard laboratory diagnostic tests were conducted. Four physicians have independently reviewed the health information of 337 of the patients for classification. Approximately 26% of patients referred to the surveillance system met the CFS case definition in all regards, 14% lacked one or more of the required eight symptom criteria, 15% were judged to have another possible or known medical illness which could account for the severe fatigue, and the remaining 45% did not meet the case definition because of histories of psychiatric disorders preceding the onset of fatigue. Minimum prevalence rates for the period 1 September 1989 to 1 September 1991 ranged from 2.0 to 7.3 per 100,000 of the general population across the four study sites and rates based on prorated data ranged from 4.6 to 11.3 per 100,000. More than 80% of the CFS cases were female, most were white, and their average age at onset was approximately 30 years.

Honda M, Kitamura K, Nakasone T, Fukushima Y, Matsuda S, Nishioka K, Matsuda J, Hashimoto N, Yamazaki S.	Laboratory of Immunology, National Institute of Health, Tokyo, Japan.	Japanese patients with chronic fatigue syndrome are negative for known retrovirus infections.	Microbiol Immunol 1993;37(10):779-84	Although chronic fatigue syndrome (CFS) is known to be the syndrome that begins with an acute flu-like illness that may be due to the exposure to an infectious agent, there has been no convincing evidence on the causative agents. Recently, human T-lymphotropic virus type II (HTLV-II)-like virus has been reported to be associated with the CFS by using HTLV Western blot analysis and polymerase chain reaction. However, some investigators could not detect HTLV-II by indirect immunofluorescence analysis. Lately, CFS patients have been reported in Japan. We detected all 30 tested patients with CFS were seronegative for HTLV-II, HTLV-I and HIV by specific peptide ELISA and Western blot. Further, PCR analysis was negative for HTLV-II and retrovirus was not detected by coculture

				method with patients' PBMC. Thus, known human retrovirus infections do not cause a CFS in Japan.

Some patients with CFS are deficient in folic acid.
James DG.		Complications of sarcoidosis. Chronic fatigue syndrome.	Sarcoidosis 1993 Mar;10(1):1-3 comment in: Sarcoidosis. 1993 Sep;10(2):138	Well-recognised complications are pulmonary fibrosis, cor pulmonale, glaucoma, cataract and nephrocalcinosis causing failure of lungs, heart, vision and kidneys. Less well-recognised is the post-sarcoidosis chronic fatigue syndrome. The afflicted join sarcoidosis patients' associations because of their profound symptoms of myalgia, fatigue, sleep reversal and low-spiritedness. The symptoms are out of proportion to the lack of physical signs and the absence of objective evidence of sarcoidosis. Management includes unremitting sympathy and replenishment of essential neurochemicals.
Jason LA, Taylor SL, Johnson S, Goldston SE, Salina D, Bishop P, Wagner L.	Department of Psychology, DePaul University, Chicago, IL 60614.	Prevalence of chronic fatigue syndrome-related symptoms among nurses.	Eval Health Prof 1993 Dec;16(4):385-99	Chronic Fatigue Syndrome is an illness that is characterized by debilitating fatigue and a group of other related symptoms. Few epidemiological studies have been conducted, and none have focused on a nursing population. The present study is the first to assess the prevalence of Chronic Fatigue Syndrome-related symptoms in a sample of nurses. Demographic characteristics, symptoms, and possible prevalence rates are presented and discussed. When using both narrow and more inclusive criteria to define this symptom complex, higher rates of this disorder were found than in previous epidemiological studies. The implications of these findings are discussed.
Kent-Braun JA, Sharma KR, Weiner MW, Massie B, Miller RG.	Department of Neurology, University of California, San Francisco.	Central basis of muscle fatigue in chronic fatigue syndrome.	Neurology 1993 Jan;43(1):125-31 comment in: Neurology. 1993 Sep;43(9):1866-7	We studied whether muscle fatigue, metabolism, or activation are abnormal in the chronic fatigue syndrome (CFS). Subjects performed both an intermittent submaximal and a sustained maximal voluntary isometric exercise protocol of the tibialis anterior muscle. The extent of fatigue, metabolic response, and changes in both M-wave amplitude and twitch tension during exercise were similar in patients and controls. The response to systemic exercise was also normal in the patients. However, voluntary activation of the tibialis was significantly lower in the patients during maximal sustained exercise. The results indicate that patients with CFS have (1) normal fatigability and metabolism at both the intracellular and systemic levels, (2) normal muscle membrane function and excitation-contraction coupling, and (3) an inability to fully activate skeletal muscle during intense, sustained exercise. This failure of activation was well in excess of that found in

				controls, suggesting an important central component of muscle fatigue in CFS.
Khan AS, Heneine WM, Chapman LE, Gary HE Jr, Woods TC, Folks TM, Schonberger LB.	Centers for Disease Control and Prevention, Atlanta, Georgia.	Assessment of a retrovirus sequence and other possible risk factors for the chronic fatigue syndrome in adults.	Ann Intern Med 1993 Feb 15;118(4):241-5	OBJECTIVE: To assess whether the human T-lymphotropic virus type II (HTLV-II) gag gene sequence, a purportedly new laboratory marker of the chronic fatigue syndrome (CFS), and other possible risk factors for CFS, particularly those associated with retroviral transmission, are associated with well-characterized CFS. DESIGN: Two matched case-control studies. SETTING: The metropolitan Atlanta area. PATIENTS: Twenty-one patients with CFS who were identified by the Centers for Disease Control and Prevention CFS surveillance system; 21 CDC employee controls (laboratory study) and 42 neighborhood controls (risk-factor study) who were matched to patients by age, race, and gender. MEASUREMENTS: Peripheral blood lymphocytes and leukocytes were assayed for the HTLV-II gag gene sequence by polymerase chain reaction and specific Southern blot hybridization. Questionnaires elicited demographic and clinical information and a history of exposures associated with retrovirus transmission (for example, blood transfusions, sexual practices, intravenous drug use). RESULTS: All patients were white and 86% were female. The median age at illness onset was 34 years (range, 16 to 51 years). The HTLV-II gag gene sequence was not identified in the blood of any patient or control under conditions in which the appropriate assay controls were positive. No statistical differences were observed between patients and controls in frequency of blood transfusions (10% compared with 7%), median number of sex partners before illness (3 compared with 3), bisexual or homosexual behavior (14% compared with 7%), intravenous drug use (0% compared with 0%), and other factors associated with retroviral infection. CONCLUSIONS: The HTLV-II gag gene sequence was not a marker for CFS in this small study of well-defined patients, nor did other characteristics of the patients and controls support the hypothesis that a retrovirus, transmitted by usual modes, was a cause of CFS.

Komaroff AL.	Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA 02115.	Clinical presentation of chronic fatigue syndrome.	Ciba Found Symp 1993;173:43-54; discussion 54-61	Chronic fatigue syndrome (CFS) is a chronic illness of uncertain aetiology characterized by at least six months of debilitating fatigue and associated symptoms. The symptoms of the syndrome are all non-specific and some (but not all) are also seen in psychiatric illness. The symptomatology suggesting an organic component to the illness includes its abrupt onset with an 'infectious-like' illness, intermittent unexplained fevers, arthralgias and 'gelling' (stiffness), sore throats, cough, photophobia, night sweats, and post-exertional malaise with systemic symptoms. The illness can last for years and is associated with marked impairment of functional health status.
Krupp LB, Jandorf L, Coyle PK, Mendelson WB.	Dept of Neurology, State University of New York, Stony Brook 11794-8121.	Sleep disturbance in chronic fatigue syndrome.	J Psychosom Res 1993 May;37(4):325-31	Sleep and fatigue characteristics were evaluated in 72 patients who met major criteria for the chronic fatigue syndrome (CFS), 57 multiple sclerosis (MS) patients preselected for fatigue complaints, and 40 healthy controls. Using previously validated rating scales, CFS patients had significant elevations in fatigue and sleep disturbance compared to the MS and healthy control groups. To confirm these subjective measures, polysomnography was carried out in a subgroup of CFS patients who included sleep disturbance as one of their symptoms on initial clinical interview. In 10 of 16 (62.5%) polysomnography revealed clinically significant and potentially treatable sleep abnormalities. Their sleep disorders included periodic movement disorder (4), excessive daytime sleepiness (3), apnea (2), and narcolepsy (1). We conclude that subjective sleep disturbance is common in CFS and some CFS patients may have objective sleep disorders.
Langsjoen PH, Langsjoen PH, Folkers K.		Isolated diastolic dysfunction of the myocardium and its response to CoQ10 treatment.	Clin Investig 1993;71(8 Suppl):S140-4	Symptoms of fatigue and activity impairment, atypical precordial pain, and cardiac arrhythmia frequently precede by years the development of congestive heart failure. Of 115 patients with these symptoms, 60 were diagnosed as having hypertensive cardiovascular disease, 27 mitral valve prolapse syndrome, and 28 chronic fatigue syndrome. These symptoms are common with diastolic dysfunction, and diastolic function is energy dependent. All patients had blood pressure, clinical status, coenzyme Q10 (CoQ10) blood levels and echocardiographic measurement of diastolic function, systolic function, and myocardial thickness recorded before and after CoQ10 replacement. At control, 63 patients were functional class III and 54 class II; all showed diastolic dysfunction; the mean CoQ10 blood level was 0.855 micrograms/ml; 65%, 15%, and 7% showed significant myocardial hypertrophy, and 87%, 30%, and 11% had elevated blood pressure readings in hypertensive disease, mitral valve prolapse

				and chronic fatigue syndrome respectively. Except for higher blood pressure levels and more myocardial thickening in the hypertensive patients, there was little difference between the three groups. CoQ10 administration resulted in improvement in all; reduction in high blood pressure in 80%, and improvement in diastolic function in all patients with follow-up echocardiograms to date; a reduction in myocardial thickness in 53% of hypertensives and 36% of the combined prolapse and fatigue syndrome groups; and a reduced fractional shortening in those high at control and an increase in those initially low.(ABSTRACT TRUNCATED AT 250 WORDS)
Lerner AM, Lawrie C, Dworkin HS.	Wayne State University School of Medicine, Royal Oak, Mich.	Repetitively negative changing T waves at 24-h electrocardiographic monitors in patients with the chronic fatigue syndrome. Left ventricular dysfunction in a cohort.	Chest 1993 Nov;104(5):1417-21	This study surveys the occurrence of repetitively negative to flat T waves, alternating with normal upright T waves in 24-h electrocardiographic recordings from a subspecialty infectious diseases outpatient practice during the years 1982 to 1990. Patients with normal resting electrocardiogram in the assayed leads, but with repetitively inverted to isoelectric abnormal T waves at Holter monitors, were considered to have abnormal readings. A total of 300 patients had undergone a 24-h Holter monitor. This group included 24 individuals with chronic fatigue syndrome (CFS). This population was restricted to individuals 50 years old or younger, and the patients with CFS are compared with the patients without CFS. One of the more striking differences between the two groups was the difference in abnormal Holter readings. The patients with CFS all had abnormal Holter readings, while 22.4 percent patients without CFS had abnormal readings ($p < 0.01$). We further report the occurrence of mild left ventricular dysfunction in 8 of 60 patients in continuing studies of this population with CFS, younger than 50 years old, and with no risk factors for coronary artery disease. All 60 patients with CFS showed repetitively flat to inverted T waves alternating with normal T waves. Stress multiple gated acquisitions (MUGAs) (labeled erythrocytes with stannous pyrophosphate) were abnormal in eight patients with CFS. Although resting ejection fractions (EFs) were normal (mean, 60 percent), with increasing work loads (Kilopon meters [Kpms]), gross left ventricular dysfunction occurred. The fatigue of patients with CFS may be related to subtle cardiac dysfunction occurring at work loads common to ordinary living.

Immunologic and psychologic therapy for patients with chronic fatigue syndrome: a	Am J Med 1993 Feb;94(2):197-203 comment in: Am J Med. 1994 Nov;97(5):493-4	PURPOSE: To evaluate the potential benefit of immunologic therapy with dialyzable leukocyte extract and psychologic treatment in the form of cognitive-behavioral therapy (CBT) in patients with chronic fatigue syndrome (CFS). PATIENTS AND METHODS: Immunologic and psychologic treatments were

		double-blind, placebo-controlled trial.	Am J Med. 1995 Apr;98(4):419-20; discussion 421-2 Am J Med. 1995 Apr;98(4):420-1; discussion 421-2	administered to 90 adult patients who fulfilled diagnostic criteria for CFS in a double-blind, randomized, and placebo-controlled study. A four-cell trial design allowed the assessment of benefit from immunologic and psychologic treatment individually or in combination. Outcome was evaluated by measurement of global well-being (visual analogue scales), physical capacity (standardized diaries of daily activities), functional status (Karnofsky performance scale), and psychologic morbidity (Profile of Mood States questionnaire), and cell-mediated immunity was evaluated by peripheral blood T-cell subset analysis and delayed-type hypersensitivity skin testing. RESULTS: Neither dialyzable leukocyte extract nor CBT (alone or in combination) provided greater benefit than the nonspecific treatment regimens. CONCLUSIONS: In this study, patients with CFS did not demonstrate a specific response to immunologic and/or psychologic therapy. The improvement recorded in the group as a whole may reflect both nonspecific treatment effects and a propensity to remission in the natural history of this disorder. Randomized Controlled Trial
Lloyd AR, Wakefield D, Hickie I.	Laboratory of Molecular Immunoregulation, National Cancer Institute, Frederick, MD 21702-1201.	Immunity and the pathophysiology of chronic fatigue syndrome.	Ciba Found Symp 1993;173:176-87; discussion 187-92	The pathophysiology of chronic fatigue syndrome (CFS) remains unknown. The syndrome often follows a recognized or presumed infection and the disorder may therefore result from a disordered immune response to a precipitating infection or antigenic challenge. Abnormalities of both humoral and cellular immunity have been demonstrated in a substantial proportion of patients with CFS. The most consistent findings are of impaired lymphocyte responses to mitogen and reduced natural killer cell cytotoxicity. Cutaneous anergy and immunoglobulin G subclass deficiencies have also been found. Further studies are needed examining cytokine levels in serum and cerebrospinal fluid, and cytokine production in vitro in patients with CFS. Interpretation of the findings of published studies of immunity is limited by probable heterogeneity in the patient groups studied, and by the lack of standardization and reproducibility in the assays used. The pattern of abnormalities reported in immunological testing in patients with CFS is consistent with the changes seen during the resolving phases of acute viral infection. These data provide circumstantial support for the hypothesis that CFS results from a disordered immune response to an infection. Longitudinal studies of immunity in patients developing CFS after defined infectious illnesses will provide the best means of further examining this hypothesis.
Lusso P, Malnati MS, Garzino-Demo A, Crowley RW, Long EO, Gallo RC.	Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20892.	Infection of natural killer cells by human herpesvirus 6.	Nature 1993 Apr 1;362(6419):458-62	Natural killer (NK) cells are a functionally defined subset of non-T, non-B lymphocytes of bone marrow origin, which induce lysis of selected target cells, including neoplastic and virus-infected cells. The NK cell function provides an important mechanism of primary defence against viruses in vivo, as demonstrated by the occurrence of multiple herpesvirus infections in patients congenitally lacking NK cells. Here we show that functionally competent CD3- NK clones can be productively infected by human herpesvirus 6 (HHV-6), a T-

				lymphotropic DNA virus that may play a role in the acquired immunodeficiency syndrome (AIDS) and in the chronic fatigue syndrome, two disorders associated with a defective NK cell activity. The infection is cytopathic and induces de novo expression of CD4, an antigen not expressed within the NK lineage, thereby predisposing NK cells to infection by human immunodeficiency virus type 1 (HIV-1). These results provide evidence that a herpesvirus can directly target and kill NK cells, a potential strategy to suppress the natural anti-viral immunity of the host.

Manu P, Lane TJ, Matthews DA.	Department of Medicine, University of Connecticut School of Medicine, University of Connecticut Health Center, Farmington 06032.	Chronic fatigue and chronic fatigue syndrome: clinical epidemiology and aetiological classification.	Ciba Found Symp 1993;173:23-31; discussion 31-42	To determine the medical and psychiatric diagnoses that have an aetiological role in chronic fatigue we conducted a prospective study of 405 (65% women) patients who presented for evaluation with this chief complaint to an academic medical centre. The average age was 38.1 years and the average duration of fatigue at entry in the study was 6.9 years. All patients were given comprehensive physical and laboratory evaluations and were administered a highly structured psychiatric interview. Psychiatric diagnoses explaining the chronic fatigue were identified in 74% of patients and physical disorders were diagnosed in 7% of patients. The most common psychiatric conditions in this series were major depression, diagnosed in 58% of patients, panic disorder, diagnosed in 14% of patients, and somatization disorder, diagnosed in 10% of patients. Primary sleep disorders, diagnosed in 2% patients, and chronic infections, confirmed in 1.6% patients, explained the majority of cases whose chronic fatigue was attributed to a physical disorder. Thirty per cent of patients met the criteria used to define the chronic fatigue syndrome (CFS). Compared with age- and gender-matched control subjects with chronic fatigue, CFS patients had a similarly high prevalence of current psychiatric disorders (78% versus 82%), but were significantly more likely to have somatization disorder (28% versus 5%) and to attribute their illness to a viral infection (70% versus 33%). We conclude that most patients with a chief complaint of chronic fatigue, including those exhibiting the features of CFS, suffer from standard mood, anxiety and/or somatoform disorders. Careful research is still needed to determine whether CFS is a distinct entity or a variant of these psychiatric illness.
Matsunaga K.	1st Department of Internal Medicine, Urafune Hospital Yokohama City University School of Medicine.	[The "anti-Ki" syndrome: major clinical features].[article in Japanese]	Rinsho Byori 1993 Aug;41(8):882-7	OBJECTIVE. To describe the major clinical features of patients with high titers of anti-Ki antibodies. METHOD AND RESULTS. Four of 172 patients with connective tissue diseases showed high titers (> 1/256) of anti-Ki antibodies. In these four patients, (1) the common clinical findings were alopecia, disabling chronic fatigue, muscle weakness, tenosynovitis, dry mouth, and abnormal glucose tolerance test; (2) anti-Ki antibodies were positive not only in patients with sicca lupus, but also in those with nonsicca lupus. In this case, anti-insulin receptor

				antibody was positive and there was a regulatory insufficiency of the pituitary. (3) Symptoms of anti-Ki antibodies share many clinical and laboratory features of chronic fatigue syndrome and fibromyalgia, that is, they may share either a common etiologic agents or a common pathogenetic pathway or both. CONCLUSION. "Anti-Ki antibody" syndrome may be a subset of sicca lupus.

McCluskey DR.	Department of Medicine, Queen's University of Belfast, UK.	Pharmacological approaches to the therapy of chronic fatigue syndrome.	Ciba Found Symp 1993;173:280-7; discussion 287-97	Although a variety of pharmacological agents have been used to treat patients with chronic fatigue syndrome none has been shown to effect a complete resolution of symptoms. Data obtained from a retrospective study and from an objective assessment of the aerobic work capacity of patients with this disorder suggest that the underlying pathophysiological abnormality is a disorder of sleep regulation. This results not only in profound fatigue and lethargy but also reduced sensory threshold for pain, disordered temperature regulation, cardiovascular abnormalities, disturbed higher cerebral function and mental depression. Drugs which modulate sleep, such as tricyclic antidepressants, have a limited effect in improving the symptoms that CFS patients experience. We suggest that other agents which affect central nervous system neurotransmitters, particularly serotonin, may have potential in the management of this condition and need to be evaluated in large controlled clinical trials.
McDonald E, David AS, Pelosi AJ, Mann AH.	Department of Epidemiology, Institute of Psychiatry, London.	Chronic fatigue in primary care attenders.	Psychol Med 1993 Nov;23(4):987-98	From 686 patients attending primary care physicians, 77 were identified by a screening procedure as having chronic fatigue. Of these, 65 were given a comprehensive psychological, social and physical evaluation. Seventeen cases (26%) met criteria for the chronic fatigue syndrome. Forty-seven (72%) received an ICD-9 diagnosis of whom 23 had neurotic depression, with a further 5 meeting criteria for neurasthenia. Forty-nine were 'cases' as defined by the revised Clinical Interview Schedule (CIS-R), and 42 if the fatigue item was excluded. Psychiatric morbidity was more related to levels of social stresses than was severity of fatigue. The main difference between these subjects and those examined in hospital settings is that the former are less liable to attribute their symptoms to wholly physical causes, including viruses, as opposed to social or psychological factors. Identification and management of persistent fatigue in primary care may prevent the secondary disabilities seen in patients with chronic fatigue

				syndromes.
McSherry J.	Department of Family Medicine, University of Western Ontario, London.	Chronic fatigue syndrome. A fresh look at an old problem.	Can Fam Physician 1993 Feb;39:336-40 comment in: Can Fam Physician. 1993 May;39:1022-4	Chronic fatigue syndrome (CFS), an organic disease of unexplained origin, affects about three people in 100,000. Symptoms last approximately 2 1/2 years, and most CFS patients return to normal health. Diagnosis of CFS is by exclusion. No single remedy has yet proven consistently beneficial. Family physicians can help by providing medical validation of disability to persons who might otherwise be seen as malingerers.
Mechanic D.	Institute for Health, Health Care Policy and Aging Research, Rutgers University, New Brunswick, NJ 08903.	Chronic fatigue syndrome and the treatment process.	Ciba Found Symp 1993;173:318-27; discussion 327-41	Fatigue is a common complaint in general practice and is often associated with psychiatric and psychosocial problems and demoralization. Although the Centers for Disease Control definition of chronic fatigue syndrome (CFS) excludes pre-existing psychiatric illness, common psychosocial problems short of a clinical disorder (such as irritability, difficulty in thinking, inability to concentrate, depression and sleep disturbance) overlap with the criteria for CFS. Psychological states can affect the course of CFS or become confused in the patient's and doctor's mind with the course of infection. The core dilemma in practice is how aggressively to pursue a possible basis for CFS when it persists in the absence of an identifiable external cause. Possibilities for exploration are numerous and potentially expensive. In practice, the persistence of doctors depends on the patient's illness behaviour, on financial and organizational factors, and on the culture of medical care and practice styles. It is essential to differentiate the appropriate management of CFS from scientific study where intensive investigation may be warranted. In practice doctors should proceed in a manner that conveys concern, supports function, and avoids dysfunctional illness behaviour and inadvertent legitimization and reinforcement of disability.

Moldofsky H.	Centre for Sleep and Chronobiology, Toronto Hospital, Canada.	Fibromyalgia, sleep disorder and chronic fatigue syndrome.	Ciba Found Symp 1993;173:262-71; discussion 272-9	Various research studies show that the amalgam of disordered sleep physiology, chronic fatigue, diffuse myalgia, and cognitive and behavioural symptoms constitutes a non-restorative sleep syndrome that may follow a febrile illness, as in the chronic fatigue syndrome. Where rheumatic complaints are prominent such a constellation of disturbed sleep physiology and symptoms also characterizes the fibromyalgia disorder. In contrast to the chronic fatigue syndrome, fibromyalgia is associated with a variety of initiating or perpetuating factors such as psychologically distressing events, primary sleep disorders (e.g. sleep apnoea, periodic limb movement disorder) and inflammatory rheumatic

				disease, as well as an acute febrile illness. The chronic fatigue syndrome and fibromyalgia have similar disordered sleep physiology, namely an alpha rhythm disturbance (7.5-11 Hz) in the electroencephalogram (EEG) within non-rapid eye movement (NREM) sleep that accompanies increased nocturnal vigilance and light, unrefreshing sleep. Aspects of cytokine and cellular immune functions are shown to be related to the sleep-wake system. The evidence suggests a reciprocal relationship of the immune and sleep-wake systems. Interference either with the immune system (e.g. by a viral agent or by cytokines such as alpha-interferon or interleukin 2) or with the sleeping-waking brain system (e.g. by sleep deprivation) has effects on the other system and will be accompanied by the symptoms of the chronic fatigue syndrome.
Morris DH, Stare FJ.	Department of Nutrition, Harvard School of Public Health, Boston, Mass.	Unproven diet therapies in the treatment of the chronic fatigue syndrome.	Arch Fam Med 1993 Feb;2(2):181-6	This report is a review of the unproven diet therapies recommended for individuals with chronic fatigue syndrome (CFS). Diet therapies promoted for the relief of CFS symptoms by the authors of five CSF self-help books were evaluated on the basis of nutritional adequacy and scientific rationale. Unproven diet therapies for patients with CFS include megavitamin/mineral supplements; royal jelly and other dietary supplements; and elimination, avoidance, and rotation diets. Claims that these therapies relieve CFS symptoms and promote recovery are anecdotal and have not been substantiated by clinical research. The yeast-avoidance and sugar-free diets, both promoted to combat Candida albicans overgrowth, are of questionable value in treating patients with CFS. The rotation diet is not balanced and does not meet the current recommended dietary intake levels. Diet strategies that call for the avoidance of food additives, preservatives, sweeteners, and other ingredients are not supported by available evidence and are not practical for patients with CFS. A diet plan for patients with CFS should be based on sound nutritional principles and common sense. Until the results of studies demonstrating the benefits of particular diet therapies in the management of CFS are available, patients with CFS are advised to eat a varied diet selected from among and within the basic food groups to ensure an adequate nutrient intake and to reach and maintain a reasonable body weight.
Morriss R, Sharpe M, Sharpley AL, Cowen PJ, Hawton K, Morris J.	MRC Clinical Pharmacology Unit, Littlemore Hospital, Oxford.	Abnormalities of sleep in patients with the chronic fatigue syndrome.	BMJ 1993 May 1;306(6886):1161-4	OBJECTIVE--To determine whether patients with the chronic fatigue syndrome have abnormalities of sleep which may contribute to daytime fatigue. DESIGN--A case-control study of the sleep of patients with the chronic fatigue syndrome and that of healthy volunteers. SETTING--An infectious disease outpatient clinic and subjects' homes. SUBJECTS--12 patients who met research criteria for the chronic fatigue syndrome but not for major depressive disorder and 12 healthy controls matched for age, sex, and weight. MAIN OUTCOME MEASURES--Subjective reports of sleep from patients' diaries and measurement of sleep patterns by polysomnography. Subjects' anxiety, depression, and functional impairment were assessed by interview. RESULTS--Patients with the chronic fatigue syndrome

				spent more time in bed than controls (544 min v 465 min, p < 0.001) but slept less efficiently (90% v 96%, p < 0.05) and spent more time awake after initially going to sleep (31.9 min v 16.6 min, p < 0.05). Seven patients with the chronic fatigue syndrome had a sleep disorder (four had difficulty maintaining sleep, one had difficulty getting to sleep, one had difficulty in both initiating and maintaining sleep, and one had hypersomnia) compared with none of the controls (p = 0.003). Those with sleep disorders showed greater functional impairment than the remaining five patients (score on general health survey 50.4% v 70.4%, p < 0.05), but their psychiatric scores were not significantly different. CONCLUSIONS--Most patients with the chronic fatigue syndrome had sleep disorders, which are likely to contribute to daytime fatigue. Sleep disorders may be important in the aetiology of the syndrome.
Morriss R.		Insomnia in the chronic fatigue syndrome.	BMJ 1993 Jul 24;307(6898):264	
Natelson BH, Cohen JM, Brassloff I, Lee HJ.	Department of Neurosciences, UMDNJ-New Jersey Medical School, Newark 07103.	A controlled study of brain magnetic resonance imaging in patients with the chronic fatigue syndrome.	J Neurol Sci 1993 Dec 15;120(2):213-7	Two neuroradiologists compared the brain MR scans of 52 patients with the CDC criteria for the chronic fatigue syndrome (CFS) with those of 52 age and sex matched controls who had undergone imaging because of histories of head trauma or headache. CFS patients had significantly more abnormal scans than controls--27% vs 2%. Abnormalities seen were foci of increased white matter T2 signal in 9 CFS patients and one control and ventricular or sulcal enlargement in 5 CFS patients. Follow up of patients with subcortical signal hyperintensities revealed 3 who had symptoms suggestive of other known medical causes of what appeared to be CFS. The data indicate that some CFS patients have some organic problem manifesting itself on neuroimaging. But, finding MR abnormalities should warn the physician that the patient's symptoms may be secondary to some other medical illness and not simply primary CFS.
Nixon PG.	Charing Cross Hospital, London.	The grey area of effort syndrome and hyperventilation: from Thomas Lewis to today.	J R Coll Physicians Lond 1993 Oct;27(4):377-83	Lewis used the diagnosis 'effort syndrome' for subjects whose ability to make and sustain effort had been reduced by homeostatic failure. A major element was depletion of the body's capacity for buffering the acids produced by exercise. In his view this systems disorder was not to be regarded as a specific organ disease, and losing sight of the metabolic element would foster the invention of fanciful, unphysiological diagnoses. His views were dismissed because normal resting plasma bicarbonate levels were considered by others in that era to exclude serious depletion of the body's total capacity for buffering the effects of exertion. Today, effort syndrome is still a useful diagnosis for a condition of exhaustion and failure of performance associated with depletion of the body's buffering systems. Other elements associated with homeostatic failure are now recognised, principally emotional hyperarousal and hyperventilation. Their physiological interrelationships are described. Effort syndrome is amenable to recovery through rehabilitation, and it may be a mistake to treat chronic fatigue syndrome

				and unspecific illness without including it in the differential diagnosis.
Norregaard J, Bulow PM, Prescott E, Jacobsen S, Danneskiold-Samsoe B.	Department of Rheumatology C, Frederiksberg Hospital, Copenhagen, Denmark.	A four-year follow-up study in fibromyalgia. Relationship to chronic fatigue syndrome.	Scand J Rheumatol 1993;22(1):35-8	The primary objectives of this study were to examine to what extent fibromyalgia patients later on developed presumpted causative somatic diseases and to examine symptoms and muscle strength some years after the diagnosis of fibromyalgia was established. A secondary objective was to describe the overlap between fibromyalgia and chronic fatigue syndrome. Only in two of 91 the muscle pain was found to be caused by another somatic disease during the median 4 year follow-up period. In one of the 83 attending subjects a somatic disease associated with muscle symptoms was established at the follow-up visit. 60 out of 83 reported increased pain, 8 reported improvement of pain. The 83 subjects showed no significant fall in muscle strength during the follow-up period. The majority reported severe fatigue but only one fifth fulfilled the proposed chronic fatigue syndrome criteria.
Pepper CM, Krupp LB, Friedberg F, Doscher C, Coyle PK.	Department of Psychology, State University of New York, Stony Brook 11794.	A comparison of neuropsychiatric characteristics in chronic fatigue syndrome, multiple sclerosis, and major depression.	J Neuropsychiatry Clin Neurosci 1993 Spring;5(2):200-5	Chronic fatigue syndrome (CFS), a controversial clinical entity characterized by severe fatigue and constitutional symptoms, has been associated with a variety of psychiatric disorders. To further understand the psychiatric profile of CFS, the authors compared patients with CFS, multiple sclerosis (MS), and major depression by using diagnostic interviews and self-report measures of Axis I disorders and personality disorders. CFS patients differed from patients with major depression, with significantly less depression and fewer personality disorders. Compared with MS patients, CFS patients did not differ with regard to personality disorders. However, they did have significantly more frequent current depression than MS patients, particularly following onset of their illness.
Ray C, Phillips L, Weir WR.	Department of Human Sciences, Brunel University, Uxbridge, Middlesex, UK.	Quality of attention in chronic fatigue syndrome: subjective reports of everyday attention and cognitive difficulty, and performance on tasks of focused attention.	Br J Clin Psychol 1993 Sep;32 (Pt 3):357-64	Patients with chronic fatigue syndrome (also known as post-viral fatigue syndrome or myalgic encephalomyelitis) commonly report cognitive difficulties concerning attention, concentration and memory. In this study, patients were compared with matched controls on two questionnaires which assess subjective difficulties with attention and general cognitive functioning, and on two tasks requiring focused attention. Patients reported significantly greater difficulty with attention on the Everyday Attention Questionnaire and more cognitive symptoms on the Profile of Fatigue-Related Symptoms. The objective tests did not clearly indicate a deficit in patients' focused attention; patients tended to perform less well on the Embedded Figures Test and the Stroop Colour-Word Interference Test, but these differences were not significant. There was, however, evidence of psychomotor retardation, with patients having longer response times for word reading and colour naming in the Stroop test. Difficulties in interpreting findings for both subjective and objective cognitive measures are discussed.
Ray C, Weir W, Stewart D, Miller P, Hyde G.	Department of Human Sciences, Brunel University, Uxbridge,	Ways of coping with chronic fatigue syndrome: development	Soc Sci Med 1993 Aug;37(3):385-91	Chronic fatigue syndrome (CFS) is a disorder of uncertain aetiology, and there is uncertainty also about the appropriate way in which patients should manage the illness. An illness management questionnaire (IMQ) was designed to assess

	Middlesex, U.K.	of an illness management questionnaire.		coping in CFS. This was completed by 207 patients, in parallel with the COPE scales (a general measure of coping that can be applied situationally), and measures of functional impairment, anxiety and depression. The IMQ yielded four factors: maintaining activity, accommodating to the illness, focusing on symptoms and information-seeking. Scales based upon these factors together predicted 26, 27 and 22% of the variance in functional impairment, anxiety and depression, respectively, and each scale had significant relationships with relevant scales of the COPE, supporting the interpretation of the factors. It is suggested that the IMQ may be employed to relate ways of coping to outcomes in CFS, and to assess coping as a mediator of change in cognitive-behavioural interventions.
Robin R, Lipkin DM, Hume GW.		Taking exception to chronic fatigue syndrome prevalence findings by Price, et al.	Public Health Rep 1993 Jan-Feb;108(1):135-7 comment on: Public Health Rep. 1992 Sep-Oct;107(5):514-22	
Sharpe M.	University of Oxford Department of Psychiatry, Warneford Hospital, UK.	Non-pharmacological approaches to treatment.	Ciba Found Symp 1993;173:298-308; discussion 308-17	Chronic fatigue syndrome (CFS) as currently defined overlaps with other syndromes including chronic pain, fibromyalgia, anxiety and depression. It also resembles historical descriptions of neurasthenia. The role of psychological (cognitive) and behavioural therapies in CFS is examined. There are both pragmatic and theoretical arguments for their application to CFS. It is pragmatic to target obvious and treatable factors including inactivity and depression. A theoretical model in which psychological, physiological and social factors interact offers a plausible rationale for such treatment but is not yet empirically proven. While there is evidence for the efficacy of this type of therapy in related syndromes, the evidence in CFS is inconclusive. A randomized controlled trial of combined cognitive and behavioural therapy currently in progress is described. Initial results suggest that most patients receiving cognitive behaviour therapy improve, especially in terms of functional impairment. It remains to be seen whether this therapy will prove to be more effective than standard general practitioner care. In the meantime cognitive behaviour therapy offers a pragmatic and rational therapy for patients with CFS. Randomized Controlled Trial Review Review, Tutorial

	Medicine, University of Toronto, Ontario, Canada.		discussion 16-22	19th century. Its first eruption was the so-called 'bed cases' or 'sofa cases' among middle-class females in the period from 1860 to about 1910. 'Neurasthenia' does not necessarily represent an early forerunner of chronic fatigue. Many patients receiving that diagnosis did not complain of fatigue. Others with functional fatigue did not receive the diagnosis 'neurasthenia'. Both medical-anecdotal and quantitative sources make it clear that by the time of the First World War, chronic fatigue was a common complaint in Europe and North America. Medical concepts of chronic fatigue since the 1930s have run along four separate lines: (1) 'postinfectious neuromyasthenia', going back to an atypical 'poliomyelitis' epidemic in 1934; (2) 'chronic Epstein-Barr virus' infection, an illness attribution that increased in frequency after the discovery in 1968 that this virus caused mononucleosis; (3) 'myalgic encephalomyelitis', dating from an epidemic at the Royal Free Hospital in London in 1955; and (4) 'fibrositis', or 'fibromyalgia', used as a rheumatological description since the turn of the century. Recently, these four separate paths have tended to converge into the diagnosis of 'chronic fatigue syndrome'.

Smith AP, Behan PO, Bell W, Millar K, Bakheit M.	Health Psychology Research Unit, School of Psychology, University of Wales College of Cardiff.	Behavioural problems associated with the chronic fatigue syndrome.	Br J Psychol 1993 Aug;84 (Pt 3):411-23	Disturbances of memory, concentration and motor function are often reported by patients with the chronic fatigue syndrome (CFS). The present study objectively evaluated these behavioural problems using a computerized test battery measuring memory, attention and motor skills. Fifty-seven CFS patients were compared with 19 matched controls and all subjects completed the performance test battery and filled in questionnaires measuring psychopathology and mood. The patients reported significantly higher levels of depression, anxiety, physical symptoms and cognitive failures than the controls. Similarly, they reported more negative affect at the time of testing. The patients were slower on psychomotor tasks, showed increased visual sensitivity and impaired attention. Digit span and free recall were not impaired but retrieval from semantic memory and logical reasoning were slower. None of the performance differences between patients and controls could be attributed to differences in psychopathology. These results agree with recent findings from other laboratories, and it is now time to consider the nature of the neurological dysfunction underlying these effects.

McHugh GL, Logigian EL.	Rheumatology/Immunology, New England Medical Center, Boston, MA 02111.	Lyme disease.	14;269(14):1812-6 comment in: JAMA. 1993 Dec 8;270(22):2682-3 JAMA. 1993 Dec 8;270(22):2682; discussion 2683 JAMA. 1993 Dec 8;270(22):2683	results of the patients evaluated in a Lyme disease clinic, both prior to referral and from current evaluation. DESIGN--Retrospective case survey of prescreened patients. SETTING--Research and diagnostic Lyme disease clinic in a university hospital. PATIENTS--All 788 patients referred to the clinic during a 4.5-year period who were thought by the referring physician or the patient to have a diagnosis of Lyme disease. MAIN OUTCOME MEASUREMENTS--Symptoms and signs of disease, immunodiagnostic tests of Lyme disease, and tests of neurological function. RESULTS--Of the 788 patients, 180 (23%) had active Lyme disease, usually arthritis, encephalopathy, or polyneuropathy. One hundred fifty-six patients (20%) had previous Lyme disease and another current illness, most commonly chronic fatigue syndrome or fibromyalgia; and in 49 patients, these symptoms began soon after objective manifestations of Lyme disease. The remaining 452 patients (57%) did not have Lyme disease. The majority of these patients also had the chronic fatigue syndrome or fibromyalgia; the others usually had rheumatic or neurological diseases. Of the patients who did not have Lyme disease, 45% had had positive serological test results for Lyme disease in other laboratories, but all were seronegative in our laboratory. Prior to referral, 409 of the 788 patients had been treated with antibiotic therapy. In 322 (79%) of these patients, the reason for lack of response was incorrect diagnosis. CONCLUSIONS--Only a minority of the patients referred to the clinic met diagnostic criteria for Lyme disease. The most common reason for lack of response to antibiotic therapy was misdiagnosis.
Steere AC.	Tufts University School of Medicine, Boston.	Current understanding of Lyme disease.	Hosp Pract (Off Ed) 1993 Apr 15;28(4):37-44	It is now the most common vector-borne disease in the United States. But because of misdiagnosis, the spread of this disease may also be more apparent than real. Lack of standardized serologic tests and varying clinical presentations do create confusion. Nevertheless, it is possible to distinguish Lyme disease from look-alike disorders, such as chronic fatigue syndrome and fibromyalgia.

Lymphocyte phenotype and function in the chronic fatigue syndrome.	J Clin Immunol 1993 Jan;13(1):30-40	Lymphocytes of 18 patients meeting the Centers for Disease Control (CDC) case definition for the chronic fatigue syndrome (CFS), 10 similar, chronically fatigued patients not fully conforming to the CDC case definition, and 17 matched, healthy individuals were studied to determine the presence of abnormalities of peripheral cell phenotype and function. Extensive phenotypic analyses of B- and T-cell subsets, natural killer (NK) cells, and macrophages were performed using single-, dual-, and three-color flow cytometry. Compared to controls, in CFS patients the percentage of CD4 T cells and CD4,CD45RA, or naive T cells, was

				reduced. The CD4,CD45RO, or memory T-cell, subset was numerically normal but expressed increased levels of adhesion markers (CD29, CD54, and CD58). CFS patient lymphocytes showed reduced proliferative responses to phytohemagglutinin, concanavalin A, and staphylococcal enterotoxin B. Lymphocytes from fatigue patients not meeting the CDC definition showed similar abnormalities. These data indicate that peripheral T cells manifest an increased state of differentiation in CFS and related conditions. This may arise as a consequence of an underlying neuropsychiatric and/or neuroendocrine disorder or because of exposure to antigens or superantigens of an infectious agent.
Straus SE.	Laboratory of Clinical Investigation, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD 20892.	Studies of herpesvirus infection in chronic fatigue syndrome.	Ciba Found Symp 1993;173:132-9; discussion 139-45	The relationship of herpesviruses to chronic fatigue syndrome has received considerable attention over the past decade. Data suggesting an association fall into three major categories. First, among acute precipitants of the syndrome are primary infections with some herpesviruses, most notably Epstein-Barr virus and cytomegalovirus. Second, a series of studies have detailed elevations of antibodies to most herpesviruses in selected chronic fatigue syndrome populations, with Epstein-Barr virus and human herpes type 6 being the objects of most scrutiny. Third, one recent study reported a greater ease of recovery of human herpes virus type 6 from chronic fatigue syndrome patients. This review article critically examines the cumulative data regarding an association between one or more herpesviruses and the chronic fatigue syndrome in the context of the known biology and epidemiology of these agents. In view of these, and additional considerations regarding study methodologies, the conclusion is drawn that herpesviruses are not dominant causes of the chronic fatigue syndrome and may not even be necessary to the perpetuation of the illness, but it is premature to dismiss entirely this latter possibility.

Fatigue, depression, and social adjustment in chronic fatigue syndrome.	Arch Dis Child 1993 Mar;68(3):384-8	The aims of this study were to determine the characteristics and perceived levels of fatigue and the prevalence of depression in children with chronic fatigue syndrome and to assess the effects of illness on schooling and social functioning. Twelve children with chronic fatigue syndrome were compared with a matched group of children with cystic fibrosis and matched healthy controls. Levels of fatigue (fatigue questionnaire), depression (children's depression inventory), and social adjustment (semistructured interview with parents) were compared between groups. Children with chronic fatigue syndrome had significantly higher median scores for physical and mental fatigue and depressive symptomatology than either comparison group and five children scored as depressed on the children's depression inventory. Schooling and social functioning were seriously disrupted. Children with chronic fatigue syndrome reported high levels of fatigue affecting both physical and mental functioning, the association with depression found in adult studies was confirmed, and social adjustment was poor.
Ware NC.	Department of Social Medicine, Harvard Medical School, Boston, MA 02115.	Society, mind and body in chronic fatigue syndrome: an anthropological view.	Ciba Found Symp 1993;173:62-73; discussion 73-82	An anthropological view of chronic fatigue syndrome places the study of illness in social context. Data from an interview study of 50 chronically fatigued patients demonstrate the relation of local social worlds--families, workplaces, communities--to the meaning and experience of illness. Negative life events and difficulties, multiple commitments, and a hectic pace are among prominent themes in the subjects' local worlds. These themes are reflected in: (1) attributions of illness onset to social sources, (2) the symbolism of the core complaint of fatigue, and (3) an illness-induced, positively valued lifestyle transformation suggesting the rejection of culturally prescribed 'busyness'. Dichotomous definitions of the relation of mind and body are shown to be part of culture, not Nature, in the paper's second section. The 'mind-body dichotomy' and the differing values attached to physical and psychological disorders by a naturalistic scientific paradigm explain the delegitimizing experiences of sufferers, who find their illness dismissed as psychosomatic and therefore 'not real'. A conceptualization of chronic fatigue syndrome which links local social worlds to psychological distress, felt bodily sensation and biological changes is proposed. Collaborative teams of social scientists and medical researchers might fruitfully pursue aspects of social context in relation to psychiatric, immunological and viral dimensions of the illness.

Wessely S.	Department of Psychological Medicine, Institute of Psychiatry, De Crespigny Park, London, UK.	The neuropsychiatry of chronic fatigue syndrome.	Ciba Found Symp 1993;173:212-29; discussion 229-37	This paper explores the relationship between chronic fatigue syndrome (CFS) and psychiatric disorder, with special reference to neuropsychiatry, Topics reviewed include (1) epidemiological evidence of central disorder in CFS; (2) evidence from longitudinal studies of an interaction between vulnerability to CFS and psychiatric disorder; and (3) evidence from neuroimaging, neuropsychology, neurophysiology and neuroendocrinology of disordered CNS function in CFS. The most impressive evidence of CNS disturbance comes from neuroendocrinological studies, which suggest a role of hypothalamic disorder as a final common pathway for CFS. It is concluded that the equal and opposite tendencies of psychiatry to be 'brainless' and neurology to be 'mindless' have led to needless controversy over the nature of CFS. Now that the contributions of psychiatric disorder to CFS, and of neurobiological dysfunction to psychiatric disorder, are both established, it will be possible to make real advances in understanding the nature of CFS.

Bell DS.	Harvard Medical School, Boston, Massachusetts.	Chronic fatigue syndrome. Recent advances in diagnosis and treatment.	Postgrad Med 1992 May 1;91(6):245-52	Chronic fatigue syndrome is a chronic debilitating illness that is marked in the majority of cases by sudden onset of fatigue and flulike symptoms. Symptoms subsequently relapse and remit and may persist for years. Physical examination typically reveals relatively minor, nonspecific abnormalities in an apparently well patient. Although immunologic abnormalities are associated with chronic fatigue syndrome, tests for these features are expensive, nonspecific, and generally reserved for research purposes. The diagnosis is made on the basis of new onset of severe fatigue, a characteristic pattern of symptoms, and exclusion of other illnesses. Treatment is aimed at alleviating symptoms and helping patients adjust to the debilitating and chronic nature of the illness. Review Literature

Berneman ZN, Ablashi DV, Li G, Eger-Fletcher M, Reitz MS Jr, Hung CL, Brus I, Komaroff AL, Gallo RC.	Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, MD 20892.	Human herpesvirus 7 is a T-lymphotropic virus and is related to, but significantly different from, human herpesvirus 6 and human cytomegalovirus.	Proc Natl Acad Sci U S A 1992 Nov 1;89(21):10552-6	An independent strain (JI) of human herpesvirus 7 (HHV-7) was isolated from a patient with chronic fatigue syndrome (CFS). No significant association could be established by seroepidemiology between HHV-7 and CFS. HHV-7 is a T-lymphotropic virus, infecting CD4+ and CD8+ primary lymphocytes. HHV-7 can also infect SUP-T1, an immature T-cell line, with variable success. Southern blot analysis with DNA probes scanning 58.8% of the human herpesvirus 6 (HHV-6) genome and hybridizing to all HHV-6 strains tested so far revealed homology to HHV-7 with only 37.4% of the total probe length. HHV-7 contains the GGGTTA repetitive sequence, as do HHV-6 and Marek's disease chicken herpesvirus. DNA sequencing of a 186-base-pair fragment of HHV-7(JI) revealed an identity with HHV-6 and human cytomegalovirus of 57.5% and 36%, respectively. Oligonucleotide primers derived from this sequence (HV7/HV8, HV10/HV11) amplified HHV-7 DNA only and did not amplify DNA from other human herpesviruses, including 12 different HHV-6 strains. Southern blot analysis with the p43L3 probe containing the 186-base-pair HHV-7 DNA fragment hybridized to HHV-7 DNA only. The molecular divergence between human cytomegalovirus, on the one hand, and HHV-6 and HHV-7, on the other, is greater than between HHV-6 and HHV-7, which, in turn, is greater than the difference between HHV-6 strains. This study supports the classification of HHV-7 as an additional member of the human beta-herpesviruses.

This article includes case material focusing on a woman who was medically diagnosed with the Epstein-Barr virus and was in psychotherapy with the author. The difficulty of managing the interplay of the real health problems and the emotional issues presented by the client is highlighted.
Calabrese L, Danao T, Camara E, Wilke W.	Cleveland Clinic Foundation, Ohio.	Chronic fatigue syndrome.	Am Fam Physician 1992 Mar;45(3):1205-13	Fatigue is one of the most common complaints among patients seen in the primary care setting. Chronic fatigue syndrome, which has recently been called chronic fatigue immune dysfunction syndrome, is distinctive, with an abrupt onset of symptoms that wax and wane for at least six months. Usually there is low-grade fever, pharyngitis and tender, but not enlarged, lymph nodes. The fatigue can be disabling and is often made worse by physical activity. Some patients with this disorder have also been found to have highly characteristic immunologic abnormalities. Treatment can be rewarding and is based on patient education and support, exercise and symptomatic therapies for abnormal sleep patterns, musculoskeletal pain and other symptoms.

Immunologically mediated fatigue: a murine model.	Clin Immunol Immunopathol 1992 Aug;64(2):161-5	Chronic fatigue syndrome (CFS) is an idiopathic disorder in which the chief symptoms is profound fatigue. To explore the relationship between immune stimulation and fatigue, we developed a murine model for quantifying fatigue: reduction in voluntary running and delayed initiation of grooming after swimming. Inoculation of female BALB/c mice with Corynebacterium parvum antigen or the relatively avirulent Me49 strain of Toxoplasma gondii induced fatigue: baseline running reduced to less than 50 and 30% for 8 and 14 days, respectively, and delayed initiation of grooming after swimming in both immunologically stimulated groups. A threefold evaluation of serum transforming growth factor-beta levels, a cytokine increased in CFS patients, was found in fatigued C. parvum- and T. gondii-inoculated mice. This murine model appears promising for investigation of the pathogenesis of immunologically mediated fatigue.

Plasma and cerebrospinal fluid monoamine metabolism in patients with chronic fatigue syndrome: preliminary findings.	Biol Psychiatry 1992 Dec 15;32(12):1065-77	The syndrome of chronic fatigue, feverishness, diffuse pains, and other constitutional complaints, often precipitated by an acute infectious illness and aggravated by physical and emotional stressors, has a lengthy history in the medical literature. The Centers for Disease Control (CDC) recently formulated a case definition, renaming the illness "chronic fatigue syndrome." Nevertheless, there remain few biological data that can validate the existence of this syndrome as distinct from a wide variety of other, largely psychiatric disorders, and little

				understanding of its pathogenesis. In the present study, basal plasma and cerebrospinal fluid levels of the monoamine metabolites, 3-methoxy-4-hydroxyphenylglycol (MHPG), 5-hydroxyindoleacetic acid (5-HIAA), and homovanillic acid (HVA) were determined in 19 patients meeting CDC research case criteria for chronic fatigue syndrome and in 17 normal individuals. Patients with chronic fatigue syndrome showed a significant reduction in basal plasma levels of MHPG and a significant increase in basal plasma levels of 5-HIAA. Although the functional significance of these findings has not been definitively elucidated, they are compatible with the clinical presentation of a syndrome associated with chronic lethargy and fatigue, and with evidence of persistent immune stimulation, and lend support to the idea that chronic fatigue syndrome represents a clinical entity with potential biological specificity.

Downey DC.	Oregon Health Sciences University, School of Dentistry, Portland 97201.	Fatigue syndromes: new thoughts and reinterpretation of previous data.	Med Hypotheses 1992 Oct;39(2):185-90	Recently, the author has identified 19 patients who have complained of marked fatigue that had abnormal responses to copper test bracelets or necklaces. At this time, 8 have been shown to have at least one enzyme deficiency in the heme pathway. These patients have been diagnosed with multiple sclerosis, chronic fatigue syndrome and other non-specific diagnoses. A lengthy but still limited review of the literature was performed regarding the following conditions: multiple sclerosis (MS), hepatic porphyria (HP), chronic fatigue syndrome (CFS) and paralytic polio (PP). The text will focus on similar epidemiologies, laboratory findings and clinical courses. Copper as a common but not unique etiologic agent will be discussed; as will the heme pathway, a biologic process that may be disordered in all.
Drago F, Romagnoli M, Loi A, Rebora A.	Department of Dermatology, University of Genoa, Italy.	Epstein-Barr virus-related persistent erythema multiforme in chronic fatigue syndrome.	Arch Dermatol 1992 Feb;128(2):217-22	BACKGROUND--Erythema multiforme (EM) has been rarely reported in Epstein-Barr virus (EBV)-associated diseases; this includes patients with chronic fatigue syndrome who have chronic or recurrent and disabling illness and an abnormal antibody reactivity to EBV. We describe a patient fulfilling the chronic fatigue syndrome diagnostic criteria who had developed an unusually persistent EM resistant to corticosteroids therapy. The EBV DNA was studied in skin EM lesions, throat washings, peripheral mononuclear cells, and plasma. The EBV antigens were studied in skin EM lesions and in mononuclear cells. The patient was

				followed up to 2 years. OBSERVATIONS--The patient had abnormal titers of antibodies against various EBV antigens and by immunofluorescence she disclosed the EBV nuclear antigen and the viral capsid antigen in the blood vessels of the affected skin. The dot blot hybridization assay detected viral DNA in throat washings and mononuclear cells, but not in plasma. The presence of the viral genomic content in lesional skin is suggested by the autoradiographic signal and by the difference from appropriate control specimens. Skin lesions and constitutional symptoms cleared after acyclovir sodium therapy and recurred after discontinuation of this therapy. CONCLUSIONS--This is the first EM case in which evidence of the EBV causal role has been provided. The association with chronic fatigue syndrome suggests the EBV role in selected cases of this syndrome.

J Manipulative Physiol Ther 1992 Oct;15(8):529-35 Erratum in: J Manipulative Physiol Ther 1992 Nov-Dec;15(9):followi	A 36-yr-old white female presented with severe fatigue and symptoms consistent with immune deficiency, but was later found to be suffering from chronic fatigue syndrome. This article discusses the diagnostic criteria for this condition. Chiropractic manipulation afforded relief of some symptoms for this patient.
Ginsburg KS, Kundsin RB, Walter CW, Schur PH.	Department of Rheumatology and Immunology, Brigham and Women's Hospital, Boston, MA 02115.	Ureaplasma urealyticum and Mycoplasma hominis in women with systemic lupus erythematosus.	Arthritis Rheum 1992 Apr;35(4):429-33	OBJECTIVE. To determine the prevalence of genitourinary mycoplasma infection in women with systemic lupus erythematosus (SLE). METHODS. Urine specimens from 49 patients with SLE and 22 patients with chronic fatigue syndrome (CFS) were cultured for mycoplasma. Patient records were reviewed for medical history and SLE disease activity. RESULTS. Sixty-three percent of the SLE patients were culture positive, compared with 4.5% of the CFS patients (P less than 0.001). Neither corticosteroid treatment, SLE activity, nor age accounted for this difference. CONCLUSION. Genitourinary mycoplasma colonization occurs significantly more frequently in SLE than in CFS.
Goldenberg DL.	Newton-Wellesley Hospital, Massachusetts.	Fibromyalgia, chronic fatigue, and myofascial pain syndromes.	Curr Opin Rheumatol 1992 Apr;4(2):247-57	During the past year many studies have been published on fibromyalgia and chronic fatigue syndromes. Randomized clinical trials using current operational diagnostic criteria were reported, but no single therapy has been highly effective in either condition. The working case definition of chronic fatigue syndrome has been criticized and suggestions for a new case definition have been made. Further understanding of the overlap of these three common disorders will also require that uniform diagnostic criteria be tested in chronic fatigue syndrome and myofascial pain syndrome.
Goodnick PJ, Sandoval R, Brickman A, Klimas NG.	Department of Psychiatry, University of Miami, Florida 33136.	Bupropion treatment of fluoxetine-resistant chronic fatigue syndrome.	Biol Psychiatry 1992 Nov 1;32(9):834-8	Chronic fatigue syndrome (CFS) includes many symptoms of major depression. For this reason, many antidepressants have been used to treat the symptoms of this disorder. Among the more recently released antidepressants are fluoxetine and bupropion. In this open study, nine CFS patients who either could not tolerate or did not respond to fluoxetine showed significant response when administered 300 mg/day of bupropion for an 8-week period in both rating of HDRS ($t = 4.80$, $p < 0.01$) and BDI ($t = 2.48$, $p < 0.05$). Furthermore, bupropion improvement in Hamilton Depression Rating Scale correlated significantly with change in plasma homovanillic acid (HVA) ($r = 0.96$, $p < 0.01$). Plasma total methylhydroxyphenolglycol (MHPG) also increased significantly during bupropion treatment ($t = 2.37$, $p = 0.05$). Measures of T1 microsomal antibodies also decreased over treatment time; increases in natural killer cell numbers correlated inversely with change in plasma levels of free MHPG ($r = -0.88$, $p < 0.05$). Bupropion responders were more likely to have trough blood levels above 30 ng/ml (chi 2 = 3.6, $p = 0.05$).

J Clin Pathol 1992 Dec;45(12):1058-61	AIM: To examine peripheral blood and skeletal muscle from patients with chronic fatigue syndrome for exogenous retrovirus. METHODS: Blood samples from 30 patients and muscle biopsy specimens of 15 patients were examined for retroviral sequences by DNA extraction, polymerase chain reaction (PCR), and Southern blotting hybridisation. Sera were examined for human foamy virus by western immunoblotting and indirect immunofluorescence techniques. RESULTS: No differences between the patient and control populations was found for any of the PCR primer sets used (gag, pol, env, and tax regions of HTLV I/II). An endogenous gag band was observed in both the patient and control groups. All sera were negative for antibody to human foamy virus. CONCLUSION: The results indicate that there is no evidence of retroviral involvement in the chronic fatigue syndrome.
Grau JM, Casademont J, Pedrol E, Fernandez-Sola J, Cardellach F, Barros N, Urbano-Marquez A.	Department of Internal Medicine, Hospital Clinic i Provincial, Barcelona, Spain.	Chronic fatigue syndrome: studies on skeletal muscle.	Clin Neuropathol 1992 Nov-Dec;11(6):329-32	Chronic fatigue syndrome represents a poorly defined disease with protean clinical manifestations, the majority of them expressed as a muscle fatigue or as inability to maintain the expected muscle strength. In the present work we studied muscle function and muscle histopathology in 20 patients fulfilling the proposed criteria for chronic fatigue syndrome. Special interest is directed towards the immunoreactive expression of class I MHC molecules comparing some inflammatory and virus-related myopathies with muscles from chronic fatigue syndrome. Only minor morphological changes were detected in 9 out of 20 patients of the series. The nonspecific morphological changes in muscle tissue and the lack of class I MHC expression does not support the viral etiology of muscle fatigue in chronic fatigue syndrome. In contrast with the reported clinical improvement with high doses of essential fatty acids, our patients' clinical condition did not improve after three months of L-carnitine therapy.
Hashimoto N, Kuraishi Y, Yokose T, Tajima N,	3rd Dept. Internal Medicine, Jikei Univ.	[Chronic fatigue syndrome--51 cases in	Nippon Rinsho 1992 Nov;50(11):2653-64	Between April 1991 and August 1992, we diagnosed 51 cases of CFS who met definition of CFS designated by CDC, 1988. They are 41 female and 11 male, and

Mochio S, Shimizu M, Yokoyama J, Kobayashi N, Nohara A, Taniguchi I, et al.	School of Medicine.	the Jikei University School of Medicine].[article in Japanese]		78% are women. At first visit, their ages are ranged from 16 to 64 years old, and approximately 45% is 20 to 30 years old. In periods of illness from onset, 39.2% of the patients are in period of 6 month to 1 year, 19.6% within 2 years, and 15.6% within 3 years, respectively. The sufferer who have symptoms of CFS over 10 years long are in 6 cases. Most of patients have already been examined by many other clinics and hospitals. They have been told as no abnormal medical condition, or often as neurosis, depressive state and autonomous imbalance etc. Interesting things are trigger of CFS. 77.5% of patients have onset of flu-like symptom, including 5 cases of acute infectious mononucleosis. In many female patients, symptoms of CFS begun after hand work in addition to psychological factors. Specific laboratory results are not shown in CBC, urinalysis, biochemical studies and inflammatory marhers. 6 cases hare positive Rheumatoid factor and positive ANF are shown in 16 cases (31.3%). Specific patterns of anti EBV antibodies are not shown. Lymphocyte subsets used by monoclonal antibodies are not specific. At the present, prognosis is good and 56.8% of CFS patients are generally improved. For severe cases, NSAID, Sulpiride, Amitryptiline and minor tranquilizer are used.
Hashimoto N.	3rd Dept. Internal Medicine, Jikei Univ. School of Medicine.	[Definition of the chronic fatigue syndrome and its issues].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2591-9	This article reviewed Definition of CFS proposed by CDC 1988. There are several issues in Definition for CFS of CDC. It is presented that other chronic clinical conditions have been satisfactorily excluded, including preexisting psychiatric diseases in (2) of major criteria. However, fibromyalgia can not be excluded from the fifth symptom of minor criteria, myalgia, and also depression from the ninth symptom. It is practically difficult to define impairment of average daily activity below 50% of the patient's premorbid activity level for a period of at least 6 months, as shown in (1) of major criteria, and it is not adapted for a first visit patient. Definition for CFS of CDC has been discussed on EBV infection, but not written on postviral fatigue syndrome and myalgic encephalomyelitis. Especially whether epidemic type of CFS is present or not was not discussed. Diagnostic criteria of CFS is necessary for clinical practice. Review Literature
Hickie I, Lloyd A, Wakefield D.	Mood Disorders Unit, Prince Henry Hospital, Little Bay, NSW.	Immunological and psychological dysfunction in patients receiving immunotherapy for chronic fatigue syndrome.	Aust N Z J Psychiatry 1992 Jun;26(2):249-56	Associations between immunological and psychological dysfunction in 33 patients with Chronic Fatigue Syndrome (CFS) were examined before and in response to treatment in a double blind, placebo-controlled trial of high dose intravenous immunoglobulin. Only those patients who received active immunotherapy demonstrated a consistent pattern of correlations between improvement in depressive symptoms and markers of cell-mediated immunity (CMI). This finding lends some support to the hypothesis that depressive symptoms in patients with CFS occur secondary to, or share a common pathophysiology with, immunological dysfunction. This pattern and the lack of strong associations between depression and immunological disturbance prior to treatment are less supportive of the view that CFS is primarily a form of

				depressive disorder or that immunological dysfunction in patients with CFS is secondary to concurrent depression.

Aust Fam Physician 1992 Mar;21(3):278-9, 283-5 comment in: Aust Fam Physician. 1993 Apr;22(4):635	There is no doubt that the chronic fatigue syndrome exists. It is a condition that is debilitating and of unknown cause. Research into chronic fatigue syndrome demonstrates possible psychiatric or organic causes. The truth may be somewhere in between. Evidence for the existence of an ongoing chronic infection is now not convincing. Treatment should be based on supportive counselling, explanation, psychiatric help (both pharmacological and non pharmacological) and a graded programme of increased activity with the eventual aim of resumption of full functioning.

Hudson JI, Goldenberg DL, Pope HG Jr, Keck PE Jr, Schlesinger L.	Biological Psychiatry Laboratory, McLean Hospital, Belmont, Massachusetts 02178.	Comorbidity of fibromyalgia with medical and psychiatric disorders.	Am J Med 1992 Apr;92(4):363-7	PURPOSE: Patients with fibromyalgia have been reported to display high rates of several concomitant medical and psychiatric disorders, including migraine, irritable bowel syndrome, chronic fatigue syndrome, major depression, and panic disorder. To test further these and other possible associations, we assessed the personal and family histories of a broad range of medical and psychiatric disorders in patients with fibromyalgia. PATIENTS AND METHODS: Subjects were 33 women (mean age 42.1 years) who each met American College of Rheumatology criteria for fibromyalgia and presented to a rheumatologist at a tertiary referral center. They received the Structured Clinical Interview for DSM-III-R (SCID); a supplemental interview, in SCID format, for other medical and psychiatric disorders, including migraine, irritable bowel syndrome, and chronic fatigue syndrome; and an interview for family history of medical and psychiatric disorders. RESULTS: Patients with fibromyalgia displayed high lifetime rates of migraine, irritable bowel syndrome, chronic fatigue syndrome, major depression, and panic disorder. They also exhibited high rates of familial major mood disorder. CONCLUSIONS: The finding that migraine, irritable bowel syndrome, chronic fatigue syndrome, major depression, and panic disorder are frequently comorbid with fibromyalgia is consistent with the hypothesis that these various disorders may share a common physiologic abnormality.
Ichise M, Salit IE, Abbey SE, Chung DG, Gray B, Kirsh JC, Freedman M.	Department of Radiology (Division of Nuclear Medicine), University of Toronto, Canada.	Assessment of regional cerebral perfusion by 99Tcm-HMPAO SPECT in chronic fatigue syndrome.	Nucl Med Commun 1992 Oct;13(10):767-72	Chronic fatigue syndrome (CFS) is a severely disabling illness of uncertain aetiology. It is characterized by a chronic, sustained or fluctuating sense of debilitating fatigue without any other known underlying medical conditions. It is also associated with both somatic and neuropsychological symptoms. Both physical and laboratory findings are usually unremarkable. Regional cerebral blood flow (rCBF) was assessed in 60 clinically defined CFS patients and 14 normal control (NC) subjects using 99Tcm-hexamethylpropyleneamine oxime (99Tcm-HMPAO) single photon emission computed tomography (SPECT). Compared with the NC group, the CFS group showed significantly lower cortical/cerebellar rCBF ratios, throughout multiple brain regions ($P < 0.05$). Forty-eight CFS subjects (80%) showed at least one or more rCBF ratios

				significantly less than normal values. The major cerebral regions involved were frontal (38 cases, 63%), temporal (21 cases, 35%), parietal (32 cases, 53%) and occipital lobes (23 cases, 38%). The rCBF ratios of basal ganglia (24 cases, 40%) were also reduced. 99Tcm-HMPAO brain SPECT provided objective evidence for functional impairment of the brain in the majority of the CFS subjects. The findings may not be diagnostic of CFS but 99Tcm-HMPAO SPECT may play an important role in clarifying the pathoaetiology of CFS. Further studies are warranted.

Kanayama Y.	Second Department of Internal Medicine, Osaka University Medical School.	[Chronic fatigue syndrome--symptoms, signs, laboratory tests, and prognosis].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2586-90	Chronic fatigue syndrome (CFS) is an undefined clinical problem and is perceived as a complex of multiple symptomatology with an unexplained persistent fatigue. Major symptoms include fatigue lasting for more than 6 months, low-grade fever, moderate lymphadenopathy, muscle and joint pain, and various psychological presentations. Since no specific laboratory tests are available, clinical diagnosis demands that known causes of chronic fatigue should be excluded. The pathogenesis is at present unknown, but it is suspected that CFS is a physical and psychological condition associated with some unrecognized infectious agent. Further study is needed to clarify the precise pathophysiology of this newly recognized entity. Review Literature

[Chronic fatigue syndrome, a case of high anti-HHV-6 antibody titer and one associated with primary hyperaldosteronism].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2673-8	Two cases of chronic fatigue syndrome (CFS) were reported which were suggestive for the study of the etiology and a cure for CFS. Case 1: A 31-year-old woman was admitted for chronic fatigue syndrome. Examination revealed a high titer of anti HHV-6 antigen of x2560 and an increased percentage of suppressor T lymphocytes in the peripheral blood. HHV-6 was speculated to be reactivated and stimulating the immune system in CFS. Case 2: A 46-year-old woman suffering from CFS had been in remission for 6 years. She was admitted for hypertension associated with right adrenal adenoma and hyperaldosteronism. After right adrenalectomy, there was a recurrence of high fever and other CFS symptoms. It

				was suggested that CFS symptoms may be ameliorated by aldosterone.
Katon W, Russo J.	Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle 98195.	Chronic fatigue syndrome criteria. A critique of the requirement for multiple physical complaints.	Arch Intern Med 1992 Aug;152(8):1604-9 comment in: Arch Intern Med. 1992 Aug;152(8):1569-70	OBJECTIVE. The purpose of this study was to test the hypothesis that the patients with chronic fatigue who have the highest number of medically unexplained physical symptoms over their lifetime would also have the highest prevalence of current and lifetime affective and anxiety disorders, lifetime affective symptoms, and the most functional disability. A further goal was to use this information to modify the current case definition to better identify a subgroup of patients with chronic fatigue syndrome who are less likely to have psychiatric illness. DESIGN. Two hundred eighty-five consecutive patients with chronic fatigue were interviewed with the National Institute of Mental Health Diagnostic Interview Schedule and completed four self-rating questionnaires measuring psychologic distress, functional disability, and the tendency to amplify symptoms. Based on previously published data, patients were divided into four groups with a progressively higher number of lifetime medically unexplained physical symptoms. The prevalence of current and lifetime psychiatric disorders, lifetime psychologic symptoms, and extent of functional impairment was then compared in these four groups of patients. MAIN RESULTS. The prevalence of current and lifetime psychiatric diagnosis and lifetime depressive symptoms increased linearly with the number of lifetime physical symptoms that the patient experienced. The extent of impairment in activities of daily living and the tendency to amplify symptoms also increased linearly with the number of medically unexplained physical symptoms. CONCLUSION. The patients with the highest numbers of medically unexplained physical symptoms had extraordinarily high rates of current and lifetime psychiatric disorders. These data suggest that the current case definition for chronic fatigue syndrome inadvertently selects for patients with the highest prevalence of lifetime psychiatric diagnoses. A recommendation based on these results is to modify the case criteria for chronic fatigue syndrome to include patients with fatigue and few physical symptoms and to identify and consider excluding patients with high numbers of physical complaints.
Kawa K.	Dept. Pediatrics, Osaka Medical Center.	[Chronic fatigue syndrome in school children].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2606-11	Chronic fatigue syndrome (CFS) is characterized by persistent or relapsing debilitating fatigue for at least 6 months without any apparent medical diagnosis that would explain the clinical presentation. Although, most of the reported patients are over age 30, CFS also affects school children. To better understand CFS, the network of the central nervous-endocrine-immune systems should be considered, and one must be careful to distinct CFS from school absenteeism and other psychosomatic disorders often seen among them. Review Literature
Kawai K, Kawai A.	Kawai Internal Medicine Clinic, Tokyo, Japan.	Studies on the relationship between chronic fatigue syndrome and Epstein-	Intern Med 1992 Mar;31(3):313-8	Among 1,153 consecutive patients, 22 patients (1.9%) who complained of chronic fatigue for a period of over 6 months without detectable causes were studied. Ten patients (0.86%) satisfied the criteria of chronic fatigue syndrome (CFS) and were classified to be definite cases of CFS. The other patients were classified as

		Barr virus in Japan.		probable cases. In order to clarify the role of Epstein-Barr virus (EBV) as a cause of CFS, we measured various antibodies for EBV. The definite cases had significantly higher titers of early antigen complex (EA)-IgG than both the probable cases and controls. We proposed the EA-IgG/EBNA ratio as the indicator of activation of EBV and attempted to estimate the degree of fatigue by the EA-IgG/EBNA ratio. The highest ratio value (16.0) of the 22 patients ratios was the most serious case. In general, the ratio correlated with the degree of fatigue. Based on these results, it was concluded that a relationship does exist between CFS and EBV.
Kitani T, Kuratsune H, Yamaguchi K.	Dep. of Internal Medicine, Osaka University.	[Diagnostic criteria for chronic fatigue syndrome by the CFS Study Group in Japan].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2600-5	Much interest recently has been given to chronic fatigue syndrome (CFS) in Japan as other countries. The CFS Study Group sponsored by the Ministry of Health and Welfare has been developed since April 1991, A diagnostic criteria for CFS was newly proposed by this group. The criteria is substantially based upon the working case definition, which was made by Holmes and colleagues in 1988. There are some modification from CDC working case definition; the criteria of probable cases of CFS was defined, and postinfectious CFS was also given. Review Literature

Kuratsune H, Yamaguti K, Hattori H, Tazawa H, Takahashi M, Yamanishi K, Kitani T.	Department of Clinical Research, Osaka University.	[Symptoms, signs and laboratory findings in patients with chronic fatigue syndrome].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2665-72	This review summarizes the symptoms, signs and laboratory abnormalities seen in 59 patients with chronic fatigue syndrome (CFS), 2 patients with post-infectious CFS and in 26 patients with possible CFS whose illnesses fulfill the criteria proposed by the study group of the Ministry of Welfare, Japan. The characteristic symptoms and signs of CFS are prolonged generalized fatigue following exercise, headache, neuropsychological symptoms, sleep disturbance and mild fever. In possible CFS patients, the frequency of mild fever, muscle weakness, myalgia and headache is low. Our standard hematologic and laboratory tests revealed a few abnormality in patients with CFS. The characteristic abnormality in CFS patients is the low values of 17-Ketosteroid-Sulfates/creatinine in morning urine and the acylcarnitine deficiency. It seems likely that this deficiency of acylcarnitine induces an energy deficit in the skeletal muscle, resulting in general fatigue, myalgia, muscle weakness and postexertional malaise in CFS patients. Virologic studies revealed no evidence of retrovirus infection with HTLV-1, HTLV-2 and HIV, but the reactivation of HHV-6 infection was apparent.
Kyle DV, deShazo RD.	University of Alabama, School of Medicine, Department of Medicine, Birmingham.	Chronic fatigue syndrome: a conundrum.	Am J Med Sci 1992 Jan;303(1):28-34	Chronic fatigue syndrome (CFS) is a multi-faceted disorder for which no etiology has been determined. This paper discusses the implications of the new clinical case definition of CFS on previous and future studies of this illness. The authors' own management approach is also discussed.
Levine PH, Jacobson S, Pocinki AG, Cheney P, Peterson D, Connelly RR, Weil R, Robinson SM, Ablashi DV, Salahuddin SZ, et al.	Environmental Epidemiology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD 20892.	Clinical, epidemiologic, and virologic studies in four clusters of the chronic fatigue syndrome.	Arch Intern Med 1992 Aug;152(8):1611-6 comment in: Arch Intern Med. 1993 Mar 8;153(5):661	BACKGROUND. The purpose of this study is to provide a case definition of chronic fatigue syndrome in an outbreak occurring in the Nevada-California region to evaluate candidate etiologic agents and observe the natural history of the illness. METHODS. Patients diagnosed as having chronic fatigue syndrome were studied by repeated interviews, questionnaires, and blood collection over a 3-year period. Serum samples were tested for antibodies to Epstein-Barr virus, human herpesvirus-6, and human T-lymphotropic viruses I and II. Leukocytes from typical cases were also assayed for human T-lymphotropic viruses I and II. RESULTS. Cases were defined as persons who had: (1) severe persistent fatigue following an acute illness appearing in an individual with no previous physical or psychological symptoms; (2) presenting signs and symptoms of an acute infection; (3) severe and persistent headache and/or myalgias; and (4) abrupt change in cognitive function or the appearance of a new mood disorder. After 3 years of follow-up, almost all study subjects were able to return to pre-illness activity. None of the viruses evaluated--human T-lymphotropic viruses I and II, Epstein-Barr virus, or human herpesvirus-6--could be etiologically linked to these outbreaks. CONCLUSION. Clinical features of outbreaks of chronic fatigue syndrome differ sufficiently to suggest different etiologic agents. Giardiasis appears to have precipitated one of the four clusters in this study but the

				cause(s) of the other three outbreaks is as yet uncertain. The overall prognosis of chronic fatigue syndrome is usually favorable.
Levine PH, Peterson D, McNamee FL, O'Brien K, Gridley G, Hagerty M, Brady J, Fears T, Atherton M, Hoover R.	Epidemiology and Biostatistics Program, National Cancer Institute, NIH, Bethesda, Maryland 20892.	Does chronic fatigue syndrome predispose to non-Hodgkin's lymphoma?	Cancer Res 1992 Oct 1;52(19 Suppl):5516s-5518s; discussion 5518s-5521s	Chronic fatigue syndrome, an illness that frequently is associated with abnormalities of cellular immunity, has been reported anecdotally to be associated with an increased incidence of lymphoid hyperplasia and malignancy. This report describes an initial analysis of population-based cancer incidence data in Nevada, focusing on the patterns of non-Hodgkin's lymphoma prior to and subsequent to well described, documented outbreaks of chronic fatigue syndrome during 1984-1986. In a study of time trends in four age groups, the observed time trends were consistent with the national trends reported in the Surveillance, Epidemiology, and End Results Program. No statistically significant increase attributable to the chronic fatigue syndrome outbreak was identified at the state level. Additional studies are in progress analyzing the data at the country level, reviewing patterns in other malignancies, and continuing to monitor the cancer patterns over subsequent years.
Linde A, Andersson B, Svenson SB, Ahrne H, Carlsson M, Forsberg P, Hugo H, Karstorp A, Lenkei R, Lindwall A, et al.	Department of Virology, National Bacteriological Laboratory, Stockholm.	Serum levels of lymphokines and soluble cellular receptors in primary Epstein-Barr virus infection and in patients with chronic fatigue syndrome.	J Infect Dis 1992 Jun;165(6):994-1000	The immunopathology in primary Epstein-Barr virus (EBV) infections and in chronic fatigue syndrome was studied by examining serum levels of interleukins (IL) and of soluble T cell receptors in serum samples. Serum samples were from patients during and 6 months after primary EBV-induced infectious mononucleosis and from patients with chronic fatigue syndrome and serologic evidence of EBV reactivation. Markers for T lymphocyte activation (soluble IL-2 and CD8) and for monocyte activation (neopterin) were significantly elevated during acute infectious mononucleosis but not in patients with chronic fatigue syndrome. Interferon-alpha, IL-1 beta, and IL-6 levels were not significantly increased in any patient group but inferferon-gamma levels were significantly increased during the acute phase of infectious mononucleosis. The levels of IL-1 alpha were significantly higher than in controls both in patients with infectious mononucleosis and in those with chronic fatigue syndrome. In the latter, the lack of most markers for lymphocyte activation found in patients with infectious mononucleosis makes it less likely that EBV reactivation causes symptoms.
Lloyd A, Hickie I, Hickie C, Dwyer J, Wakefield D.	Department of Immunology, Prince Henry Hospital, Sydney, Australia.	Cell-mediated immunity in patients with chronic fatigue syndrome, healthy control subjects and patients with major depression.	Clin Exp Immunol 1992 Jan;87(1):76-9	The chronic fatigue syndrome (CFS) is characterized by severe persistent fatigue and neuropsychiatric symptoms. It has been proposed that the abnormalities in cell-mediated immunity which have been documented in patients with CFS may be attributable to a clinical depression, prevalent in patients with this disorder. Cell-mediated immune status was evaluated in patients with carefully defined CFS and compared with that of matched subjects with major depression (non-melancholic, non-psychotic) as well as healthy control subjects. Patients with CFS demonstrated impaired lymphocyte responses to phytohaemagglutinin (PHA) stimulation, and reduced or absent delayed-type hypersensitivity (DTH) skin responses when compared either with subjects with major depression or with

				healthy control subjects (P less than 0.05 for each analysis). Although depression is common in patients with CFS, the disturbances of cell-mediated immunity in this disorder differ in prevalence and magnitude from those associated with major depression. These observations strengthen the likelihood of a direct relationship between abnormal cell-mediated immunity and the etiology of CFS.
Lloyd AR, Pender H.	Department of Infectious Diseases, Prince Henry Hospital, Little Bay, NSW.	The economic impact of chronic fatigue syndrome.	Med J Aust 1992 Nov 2;157(9):599-601 comment in: Med J Aust. 1993 Feb 15;158(4):286-7	OBJECTIVE: To estimate the economic impact of chronic fatigue syndrome (CFS) on the individual, the government, and the community. DESIGN: The financial burden produced by CFS was studied by calculating the direct and indirect costs arising from the disorder. Data regarding use of health resources, income and employment were obtained by questionnaire from patients with CFS. In addition, aggregate Medicare data on the incidence and fees charged for each Schedule item for these patients was obtained. SETTING: The Richmond Valley, New South Wales. PARTICIPANTS: Forty-two patients with CFS identified in our population-based prevalence study. RESULTS: The conservative estimate of the per annum costs of CFS in the Richmond Valley, with a prevalence of 37.1 cases per 100,000, was $396,000. If extrapolated to the Australian population, we estimate CFS would generate an annual cost of at least $59 million. CONCLUSION: This disorder constitutes a large but neglected area of health resource utilisation and economic burden.
Lozano de Leon F, Gutierrez Fernandez J, Martin Mazuelos E, Garcia-Bragado F.	Unidad de Enfermedades Infecciosas, Hospital Universitario de Valme, Sevilla.	[Infection by human herpesvirus type 6: epidemiology, immunopathology and clinical implications].[article in Spanish]	Rev Clin Esp 1992 Jan;190(1):37-42	The human herpesvirus type 6 has been discovered recently and is the object of numerous investigations. Even though, its morphology is very close to the cytomegalovirus, its epidemiologic, immunopathologic and clinic characteristics are similar to the Epstein-Barr virus. Like the latter, HHV-6 persists latent in the host during all his live, frequently relapsed and is ubiquitous. Exanthema subitum in children and mononucleosis-like syndrome in adults have been attributed to acute HHV-6 infection. Under certain conditions, the development of chronic fatigue syndrome, some lymphoproliferative disorders and, perhaps, others diseases can be influenced by the persistent activity of this infection furthermore, HHV-6 can be a cofactor in infection with HIV and provokes a faster evolution and more severe illness.
Lynch S, Montgomery S, Seth R.		Chronic fatigue syndrome.	Br J Gen Pract 1992 Jan;42(354):39-40 comment on: Br J Gen Pract. 1991 Nov;41(352):479-80	
Lynch SP, Seth RV, Main J.	St James University Hospital, Leeds.	Monospot and VP1 tests in chronic fatigue syndrome and major depression.	1348: J R Soc Med 1992 Sep;85(9):537-40	Thirty-four patients with chronic fatigue syndrome (CFS) were compared with controls with DSM-III-R major depression on the Monospot and VP1 antigen tests. There was no significant difference in the numbers initially VP1 positive in the groups (11/34 and 7/34 positive in the chronic fatigue and major depression group respectively). Four CFS but no depressed patients were Monospot positive

				initially. No patient was both Monospot and VP1 positive. Patients positive on the tests were offered a repeat 6 months later. Eight of the 11 VP1 positive patients in the CFS group were retested and four remained positive, but none of the four depressed patients retested remained positive. No patient retested remained Monospot positive. The Monospot and VP1 tests appear to have little discriminating ability between these groups as screening tests and their predictive validity is unclear.
Mahnke C, Kashaiya P, Rossler J, Bannert H, Levin A, Blattner WA, Dietrich M, Luande J, Lochelt M, Friedman-Kien AE, et al.	Projektgruppe Humane Retroviren, DKFZ, Heidelberg, Federal Republic of Germany.	Human spumavirus antibodies in sera from African patients.	Arch Virol 1992;123(3-4):243-53	Serum samples collected from patients with a wide variety of diseases from African and other countries were tested for antibodies to the human spumaretrovirus (HSRV). A spumaviral env-specific ELISA was employed as screening test. Out of 3020 human sera screened, 106 were found to be positive (3.2%). While the majority of patients' sera from Europe (1581) were negative, 26 were positive (1.6%). Sera from healthy adult blood donors (609), from patients with multiple sclerosis (48), Graves' disease (45), and chronic fatigue syndrome (41) were negative or showed a very low prevalence for spumaviral env antibodies. A higher percentage of seropositives (6.3%) were found among 1338 African patients from Tanzania, Kenya, and Gabon. Out of 1180 patients from Tanzania, 708 suffered from tumors, 75 from AIDS, and 128 had gynecological problems; 51 of the Tanzanian patients were HSRV seropositive (4.3%). A particularly high percentage of 16.6% seropositives were identified among nasopharyngeal carcinoma patients (NPC) from Kenya and Tanzania consistent with results reported 10 years ago. However, 20 nasopharyngeal carcinoma patients from Malaysia were HSRV-seronegative. In selected cases, sera from seropositive individuals were reacted with proteins from HSRV-infected cells in vitro. HSRV env- and gag-specific antibodies were specifically detected by these sera in Western blots. The results indicate spumavirus infections in human patients with various diseases at a relatively low prevalence worldwide; in African patients, however, the prevalence of spumavirus infections is markedly higher.
Manu P, Lane TJ, Matthews DA.	Department of Psychiatry, University of Connecticut Health Center, Farmington 06032.	The pathophysiology of chronic fatigue syndrome: confirmations, contradictions, and conjectures.	Int J Psychiatry Med 1992;22(4):397-408	OBJECTIVE: To examine published data regarding patient cohorts with the recently defined chronic fatigue syndrome. METHOD: Review of thirty-two peer-assessed research publications that included full disclosure of the methodology employed; classification of the findings as confirmed, contradictory, or non-duplicated. RESULTS: Research studies have confirmed that the majority of patients with the chronic fatigue syndrome: 1) are white middle-aged women, 2) have a high prevalence of current major depression and somatization disorder, 3) have abnormal personality traits, 4) believe that their fatigue has a physical cause, and 5) show mild abnormalities of humoral immunity. Contradictory data have been presented with regard to: 1) the time of onset of depressive disorders, 2) the etiologic role of herpetic and enteroviral infections, 3) the presence of abnormal cellular immunity, and 4) the clinical utility of immunoglobulin therapy.

				Non-duplicated research has indicated 1) hypothalamic-pituitary-adrenal axis dysfunction, 2) abnormalities on magnetic resonance images of the brain, 3) altered cytokine production, and 4) the possibility of retroviral infection. CONCLUSIONS: As presently defined, the chronic fatigue syndrome has many of the clinical and biological features associated with depressive and somatoform disorders. A specific etiologic role for infections or immune dysfunction has not been confirmed.

Matsuda J, Gohchi K.	Department of Medicine, Teikyo University School of Medicine.	[Overview of our patients with chronic fatigue syndrome (CFS) from the pathoetiological aspects].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2635-40	We interviewed 285 patients who visited our department claiming with a complaint of chronic fatigue syndrome (CFS) and subsequently diagnosed 55 as having CFS, according to the criteria for CFS of the centers for disease control (CDC). We measured various virus antibody titers, 2-5, adenylate synthetase levels in the serum lymphocyte subset in blood, employing a double staining technique with monoclonal antibodies. In this paper, we pathoetiology of CFS, based on our findings and other researchers' is discussed.
Matsuda J.	Department of Medicine, Teikyo University School of Medicine.	[Chronic fatigue syndrome].[article in Japanese]	Nippon Rinsho 1992 Apr;50(4):887-91	Chronic fatigue syndrome (CFS), which is characterized by devastating fatigue, mild fever, lymphadenopathy, headache, myalgia, insomnia and neuropsychiatric disorders, now has drawn much attentions from many physicians, researchers and even peoples in general society world wide. The pathogenesis of CFS is still remains to be clarified and clinico-pathological difference between CFS and mood disorder is controversial. In this paper, CFS would be reviewed in detail.
Matsumoto Y, Ninomiya S.	Second Department of Internal Medicine, Nagoya City University Medical School.	[Allergy among Japanese patients with chronic fatigue syndrome].[article in Japanese]	Arerugi 1992 Dec;41(12):1722-5	Allergy is a common feature of patients with chronic fatigue syndrome (CFS). Because of this strong association, we attempted to explore the prevalence of allergies among Japanese patients with CFS. Of the present 18 patients, 78% had allergies during their premorbid and/or postmorbid conditions. Their allergies were mainly cutaneous reactions including drug allergies and 43% of the patients had 2 or more allergic reactions. In the case of a premorbid condition, allergies improved spontaneously after onset of CFS. Clinical manifestations of CFS, however, became worse during the period of an association with allergies. Immunologic tests, including peripheral blood lymphocyte-subsets, blastogenesis, natural killer-cell functions and cytokine-assays, were not any correlation between both patients with and without allergies.
McCluskey DR, Riley MS.	Department of Medicine, Royal Victoria Hospital, Belfast, Ireland.	Chronic fatigue syndrome.	Compr Ther 1992 Apr;18(4):13-6	Chronic Fatigue Syndrome appears to represent a spectrum of disorders in which a variety of pathophysiological mechanisms may operate. While the initiating event in the majority of patients is a pyrexial illness, possibly due to enterovirus infection, evidence of persisting infection or inflammatory changes in muscle

				and/or brain remain unconvincing. CFS patients display a definite reduced aerobic work capacity compared to normal control subjects, but this may reflect a state of deconditioning resulting from prolonged physical inactivity. They also have an altered perception of their level of exertion and premorbid fitness. The characteristic fluctuation in symptoms, with periods of relapses and partial remissions, may indicate that some central disorder of sensory perception is operational. It may be that a primary sleep disorder results in a reduced sensory threshold for afferent stimuli from muscle. This could well account for many of the subjective symptoms which patients experience. Much more research is clearly necessary if we are to achieve a better understanding of this distressing and at present enigmatic disorder.

Nishikai M.	Department of Internal Medicine, Second Tokyo National Hospital.	[Chronic fatigue syndrome--study of 51 cases treated at the Second Tokyo National Hospital].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2641-7	Fifty-one patients with chronic fatigue syndrome (CFS) were studied. Tender points, which are a characteristic clinical feature of fibromyalgia, were found in all but two of the patients at 11.4 points (mean) per patient. IgG antibody titers to EB virus viral capsid antigen were more elevated in the CFS patient group compared to that of the control ($p < 0.0015$). IgG antibody titers to HHV-6 were not higher in the patient group. NK cell activity was not more decreased in the patient group, whereas, the mean number of NK cells was lower ($p < 0.005$) in the patient group, when CD57 was used as the NK cell marker. Viral infections and/or disorders in cellular immunity may be important factors in the pathogenesis of CFS.
Ogawa R, Toyama S, Matsumoto H.	Department of Internal Medicine, Kanebo Memorial Hospital.	[Chronic fatigue syndrome--cases in the Kanebo Memorial Hospital].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2648-52	In our hospital, 134 patients (28 male, 106 female, 10-82 years of age) were diagnosed as having chronic fatigue syndrome (CFS). Some patients had mild elevation of antibodies against Epstein-Barr Virus and immunologic abnormalities (natural killer cell dysfunction and high rates of skin reactivity to house dust, pollen, drugs and common food). In the patients with immunologic abnormalities, we found decreases in serum concentrations of arachidonic acid and dihomogamma-linolenic acid. A Kampo medicine, Ren-Shen-Yang-Rong-Tang was used in the management of 134 patients and 98 patients returned to work or

				school.
Okano M.	Department of Pediatrics, Hokkaido University School of Medicine.	[Viral infection and its causative role for chronic fatigue syndrome].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2617-24	Patients with chronic fatigue syndrome (CFS), of unknown etiology, have been increasingly reported. This syndrome is characterized by debilitating fatigue, lymphadenopathy, and fever. Herein, I focus on and review this syndrome from the view point of the causative role of viral infection. Since the symptoms of CFS are similar to those of chronic infectious mononucleosis (CIM) or chronic Epstein-Barr virus infection (CEBV), the role of EBV has been intensively studied. The etiological relationship between EBV and CFS, however, is questioned, like other lymphotropic viruses, including human retroviruses, adenoviruses and human herpesvirus 6. Additionally, severe chronic active EBV infection syndrome (SCAEBV) is also discussed in this review because symptoms of this disorder are similar to those of CFS but more severe in degree. Currently, the cause(s) and treatment of CFS are enigmatic and require further research and multidisciplinary study. Review Literature

Price RK, North CS, Wessely S, Fraser VJ.	Department of Psychiatry, Washington University School of	Estimating the prevalence of chronic fatigue syndrome and	Public Health Rep 1992 Sep-Oct;107(5):514-22 comment in: Public	Chronic fatigue syndrome is a poorly understood disease characterized by debilitating fatigue and neuromuscular and neuropsychological symptoms. Despite numerous studies on the subject, the epidemiology of the syndrome in

	Medicine, St. Louis, MO 63110.	associated symptoms in the community.	Health Rep. 1993 Jan-Feb;108(1):135-7	the community remains largely unexplored. An estimate of the prevalence in the population is presented, approximating the Centers for Disease Control criteria as well as the prevalence estimates of the fatigue symptom complex that include fatigue, disability, and neuromuscular and neuropsychological symptoms. The study population consisted of a very large, multicenter, stratified, and random sample of a general population health survey known as the Epidemiologic Catchment Area Program. Data used for this study were gathered between 1981 and 1984. The Diagnostic Interview Schedule, a highly structured mental health interview, was used to assess the lifetime prevalence of medical and psychological symptoms. Chronic fatigue was common. A total of 23 percent of the subjects reported having experienced the symptom of persistent fatigue sometime during their lives. Chronic fatigue syndrome, however, as defined by the Centers for Disease Control, appeared to be quite rare in the general population. Only 1 of 13,538 people examined was found to meet a diagnosis of the syndrome with an approximation of the CDC criteria. Fatigue symptom complex was frequently related to medical or psychiatric illness or substance abuse; thus, persons meeting partial criteria of chronic fatigue syndrome were also found to be rare when psychiatric or medical exclusions were applied.
Ray C, Weir WR, Cullen S, Phillips S.	Department of Human Sciences, Brunel University, Uxbridge, Middlesex, U.K.	Illness perception and symptom components in chronic fatigue syndrome.	J Psychosom Res 1992 Apr;36(3):243-56	Two-hundred and eight patients with chronic fatigue syndrome (post-viral fatigue syndrome) completed a questionnaire which dealt both with their illness in general and with the extent to which they experienced specific symptoms. A factor analysis of the symptom data yielded four components: emotional distress; fatigue; somatic symptoms; and cognitive difficulty. Emotional disturbance is a common feature of the disorder and its role has been widely debated. When the symptom components were considered independently, fatigue, somatic symptoms and cognitive difficulty were associated with questionnaire items relating to general illness severity, but emotional distress was not. Thus negative emotions did not contribute directly to patients' perception of illness severity. They were, however, correlated with the other symptom components. It is argued that this correlation reflects a reciprocal influence, with negative emotions exacerbating fatigue and other key symptoms and the debilitating nature of these symptoms enhancing emotional vulnerability.

Aust N Z J Psychiatry 1992 Mar;26(1):64-72 comment in: Aust N Z J Psychiatry. 1992 Jun;26(2):329-30	The state of chronic fatigue syndrome (CFS) as abnormal illness behaviour or as biologically determined disease is undecided. The ensuing, often public, debate has confused the community and has led to sharp differences in the therapeutic approach to individual patients. These challenges are compounded when the patient is an adolescent and intergenerational issues enter the picture. Two adolescent cases with different outcomes are presented and the principles of a rehabilitation approach to treatment are outlined which attempt to avoid being drawn into unproductive debates about aetiology.

Scheffers MK, Johnson R Jr, Grafman J, Dale JK, Straus SE.	Cognitive Neurophysiology Unit, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD 20892.	Attention and short-term memory in chronic fatigue syndrome patients: an event-related potential analysis.	Neurology 1992 Sep;42(9):1667-75	We recorded event-related brain potentials (ERPs) from 13 patients with chronic fatigue syndrome (CFS) and 13 matched normal controls. To assess attentional and memory deficits in CFS patients, we used a short-term memory task in which events occurred in different spatial locations and the patients made a rapid-response (RT) when a letter in a relevant location matched a letter in the prememorized set (Attention paradigm). Time-on-task effects on the ERP and behavioral measures were assessed over the 2 1/4-hour duration of this task. Both groups also performed a visual Oddball paradigm, with an RT, before and after the Attention paradigm. The patients' RTs were much more variable and, in nine of 13 cases, slower than the mean RT of the controls in both paradigms. The patients' memory performance was not significantly different from that of the controls and there were no group differences in the overall amplitude, latency, or scalp distribution of the N1, P2, N2, or P300 components of the ERP in either paradigm. The ERP and performance data from both paradigms suggest that perceptual, attentional, and short-term memory processes were unaffected in CFS patients and that the differences were limited to response-related processes.
Schluederberg A, Straus SE, Peterson P, Blumenthal S, Komaroff AL, Spring SB, Landay A, Buchwald D.	National Institute of Allergy and Infectious Diseases, Bethesda, MD.	NIH conference. Chronic fatigue syndrome research. Definition and medical outcome assessment.	Ann Intern Med 1992 Aug 15;117(4):325-31	A workshop was held 18 to 19 March 1991 at the National Institutes of Health to address critical issues in research concerning the chronic fatigue syndrome (CFS). Case definition, confounding diagnoses, and medical outcome assessment by laboratory and other means were considered from the perspectives of key medical specialties involved in CFS research. It was recommended that published Centers for Disease Control (CDC) case-definition criteria be modified to exclude fewer patients from analysis because of a history of psychiatric disorder. Specific

				recommendations were made concerning the inclusion or exclusion of other major confounding diagnoses, and a standard panel of laboratory tests was specified for initial patient evaluation. The workshop emphasized the importance of recognizing other conditions that could explain the patient's symptoms and that may be treatable. It was viewed as essential for the investigator to screen for psychiatric disorder using a combination of self-report instruments followed by at least one structured interview to identify patients who should be excluded from studies or considered as a separate subgroup in data analysis. Because CFS is not a homogeneous abnormality and because there is no single pathogenic mechanism, research progress may depend upon delineation of these and other patient subgroups for separate data analysis. Despite preliminary data, no physical finding or laboratory test was deemed confirmatory of the diagnosis of CFS. For assessment of clinical status, investigators must rely on the use of standardized instruments for patient self-reporting of fatigue, mood disturbance, functional status, sleep disorder, global well-being, and pain. Further research is needed to develop better instruments for quantifying these domains in patients with CFS.

Shimizu T.	Dept. of Neurology, Teikyo University	[Neuro-psychiatric aspects of chronic	Nippon Rinsho 1992 Nov;50(11):2630-4	Chronic fatigue syndrome (CFS) is easily differentiated from various neurological organic disorders by conventional clinical examinations. The most important

	Medical School.	fatigue syndrome].[article in Japanese]		disease for distinguishment from CFS is fibromyalgia syndrome, in which the prominent and cardinal feature is a deprivation of stage 4 slow wave sleep. Experimentally, the sleep disturbance in controls can induce general myalgia, muscle tender points, severe fatigue and stiffness on awakening. The EEG abnormality is slow alpha wave contaminants on slow wave background, which is identical to EEG of CFS. The results clearly imply that CFS is not a hysterical or psychogenic disease, and that fibromyalgia may be a central fundamental of CFS. Fibromyalgia, however, has distinct features such as no antecedent inflammatory process and no endemics. Therefore, the syndrome has features distinct from, in addition to common features to CFS. It is also very difficult to distinguish CFS from depression. The above-mentioned features can be observed in depression. Now, study of brain blood flow or metabolism by PET or SPECT can be a possible tool for establishment of the CFS identity. Review Literature

[A case of chronic fatigue syndrome who showed a beneficial effect by intravenous administration of magnesium sulphate].[article in Japanese]	Arerugi 1992 Nov;41(11):1605-10	We have treated a case of chronic fatigue syndrome with atopic diathesis was had suffered general malaise, low grade fever, swelling of the lymph nodes, myalgias and arthralgias for a long time. A 29-year-old female, who had been treated for atopic dermatitis for 5 years, complained of general malaise in May 1990. She was admitted to the nearest hospital in December 1990 because of low grade fever, swelling of the lymph nodes and an elevation of antinuclear antibody (2520x). She was transferred to our hospital in May 1991. A diagnosis of collagen disease was not compatible with her condition. In addition to general malaise, fever and lymph node swelling, headache, myalgias, muscle weakness, arthralgias and insomnia were observed, and a diagnosis of chronic fatigue syndrome was made based on the working case definition proposed by Holmes et al. Although eosinophilia, a high serum level of IgE, and elevation of RAST scores, low NK and ADCC activity, and a reduced level of NK cells in the peripheral blood were detected, serum antibodies to a number of viruses were in the normal range. Treatments with non-steroid anti-inflammatory drugs, minor tranquilizers and antidepressant drugs were not effective at all. An administration of magnesium sulphate was intravenously performed once a week in order to improve her condition, especially severe general malaise. After about 6-week's administration

				of magnesium sulphate, she noticed reduced easy fatigability and an improvement in her impaired daily activities. Finally she was able to leave the hospital in January 1992.(ABSTRACT TRUNCATED AT 250 WORDS)
Thoolen IM, de Vries TW.	Kinderkliniek Academisch Ziekenhuis Groningen.	[Chronically tired or the chronic fatigue syndrome in an adolescent].[article in Dutch]	Tijdschr Kindergeneeskd 1992 Jun;60(3):63-7	To fulfill the criteria of the chronic fatigue syndrome a patient must have new onset persistent or relapsing, debilitating fatigue or easy fatigability. The symptoms do not resolve with bedrest and are severe enough to reduce or impair average daily activity below 50% of the patient's premorbid activity level for a period of at least 6 months. Other clinical conditions that may produce similar symptoms must be excluded. Using a case history the (differential) diagnosis, treatment and prognosis of the chronic fatigue syndrome are discussed.
Uchida A.	Dept. Late Effect Studies, Kyoto University.	[Therapy of chronic fatigue syndrome].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2679-83	Chronic fatigue syndrome (CFS) is characterized by unexplained, debilitating fatigue or easy fatigability lasting longer than six months. While a number of clinical trials have been performed in CFS patients, there is currently no established therapy for CFS. Treatment with acyclovir of CFS patients is ineffective. Intravenous immunoglobulin therapy appears to be effective, though the results are controversial. Antidepressants might help the associated depression and anxiety but not other symptoms. Trials with magnesium have improved the well-being of patients. Restoration of NK activity by biological response modifiers, such as sizofirann, resulted in restoration of NK cell activity and recovery from CFS. Taken together, immunological abnormalities may be involved in CFS, and its restoration may produce clinical benefit in CFS. Review Literature
Uchida A.	Dept. Late Effect Studies, Kyoto University.	[Chronic fatigue immune dysfunction syndrome].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2625-9	Chronic fatigue syndrome (CFS) is characterized by unexplained, debilitating fatigue or easy fatigability lasting longer than six months. While a viral basis of infection is proposed to be the cause of CFS, other viral infections do not generally persist after several weeks. Immunological disorders, including abnormal functions and distributions of T lymphocytes, B lymphocytes, natural killer (NK) cells, and monocyte/macrophages, are described in CFS. NK cells are known to play an important role in host resistance against viral infection as well as in the regulation of the immune systems. Restoration of NK activity resulted in recovery from CFS. Taken together, immunological abnormalities, especially dysfunction of NK cells, may be involved in CFS. Review Literature
Ur E, White PD, Grossman A.	Department of Endocrinology, St. Bartholomew's Hospital, London, England.	Hypothesis: cytokines may be activated to cause depressive illness and chronic fatigue syndrome.	Eur Arch Psychiatry Clin Neurosci 1992;241(5):317-22	Abnormalities in the regulation of the hypothalamo-pituitary-adrenal (HPA) axis are a well recognised feature of endogenous depression. The mechanism underlying this phenomenon remains obscure although there is strong evidence suggesting excessive CRH activity at the level of the hypothalamus. We propose a novel hypothesis in which we suggest that the aetiological antecent to CRH hyperactivity is cytokine activation in the brain. It is now well established both that interleukins -1 and -6 are produced in a number of central loci and that

				cytokines are potent stimulators of the HPA axis. Hence, we suggest that activation of IL-1 and IL-6 by specific mechanisms (such as neurotropic viral infection) in combination with the consequent CRH-41 stimulation, may (via their known biological effects) underly many of the features found in major depression and other related disorders, particularly where chronic fatigue is a prominent part of the symptom complex. This theory has considerable heuristic value and suggests a number of experimental stratagems which may employed in order to confirm or reject it.

Ware NC, Kleinman A.	Department of Social Medicine, Harvard Medical School, Boston, Massachusetts 02115.	Culture and somatic experience: the social course of illness in neurasthenia and chronic fatigue syndrome.	Psychosom Med 1992 Sep-Oct;54(5):546-60	An anthropological view of culture and somatic experience is presented through elaboration of the notion that illness has a social course. Contemporary anthropology locates culture in local worlds of interpersonal experience. The flow of events and processes in these local worlds influences the waxing and waning of symptoms in a dialetic involving body and society over time. Conversely, symptoms serve as a medium for the negotiation of interpersonal experience, forming a series of illness-related changes in sufferers' local worlds. Thus, somatic experience is both created by and creates culture throughout the social course of illness. Findings from empirical research on neurasthenia in China, and chronic fatigue syndrome (CFS) in the United States, corroborate this formulation. Attributions of illness onset to social sources, the symbolic linking of symptoms to life context, and the alleviation of distress with improvement in circumstances point to the sociosomatic mediation of sickness. Transformations occasioned by illness in the lives of neurasthenic and CFS patients confirm the significance of bodily distress as a vehicle for the negotiation of change in interpersonal worlds. An indication of some of the challenges anthropological thinking poses for psychosomatic medicine concludes the discussion.
Welch LS, Sokas R.	Division of Occupational and Environmental Medicine, George Washington University School of Medicine, Washington, DC 20037.	Development of multiple chemical sensitivity after an outbreak of sick-building syndrome.	Toxicol Ind Health 1992 Jul-Aug;8(4):47-50	Investigation of this outbreak raises some important points for future research. Although for various reasons the case ascertainment for MCS was not complete, the three MCS patients described here all had preexisting conditions that may have put them at risk. In addition, one person among the 20 described had chronic fatigue syndrome but did not develop MCS. Many of the persons described here continue to have ongoing complaints that are not MCS. Significant exacerbation of preexisting allergic disease and new onset of asthma occurred

				among those patients. As a group, they did not recover completely after the outbreak; several are no longer working in the building but in alternative work spaces. An important distinction should be made between individuals who met the definition used here for MCS and others who had significant exacerbation of some better-defined illness brought on by building conditions. New onset of MCS was a partial but not complete explanation of the clinical course for this group of 20 persons.

Whelton CL, Salit I, Moldofsky H.	Department of Psychiatry, University of Toronto, Toronto Hospital, Canada.	Sleep, Epstein-Barr virus infection, musculoskeletal pain, and depressive symptoms in chronic fatigue syndrome.	J Rheumatol 1992 Jun;19(6):939-43	Sleep physiology, viral serology and symptoms of 14 patients with chronic fatigue syndrome (CFS) were compared with 12 healthy controls. All patients described unrefreshing sleep and showed a prominent alpha electroencephalographic nonrapid eye movement (7.5-11.0 Hz) sleep anomaly (p less than or equal to 0.001), but had no physiologic daytime sleepiness. There were no group differences in Epstein-Barr virus (EBV) antibody titers. The patient group had more fibrositis tender points (p less than 0.0001), described more somatic complaints (p less than 0.0001), and more depressive symptoms (p less than 0.0001). Patients with CFS do not show evidence for a specific chronic EBV infection, but show altered sleep physiology, numerous tender points, diffuse pain, and depressive symptoms. These features are similar to those found in fibromyalgia syndrome.
Winters EG, Quinet RJ.	Dept of Internal Medicine, Ochsner Clinic, New Orleans, LA 70121.	Chronic fatigue syndrome.	J La State Med Soc 1992 Jun;144(6):260-70	The chronic fatigue syndrome (CFS) is a poorly understood condition with nonspecific signs and symptoms, especially debilitating fatigue. Most patients can pinpoint the onset of their illness and usually describe a flu-like state. The search for an etiologic agent has focused on a number of viruses such as Epstein-Barr, enteroviruses, retroviruses, and human herpesvirus-6. Evidence supports persistent viral infection in a small percentage of CFS patients. Immunologic abnormalities do exist in CFS, which indicate the presence of immune activation in CFS patients. Although abnormal muscle biopsies have been found in some patients with CFS, strength and endurance appear normal, but perception of exertion may be abnormal. Patients with chronic fatigue have a high incidence of

				premorbid and concurrent psychiatric disorders, and on physical examination many often have reproducible tender points similar to fibromyalgic patients. Clinical evaluation should rule out other potential causes of fatigue, but elaborate diagnostic tests are seldom required. Presently, no specific treatment exists for CFS. A cognitive behavioral approach with or without the use of tricyclics has been advocated. Patients should be encouraged to maintain functional status and should not be discouraged from exercise. Several medications have been tried but with no definite clinical benefit.
Wong R, Lopaschuk G, Zhu G, Walker D, Catellier D, Burton D, Teo K, Collins-Nakai R, Montague T.	Department of Medicine, University of Alberta, Edmonton, Canada.	Skeletal muscle metabolism in the chronic fatigue syndrome. In vivo assessment by 31P nuclear magnetic resonance spectroscopy.	Chest 1992 Dec;102(6):1716-22	BACKGROUND: Previous study of patients with chronic fatigue syndrome (CFS) has demonstrated a markedly reduced dynamic exercise capacity, not limited by cardiac performance and in the absence of clinical neuromuscular dysfunction, suggesting the possibility of a subclinical defect of skeletal muscle. METHODS: The in vivo metabolism of the gastrocnemius muscles of 22 CFS patients and 21 normal control subjects was compared during rest, graded dynamic exercise to exhaustion and recovery, using 31P nuclear magnetic resonance (NMR) spectroscopy to reflect minute-to-minute intracellular high-energy phosphate metabolism. RESULTS: Duration of exercise was markedly shorter in the CFS patients (8.1 +/- 2.8 min) compared with the normal subjects (11.3 +/- 4.3 min) (p = 0.005). There were large changes in phosphocreatine (PCr), inorganic phosphate (Pi), and pH from rest to clinical fatigue in all subjects, reflecting the high intensity of the exercise. The temporal metabolic patterns were qualitatively similar in the CFS patients and normal subjects. There were early and continuous changes in PCr and Pi that peaked at the point of fatigue and rapidly reversed after exercise. In contrast, pH was relatively static in early exercise, not declining noticeably until 50 percent of total exercise duration was achieved, and reaching a nadir at 2 min postexercise, before rapidly reversing. There were no differences in pH at rest (7.08 +/- 0.04 vs 7.10 +/- 0.04), exhaustion (6.85 +/- 0.17 vs 6.76 +/- 0.17) or early (6.64 +/- 0.25 vs 6.56 +/- 0.24) or late recovery (7.09 +/- 0.04 vs 7.10 +/- 0.05), CFS patients vs normal subjects, respectively (NS). Neither were there intergroup differences (NS) in PCr or Pi. Although, quantitatively, the changes in PCr, Pi, and pH were marked and similar in both groups from rest to exhaustion, the changes all occurred much more rapidly in the CFS patients. Moreover, adenosine triphosphate (ATP) was significantly (p = 0.007) less at exhaustion in the CFS group. CONCLUSIONS: Patients with CFS and normal control subjects have similar skeletal muscle metabolic patterns during dynamic exercise and reach similar clinical and metabolic end points. However, CFS patients reach exhaustion much more rapidly than normal subjects, at which point they also have relatively reduced intracellular concentrations of ATP. These data suggest a defect of oxidative metabolism with a resultant acceleration of glycolysis in the working skeletal muscles of CFS patients. This metabolic defect

				may contribute to the reduced physical endurance of CFS patients. Its etiology is unknown. Whether CFS patients' overwhelming tiredness at rest has a similar metabolic pathophysiology or etiology also remains unknown.
Wood C, Magnello ME, Sharpe MC.	Department of Biological Anthropology, University of Oxford.	Fluctuations in perceived energy and mood among patients with chronic fatigue syndrome.	J R Soc Med 1992 Apr;85(4):195-8 comment in: J R Soc Med. 1992 Sep;85(9):587 J R Soc Med. 1992 Sep;85(9):588	Patients currently suffering or recently recovered from chronic fatigue syndrome (CFS) were compared with each other and with a group of well-matched controls in a study of diurnal variation in levels of perceived mental and physical energy and positive and negative affect. Patients who were currently ill showed diurnal variation in patterns of energy, with maximum levels being recorded between 10.00 h and 12.00 h which were significantly higher ($P < 0.05$) than energy levels recorded on rising or retiring. This pattern was similar to the controls but average energy levels at each time point were lower ($P < 0.05$) among the ill patients. Recovered patients showed the same pattern, with mean energy levels falling between those of the ill patients and controls. Similar diurnal patterns were found for perceptions of positive, though not negative affect. Correlations between physical and mental energy and between both of these energy variables and positive affect were high ($r = 0.75$ to 0.85) in both controls and CFS patients. However, correlations with negative affect were low (eg $r = -0.10$) and non-significant. Total scores on the Hospital Anxiety and Depression Scale (HAD) were significantly higher ($P < 0.05$) among patients who were still ill than those who had recovered. Scores on the HAD Depression (but not Anxiety) subscale were also significantly higher among those who were still ill ($P < 0.01$). These findings may be of value in facilitating programmes of cognitive-behavioural modification intended to aid the recovery of patients with CFS.

Woodward CG, Cox RA.	Public Health Laboratory, Leeds, U.K.	Epstein-Barr virus serology in the chronic fatigue syndrome.	J Infect 1992 Mar;24(2):133-9	The antibody profiles against Epstein-Barr virus were studied in 136 patients presenting with chronic fatigue syndromes. These profiles were compared with a panel of sera from blood donors. The patients exhibited higher titres in a combined assay for antibodies to the Restricted (R) and Diffuse (D) components of the Early Antigen complex than controls (P less than 0.001) but titres against these antigens were not useful on an individual patient basis. The patients who displayed elevated titres of antibodies to Early Antigens did not differ clinically from those displaying titres in the control range. Four of nine patients who had increased antibodies to Early Antigens also had evidence of active enterovirus infection.

Yamanishi K.	Research Institute for Microbial Diseases, Osaka University.	[Chronic fatigue syndrome and virus infection: human herpesvirus 6 (HHV-6) infection].[article in Japanese]	Nippon Rinsho 1992 Nov;50(11):2612-6	Chronic fatigue syndrome (CFS) is newly-recognized disease characterized by chronic and debilitating fatigue. It has been suggested that viral infection may be involved in this syndrome from the results of clinical examination, including increased activity of 2',5'-synthetase in leukocytes of patients. The following viruses have been reported as etiologic agents of this disease. First, many studies have found elevated levels of IgG to viral capsid antigen and early antigens to Epstein-Barr virus (EBV), but low titer or absence of antibody to EBV-associated nuclear antigen. Second, the enteroviruses have also been implicated as possible causative agent of CFS, because virus could be isolated from patients. Recently it was also reported that antibodies to human T-lymphotropic virus (HTLV) and HTLV type II (HTLV-II) gag sequence were detectable in patients. Finally several reports state that human herpesvirus 6 (HHV-6) could be isolated from CFS patients in the high frequency. In conclusion, it is still early to identify the etiologic agent from these reports, and more effort is needed. Review Literature

Abbey SE, Garfinkel PE.	Department of Psychiatry, Toronto Hospital, Ont., Canada.	Neurasthenia and chronic fatigue syndrome: the role of culture in the making of a diagnosis.	Am J Psychiatry 1991 Dec;148(12):1638-46 comment in: Am J Psychiatry. 1992 Dec;149(12):1753;	Chronic fatigue syndrome is an increasingly popular diagnosis consisting of multiple psychiatric and somatic symptoms. It bears a striking resemblance to the nineteenth-century diagnosis of neurasthenia. Both disorders arose during periods characterized by a preoccupation with commerce and material success and major changes in the role of women. They illustrate the role of culture in the development of a new diagnosis that emphasizes a "medical" rather than "psychiatric" etiology. The authors argue that chronic fatigue syndrome will meet the same fate as neurasthenia--a decline in social value as it is demonstrated that the majority of its sufferers are experiencing primary psychiatric disorders or psychophysiological reactions and that the disorder is often a culturally sanctioned form of illness behavior.
Abbey SE, Garfinkel PE.	Department of Psychiatry, Toronto Hospital, Ontario, Canada.	Chronic fatigue syndrome and depression: cause, effect, or covariate.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S73-83	Depressed mood and the psychiatric diagnosis of major depressive episode (MDE) are common findings in patients with chronic fatigue syndrome (CFS). The relationship between depression and CFS is unclear and may be explained by one of four models: (1) CFS is an atypical manifestation of MDE; (2) depression is the result of CFS as either an organic mood syndrome or an adjustment reaction; (3) CFS and MDE are covariates; and (4) the diagnosis of MDE is artifactual. The evidence for these models is discussed. The potentially confounding effect of depression on tests of immune function and neuropsychological testing is described. The implications of these different models for the design of studies of CFS are examined.

Genomic polymorphism, growth properties, and immunologic variations in human herpesvirus-6 isolates.	Virology 1991 Oct;184(2):545-52	Fifteen human herpesvirus-6 (HHV-6) isolates from normal donors and patients with AIDS, systemic lupus erythematosis, chronic fatigue syndrome, collagen-vascular disease, leukopenia, bone marrow transplants, Exanthem subitum (roseola), and atypical polyclonal lymphoproliferation were studied for their tropism to fresh human cord blood mononuclear cells, growth in continuous T cell lines, reactivity to monoclonal antibodies, and by restriction enzyme banding patterns. All isolates replicated efficiently in human cord blood mononuclear cells, but mitogen stimulation of the cells prior to infection was required. The ability to infect continuous T-cell lines varied with the isolates. Isolates similar to GS prototype infected HSB2 and Sup T1 cells and did not infect Molt-3 cells, whereas isolates similar to Z-29 infected Molt-3 cells but not HSB2 and Sup T1 cells. Some of the monoclonal antibodies directed against the HHV-6 (GS) isolate showed reactivity with all isolates tested, but others only reacted with HHV-6 isolates similar to the GS isolate and not with those similar to Z-29 isolate. Restriction enzyme analysis using EcoRI, BamHI, and HindIII revealed that HHV-6 isolates from roseola, bone marrow transplant, leukopenia, and an HIV-1-positive AIDS patient from Zaire (Z-29) were closely related but distinct from GS type

				HHV-6 isolates. Based on the above findings, we propose that, like herpes simplex virus types 1 and 2, the 15 HHV-6 isolates analyzed can be divided into group A (GS type) and group B (Z-29 type).
Ablashi DV, Salahuddin SZ, Josephs SF, Balachandran N, Krueger GR, Gallo RC.	National Cancer Institute, NIH, Bethesda, MD 20892.	Human herpesvirus-6 (HHV-6) (short review).	In Vivo 1991 May-Jun;5(3):193-9	Human Herpesvirus-6 is the etiological agent of Roseola infantum and approximately 12% of heterophile antibody negative infectious mononucleosis. HHV-6 is T-lymphotropic, and readily infects and lyses CD4+ cells. The prevalence rate of HHV-6 in the general population is about 80% (as measured by IFA) with an IgG antibody titer of 1:80. A lower prevalence, however, is observed in some countries. HHV-6 is reactivated in various malignant and non-malignant diseases as well as in Chronic Fatigue Syndrome and transplant patients. Furthermore, elevated antibody titers were also observed in lymphoproliferative disorders, auto-immune diseases and HIV-1 positive AIDS patients. There appears to be some strain variability in HHV-6 isolates. The GS isolates of HHV-6 (prototype) was resistant to Acyclovir, Gancyclovir, but its replication was inhibited by Phosphonoacetic acid and Phosphoformic acid. HHV-7 isolated from healthy individuals showed, by restriction analysis, that 6 out of 11 probes derived from two strains of HHV-6, cross-hybridized with DNA fragments, derived from HHV-7.

Armon C, Kurland LT.	Department of Neurology, Mayo Clinic, Rochester, Minnesota 55905.	Chronic fatigue syndrome: issues in the diagnosis and estimation of incidence.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S68-72	This article critiques the current working definition of chronic fatigue syndrome. The concerns raised about the current working definition are the following: prolonged or excessive exertion is not addressed explicitly; duration and quality of bed rest are not specified; a socioeconomic ascertainment bias is present; data from history and physical findings are not clearly separated and are relegated to minor criteria; and the rigor of neurologic and psychiatric evaluations is not specified. We propose a flow chart that addresses the possible modes of evolution of chronic fatigue syndrome for patients; this chart may yield more homogeneous subgroups of individuals with this syndrome or enable some patients to avert the syndrome.
Arnason BG.	Department of	Nervous system-	Rev Infect Dis 1991 Jan-	This essay is based on the premise that certain individuals may have a biologically

	Neurology, University of Chicago, Illinois 60637.	immune system communication.	Feb;13 Suppl 1:S134-7	determined propensity to respond to infection that is manifested by the development of disease such as chronic fatigue syndrome; the sequence of events that leads to this response involves the immune system. Biochemical pathways between the immune and nervous systems are reviewed, and the role of various products in the systemic circulation, including interleukin-1, pituitary hormone, and catecholamines, is highlighted. This premise could be tested by measuring levels of these substances in carefully selected patients and controls.

Electrophoretic analysis of human herpesvirus 6 polypeptides immunoprecipitated from infected cells with human sera.	J Infect Dis 1991 Jan;163(1):29-34	Proteins of human herpesvirus 6 (HHV-6) eliciting human antibody responses were examined in serum from healthy adults and patients with AIDS, chronic fatigue syndrome, Hodgkin's disease, and Sjogren's syndrome. HHV-6 IgG antibody titers measured by immunofluorescence (IF) ranged from 1:10 to 1:1280. Lysates of HHV-6-infected and uninfected cells labeled with [35S]methionine, [3H]glucosamine, and 125I were immunoprecipitated with sera and analyzed electophoretically. Sera with IF titers greater than or equal to 1:20 immunoprecipitated greater than 20 [35S]methionine-labeled HHV-6 polypeptides of approximately 26-180 kDa. At least 10 HHV-6 glycoproteins and 8 HHV-6 polypeptides associated with the surfaces of infected cells were recognized by human sera. The approximate molecular masses of glycoproteins immunoprecipitated by human sera were similar to those immunoprecipitated by monoclonal antibodies. The labeling intensity of HHV-6 protein bands increased with increasing IF titer, and the effect was most prominent for HHV-6 glycopolypeptides. No reactivities with specific HHV-6 polypeptide(s) were characteristic of a given patient group. These findings suggest that HHV-6 glycoproteins are good targets for human antibody responses.
Barofsky I, Legro MW.	Institute of Social Oncology, Silver Spring, Maryland.	Definition and measurement of fatigue.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S94-7	Although fatigue is a key component of the chronic fatigue syndrome, its definition and measurement remain relatively undeveloped. Most research on fatigue has been oriented towards work or performance of tasks and has involved laboratory studies of healthy individuals, while the study of fatigue as encountered in clinical settings has received minimal attention from investigators. This paper recommends that the natural history of chronic fatigue in its various clinical presentations be studied and that standardized assessment tools be used in this process. An investigation of the tools available for the assessment of fatigue yielded single-item, unidimensional, and multidimensional

				instruments. Additionally, the apparent association between affective illness and the chronic fatigue syndrome is addressed, and the fact that this relationship depends on issues of measurement is explored.
Becker JT.	Department of Psychiatry, University of Pittsburgh School of Medicine, Pennsylvania.	Methodologic considerations in assessment of cognitive function in chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S112-3	Rigorous and standardized assessment of cognitive function is an important component of any multidisciplinary study of chronic fatigue syndrome. The present paper describes some methodologic issues that need to be addressed to maximize the yield from any neuropsychiatric evaluation of the syndrome.
Bell KM, Cookfair D, Bell DS, Reese P, Cooper L.	Monroe County Health Department, Rochester, New York 14692.	Risk factors associated with chronic fatigue syndrome in a cluster of pediatric cases.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S32-8	After seven pediatric cases of chronic fatigue syndrome (CFS) were diagnosed in a farming community in upstate New York, a questionnaire regarding symptoms and potential risk factors of CFS was distributed to all students enrolled in the same school district. Twenty-one students with symptoms of CFS were identified. Two controls per case matched for age and sex were randomly selected from questionnaire respondents. Health status was verified for all subjects by telephone, and diagnosis of CFS was confirmed by a physician. Information was collected on the following factors: symptoms of CFS among other family members; history of allergy/asthma; consumption of raw milk, raw eggs, raw cheese, or raw meat; water supply; exposure to animals; home heating source; proximity to farmland/orchards; tick bite; blood transfusion; camping; and appendicitis. Logistic-regression analyses indicated that the best model (characterized by symptoms among other family members, recent ingestion of raw milk, and history of allergy/asthma) produced significant estimates of relative risk (P less than .05) of 35.9, 44.3, and 23.3, respectively, for the three factors (corrections were made for the effect of the other covariates). These data suggest that a combination of host and environmental factors, including an infectious agent or agents, are involved in the etiology of CFS.
Bertram G, Dreiner N, Krueger GR, Ramon A, Ablashi DV, Salahuddin SZ, Balachandram N.	ENT Clinic Dortmud, University Witten-Herdecke, F.R.G.	Frequent double infection with Epstein-Barr virus and human herpesvirus-6 in patients with acute infectious mononucleosis.	1492: In Vivo 1991 May-Jun;5(3):271-9	Clinical infectious mononucleosis (IM) represents a benign self-limited form of lymphoproliferative disease which is usually caused by infection with Epstein-Barr virus (EBV). Microscopic characteristics of this lymphoproliferative disorder, however, are not ultimately specific for EBV infection, but can also be seen in infections with other lymphotropic viruses, especially of the herpesvirus family. Human herpesvirus-6 (HHV-6) infection can apparently be associated with a number of diseases also seen in EBV infection. Also, postinfectious chronic fatigue syndrome (PICFS) which may follow IM is in more than 60% of the cases accompanied by persistent active HHV-6 infection. We thus screened serologically 215 cases of acute IM for evidence for infection with EBV, HHV-6 and CMN. Patients were tentatively grouped into those having primary infection or reactivated (probably non-primary) infections. Cases were followed for two years to monitor changes in titers. Of all 215 cases, 211 (98.1%) were positive for EBV, 137 (63.7%) for primary infections, 21 (9.8%) for reactivated infection, and

				53 (24.6%) for latent EBV. Thirty-three (15.3%) cases had primary HHV-6 infection, 63 (29.3%) active or reactivated HHV-6 infection, and 71 (33.9%) latent HHV-6. Double active EBV and HHV-6 infection, including primary and reactivated infections, amounted to 89 (39.5%) cases. Cytomegalovirus (CMV) antibody titers were found in 81 (37%) cases, 48 (22.3%) of which indicated latent infection and 33 (15.3%) active infection. Only two cases had evidence of active CMV infection alone, 1 cases of active CMV and HHV-6 infection. Serologic titers in 12 (5.6%) cases indicated combined active infection with CMV, EBV and HHV-6.(ABSTRACT TRUNCATED AT 250 WORDS)
Blakely AA, Howard RC, Sosich RM, Murdoch JC, Menkes DB, Spears GF.	Department of Psychological Medicine, Otago Medical School, University of Otago, Dunedin, New Zealand.	Psychiatric symptoms, personality and ways of coping in chronic fatigue syndrome.	Psychol Med 1991 May;21(2):347-62	This study aimed to investigate the psychological characteristics of chronic fatigue syndrome (CFS: Holmes et al. 1988). A battery of psychometric instruments comprising the General Health Questionnaire (GHQ), the Beck Depression Inventory (BDI), the Minnesota Multiphasic Personality Inventory (MMPI) and the Lazarus Ways of Coping (WoC) inventory, was administered to a sample of clinically-defined CFS sufferers (N = 58), to a comparison group of chronic pain (CP) patients (N = 81) and to a group of healthy controls matched for sex and age with the CFS sample (N = 104). Considerable overlap was found between CFS and CP patients at the level of both physical and psychological symptoms. This raises the possibility that CFS sufferers are a sub-population of CP patients. However, while there was some commonality between CFS and CP patients in terms of personality traits, particularly the MMPI 'neurotic triad' (hypochondriasis, depression and hysteria), CFS patients showed more deviant personality traits reflecting raised levels on the first MMPI factor, emotionality. Moreover, results were not consistent with the raised emotionality being a reaction to the illness, but rather were consistent with the hypothesis that emotionality is a predisposing factor for CFS. The majority of CFS patients fell within four personality types, each characterized by the two highest MMPI scale scores. One type (N = 20) reported a lack of psychological symptoms or emotional disturbance contrary to the overall trend for the CFS sample. This group conformed to the ICD-10 classification of neurasthenia.

	Francisco.	occupational issues.		about physical illness is all important, both by what they say and how they treat. In the process of interaction, they can promote or discourage disability. The role of the physician in the workplace is to determine if an illness is work related, if it is disabling, if it requires treatment, and what treatment. The physician must advise if the worker can continue in his or her usual and customary employment and, if not, if he or she can be vocationally rehabilitated from a medical standpoint. Conditions in which physical symptoms are unsupported by physical findings and have diagnostic labels that describe the disorder without indicating either cause or pathology are especially troubling for the physician who must decide if the patient's job caused the symptoms.
Buchwald D, Komaroff AL.	Department of Medicine, Harborview Medical Center, University of Washington School of Medicine, Seattle.	Review of laboratory findings for patients with chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S12-8	Various abnormalities revealed by laboratory studies have been reported in adults with chronic fatigue syndrome. Those most consistently reported include depressed natural killer cell function and reduced numbers of natural killer cells; low levels of circulating immune complexes; low levels of several autoantibodies, particularly antinuclear antibodies and antithyroid antibodies; altered levels of immunoglobulins; abnormalities in number and function of lymphocytes; and modestly elevated levels of two Epstein-Barr virus-related antibodies, immunoglobulin G to viral capsid antigen and to early antigen.

Butler S, Chalder T, Ron M, Wessely S.	Department of Psychiatry, National Hospital for Neurology and Neurosurgery, Queen Square, London, UK.	Cognitive behaviour therapy in chronic fatigue syndrome.	J Neurol Neurosurg Psychiatry 1991 Feb;54(2):153-8	Fifty patients fulfilling operational criteria for the chronic fatigue syndrome (CFS), and who had been ill for a mean of five years, were offered cognitive behaviour therapy in an open trial. Those fulfilling operational criteria for depressive illness were also offered tricyclic antidepressants. The rationale was that a distinction be drawn between factors that precipitate the illness and those that perpetuate it. Among the latter are cognitive factors such as the belief that physical symptoms always imply tissue damage, and behavioural factors such as persistent avoidance of activities associated with an increase in symptoms. Therapy led to substantial improvements in overall disability, fatigue, somatic and psychiatric symptoms. The principal problems encountered were a high refusal rate and difficulties in treating affective disorders. Outcome depended more on the strength of the initial attribution of symptoms to exclusively physical causes, and was not influenced by length of illness. These results suggest that current views on both treatment and prognosis in CFS are unnecessarily pessimistic. It is also suggested that advice currently offered to chronic patients, to avoid physical and mental activity, is counterproductive.
Byrne E.	Neurology Department,	The chronic fatigue	Clin Exp Neurol	The chronic fatigue syndrome is one of the most common medical problems in

	St. Vincent's Hospital, Melbourne.	syndrome: a reappraisal and unifying hypothesis.	1991;28:128-38	Western countries. Research work in virology, immunology, metabolic medicine and psychiatry in this area is reviewed and a disease model proposed. The chronic fatigue syndrome can be considered as a continuum ranging from cases with chronic viraemia on the one hand to instances of frank psychiatric illness on the other. In the majority of patients the fully evolved syndrome may involve an interaction of premorbid factors (psychological, immunological), environmental trigger factors (virus) and enhancing factors (emotional response to illness). A Venn diagram is a convenient way of expressing this concept.

Chao CC, Janoff EN, Hu SX, Thomas K, Gallagher M, Tsang M, Peterson PK.	Department of Medicine, Hennepin County Medical Center, Minneapolis, MN 55415.	Altered cytokine release in peripheral blood mononuclear cell cultures from patients with the chronic fatigue syndrome.	Cytokine 1991 Jul;3(4):292-8	Chronic fatigue syndrome (CFS) is an idiopathic illness associated with a variety of immunologic abnormalities. To investigate potential pathogenetic mechanisms, we evaluated serum levels and peripheral blood mononuclear cell (PBMC) production of selected cytokines and immunoglobulins. Serum bioactive transforming growth factor beta (TGF-beta) levels were higher (P less than 0.01) in patients with CFS (290 +/- 46 pg/mL) than in control subjects (104 +/- 18 pg/mL), but levels of other cytokines tested were not different. Lipopolysaccharide-stimulated release of interleukin 1 beta (IL-1 beta), IL-6, and tumor necrosis factor-alpha was increased (P less than 0.05) in PBMC cultures from patients with CFS versus control subjects; enhanced (P less than 0.01) IL-6 release to phytohemagglutinin was also observed. In contrast, TGF-beta release in response to lipopolysaccharide was depressed (P less than 0.01) in PBMC cultures derived from patients with CFS. No differences in IL-2 and IL-4 or immunoglobulin production were observed. The enhanced release of inflammatory cytokines by stimulated PBMC from patients with CFS suggests that these cells are primed for an increased response to immune stimuli. These data also suggest an association between abnormal regulation of TGF-beta production in vivo and in vitro with the immunologic consequence of CFS.
Cluff LE.	Robert Wood Johnson Foundation, Princeton, New Jersey.	Medical aspects of delayed convalescence.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S138-40	Disease and illness are not synonymous. In most instances, disease is demonstrable by anatomic, physiologic, biochemical, microbiologic, or immunologic abnormalities. Disease is a pathologic process. Not all persons with a disease are sick or ill. Symptoms of illness associated with a disease may be manifest or persist after the disease has disappeared. The absence of demonstrable disease, however, does not necessarily mean that symptoms of illness are unreal. Recovery from disease and recovery from illness are not always equated. Many factors, including personal characteristics and social circumstances, can be responsible for recovery from disease and illness. Chronic fatigue syndrome or symptoms of illness can persist in some patients but not in others after many different diseases.

Comtois R.	Hopital Notre-Dame, Montreal, Quebec.	[Chronic fatigue: myth or reality]?[article in French]	Union Med Can 1991 Jan-Feb;120(1):10-6	Chronic fatigue is one of the most common complaints. However, it can be a vexing problem in clinical practice. In contrast to serum cholesterol or blood pressure, fatigue may seem immeasurable. The management of fatigue is often complicated by the uncertainty surrounding of its cause and the frequent lack of specific therapy. Recently, criteria were established for the diagnosis of chronic fatigue syndrome. This working case definition does provide some guidance for the practicing physician.

Covington EC.	Department of Psychiatry, Cleveland Clinic Foundation, Ohio.	Depression and chronic fatigue in the patient with chronic pain.	Prim Care 1991 Jun;18(2):341-58	Chronic benign pain is commonly associated with chronic fatigue and depression. Depression and chronic fatigue syndrome are also associated with each other and often include pain. Psychologic factors are prominent in these conditions, and they may share neurobiologic factors as well. Management requires separately addressing each component of patients' distress and usually includes physical rehabilitation, education, administration of nonhabituating medications and often counseling. Depression may be a favorable prognostic sign, as it suggests a treatable condition and provides incentive for recovery.
Cox IM, Campbell MJ, Dowson D.	Medical School, University of Southampton, UK.	Red blood cell magnesium and chronic fatigue syndrome.	Lancet 1991 Mar 30;337(8744):757-60 comment in: Lancet. 1991 Jul 6;338(8758):66 Lancet. 1991 May 4;337(8749):1094-5 Lancet. 1991 Sep 7;338(8767):641 Lancet. 1992 Jul 11;340(8811):124-5	The hypotheses that patients with chronic fatigue syndrome (CFS) have low red blood cell magnesium and that magnesium treatment would improve the wellbeing of such patients were tested in a case-control study and a randomised, double-blind, placebo-controlled trial, respectively. In the case-control study, 20 patients with CFS had lower red cell magnesium concentrations than did 20 healthy control subjects matched for age, sex, and social class (difference 0.1 mmol/l, 95% confidence interval [CI] 0.05 to 0.15). In the clinical trial, 32 patients with CFS were randomly allocated either to intramuscular magnesium sulphate every week for 6 weeks (15 patients) or to placebo (17). Patients treated with magnesium claimed to have improved energy levels, better emotional state, and less pain, as judged by changes in the Nottingham health profile. 12 of the 15 treated patients said that they had benefited from treatment, and in 7 patients energy score improved from the maximum to the minimum. By contrast, 3 of the

				17 patients on placebo said that they felt better (difference 62%, 95% CI 35 to 90), and 1 patient had a better energy score. Red cell magnesium returned to normal in all patients on magnesium but in only 1 patient on placebo. The findings show that magnesium may have a role in CFS. Randomized Controlled Trial

Dale JK, Di Bisceglie AM, Hoofnagle JH, Straus SE.	Medical Virology Section, Laboratory of Clinical Investigation, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20892.	Chronic fatigue syndrome: lack of association with hepatitis C virus infection.	J Med Virol 1991 Jun;34(2):119-21	Chronic fatigue syndrome (CFS) is a debilitating heterogeneous disorder lacking consistent, objective physical or laboratory abnormalities. Among the hypothetical etiologies for CFS are chronic viral infections. The present controlled seroprevalence study found that, among typical CFS patients, evidence of hepatitis C virus (HCV) infection is uncommon. Only one of 36 patients and none of 14 controls were anti-HCV positive. The positive patient had persistent aminotransferase elevations and prior posttransfusion hepatitis. Thus HCV infection is not a common feature of CFS and should not be routinely sought.
Daugherty SA, Henry BE, Peterson DL, Swarts RL, Bastien S, Thomas RS.	Department of Family Medicine, University of Nevada School of Medicine, Reno 89557.	Chronic fatigue syndrome in northern Nevada.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S39-44	The clinical and laboratory findings from studies of patients with chronic fatigue syndrome (CFS) from northern Nevada are summarized. Physicians caring for these patients have estimated that greater than 400 patients with CFS from northern Nevada and nearby communities in California were identified between 1984 and 1988. As a result of these studies, a cluster of clinical and laboratory features associated with the illness in moderately to severely affected patients has been identified: profound fatigue of prolonged duration; cervical lymphadenopathy; recurrent sore throat and/or symptoms of influenza; loss of cognitive function manifested by loss of memory and loss of ability to concentrate; myalgia; impairment of fine motor skills; abnormal findings on magnetic resonance imaging brain scan; depressed level of antibody to Epstein-Barr virus (EBV) nuclear antigen; elevated level of antibody to EBV early antigen restricted component; elevated ratio of CD4 helper to CD8 suppressor cells; and strong evidence of association of this syndrome with infection with human herpesvirus 6. More-serious and longer-lasting neurologic impairments, including seizures, psychosis, and dementia, have also been observed in some of these patients.
David AS, Wessely S, Pelosi AJ.	King's College Hospital, London.	Chronic fatigue syndrome: signs of a new approach.	Br J Hosp Med 1991 Mar;45(3):158-63 comment in: Br J Hosp Med. 1991 Oct;46(4):270	Persistent media highlighting of the plight of patients suffering from severe fatigue of unknown cause (postviral fatigue syndrome or myalgic encephalomyelitis) has at last been matched by professional attention. Recent research has started to clarify the roles of infective, neuromuscular and psychiatric factors in the illness, but pathophysiological mechanisms remain obscure.

Straus SE, Laue L, Listwak SJ, Kruesi MJ, Chrousos GP, Gold PW.	Neuroendocrinology Branch, National Institute of Mental Health, National Institutes of Health, Bethesda, Maryland.	activation of the hypothalamic-pituitary-adrenal axis in patients with chronic fatigue syndrome.	1991 Dec;73(6):1224-34	fatigue for at least 6 months in the absence of a medical diagnosis that would explain the clinical presentation. Because primary glucocorticoid deficiency states and affective disorders putatively associated with a deficiency of the arousal-producing neuropeptide CRH can be associated with similar symptoms, we report here a study of the functional integrity of the various components of the hypothalamic-pituitary-adrenal axis in patients meeting research case criteria for chronic fatigue syndrome. Thirty patients and 72 normal volunteers were studied. Basal activity of the hypothalamic-pituitary-adrenal axis was estimated by determinations of 24-h urinary free cortisol-excretion, evening basal plasma total and free cortisol concentrations, and the cortisol binding globulin-binding capacity. The adrenal cortex was evaluated indirectly by cortisol responses during ovine CRH (oCRH) stimulation testing and directly by cortisol responses to graded submaximal doses of ACTH. Plasma ACTH and cortisol responses to oCRH were employed as a direct measure of the functional integrity of the pituitary corticotroph cell. Central CRH secretion was assessed by measuring its level in cerebrospinal fluid. Compared to normal subjects, patients demonstrated significantly reduced basal evening glucocorticoid levels (89.0 +/- 8.7 vs. 148.4 +/- 20.3 nmol/L; P less than 0.01) and low 24-h urinary free cortisol excretion (122.7 +/- 8.9 vs. 203.1 +/- 10.7 nmol/24 h; P less than 0.0002), but elevated basal evening ACTH concentrations. There was increased adrenocortical sensitivity to ACTH, but a reduced maximal response [F(3.26, 65.16) = 5.50; P = 0.0015). Patients showed attenuated net integrated ACTH responses to oCRH (128.0 +/- 26.4 vs. 225.4 +/- 34.5 pmol/L.min, P less than 0.04). Cerebrospinal fluid CRH levels in patients were no different from control values (8.4 +/- 0.6 vs. 7.7 +/- 0.5 pmol/L; P = NS). Although we cannot definitively account for the etiology of the mild glucocorticoid deficiency seen in chronic fatigue syndrome patients, the enhanced adrenocortical sensitivity to exogenous ACTH and blunted ACTH responses to oCRH are incompatible with a primary adrenal insufficiency. A pituitary source is also unlikely, since basal evening plasma ACTH concentrations were elevated. Hence, the data are most compatible with a mild central adrenal insufficiency secondary to either a deficiency of CRH or some other central stimulus to the pituitary-adrenal axis. Whether a mild glucocorticoid deficiency or a putative deficiency of an arousal-producing neuropeptide such as CRH is related to the clinical symptomatology of the chronic fatigue syndrome remains to be determined.

Evans AS.	Department of Epidemiology and Public Health, Yale University School of Medicine, New Haven, Connecticut 06510.	Chronic fatigue syndrome: thoughts on pathogenesis.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S56-9	Studies have shown that a proportion of patients with severe chronic infection due to Epstein-Barr virus (EBV) lack antibody to a component of EBV nuclear antigen. However, it is not clear whether this circumstance is one of cause or effect in regard to the pathogenesis of chronic fatigue syndrome (CFS); it is clearly not pathognomonic since it also occurs in persons infected with the human immunodeficiency virus and--rarely--in those with other EBV-related conditions. Stress and depression may be other pathogenetic mechanisms that could reactivate EBV and lead to CFS; examples of this phenomenon are given. The syndrome might also follow certain other viral infections as part of a process that has been called postinfectious neurasthenia. Currently, the cause(s) and cure of CFS, a common and distressing syndrome, are enigmatic and require multidisciplinary study.
Fark AR.	Department of Family Medicine, Burns Clinic Medical Center, Michigan, Royne City, MI 49712.	Infectious mononucleosis, Epstein-Barr virus, and chronic fatigue syndrome: a prospective case series.	J Fam Pract 1991 Feb;32(2):202, 205-6, 209 comment in: J Fam Pract. 1991 May;32(5):456	Epstein-Barr viral infection, specifically infectious mononucleosis, typically has a more protracted course than other acute viral illnesses. Some recent observers have additionally suggested the possibility that Epstein-Barr virus (EBV) is the etiologic infectious agent in chronic fatigue syndrome, based on the finding of higher proportions of elevated antibodies to the EBV early antigen in some patients complaining of chronic fatigue. Straus et al reported on 23 patients with chronic fatigue, 83% of whom exhibited persistently elevated antibodies in modest titer to the early antigen. Ten of these patients had never fully recovered from an episode of acute infectious mononucleosis. Other studies had noted similar associations between persistently elevated antibodies to EBV-specific antigens and chronic symptoms in patients who presented with chronic symptoms after mononucleosis. Three important antigen complexes, demonstrable by immunofluorescence procedures, are expressed in EBV-infected cells. The early antigen is thought to function perhaps in early replication of viral DNA. A late antigenic complex, the viral capsid antigen, may represent, in addition to structural capsid proteins, components of the viral enzymatic machinery for late phases of replication or transformation. The Epstein-Barr nuclear antigen is felt to function in viral transformation of host cells.
Furman JM.	Department of Otolaryngology, University of Pittsburgh, Pennsylvania.	Testing of vestibular function: an adjunct in the assessment of chronic fatigue	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S109-11	Patients with chronic fatigue syndrome (CFS) often complain of dysequilibrium that is nonspecific. The basis of this complaint is unknown but may be related to vestibular system abnormalities, in that an association between inner-ear deficits and infectious mononucleosis has been established in the medical literature. An

		syndrome.		overview of quantitative vestibular function testing is given, including vestibulo-ocular and vestibulospinal tests. The basic principles of caloric and rotational testing are provided, including the interaction between vision and the vestibular system. Moving-platform posturography is described. Preliminary results from quantitative vestibular function testing of a small group of individuals with CFS are provided.
Goldenberg DL.	Newton-Wellesley Hospital, Newton, Massachusetts.	Fibromyalgia, chronic fatigue syndrome, and myofascial pain syndrome.	Curr Opin Rheumatol 1991 Apr;3(2):247-58	There continues to be an emerging body of literature related to fibromyalgia and the related conditions chronic fatigue syndrome and myofascial pain. During the past year, the most notable contributions included a large multicenter study providing new diagnostic criteria for the classification of fibromyalgia and clinical studies describing the overlap of fibromyalgia, chronic fatigue syndrome, and myofascial pain. Pathophysiologic studies were often preliminary and uncontrolled but the focus of these studies on abnormal nociception, neurohormones, and muscle metabolism provides an exciting hypothesis to unify pain, fatigue, and sleep disturbances, the primary symptoms of fibromyalgia. Unfortunately, new therapeutic trials were neither innovative nor especially encouraging.
Gorensek MJ.	Department of Infectious Disease, Cleveland Clinic Florida, Ft. Lauderdale, Florida.	Chronic fatigue and depression in the ambulatory patient.	Prim Care 1991 Jun;18(2):397-419	Fatigue, pain, and emotional upset remain the most common problems affecting humanity and for which we still know so very little. Chronic fatigue syndrome is most likely a number of as yet unproven various undifferentiated illnesses that are exceedingly difficult to distinguish from depression. There probably is a subset of patients with CFS who do have true immune dysfunction and persistent viral infection, and this particular group of patients should be further investigated. This group is the minority of patients who present with chronic fatigue. Although chronic fatigue syndrome may be the result of an organic illness in psychologically susceptible individuals, it remains most important to assess underlying psychologic factors that then need to be addressed. These factors may very likely have a profound effect on immune function, but more research is needed in this area. The diagnostic evaluation of patients with chronic fatigue syndrome should initially focus on causes for fatigue other than Epstein-Barr viral infection. Significant underlying medical conditions should be ruled out, and extensive inquiry into symptoms suggestive of depression and anxiety should be aggressively pursued. Treatment should include psychiatric support and counseling, good nutrition, adequate rest, and a gradual increase in activity. Anti-inflammatory agents and serotonin-replenishing antidepressants are helpful when muscle pain and tenderness are a major part of the patient's symptoms. Psychoactive drugs are useful when indicated. Low doses of antidepressants such as doxepin (10-25 mg at night) are generally well tolerated and have shown efficacy in numerous patients, although there are no reports of controlled trials.

Cognitive and mood-state changes in patients with chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S45-52	In this paper the cognitive and psychiatric impairments associated with chronic fatigue syndrome (CFS) and related disorders are reviewed. It is concluded that while acute mononucleosis and infection with Epstein-Barr virus occasionally result in impaired cognition, such changes have not yet been objectively verified in patients with CFS. However, when patients with CFS are carefully studied, concurrent or premorbid psychiatric disorders are revealed at a greater than chance level. Finally, some suggestions are offered regarding improved neuropsychological assessment of fatigue, concentration, and attention for patients with CFS. The findings to date, while suggesting that psychological predisposition may play a role in the expression of CFS, are still inconclusive regarding the etiology of CFS.
Grufferman S.	Department of Clinical Epidemiology and Preventive Medicine, University of Pittsburgh School of Medicine, Pennsylvania 15261.	Issues and problems in the conduct of epidemiologic research on chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S60-7	The epidemiologic research approach is perhaps most appropriate for initial studies of chronic fatigue syndrome since the syndrome is vaguely defined, scientific knowledge about it is limited, and an infectious etiology is suspected. Several priority needs appropriate for epidemiologic research are identified, including a refinement of diagnostic criteria; a greater understanding of the natural history of the syndrome; basic incidence, prevalence, and mortality statistics; information on whether asymptomatic cases exist; etiologic studies of possible heterogeneity of cases; investigations of clusters of cases; and determinations of whether patients with the syndrome have an increased risk of malignancy. Because of the lack of cogent etiologic hypotheses regarding the syndrome, case-control studies are identified as a high priority for research. The many difficulties encountered in conducting such research are discussed and approaches to dealing with these problems are suggested.
Gupta S, Vayuvegula B.	Division of Basic and Clinical Immunology, University of California, Irvine 92717.	A comprehensive immunological analysis in chronic fatigue syndrome.	Scand J Immunol 1991 Mar;33(3):319-27	A detailed analysis of cell-mediated and antibody-mediated immunity was performed in 20 CDC-defined patients with chronic fatigue syndrome (CFS) and 20 age- and sex-matched healthy controls. CD3+, CD4+, CD8+, and CD20+ lymphocytes were comparable in two groups. Natural killer cells as defined by

				CD16, CD56 and CD57 antigens were significantly reduced in CFS. A significant increase in the proportions of CD4+ ICAM 1+ T cells was observed in CFS. Monocytes from CFS displayed increased density (as determined by mean fluorescence channel numbers) of intercellular adhesion molecule 1 (ICAM-1) and lymphocyte function associated antigen 1 (LFA-1), but showed decreased enhancing response to recombinant interferon-gamma in vitro. The lymphocyte DNA synthesis in response to phytohaemoglobulin (PHA), Concanavalin A (Con A) and pokeweed mitogen (PWM) was normal but the response to soluble antigens was significantly reduced. Serum IgM, IgG, IgA, and IgG subclasses were normal. In vivo specific antibody response to pneumococcus vaccine was depressed in CFS. Forty percent of patients showed titres of anti-human herpes virus 6 (anti-HHV-6) antibody higher than that in the controls (greater than or equal to 1/80). These data suggest immunological dysfunction in patients with chronic fatigue syndrome. The significance of these observations is discussed.
Hawton KE, Hengeveld MW.	Warneford Hospital, Psychiatrische Universiteitskliniek, Oxford, Engeland.	[Chronic fatigue syndrome; psychiatric aspects].[article in Dutch]	Ned Tijdschr Geneeskd 1991 Oct 26;135(43):2014-7	
Hayden SP.	Department of Internal Medicine, Cleveland Clinic Foundation, Ohio 44195.	A practical approach to chronic fatigue syndrome.	Cleve Clin J Med 1991 Mar-Apr;58(2):116-20	Chronic fatigue may have several physical causes, but a psychiatric condition is often involved. A substantial minority of patients are not diagnosed by conventional tests and do not respond to antidepressant therapy. These patients should be referred for psychiatric opinion or observed for new developments. Extensive virologic testing and unorthodox treatment approaches have no scientific basis at present. Claims of dramatic new diagnostic tests or therapy should be treated with caution because of the long history of unsuccessful attempts to categorize chronic fatigue into one diagnosis and the strong placebo effect shown in controlled trials.

Hilgers A, Krueger GR, Lembke U, Ramon A.	International Institute of Immunopathology, Inc. Cologne, Washington, DC.	Postinfectious chronic fatigue syndrome: case history of thirty-five patients in Germany.	In Vivo 1991 May-Jun;5(3):201-5	Thirty-five patients with chronic fatigue syndrome according to the criteria of Holmes were followed for periods of up to eight years. The most frequent symptoms were severe fatigue, arthralgias and myalgias, recurrent oropharyngitis and various psychiatric disorders. More than half of the patients

				suffered from neuropathy, lymphadenopathy, gastrointestinal complaints and recurrent low-grade fever. Recurrent or persistent activity of human herpesvirus -6 infection was seen in 73% of the patients and of Epstein-Barr virus in 34.4%. In addition, various other infections were diagnosed at lower frequency. Initial routine immunologic screening revealed various types of deficiencies, these were yet inconsistent and variable when different patients were compared with each other. Tentative treatments included in immunoglobulins, nonspecific immunostimulation and virostatic drugs. No consistently positive results were obtained with any treatment schedule although immunoglobulins appeared the most efficient measure. In addition, psychologic care of the patients is indicated, since disturbances in the psycho-neuroimmunologic regulation may play a significant role in the pathogenesis of the disease.
Holmes GP.	Epidemiology Office, Centers for Disease Control, Atlanta, Georgia 30333.	Defining the chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S53-5	The recently published working definition of the chronic fatigue syndrome (CFS) is a necessary first step toward a consistent effort to research this controversial illness. Before this definition was developed, cases often were defined vaguely, according to the perceptions and biases of the individual researchers, so that the results of some studies were unclear. However, few specific diagnostic parameters for CFS exist, and the new definition may not delineate a single clinicopathologic entity. Future efforts at researching this illness should be aimed at identifying parameters that differentiate CFS from psychiatric conditions such as major depression and from other defined chronic diseases. Because CFS may be the result of multiple disease processes, the separate study of well-defined subgroups of patients with CFS is appropriate. Such subgroups of patients are probably more likely to have common pathogenetic features than are patients with CFS as a whole group.
Ho-Yen DO, McNamara I.	Raigmore Hospital, Inverness.	General practitioners' experience of the chronic fatigue syndrome.	Br J Gen Pract 1991 Aug;41(349):324-6 comment in: Br J Gen Pract. 1991 Nov;41(352):480	In order to examine the prevalence of patients with symptoms fulfilling the criteria for the chronic fatigue syndrome an extensive survey was carried out of general practitioners on 10 local government lists in two health boards (91% response rate). At the same time practitioners' attitudes to the syndrome and their experience in terms of workload and the characteristics of patients affected were documented. The majority of general practitioners (71%) accepted the existence of chronic fatigue syndrome, but 22% were undecided. The doctors reported a prevalence among their patients of 1.3 per 1000 patients (range 0.3-2.7 for the 10 areas) with a peak in the 30-44 years age group. Female patients were more commonly affected than males (sex ratio 1.8:1.0), but the severity of illness and the use of general practitioner's time was the same among male and female patients. Patients in occupations where they were exposed to infection were affected (teachers and students, 22% of sample; hospital workers, 7%), but many patients were unskilled (8%) and skilled workers (9%). Patients suffering from the chronic fatigue syndrome appear to be a real and distinct group for

				general practitioners and may represent a substantial part of the workload of doctors in particular areas.

Jones JF, Streib J, Baker S, Herberger M.	Department of Pediatrics, National Jewish Center for Immunology and Respiratory Medicine, Denver, Colorado 80206.	Chronic fatigue syndrome: I. Epstein-Barr virus immune response and molecular epidemiology.	J Med Virol 1991 Mar;33(3):151-8	Patients with chronic fatigue syndrome were compared to healthy seropositive control subjects in an open study and a case-control study analyzing spontaneous transformation rates of peripheral blood lymphocytes, EBV viral genome characteristics as determined by DNA restriction fragment polymorphisms, and antibody production by Western blot analysis. Thirty percent of patients versus 8% of control subjects underwent spontaneous transformation in the two studies. Viral genome patterns were overall similar to one another, with polymorphisms frequently present in BamHI B', K, H, and Y fragments. Only one line was found with the EBNA-2B genotype. Nineteen lines were found to contain viral DNA in the linear form suggesting active lytic replication. Western blot studies suggested that ill subjects made antibodies to lytic proteins more frequently than did healthy control subjects. Lack of control of EBV outgrowth in vitro is correlated with antibody evidence of active infection in vivo in some patients with chronic fatigue syndrome.
Jones JF.	Department of Pediatrics, National Jewish Center for Immunology and Respiratory Medicine, Denver, Colorado 80206.	Serologic and immunologic responses in chronic fatigue syndrome with emphasis on the Epstein-Barr virus.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S26-31	Although patients with chronic fatigue syndrome (CFS) can be diagnosed by clinical criteria, the lack of specific laboratory criteria delays or prevents the diagnosis and contributes to the quasi-disease status of the syndrome. A resurgence of interest in the syndrome has followed reports suggesting that CFS may be associated with chronic active infection due to the Epstein-Barr virus. Analysis of reports to date shows that the mean titers of antibodies to viral capsid antigen and to early antigen are greater for patients with CFS than for healthy individuals; this is particularly evident in cases for which serial samples were tested. However, these differences do not prove the cause of CFS. Cell-mediated immune responses in patients with CFS vary from study to study, and the number and function of natural killer cells in those patients are the most variable factors. Rates of isolation of virus from saliva do not differ, but in one comparison study with a large number of subjects, more lymphocytes that

				contained virus were isolated from patients than from controls. Other viruses, such as the Coxsackie B virus, have been implicated as causes of CFS in studies from Great Britain. The use of a working definition of CFS and standardized tests to address abnormalities revealed by laboratory tests among homogeneous populations should allow determination of useful tests for the diagnosis of CFS and studies of its mechanisms.

Katon WJ, Buchwald DS, Simon GE, Russo JE, Mease PJ.	Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle 98195.	Psychiatric illness in patients with chronic fatigue and those with rheumatoid arthritis.	J Gen Intern Med 1991 Jul-Aug;6(4):277-85 comment in: J Gen Intern Med. 1991 Jul-Aug;6(4):378-9	OBJECTIVES: To identify psychiatric differences between patients with chronic fatigue and those with rheumatoid arthritis and to investigate whether patients meeting Centers for Disease Control (CDC) criteria for chronic fatigue syndrome (CFS) can be differentiated from patients with chronic fatigue on measures of disability and psychosocial distress. DESIGN: Cross-sectional study comparing 98 patients with chronic fatigue with 31 patients with rheumatoid arthritis on structured psychiatric interviews and patient questionnaires. Nineteen patients meeting CDC criteria for CFS were compared with 79 patients with chronic fatigue not meeting CDC criteria on questionnaires measuring disability and psychosocial distress. SETTING: Consecutive patients with chronic fatigue were selected from a chronic fatigue clinic at the University of Washington, and 31 consecutive patients with rheumatoid arthritis were sampled from a private rheumatology practice. MAIN RESULTS: Patients with chronic fatigue had a significantly higher prevalence of lifetime major depression and somatization disorder than did patients with rheumatoid arthritis. Patients with chronic fatigue also had a significantly higher prevalence of current and lifetime psychiatric diagnoses. Only 19 of 98 patients with chronic fatigue met CDC criteria for CFS. Patients meeting CDC criteria for CFS could not be differentiated from the larger group of patients with chronic fatigue on any study variable. CONCLUSIONS: Patients with chronic fatigue have a significantly higher burden of psychiatric illness than do patients with rheumatoid arthritis. The psychiatric illness preceded the development of chronic fatigue in over half the patients. Centers for Disease Control criteria for CFS did not select a subset of chronic fatigue patients who could be differentiated on disability or psychosocial parameters from patients with chronic fatigue who did not meet CDC criteria.
Komaroff AL, Buchwald D.	Department of Medicine, Brigham and Women's Hospital, Harvard Medical School,	Symptoms and signs of chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S8-11	This review summarizes the symptoms and signs seen in patients with chronic fatigue syndrome (CFS). It is based on the authors' experience with two cohorts of approximately 510 patients with chronic debilitating fatigue and on the reported experience of other investigators with similar patients. The most

	Boston, Massachusetts 02115.			characteristic symptoms of CFS are the sudden onset of an infectious-type illness, the subsequent chronic and debilitating fatigue, and postexertional malaise; many patients also have recurrent fevers, pharyngitis, adenopathy, myalgias, sleep disorders, and cognitive impairment.
Kroenke K.	Department of Medicine, Uniformed Services University of Health Sciences, Bethesda, MD 20814.	Chronic fatigue syndrome: is it real?	Postgrad Med 1991 Feb 1;89(2):44-6, 49-50, 53-5 comment in: Postgrad Med. 1991 Nov 15;90(7):23-4	Epstein-Barr virus is no longer considered an important cause of chronic fatigue syndrome. Instead, the disease is probably related to an underlying psychiatric disorder, subtle immunologic dysfunction, or an interaction between these two factors. A carefully taken history, physical examination, and simple laboratory testing are usually sufficient to establish the diagnosis. Therapy with antidepressants or nonsteroidal anti-inflammatory drugs may be effective in selected patients. Thorough follow-up conducted with empathy and optimism is important in all cases.
Krueger GR, Ablashi DV, Josephs SF, Salahuddin SZ, Lembke U, Ramon A, Bertram G.	Immunopathology Laboratory, University of Cologne, F.R.G.	Clinical indications and diagnostic techniques of human herpesvirus-6 (HHV-6) infection.	In Vivo 1991 May-Jun;5(3):287-95	The sixth member of the human herpesvirus family, HHV-6, causes early childhood infection with subsequent latency and antibody prevalence of about 60-80%. Active infection is related to a number of acute and chronic diseases such as exanthem subitum, certain cases of infectious mononucleosis and other immunoproliferative syndromes, autoimmune disorders and so-called postinfectious chronic fatigue syndrome. The clinical diagnosis of HHV-6 associated diseases requires detailed clinical differential diagnostic procedures and meticulous serological testing with exclusion of other herpesvirus infections or cross-reactivity between such infections. Diagnostic efforts, however, are warranted by certain indications for therapeutic intervention. The current review summarizes indications, techniques and limitations for the serological diagnosis of HHV-6 infection.
Krupp LB, Mendelson WB, Friedman R.	Department of Neurology, State University of New York, Stony Brook 11794.	An overview of chronic fatigue syndrome.	J Clin Psychiatry 1991 Oct;52(10):403-10 comment in: J Clin Psychiatry. 1992 Aug;53(8):296	BACKGROUND: Psychological and immunologic factors both appear to contribute to chronic fatigue syndrome (CFS). By comparing CFS with other disorders in which fatigue is a prominent symptom, the association between fatigue, psychological vulnerability, depression, and immune function may be further defined. Recent data from psychological, neurologic, and immunologic studies that address these issues are reviewed. METHOD: Articles and abstracts covering CFS and related topics of fatigue, depression, and postinfectious syndromes were identified through MEDLINE and Index Medicus (1980-1990) and by bibliographic review of pertinent review articles. RESULTS: The 1988 definition of CFS by the Centers for Disease Control encompasses several conditions in which the major characteristic is severe fatigue associated with constitutional symptoms. Several studies have identified immune dysfunction in CFS patients, but the specificity of these findings remains unclear. Most studies have shown that CFS patients, compared with other patients with chronic medical illness, experience more disabling fatigue. Some investigators have found a higher incidence of concurrent and past psychiatric illness in CFS patients compared with other medical patients,

				thereby suggesting an underlying psychopathology in CFS. However, other studies have not found a higher than expected incidence of past depression in CFS patients and have further shown that many CFS patients have no identifiable psychopathology. CONCLUSION: CFS appears to be a heterogenous entity. Although there may be a high coincidence of major depression in CFS, a substantial proportion of patients lack any identifiable DSM-III-R psychiatric disorder yet still manifest the syndrome, thereby suggesting it has an autonomous entity. Despite the evolving nature of our current understanding of CFS, a rational diagnostic and therapeutic approach to CFS is possible.
Kulig JW.		Chronic Fatigue Syndrome and Fibromyalgia in Adolescence.	Adolesc Med 1991 Oct;2(3):473-484	A complaint of persistent, debilitating fatigue in an adolescent, accompanied by symptoms that meet the recently adopted criteria for chronic fatigue syndrome (CFS), presents a difficult challenge for the clinician. This article describes the diagnostic criteria for CFS and fibromyalgia, and discusses the epidemiology, etiology, and management of these conditions.

Lam RW.	Department of Psychiatry, University of British Columbia, Vancouver.	Seasonal affective disorder presenting as chronic fatigue syndrome.	Can J Psychiatry 1991 Nov;36(9):680-2	Although operational criteria have been recently proposed to better define chronic fatigue syndrome (CFS), it remains a controversial diagnosis. There are many overlapping symptoms between CFS and major depression. The author presents two patients with seasonal affective disorder, who responded to phototherapy and had previously been diagnosed as CFS. Because of the consequences of treatment, seasonal and non seasonal depression need to be ruled out in patients with chronic fatigue symptoms.
Landay AL, Jessop C, Lennette ET, Levy JA.	Department of Immunology/Microbiology, Rush-Presbyterian-St. Luke's Medical Center, Chicago, Illinois.	Chronic fatigue syndrome: clinical condition associated with immune activation.	Lancet 1991 Sep 21;338(8769):707-12	There is much conflicting immunological and viral data about the causes of chronic fatigue syndrome (CFS); some findings support the notion that CFS may be due to one or more immune disorders that have resulted from exposure to an infectious agent. In the present study, flow cytometry and several different monoclonal antibodies recognising T, B, and natural killer (NK) cell populations as well as activation and cell adhesion antigens were used to study 147 individuals with CFS. Compared with healthy controls, a reduced CD8 suppressor cell population and increased activation markers (CD38, HLA-DR) on CD8 cells were found. The differences were significant ($p = 0.01$) in patient with major symptoms of the disease. These immunological indices were not observed in 80 healthy

				individuals, in 22 contacts of CFS patients, or in 43 patients with other diseases. No correlation of these findings in CFS patients with any known human viruses could be detected by serology. The findings suggest that immune activation is associated with many cases of CFS.
Lane TJ, Manu P, Matthews DA.	Department of Medicine, University of Connecticut School of Medicine, Farmington 06032.	Depression and somatization in the chronic fatigue syndrome.	Am J Med 1991 Oct;91(4):335-44 comment in: Am J Med. 1992 Jun;92(6):710 Am J Med. 1994 May;96(5):485-6	PURPOSE: To report the prevalence, clinical features, and diagnostic associations of the proposed chronic fatigue syndrome (CFS) in a cohort of patients with chronic fatigue and to assess the usefulness of a structured psychiatric interview for detecting previously unrecognized psychiatric morbidity in patients with CFS. PATIENTS AND METHODS: A consecutive sample of 200 adult patients with a chief complaint of chronic fatigue was prospectively evaluated in a referral-based clinic within a university general medicine practice. All patients received a thorough medical history, physical examination, diagnostic laboratory testing, and portions of the Diagnostic Interview Schedule, version III-A. The criteria for CFS were applied, and patients with CFS were compared with matched control subjects from the inception cohort. RESULTS: The 60 patients with CFS had similar likelihoods of current psychiatric disorders (78% versus 82%), active mood disorders (73% versus 77%), and preexisting psychiatric disorders (42% versus 43%) when compared with fatigued control subjects. Patients with CFS were more likely to have somatization disorder (p less than 0.001) and to attribute their illness to a physical cause (p less than 0.005) than fatigued controls. Patients with CFS also displayed functional symptoms, often lifelong, which are not part of the case definition of CFS. Depressive features in patients with CFS were similar to those of control subjects, but a trend toward suicidal behavior was noted. CONCLUSIONS: Patients with CFS have a high prevalence of unrecognized, current psychiatric disorders, which often predate their fatigue syndrome. Assessment of patients with CFS should include a structured psychiatric evaluation.
Leventhal LJ, Naides SJ, Freundlich B.	Department of Medicine, University of Pennsylvania School of Medicine, Philadelphia.	Fibromyalgia and parvovirus infection.	Arthritis Rheum 1991 Oct;34(10):1319-24	An infectious cause of fibromyalgia (FM) has been hypothesized based upon the observed similarity of this entity and chronic fatigue syndrome. Three patients developed symptoms of FM after documented episodes of acute parvovirus B19 infections. B19 antibody determinations were obtained approximately 1 month after the symptoms began; both IgM and IgG titers were positive at that time. All 3 patients met criteria for FM. Polysomnography performed on 2 of the patients revealed profound alpha-wave intrusion throughout nonrapid eye movement sleep. A more careful search for viral infections in FM patients whose symptoms appear following a "flu-like" illness appears warranted.
Lewis SF, Haller RG.	Department of Physiology, University of Texas Southwestern Medical Center, Dallas.	Physiologic measurement of exercise and fatigue with special reference	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S98-108	Oxidative metabolism is the major source of energy for muscle activity, and maximal oxygen uptake (VO2max), the product of maximal cardiac output and maximal arteriovenous oxygen difference, indicates individual capacity for oxidative metabolism and performance of exercise by the large muscles.

		to chronic fatigue syndrome.		Strength, a function of muscle cross-sectional area, motor-unit recruitment, and neuromuscular coordination, is the ability to develop force in a single, brief, maximal-effort voluntary contraction of rested muscle. Weakness is a diminished ability of rested muscle to exert maximal force. Fatigue is a loss of maximal force-generating capacity that develops during muscular activity, likely originates within muscle itself, and persists until muscle is fully recovered. Individual perception of motor effort can be determined with standardized rating scales. These concepts are discussed in detail, their relevance to the pathophysiology of exercise in chronic fatigue syndrome is analyzed, and a general strategy of exercise evaluation pertinent to chronic fatigue syndrome is presented.

Lloyd AR, Gandevia SC, Hales JP.	Department of Clinical Neurophysiology, Prince Henry Hospital, Sydney, Australia.	Muscle performance, voluntary activation, twitch properties and perceived effort in normal subjects and patients with the chronic fatigue syndrome.	Brain 1991 Feb;114 (Pt 1A):85-98	The decrease in maximal force-generating capacity, the degree of central activation of the muscle, and the subjective perception of effort were measured during prolonged submaximal isometric exercise in 12 male patients suffering from the 'chronic fatigue syndrome' and 13 naive, healthy male subjects. Maximal voluntary isometric torque generated by the elbow flexors was measured before, and at 5 min intervals during an endurance sequence of 45 min of repetitive isometric contractions (6 s duration, 4 s rest interval) producing 30% of the initial maximal voluntary torque. Electrical stimuli were also delivered to the elbow flexors to measure the contractile force in the intervals between voluntary contractions. The degree of central motor activation during maximal voluntary contractions was assessed using a sensitive method of twitch interpolation. In addition, the perceived effort required to achieve the target submaximal contractions was recorded using a standardized self-report scale. A high degree of central activation was achieved in maximal contractions during the endurance sequence both in the patients (mean of maximal force 93.6%; SD 7.8%), and in the control subjects (mean 90.9%; SD 9.5%). The relative torque produced by either voluntary or electrically stimulated contractions was not significantly different between patients and control subjects throughout the test. There was no significant difference in the perceived exertion between the patients and control subjects. These findings support the concept that neither poor motivation, nor muscle contractile failure is important in the pathogenesis of 'fatigue' in patients with the chronic fatigue syndrome.
Lopis R.		A personal encounter with a mystery illness.	Aust Fam Physician 1991 Mar;20(3):316-7	I urge all practitioners to accept that 'chronic fatigue' patients have genuine symptoms. This disease can cause depression, but for most patients it is not caused by depression. I acknowledge that a depressed patient can develop the

				chronic fatigue syndrome in the same way that they can contract any other disease. If you are unable to diagnose a patient with these symptoms please refer them to a centre specialising in this devastating and poorly understood disease.
Lynch S, Main J, Seth R.		Definition of chronic fatigue syndrome (CFS)	Br J Psychiatry 1991 Sep;159:439-40 comment in: Br J Psychiatry. 1992 Jan;160:127-8 comment on: Br J Psychiatry. 1991 May;158:717	
Lynch S, Seth R, Montgomery S.	St Mary's Hospital Medical School, London.	Antidepressant therapy in the chronic fatigue syndrome.	Br J Gen Pract 1991 Aug;41(349):339-42 comment in: Br J Gen Pract. 1991 Nov;41(352):479-80 Br J Gen Pract. 1991 Nov;41(352):480	The chronic fatigue syndrome is a condition receiving increasing recognition. Symptoms of depression are not infrequent and may be persistent and severe enough to warrant treatment. The controversy over the use of antidepressant therapy in this condition may present a dilemma for the general practitioner considering possible treatments. This paper draws on the literature and on the authors' own observations of patients with the chronic fatigue syndrome to suggest guidelines for the use of antidepressant therapy.
Malleson PN.	Research Centre, University of British Columbia, Vancouver, Canada.	Pain syndromes, disability, and chronic disease in childhood.	Curr Opin Rheumatol 1991 Oct;3(5):860-6	Childhood disability and chronic disease are common, and their prevalence is increasing as children survive with conditions that were previously fatal. It is important that physicians in training learn about disability and handicap, and the functioning of multidisciplinary teams to manage these problems. Chronic ill-health is often very expensive to manage, and some serious and creative thinking about the best way to fund such health care is urgently needed. Pediatric rheumatologists are involved with the care of many children with chronic and recurrent musculoskeletal pain; however, they have not perhaps focused enough research effort on the investigation of pain and its management. Whether reflex neurovascular dystrophy, fibromyalgia, and chronic fatigue syndrome are part of a disease continuum is unclear, but it seems probable that psychosocial problems are often important contributing factors in all three conditions. Immunoglobulin subclass deficiencies are being increasingly delineated, occurring in chronic fatigue syndrome as well as many other disease states. Their clinical relevance still remains, for the most part, uncertain. Short stature occurs in many chronic illnesses, and the role of growth hormone treatment in these conditions is beginning to be investigated.
Mantysaari M.		Aerobic work capacity in chronic fatigue syndrome.	BMJ 1991 Jan 5;302(6767):50 comment on: BMJ. 1990 Oct 27;301(6758):953-6	
Matthews DA, Lane TJ, Manu P.	Division of General Medicine, University of	Antibodies to Epstein-Barr virus in patients	South Med J 1991 Jul;84(7):832-40	To clarify the role of Epstein-Barr virus (EBV) infection and the value of EBV antibody testing in evaluating patients with chronic fatigue, we studied 200

	Connecticut School of Medicine, Farmington.	with chronic fatigue.		consecutive patients with chronic fatigue (mean duration, 9 years). Complete EBV serologic panels were obtained for 154 patients, 35 (23%) of whom met serologic or clinical criteria for chronic or reactivated EBV infection. We compared these patients with chronic EBV infection (CEBV cases) to 35 age- and sex-matched patients who were selected from the same cohort of fatigued patients but who did not meet the criteria (CEBV control subjects). We found few differences between groups in demographic characteristics, clinical features, and symptoms; CEBV cases were more likely to meet criteria for the proposed chronic fatigue syndrome (14% vs 0%), and to report that they suffered from an influenza-like illness at the onset of their fatigue syndrome (34% vs 12%), that they lost their job because of their fatigue (37% vs 11%), and that their fatigue was improved by recreational activity (26% vs 3%). Physical examination and laboratory testing showed few abnormalities in either group. Psychiatric morbidity was common in both groups, including mood disorders (63% of CEBV cases vs 54% of CEBV controls), anxiety (11% vs 9%) and somatization disorder (9% in each group). We conclude that EBV serologic patterns have little clinical usefulness in evaluating patients with chronic fatigue.
Matthews DA, Manu P, Lane TJ.	Division of General Medicine, University of Connecticut Health Center, Farmington 06030.	Evaluation and management of patients with chronic fatigue.	Am J Med Sci 1991 Nov;302(5):269-77	Chronic fatigue is a common and disabling problem in primary care practice. The differential diagnosis of chronic fatigue is extensive and includes medical disorders, altered physiologic states (eg, pregnancy, exertion), psychiatric disorders, lifestyle derangements, drugs, and controversial entities (eg, chronic candidiasis, food allergies, environmental illness, and chronic fatigue syndrome). The most common diagnoses are psychiatric disorders, including mood, anxiety, and somatoform disorders. A comprehensive approach to diagnosis and management is necessary, including structured psychiatric interviewing, functional assessment, and elicitation of the patient's diagnostic beliefs. Patients often believe they are suffering from an organic medical disorder (eg, viral or immunologic) and resist psychiatric labelling of their symptoms and referral to mental health practitioners. Establishing and maintaining rapport, having a flexible approach, and demonstrating a personal concern for the patient is essential. Drug therapy for specific psychiatric and medical illnesses and cognitive-behavioral approaches for enhancing coping mechanisms are effective.
McBride SJ, McCluskey DR.	Department of Immunology, Queen's University & Royal Victoria Hospital, Belfast, UK.	Treatment of chronic fatigue syndrome.	Br Med Bull 1991 Oct;47(4):895-907	Chronic Fatigue Syndrome is a disorder which is characterised by profound fatigue together with a variety of other subjective clinical features which persist over a prolonged period of time. The aetiology remains at present uncertain and therefore rational therapeutic strategies are difficult to plan. This paper reviews currently used forms of treatment aimed at correcting the possible pathophysiological mechanisms and discusses the problems associated with the management of this condition.

Meadows LM, Walther P, Ozer H.	Division of Medical Oncology, School of Medicine, University of North Carolina, Chapel Hill.	alpha-Interferon and 5-fluorouracil: possible mechanisms of antitumor action.	Semin Oncol 1991 Oct;18(5 Suppl 7):71-6	We have treated 17 patients with 5-fluorouracil (5-FU, 300 mg/m2/d by continuous ambulatory infusion for 8 weeks) and interferon alfa-2b (escalating doses to cohorts of three to five patients, given subcutaneously on a daily schedule at 2.0, 3.5, 5.0, and 10.0 x 10(6) IU/m2). The two major toxicities observed were mucositis, which occurred in 10 patients at 2 weeks and required interruption of therapy and 5-FU dose reduction, and chronic fatigue syndrome, which required reduction of the dose of interferon alfa-2b. Other toxicities seen included elevation in BUN/creatinine, elevation in liver function tests, alopecia, diarrhea, confusion, and myelosuppression. No toxic deaths occurred. Five responses were observed: two complete responses, two partial responses, and one minor response, all in patients with gastrointestinal malignancy; three of the responding patients had previously failed 5-FU-containing regimens. When we measured 5-FU plasma levels in nine of our patients, they were at or below 1 ng/mL in most patients; however, within 1 hour of administration of interferon alfa-2b, plasma levels rose 16-fold. This elevation of 5-FU levels persisted for at least 24 hours, and could not be accounted for on the basis of altered interleukin-6 levels. When the regimen was tested in eight patients with metastatic renal cell carcinoma as part of a pilot study, three partial responses were observed, and no patient developed disease progression while on treatment. The combination of 5-FU, given by continuous infusion, and interferon alfa-2b, given daily, appears worthy of advancement to phase II trials.

Milton JD, Clements GB, Edwards RH.	Department of Medicine, University of Liverpool, UK.	Immune responsiveness in chronic fatigue syndrome.	Postgrad Med J 1991 Jun;67(788):532-7 comment in: Postgrad Med J. 1992 Jan;68(795):66-7	We have endeavoured to find immunological indications of chronic virus infection in patients with chronic fatigue syndrome (myalgic encephalomyelitis) and to investigate immune responsiveness to viruses in such patients in comparison with normal subjects and patients with muscular dystrophy. Levels of circulating IgM immune complexes were elevated (above the 95% normal control range) in 10 (17%) of 58 patients with chronic fatigue syndrome, which was not significantly different from the normal controls or from dystrophy controls (by Mann Whitney U test). Levels of IgG complexes were only increased in 10% of patients. Lymphocyte proliferation in response to concanavalin A (Con A), assessed by increase in 3H-thymidine incorporation, did not differ between 14 patients and 18 normal subjects. The proliferative response to Coxsackie B virus antigen did not differ between chronic fatigue patients and normal subjects when expressed either as an increase in counts or as a stimulation index. Adjustment of the counts in relation to the proliferation response to Con A, as an indication of the overall proliferative response of the cell preparation, did not reveal any hidden difference. IgM antibodies to Coxsackie B viruses were not found in any of 20 patients and in 1 of 20 dystrophy controls. Significant levels of neutralizing antibodies to Coxsackie B viruses 1-5 were found in 6 out of 19 (32%) patients compared with 4 out of 17 (24%) dystrophy controls, which does not differ from currently expected normal incidence. Antibody titres to other respiratory viruses were also not notably different between the patient and control groups.(ABSTRACT TRUNCATED AT 250 WORDS)

Pagano JS.	Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill 27599-2975.	Detection of Epstein-Barr virus with molecular hybridization techniques.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S123-8	The cord-blood transformation assay remains the standard method for detecting Epstein-Barr virus (EBV) in secretions. However, newer methods are much faster and more sensitive, although most are still regarded as research procedures. The most useful of these are Southern blot hybridization, particularly the variation that employs terminal genomic probe analysis; in situ cytohybridization; and polymerase chain reaction analyses. Use of these methods alone or in combination should disclose the infected cell type, whether the infection is productive or latent, and the presence of multiple strains of EBV. Such

				information may help establish whether EBV is a causal agent in chronic fatigue syndrome.
Peterson PK, Schenck CH, Sherman R.	Department of Medicine, Hennepin County Medical Center, Minneapolis.	Chronic fatigue syndrome in Minnesota.	Minn Med 1991 May;74(5):21-6 comment in: Minn Med. 1991 Sep;74(9):7-8	Chronic fatigue syndrome (CFS), an illness characterized by debilitating fatigue and a number of associated symptoms, was identified in 135 patients using the case definition provided in 1988. The demographic features of these patients, 97% of whom resided in Minnesota, were similar to those reported elsewhere. About three-fourths of the cases occurred between 1984 and 1989, and in 123 (91.1%), the illness began with what appeared to be an acute infection. Patients had been ill for an average of 4.3 years before enrollment in the study. Fatigue was their most troublesome symptom, although a majority of the patients rated most of the general symptoms and neuropsychological complaints associated with CFS as moderate or severe. Follow-up data obtained on 62 patients one year after initial evaluation revealed that none had completely recovered. However, about 40% reported some improvement in each of the CFS symptoms.

Pope HG Jr, Hudson JI.	McLean Hospital, Belmont, Massachusetts.	A supplemental interview for forms of "affective spectrum disorder".	Int J Psychiatry Med 1991;21(3):205-32	OBJECTIVE: Recent evidence suggests that a number of psychiatric and medical conditions may be members or candidate members of a larger family of conditions, which we have termed "affective spectrum disorder (ASD)." In order to facilitate further research into this concept, we drafted seven interview modules, using the format of the Structured Clinical Interview for DSM-III-R (SCID), designed to diagnose the following psychiatric and medical disorders: irritable bowel syndrome, narcolepsy, Tourette's disorder, migraine, fibromyalgia, chronic fatigue syndrome, and kleptomania. METHOD: Published operational diagnostic criteria for these seven disorders were sought in the literature. Questions in SCID format were then drafted in accordance with these operational criteria. Draft modules were then sent to experts familiar with each of the disorders and suggestions and revisions from these experts incorporated into the final modules. RESULTS: The complete supplemental interview is presented with this report. Preliminary experience with this interview in more than 100 patients tentatively suggests that it is reliable for diagnosing the disorders in question; however, a formal test-retest reliability assessment is still required. CONCLUSIONS: It is hoped that this supplemental interview, used in conjunction with the SCID, will be helpful in further studies of the epidemiology, pathogenesis, and treatment of these possible forms of affective spectrum disorder.
Purtilo DT.		Dual infections of the	Can Dis Wkly Rep 1991	The etiologic bases of CFS are undetermined at the present time. It is very

		immune system in patients with chronic active Epstein-Barr virus infection mimicking chronic fatigue syndrome.	Jan;17 Suppl 1E:29-32	important to distinguish the patients with CFS as defined by the Centers for Disease Control (CDC) case definition of Holmes et al. from patients with physical and laboratory findings suggesting dual infections and/or underlying immunodeficiency. Particularly fruitful might be a longitudinal immunovirologic study of patients who exhibit CFS following a well-documented viral infection.
Radvila A.	Medizinische Universitatspoliklinik, Inselspital, Bern.	[Intense fatigue in humans. Psychosocial and cultural aspects].[article in German]	Ther Umsch 1991 Nov;48(11):756-61	A differentiation between the normal sensation of tiredness and the symptom "fatigue" is often difficult. Both are influenced by cultural, social, psychological and biological factors, which can lead--interactively--to symptom formation. Psychiatric disorders frequently associated with fatigue are all forms of depression, somatization and anxiety disorders, chronic pain states and drug abuse among many others. In at least 2/3 of patients with the fashionable chronic fatigue syndrome--formerly called neurasthenia--a psychiatric diagnosis can be made, most of them also suffer from many symptoms attributes to the autonomous nervous system. The clinical approach should be cautious avoiding diagnostic and therapeutic overaction and therapy should emerge from a diagnosis properly assessed.

Redmond CK.	Department of Biostatistics, University of Pittsburgh, Pennsylvania 15261.	Analysis of clinical, epidemiologic, and laboratory data on chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S90-3	Much of the research conducted on chronic fatigue syndrome (CFS) is exploratory. The researchers' overall goal is to use clinical, epidemiologic, and laboratory data to provide clues about the etiology of this syndrome. In preparation for this symposium, a review of numerous publications on CFS has indicated that the literature generally does not reflect the application of optimal statistical methods for exploration of data. Whenever the researchers' aim is to generate hypotheses, modern methods designed specifically for exploratory data analysis are likely to provide greater insights into any patterns of data than are the traditional approaches to hypothesis testing. In addition, the use of formal methods of data synthesis for ongoing and future research on CFS is a means of strengthening collaborative efforts and of improving the ability of researchers to interpret the evidence available that relates to specific etiologic factors. The inclusion on the research team of experienced biostatisticians, who would oversee the statistical methods and the development of innovative analyses, is recommended.

Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S87-9	Unresolved aspects of chronic fatigue syndrome can be addressed by research involving biologic markers. These may be any molecular, biochemical, physiological, or other biologic parameter obtainable from biologic specimens. The use of biologic markers in research requires their validation as dependent or independent variables. Additionally, other characteristics of markers such as reliability of assays, background level, confounding factors, interpretations, and legal and ethical implications should be considered before the use of markers in research. A checklist is provided for evaluating a biologic marker before its inclusion in research.

Shafran SD.	Division of Infectious Diseases, Walter C. MacKenzie Health Sciences Centre, University of Alberta, Edmonton, Canada.	The chronic fatigue syndrome	Am J Med 1991 Jun;90(6):730-9.	The chronic fatigue syndrome (CFS) was formally defined in 1988 to describe disabling fatigue of at least 6 months' duration of uncertain etiology. Reports of CFS have emerged from the United States, Canada, the United Kingdom, Australia, New Zealand, Israel, Spain, and France. The disease primarily affects individuals between 20 and 50 years of age, and there is a preponderance of females. Although a triggering infectious illness is reported by most patients with CFS, there is no convincing evidence causally linking any currently recognized infectious agent to CFS. Multiple minor immunologic aberrations are frequent but inconsistent and of uncertain significance. There is no consistent evidence for myopathy or physical deconditioning. Depression is found in approximately 50% of CFS patients, with depression preceding the physical symptoms in half of the cases. No therapy has been proved effective in controlled clinical trials with prolonged follow-up, although antidepressants have not been formally evaluated. The long-term prognosis of patients with CFS has not been well studied, but CFS appears to be a disease of prolonged duration with considerable

				morbidity but no mortality. Further research into the pathogenesis and treatment of CFS is necessary.

A randomized comparison of two doses of human lymphoblastoid interferon-alpha in hairy cell leukemia. Wellcome HCL Study Group.	Blood 1991 Dec 15;78(12):3133-41	One hundred thirty-eight patients with hairy cell leukemia were randomized to receive either a dose of 2.0 megaunits (MU)/m2 or a 10-fold lower dose of 0.2 MU/m2 of a highly purified natural alpha-interferon, administered daily for 28 days followed by a three times a week schedule. Ninety-seven of these patients had previously undergone splenectomy, but otherwise none of the patients had received prior therapy for their leukemia. The two doses were comparable in their effect on improving the neutrophil and platelet count, whereas the higher dose had a greater beneficial effect on the hemoglobin level and a greater antileukemic effect on the marrow. Acute toxicity in the form of a flu-like syndrome, neurologic side effects, neutropenia, and the need for platelet transfusions was observed less frequently in the low-dose group, as was the chronic fatigue syndrome. No neutralizing antibody activity was seen in the sera from 61 patients examined. Because of its beneficial effect on the neutrophil and platelet count and a lower degree of toxicity (ie, a superior therapeutic/toxicity ratio), the low dose is recommended as initial therapy in patients with hairy cell leukemia. This therapy may be followed by dose escalation once clinical improvement is observed. Randomized Controlled Trial
Smith JL.	Bascom Palmer Eye Institute, University of Miami School of Medicine, Florida.	Neuro-ocular Lyme borreliosis.	Neurol Clin 1991 Feb;9(1):35-53	Any patient who has a Bell's palsy (unilateral or bilateral), aseptic meningitis, chronic fatigue syndrome, atypical radiculoneuropathy, presenile dementia, atypical myopathy, or symptoms of atypical rheumatoid arthritis should be asked specifically about the following: visits to highly endemic areas, any known tick bites, any skin lesion suggestive of erythema migrans, any history of palpitations or of prior Bell's palsy, aching in joints (especially the knees), paresthesias, chronic fatigue and depression, forgetfulness, and eye problems. Any patient showing a chronic iritis with posterior synechiae, vitritis in one or both eyes, an atypical pars planitis-like syndrome, big blind spot syndrome, and swollen or hyperemic optic discs should be asked the same questions. The physician should send one red-top tube of blood containing 2 to 3 ml serum to Microbiology Reference Laboratory, 10703 Progress Way, Cypress, CA 90630-4714, requesting a Lyme/treponemal panel. For $90 the patient will receive an RPR test with titer, serum FTA-ABS test, serum Lyme IFA IgG and IgM, and a serum Lyme ELISA test. If these tests are within normal limits and the physician is still suspicious, a Western blot can be ordered on serum. A green top tube with fresh white blood

				cells sent out by overnight express on a Monday or Tuesday will produce a Lyme PCR and a lymphocyte stimulation test. Finally, R.K. Porschen, director of MRL Laboratory, will provide information on the urine antigen test on an investigational basis. A careful history with emphasis on the specific questions noted above, a complete neuro-ophthalmological and physical examination ruling out other causative problems, and the laboratory studies here discussed will usually provide sufficient data to choose therapy. Much further active research into Lyme borreliosis is an important priority in medicine.

Straus SE.	Medical Virology Section, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20892.	History of chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S2-7	Chronic fatigue syndrome is not a new medical condition. For centuries its confusing array of features has been attributed to numerous environmental, metabolic, infectious, immunologic, and psychiatric disturbances. This is a review and critique of many of these alternative diagnoses, sufficient to provide a historical background for current thinking about the disorder.
Strickland MC.	Department of Psychiatry, Cleveland Clinic Florida, Ft. Lauderdale, Florida.	Depression, chronic fatigue syndrome, and the adolescent.	Prim Care 1991 Jun;18(2):259-70	To summarize, CFS and depression present very real problems for adolescent patients, their families, and their physicians. The wealth of symptoms presented may signal the presence of any number of psychiatric or physiologic disorders. As part of the evaluation to rule out other maladies, the physician must identify the developmental issues and life stress events with which patients or their families are struggling. Helping patients to accept psychiatric referral to address these issues is indicated if it is thought that they may be contributing to the onset or maintenance of the symptoms. Referral is also indicated if a protracted clinical course evolves and the patient's normal course of growth and development appears to be in jeopardy.
Sumaya CV.	Department of Pediatrics, University of Texas Health Science Center, San Antonio.	Serologic and virologic epidemiology of Epstein-Barr virus: relevance to chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S19-25	Patients considered to have chronic fatigue syndrome (CFS) have been reported to exhibit an increased antibody response to Epstein-Barr virus (EBV) early antigen complex and capsid antigen, findings that suggest some relationship between EBV and CFS. However, the serologic findings have not been totally consistent among different study groups, and the antibody patterns in asymptomatic individuals may be similar. Moreover, patients with symptomatology indicative of CFS do not appear to have an abnormal burden of EBV in body fluids and manifest only a variable, mild degree of EBV-specific cell-mediated responses. The evidence is growing that the serologic findings of an enhanced EBV state in individuals with CFS-like manifestations, as well as the subsequent reports of increased antibody titers to other viruses, reflect a generalized underlying immunologic dysfunction in these patients. Future studies

				with criteria-defined CFS study groups in which determinations are made of antibody responses to newly identified EBV-associated nuclear antigen components and distinct EBV proteins in addition to specific virologic and immunologic analyses of EBV may be worthwhile as a means of clarifying the association between EBV and CFS.

Assessment of depression in patients with chronic fatigue syndrome.	Rev Infect Dis 1991 Jan-Feb;13 Suppl 1:S114-8	Assessment of the relationship of depression to chronic fatigue syndrome (CFS) is a complicated but important topic. This relationship may range from the misdiagnostic (i.e., depression misidentified as CFS) to the etiologic (i.e., CFS causes an organic affective syndrome). Assessment should focus on the symptoms and syndromes of depressive disorder, utilization of a single rating scale to assess presumed depression is discouraged, and alternate approaches to classification that allow for symptomatic overlap of a major depressive disorder and CFS are suggested. Careful attention needs to be given to the use of external validating criteria in empiric studies, such as natural history, clinical course (including treatment response), and family history.

Wood GC, Bentall RP, Gopfert M, Edwards RH.	Department of Medicine, Royal Liverpool Hospital.	A comparative psychiatric assessment of patients with chronic fatigue syndrome and muscle disease.	Psychol Med 1991 Aug;21(3):619-28	The psychiatric status of patients with chronic fatigue syndrome (N = 34) and muscle disease (N = 24) attending a general medical clinic was studied. Among fatigue patients 14 (41.2%) were cases and a further 9 (26.5%) were subcases of psychiatric disorder as defined by CATEGO. A variety of diagnoses was found. Significantly fewer of the muscle patients had a psychiatric disorder with 3 (12.5%) being cases and 1 (4%) a subcase. The relative risk of psychiatric disorder in patients with chronic fatigue syndrome compared to patients with muscle disease was 3.3:1.
Woods TO, Goldberg DP.	Mental Illness Research Unit, University of Manchester, UK.	Psychiatric perspectives: an overview.	Br Med Bull 1991 Oct;47(4):908-18	This chapter reviews the evidence concerning the importance of psychological and social factors in the aetiology and pathogenesis of chronic fatigue syndrome. The diagnosis is often offered to doctors by patients; and we consider attribution, stigma, collusion between doctor and patient, and abnormal illness behaviour in this context. We then give a brief description of a model for common mental disorders, and show how chronic fatigue syndrome relates to this model. It emerges that there are special vulnerability factors in these patients' personalities before the viral illness, but the disorder is seen as being released by the viral illness. By the time the disorder becomes established the original causal nexus is seen as no longer so important, and the disorder can be seen as a form of abnormal illness behaviour maintained by special factors. The implications for treatment are then considered.

Wysenbeek AJ, Shapira Y, Leibovici L.	Department of Medicine B, Beilinson Medical Center, Petah Tiqva, Israel.	Primary fibromyalgia and the chronic fatigue syndrome.	Rheumatol Int 1991;10(6):227-9	Thirty-three primary fibromyalgia patients were investigated for chronic fatigue syndrome symptoms. Significant fatigue was reported by 21/33 patients (63.6%), and patients reported various flulike symptoms, yet only 7/33 patients (21.2%) fulfilled criteria for the chronic fatigue syndrome. Only one patient reported painful lymph glands and four patients reported fever. Thus, symptoms of painful glands or fever might serve as clinical indicators, distinguishing between fibromyalgia and the chronic fatigue syndrome.
Yeomans JD, Conway SP.	Department of Psychiatry, St Jame's University Hospital,	Biopsychosocial aspects of chronic fatigue syndrome (myalgic	J Infect 1991 Nov;23(3):263-9	Fifteen patients, with a primary complaint of chronic fatigue, were referred to a physician by their general practitioners. Psychological distress, measured by simple psychiatric rating scales was common, but specific psychiatric diagnoses,

	Leeds, U.K.	encephalomyelitis).		derived from a comprehensive diagnostic interview, occurred less frequently. One questionnaire (Montgomery-Asberg depression rating scale) found emotional distress in 93%, but the diagnostic instrument (Present State Examination) suggested depressive syndromes in only two patients (13%). There were significant occupational difficulties in 87%. No consistently abnormal indices of biochemical or immunological function were found, nor evidence of acute or chronic infection. Chronic fatigue syndrome (CFS) is associated with physical, psychological and social distress. The illness cannot be defined using just one of these dimensions. Such a unilateral approach has resulted in unnecessary controversy over the nature of the 'real' core of CFS. A problem-oriented approach, recognising the multi-factorial and overlapping cause and effect issues in CFS, may be of more benefit to patients.

Abbey SE, Garfinkel PE.	Toronto Hospital, Toronto General Division, Ontario.	Chronic fatigue syndrome and the psychiatrist.	Can J Psychiatry 1990 Oct;35(7):625-33	The number of patients who are identified as having chronic fatigue syndrome (CFS) has increased, and as a result, chronic fatigue syndrome has received widespread attention. Research has demonstrated that cognitive, affective and behavioural symptoms are prominent in CFS. Psychiatrists are therefore being asked to participate in the assessment and management of patients with this syndrome. This paper will provide an overview of the clinical characteristics of CFS and the current empirical findings related to its pathology, and will conclude with a discussion of the management of these patients. Publication Types: Review Review, Tutorial
Ablashi DV, Josephs SF, Buchbinder A, Hellman K, Nakamura S, Llana T, Lusso P, Kaplan M, Dahlberg J, Memon S, et al.	Laboratory of Cellular and Molecular Biology, National Cancer Institute, Bethesda, MD.	Human B-lymphotropic virus (human herpesvirus-6).	J Virol Methods 1988 Sep;21(1-4):29-48	Human B-lymphotropic virus (HBLV), also known as human herpesvirus-6 (HHV-6) was first isolated in 1986 from AIDS patients and patients with other lymphoproliferative disorders. HBLV is distinct from known human herpesviruses, biologically, immunologically and by molecular analysis. HBLV can infect and replicate in fresh and established lines of hemopoietic cells and cells of neural origin, suggesting wide tropism. The prevalence of HBLV antibody in the normal population was 26% though clear differences between different populations were observed. The prevalence of HBLV antibody an elevated antibody titer was higher in sera from certain malignancies, Sjogren's syndrome and sarcoidosis. Antibody to HBLV was also elevated in AIDS patients and patients with chronic fatigue syndrome. HBLV-DNA was detected in some B-cell lymphomas. The broad in vitro tropism, combined with immunological and molecular evidence of HBLV infection in individuals raise the question of the pathogenicity of this virus in some diseases. Because in vitro co-infection of CD4 cells by HBLV and HIV leads to enhanced degeneration, this raises the possibility that infection in AIDS patients by both viruses can aggravate the HIV-induced immunodeficiency. Specific reagents and immunological and molecular assays are currently being investigated, which will aid in virus detection in cells from patients, and in elucidating the possible pathogenesis of HBLV.
Ablashi DV, Lusso P, Hung CL, Salahuddin SZ, Josephs SF, Llana T, Kramarsky B, Biberfeld P, Markham PD, Gallo RC.	Laboratory of Cellular and Molecular Biology, National Cancer Institute, Bethesda, MD 20892.	Utilization of human hematopoietic cell lines for the propagation and characterization of HBLV (human herpesvirus 6).	Int J Cancer 1988 Nov 15;42(5):787-91	Details of the productive infection of established human cell lines of diverse origin by HBLV (also designated Human Herpesvirus 6) are described in this report. The infection and replication of HBLV in several T and B lymphoid and other cell lines was observed by electron microscopic examination, by the detection of viral antigen expression by indirect immunofluorescence assay (IFA) and by the presence of HBLV DNA by Southern blot hybridization. Several of these cell lines produced large amounts of virus. For this reason and because of the absence of other human herpesviruses, these lines have provided a valuable resource for the preparation of reagents and the development of assays for the detection and characterization of HBLV. The isolation and characterization of new

				HBLV isolates from patients with chronic fatigue syndrome were also facilitated by using some of the cell lines reported here. The host range of HBLV in established cell lines, therefore, does not appear to be limited to the B lymphocytes, as initially suggested by in vivo studies. The infection of T and B lymphocytes, megakaryocytes and neuronal cells in vitro suggests a need for the evaluation of diverse hematological and neurological disorders to shed light on a possible HBLV involvement.

Altay HT, Toner BB, Brooker H, Abbey SE, Salit IE, Garfinkel PE.	Department of Psychology, York University, Ontario, Canada.	The neuropsychological dimensions of postinfectious neuromyasthenia (chronic fatigue syndrome): a preliminary report.	Int J Psychiatry Med 1990;20(2):141-9	Postinfectious neuromyasthenia (PIN) is a clinical syndrome of protracted and incomplete recovery after an apparent viral-like illness. Medical investigation yields few abnormalities which might account for the symptomatology. A substantial number of PIN patients complain of cognitive changes. Specific complaints include impaired attention, concentration and abstraction skills. This study was designed to systematically investigate whether the aforementioned subjective complaints could be quantified objectively using standard neuropsychological instruments. Results indicated that on all tests but one, the subjects' performances were significantly higher than those of their age matched groups in the normative data. Specifically, PIN patients scored significantly better than their age matched norms on tests of concentration, attention and abstraction. What is most striking is the discrepancy between the subjective complaints of cognitive impairment and the objective results of the subjects' performances on all tests. These findings suggest that psychological factors may play an important role in the cognitive functioning of individuals diagnosed with postinfectious neuromyasthenia.

Department of Biochemistry, Charing Cross and Westminster Medical School, London, U.K.	Persistence of enteroviral RNA in chronic fatigue syndrome is associated with the abnormal production of equal	J Gen Virol 1990 Jun;71 (Pt 6):1399-402	A subgenomic restriction fragment from cDNA prepared from Coxsackie B2 virus (CVB2) RNA was subcloned into a riboprobe vector allowing the production of enteroviral group-specific RNA probes complementary to either the positive (genomic) or negative (template) strand of enteroviral RNA. These riboprobes were used to follow productive infection of cultured cells by CVB2; as expected, positive strand RNA was synthesized in approximately 100-fold excess over

		amounts of positive and negative strands of enteroviral RNA.		negative strand. RNA was extracted from muscle biopsy samples from patients with chronic fatigue syndrome and probed for the presence of enteroviral RNA. In cases where enteroviral RNA was detected the amounts of positive and negative strands of enteroviral RNA were approximately equal, in contrast to the situation in lytic infection of cultured cells. This suggests that enterovirus persistence in muscle is due to a defect in control of viral RNA synthesis.

Tired, weak, or in need of rest: fatigue among general practice attenders.	BMJ 1990 Nov 24;301(6762):1199-202 comment in: BMJ. 1991 Jan 19;302(6769):181 BMJ. 1991 Jan 5;302(6767):50	OBJECTIVES--To determine the prevalence and associations of symptoms of fatigue. DESIGN--Questionnaire survey. SETTING--London general practice. PARTICIPANTS--611 General practice attenders. MAIN OUTCOME MEASURES--Scores on a fatigue questionnaire and reasons given for fatigue. RESULTS--10.2% Of men (17/167) and 10.6% of women (47/444) had substantial fatigue for one month or more. Age, occupation, and marital status exerted minor effects. Subjects attributed fatigue equally to physical and non-physical causes. Physical ill health, including viral infection, was associated with more severe fatigue. Women rather than men blamed family responsibilities for their fatigue. The profile of persistent fatigue did not differ from that of short duration. Only one person met criteria for the chronic fatigue syndrome. CONCLUSIONS--Fatigue is a common complaint among general practice attenders and can be severe. Patients may attribute this to physical, psychological, and social stress.
Denman AM.	Division of Immunological Medicine, Northwick Park Hospital, Harrow, Middlesex, UK.	The chronic fatigue syndrome: a return to common sense.	Postgrad Med J 1990 Jul;66(777):499-501	
Ewig S, Dengler HJ.	Medizinische Klinik der Universitat Bonn.	[Chronic fatigue syndrome].[article in German]	Klin Wochenschr 1990 Aug 17;68(16):789-96	Reports on conditions of chronic fatigue associated with other somatopsychic symptoms after acute viral infections have led to the hypothesis of a "chronic fatigue syndrome" (CFS). Historical disease descriptions, like e.g. "myalgic encephalomyelitits", were updated by means of modern virological diagnostic techniques and data analysis. Several viral agents like enteroviruses, Epstein-Barr virus, Human-Herpesvirus 6 and other herpesviruses have been implicated for possible underlying infections. A preliminary disease definition by the Center for Disease Control (CDC) seeks to provide a rational basis for further etiological studies. In fact, there is growing consensus that the syndrome comprises various separate disease entities and causative agents. Today we can tentatively differentiate a "chronic mononucleosis" after infection with Epstein-Barr virus, an etiologically undetermined "postviral fatigue syndrome" and a fatigue syndrome

				of the myalgic type after Coxsackie-B virus infection. Furthermore, a valid diagnosis of CFS must be based on the exclusion of defined other diseases and the awareness of dealing with a hypothetical concept. As a result, current knowledge does not yet allow specific therapeutic recommendations.

Goldenberg DL, Simms RW, Geiger A, Komaroff AL.	Arthritis-Fibrositis Center, Newton-Wellesley Hospital, MA 02162.	High frequency of fibromyalgia in patients with chronic fatigue seen in a primary care practice.	Arthritis Rheum 1990 Mar;33(3):381-7	We administered a standardized history questionnaire and performed a tender point examination on 27 patients with debilitating fatigue of at least 6 months duration, seen in a primary care practice, as well as on 20 patients with fibromyalgia. Sixteen of the 27 patients with chronic fatigue met the full criteria for the working case definition of chronic fatigue syndrome (CFS). Eight patients with chronic fatigue denied having any current persistent, diffuse musculoskeletal pain, and their tender point scores were similar to those in 10 normal control subjects. In contrast, 19 patients with chronic fatigue (70%) had persistent, diffuse musculoskeletal pain. The results of their tender point examinations were similar to those of the patients with fibromyalgia. Thus, the majority of these patients with debilitating chronic fatigue, including those who met criteria for CFS, met the historical and tender point diagnostic criteria for fibromyalgia. The presence of current musculoskeletal pain will identify those CFS patients who have fibromyalgia.
Goldenberg DL.	Newton-Wellesley Hospital, Department of Medicine, Tufts University School of Medicine, MA 02162.	Fibromyalgia and its relation to chronic fatigue syndrome, viral illness and immune abnormalities.	J Rheumatol Suppl 1989 Nov;19:91-3	Fibromyalgia and chronic fatigue syndrome have similar clinical and demographic features. We found that most patients with chronic fatigue syndrome have a tender point examination similar to patients with fibromyalgia. Similar pathophysiologic mechanisms are also being explored in each syndrome, including a potential role for viral induced immune dysfunction.
Goodnick PJ.		Bupropion in chronic fatigue syndrome.	Am J Psychiatry 1990 Aug;147(8):1091	
Goodwin SD, Sproat TT, Russell WL.	College of Pharmacy, University of Florida, Gainesville.	Management of Lyme disease.	Clin Pharm 1990 Mar;9(3):192-205	The microbiology, transmission, epidemiology, pathogenesis, clinical manifestations, diagnosis, and treatment of Lyme disease are reviewed. Lyme disease, a tick-borne syndrome, was first described in 1975. The etiologic agent of Lyme disease is Borrelia burgdorferi, a slow-growing spirochete. Lyme disease is the most prevalent tick-borne disease in this country; endemic areas in the United States include the northeastern, north central, and western regions. Both infectious and immunologic mechanisms are important factors in the pathogenesis of Lyme disease. The primary mechanism, however, is thought to

				be infectious. Three stages of Lyme disease have been described; stage I, characterized by erythema chronicum migrans and flu-like symptoms; stage II, characterized by dermatologic, ophthalmologic, neurologic, and cardiac disorders; and stage III, characterized by arthritis, a multiple sclerosis-like syndrome, psychiatric disorders, and a chronic fatigue syndrome. Therapy with penicillin or tetracycline hastens the resolution of stage I symptoms. Treatment duration normally ranges between 10 days and three weeks. Tetracycline or doxycycline appears to be more effective than penicillin in preventing the development of late Lyme disease. Although intravenous penicillin G and ceftriaxone are both effective for the treatment of late Lyme disease, many clinicians consider ceftriaxone to be the agent of choice. Whether exposed patients from endemic areas should receive antimicrobial prophylaxis is controversial. Further clinical studies are needed to determine optimal therapy for the various stages of Lyme disease, particularly Lyme arthritis.
Greenberg DB.	Department of Psychiatry, Massachusetts General Hospital Cancer Center, Boston.	Neurasthenia in the 1980s: chronic mononucleosis, chronic fatigue syndrome, and anxiety and depressive disorders.	Psychosomatics 1990 Spring;31(2):129-37	In the 1980s, patients suffering from unexplained fatigue and what seemed like a prolonged attack of acute mononucleosis were given the diagnosis of chronic mononucleosis or chronic infection with the Epstein-Barr virus. Although the diagnosis has great appeal, the Epstein-Barr virus does not cause the syndrome (CFS) of chronic fatigue, which has been renamed and redefined chronic fatigue syndrome to remove the inference that the virus is its cause. From a historical perspective, both syndromes represent the 1980s equivalent of neurasthenia, a disease of fatigue that influenced the development of psychiatric nosology. Because patients with depression and anxiety also have chronic fatigue and because most patients with CFS have an affective disorder, the assessment of organic causes of this syndrome requires careful psychiatric diagnosis and treatment. Defining chronic fatigue syndrome as a medical disorder may deprive patients of competent treatment of their affective disorder.
Hellinger WC, Smith TF, Van Scoy RE, Spitzer PG, Forgacs P, Edson RS.	Division of Infectious Diseases and Internal Medicine, Mayo Clinic, Rochester, MN 55905.	Chronic fatigue syndrome and the diagnostic utility of antibody to Epstein-Barr virus early antigen.	JAMA 1988 Aug 19;260(7):971-3 comment in: JAMA. 1989 Mar 3;261(9):1277-8	Antibody to Epstein-Barr virus (EBV) early antigen has been said to be the most specific indicator of symptomatic chronic EBV infection. We studied the clinical utility of this serologic test in the evaluation of patients with chronic fatigue. Thirty patients with chronic fatigue and highly elevated titers of antibody to early antigen (greater than or equal to 1:160) were compared with 30 age- and sex-matched controls with no antibody to early antigen. There were no significant differences noted between patients and controls at the initial evaluation (symptoms, physical examination, laboratory data). Follow-up information, available for 15 matched pairs, showed no differences in outcome between patients and controls. We conclude that the antibody to EBV early antigen is not helpful in the clinical evaluation of patients with chronic fatigue.
Hickie I, Lloyd A, Wakefield D, Parker G.	Division of Psychiatry, Prince Henry Hospital,	The psychiatric status of patients with the	Br J Psychiatry 1990 Apr;156:534-40	The prevalence of psychiatric disorder in 48 patients with chronic fatigue syndrome (CFS) was determined. Twenty-two had had a major depressive (non-

	Sydney, Australia.	chronic fatigue syndrome.	comment in: Br J Psychiatry. 1990 Sep;157:447-50 Br J Psychiatry. 1991 May;158:717	endogenous) episode during the course of their illness, while seven had a current major (non-endogenous) depression. The pre-morbid prevalence of major depression (12.5%) and of total psychiatric disorder (24.5%) was no higher than general community estimates. The pattern of psychiatric symptoms in the CFS patients was significantly different to that of 48 patients with non-endogenous depression, but was comparable with that observed in other medical disorders. Patients with CFS were not excessively hypochondriacal. We conclude that psychological disturbance is likely to be a consequence of, rather than an antecedent risk factor to the syndrome.

Holmes GP, Kaplan JE, Gantz NM, Komaroff AL, Schonberger LB, Straus SE, Jones JF, Dubois RE, Cunningham-Rundles C, Pahwa S, et al.	Division of Viral Diseases, Centers for Disease Control, Atlanta, Georgia.	Chronic fatigue syndrome: a working case definition.	Ann Intern Med 1988 Mar;108(3):387-9	The chronic Epstein-Barr virus syndrome is a poorly defined symptom complex characterized primarily by chronic or recurrent debilitating fatigue and various combinations of other symptoms, including sore throat, lymph node pain and tenderness, headache, myalgia, and arthralgias. Although the syndrome has received recent attention, and has been diagnosed in many patients, the chronic Epstein-Barr virus syndrome has not been defined consistently. Despite the name of the syndrome, both the diagnostic value of Epstein-Barr virus serologic tests and the proposed causal relationship between Epstein-Barr virus infection and patients who have been diagnosed with the chronic Epstein-Barr virus syndrome remain doubtful. We propose a new name for the chronic Epstein-Barr virus syndrome--the chronic fatigue syndrome--that more accurately describes this symptom complex as a syndrome of unknown cause characterized primarily by chronic fatigue. We also present a working definition for the chronic fatigue syndrome designed to improve the comparability and reproducibility of clinical research and epidemiologic studies, and to provide a rational basis for evaluating patients who have chronic fatigue of undetermined cause.

Jones JF, Williams M, Schooley RT, Robinson C, Glaser R.	Department of Pediatrics National Jewish Center for Immunology and Respiratory Medicine, Denver, CO 80206.	Antibodies to Epstein-Barr virus-specific DNase and DNA polymerase in the chronic fatigue syndrome.	Arch Intern Med 1988 Sep;148(9):1957-60	In an attempt to examine further the association between active Epstein-Barr virus (EBV) infection and the chronic fatigue syndrome (chronic EBV syndrome, or chronic or atypical mononucleosis), antibodies acting against EBV-specific DNase and DNA polymerase, which are expressed only during virus replication, were assayed. Serum samples from 25 healthy EBV-seropositive individuals neutralized 3.5 +/- 5.1 U (mean +/- SD) of DNase activity and 14.7 +/- 8.5 U of DNA

				polymerase activity. From these values were selected upper limits of anti-EBV enzyme activity of 17.9 and 31.3 U neutralized in normal individuals, respectively (representing the 95% confidence limit). Serum samples from six groups of subjects representing a variety of EBV-related illnesses were then studied. Only patients with notably elevated anti-EBV antibody titers to viral capsid antigen (VCA) (greater than 10,000) had elevated levels of anti-EBV DNase (38 to 56 U neutralized) and anti-EBV DNA polymerase (72 to 106 U neutralized). Three additional patients and two geriatric controls with average anti-EBV early antigen/VCA titers had slightly elevated levels of antibody to EBV DNA polymerase. IgA anti-VCA, anti-early antigen antibodies, or both, were also detected in the same patients who had high EBV DNase and polymerase antibody levels. These antibody profiles are similar to those in patients with nasopharyngeal carcinoma. Since three of the six patients with elevated anti-EBV enzyme antibody levels developed fatal lymphomas, patients with chronic EBV and this antibody profile might be in another illness category at risk for malignant disease.
Jones JF.	Department of Paediatrics, National Jewish Center for Immunology and Respiratory Medicine, Denver, Colorado 80206.	Epstein-Barr virus and the chronic fatigue syndrome: a short review.	Microbiol Sci 1988 Dec;5(12):366-9	Chronic Fatigue Syndrome (CFS), previously known as neuroasthenia is often considered to be due to psychiatric causes. Evidence for a possible role for the Epstein-Barr virus in CFS is summarized. A plea is made for physicians to accept CFS as a non-psychiatric chronic illness to encourage further research into a clear definition of the syndrome.
Kaslow JE, Rucker L, Onishi R.	Division of Basic and Clinical Immunology, University of California Irvine Medical Center, Orange 92668.	Liver extract-folic acid-cyanocobalamin vs placebo for chronic fatigue syndrome.	Arch Intern Med 1989 Nov;149(11):2501-3	Chronic fatigue syndrome is a recently defined entity for which clinical criteria were proposed by the Centers for Disease Control, Atlanta, Ga. A frequently advocated treatment in Southern California is an injectable solution of bovine liver extract containing folic acid and cyanocobalamin (LEFAC). We conducted a double-blind, placebo-controlled, crossover trial of intramuscular LEFAC in 15 patients who met the Centers for Disease Control criteria for chronic fatigue syndrome. Although patients responded to placebo and LEFAC by several criteria of functional status, no significant difference was apparent between response to placebo and that to LEFAC. The placebo response appeared to be strong. Randomized Controlled Trial

Klimas NG, Salvato FR, Morgan R, Fletcher MA.	Miami Veterans Administration Medical	Immunologic abnormalities in chronic	J Clin Microbiol 1990 Jun;28(6):1403-10	The chronic fatigue syndrome (CFS), formerly known as chronic Epstein-Barr virus syndrome, is a clinical state of some complexity and uncertain etiology. In order

	Center, Florida.	fatigue syndrome.		to characterize in a comprehensive manner the status of laboratory markers associated with cellular immune function in patients with this syndrome, 30 patients with clinically defined CFS were studied. All of the subjects were found to have multiple abnormalities in these markers. The most consistent immunological abnormality detected among these patients, when compared with normal controls, was low natural killer (NK) cell cytotoxicity. The number of NK cells, as defined by reactivity with monoclonal antibody NKH.1 (CD56), was elevated, but the killing of K562 tumor cells per CD56 cell was significantly diminished. Lymphoproliferative responses after stimulation with phytohemagglutinin and pokeweed mitogen were decreased in most patients when compared with those in normal controls, as was the production of gamma interferon following mitogen stimulation. Lymphocyte phenotypic marker analysis of peripheral blood lymphocytes showed that there were significant differences between patients with CFS and controls. There was an increase in the percentage of suppressor-cytotoxic T lymphocytes, CD8, and a proportionally larger increase in the number of CD8 cells expressing the class II activation marker. Most patients had an elevated number of CD2 cells which expressed the activation marker CDw26. The numbers of CD4 cells and the helper subset of CD4+CD29+ cells in patients with CFS were not different from those in controls. There was, however, a significant decrease in the suppressor inducer subset of CD4+ CD45RA+ cells.(ABSTRACT TRUNCATED AT 250 WORDS)

Komaroff AL, Goldenberg D.	Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA 02115.	The chronic fatigue syndrome: definition, current studies and lessons for fibromyalgia research.	J Rheumatol Suppl 1989 Nov;19:23-7	Chronic fatigue syndrome (CFS) is characterized by chronic, debilitating fatigue lasting greater than 6 months. Frequent chronic and recurrent findings include fever, pharyngitis, myalgias, adenopathy, arthralgias, difficulties in cognition and disorders of mood. In the majority of patients, the illness starts suddenly with an acute, "flu-like" illness. The following laboratory abnormalities are seen with some frequency, although none are seen in all patients: lymphocytosis, atypical lymphocytosis, monocytosis, elevation of hepatocellular enzymes, low levels of antinuclear antibodies, varying levels of antithyroid antibodies, partial hypergammaglobulinemia, elevated CD4:CD8 ratio, decreased cytolytic activity of natural killer cells, and low levels of immune complexes. Clinical and serologic studies suggest an association of CFS with all of the human herpesviruses, particularly Epstein-Barr virus (EBV) and the recently discovered human B lymphotropic virus (HBLV) or human herpesvirus 6; neither EBV nor HBLV has yet been shown to play a causal role in the illness. Preliminary evidence suggests that many of these features of CFS also are seen in patients with fibromyalgia.

Komaroff AL.	Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.	Chronic fatigue syndromes: relationship to chronic viral infections.	J Virol Methods 1988 Sep;21(1-4):3-10	Chronic fatigue syndrome (CFS) is a newly-recognized clinical entity characterized by chronic, debilitating fatigue lasting longer than six months. Common associated findings are chronic and recurrent fever, pharyngitis, myalgias, adenopathy, arthralgias, difficulties in cognition and disorders of mood. In the majority of patients, the illness starts suddenly with an acute, 'flu-like' illness. The following abnormalities are seen with some frequency although none are seen in all patients: lymphocytosis, atypical lymphocytosis, monocytosis, elevation of hepatocellular enzymes, low levels of antinuclear antibodies, low levels of immune complexes. Clinical and serologic studies suggest an association of CFS with all of the human herpesviruses, particularly Epstein-Barr virus (EBV) and the recently-discovered human B-lymphotropic virus (HBLV) or human herpesvirus-6; neither EBV nor HBLV has yet been shown to play a causal role in the illness.
Koo D.		Chronic fatigue syndrome. A critical appraisal of the role of Epstein-Barr virus.	West J Med 1989 May;150(5):590-6	The symptom complex currently designated the chronic fatigue syndrome was previously termed the chronic or chronic active Epstein-Barr virus syndrome or the chronic mononucleosis syndrome, prematurely assuming an etiologic role for the Epstein-Barr virus (EBV). This presumption derived from the fact that some patients with the chronic fatigue syndrome have very high or very low titers of certain antibodies to EBV. A review of seroepidemiologic patterns of response to EBV and of studies of patients with the chronic fatigue syndrome shows that these antibody titers overlap considerably both with those of controls or other healthy persons and with those of patients with other illnesses. Given the high prevalence of exposure to EBV, it would be difficult to determine whether the virus caused the syndrome or whether the antibody elevations resulted from the illness, even if distinct differences in titers existed. Other methodologic issues of control selection, laboratory test comparability, and differing case definitions pose problems in studying this syndrome. The recently published working case definition should facilitate the continuing search for causes.
Krueger GR, Sander C.	Institute of Pathology, University of Cologne, FRG.	What's new in human herpesvirus-6? Clinical immunopathology of the HHV-6 infection.	Pathol Res Pract 1989 Dec;185(6):915-29	Human herpesvirus-6 (HHV-6), formerly known as human B-lymphotropic virus (HBLV), was first isolated in 1986 from patients with lymphoproliferative disorders and AIDS. Antibody prevalence against HHV-6 varies between about 60-80% indicating a widespread latent infection. Although HHV-6 infects in vivo primarily T-lymphocytes, it is associated with similar diseases as in infection with Epstein-Barr virus (EBV), a clearly B-lymphotropic virus. Reactivation of latent HHV-6 infection in patients with subnormal host defense may cause persistent active infection with so-called postinfectious chronic fatigue syndrome (PICFS) or may contribute to other pathologies such as immune deficiency itself, autoimmune disorders or progressive lymphoproliferation. Coinfection of CD4 cells by HHV-6 and human immunodeficiency virus (HIV 1) in AIDS patients can aggravate HIV-induced acquired immune deficiency. These characteristics of the

				only recently detected new virus justify further intense investigation. Review Literature
Kruesi MJ, Dale J, Straus SE.	National Institute of Mental Health, Child Psychiatry Branch, Bethesda, Md 20892.	Psychiatric diagnoses in patients who have chronic fatigue syndrome.	J Clin Psychiatry 1989 Feb;50(2):53-6 Erratum in: J Clin Psychiatry 1989 Apr;50(4):148 comment in: J Clin Psychiatry. 1990 Apr;51(4):169 J Clin Psychiatry. 1990 Feb;51(2):86	Patients with persistent fatigue are often suspected of having psychiatric illnesses, particularly depression. The authors used the Diagnostic Interview Schedule to assess the lifetime prevalence of psychiatric disorders in 28 patients who met Centers for Disease Control case definition criteria for chronic fatigue syndrome. Compared with studies of the general population and studies of chronically medically ill patients who received the same structured interview, the rates of psychiatric illness in patients with the chronic fatigue syndrome appeared high. An examination of the medical histories of the 28 patients indicated that psychiatric disorders more often preceded the chronic fatigue than followed it.

Lloyd A, Hickie I, Wakefield D, Boughton C, Dwyer J.	Department of Infectious Diseases, Prince Henry Hospital, Sydney, Australia.	A double-blind, placebo-controlled trial of intravenous immunoglobulin therapy in patients with chronic fatigue syndrome.	Am J Med 1990 Nov;89(5):561-8 comment in: Am J Med. 1990 Nov;89(5):551-3 Am J Med. 1991 Jun;90(6):768 Am J Med. 1991 Oct;91(4):443-4 Am J Med. 1991 Sep;91(3):320-1	PURPOSE: The chronic fatigue syndrome (CFS) is characterized by profound fatigue, neuropsychiatric dysfunction, and frequent abnormalities in cell-mediated immunity. No effective therapy is known. PATIENTS AND METHODS: Forty-nine patients (40 with abnormal cell-mediated immunity) participated in a randomized, double-blind, placebo-controlled trial to determine the effectiveness of high-dose intravenously administered immunoglobulin G. The patients received three intravenous infusions of a placebo solution or immunoglobulin at a dose of 2 g/kg/month. Assessment of the severity of symptoms and associated disability, both before and after treatment, was completed at detailed interviews by a physician and psychiatrist, who were

				unaware of the treatment status. In addition, any change in physical symptoms and functional capacity was recorded using visual analogue scales, while changes in psychologic morbidity were assessed using patient-rated indices of depression. Cell-mediated immunity was evaluated by T-cell subset analysis, delayed-type hypersensitivity skin testing, and lymphocyte transformation with phytohemagglutinin. RESULTS: At the interview conducted by the physician 3 months after the final infusion, 10 of 23 (43%) immunoglobulin recipients and three of the 26 (12%) placebo recipients were assessed as having responded with a substantial reduction in their symptoms and recommencement of work, leisure, and social activities. The patients designated as having responded had improvement in physical, psychologic, and immunologic measures (p less than 0.01 for each). CONCLUSION: Immunomodulatory treatment with immunoglobulin is effective in a significant number of patients with CFS, a finding that supports the concept that an immunologic disturbance may be important in the pathogenesis of this disorder. Randomized Controlled Trial

Lloyd AR, Hickie I, Boughton CR, Spencer O, Wakefield D.	Department of Immunology, Prince Henry Hospital, Little Bay, NSW.	Prevalence of chronic fatigue syndrome in an Australian population.	Med J Aust 1990 Nov 5;153(9):522-8	An epidemiological study was undertaken to provide the first reported estimate of the point prevalence of chronic fatigue syndrome in an Australian community. After a pilot study in a separate location, the population of the Richmond Valley, New South Wales, was sampled using a structured case-finding technique, which included notification from local medical practitioners, the use of a screening questionnaire and standardised interviews conducted by a physician and psychiatrist. In addition, investigations were performed to exclude alternative diagnoses and to assess cell-mediated immunity. Forty-two patients with chronic fatigue syndrome, with a female:male ratio of 1.3:1.0, were detected in a population of 114,000. The mean age at onset of symptoms was 28.6 years (SD, 12.3 years), and the median duration of symptoms from onset to sampling date was 30 months. The social status of the patients was distributed in accordance with that of the remainder of the population sampled, with no bias towards the middle or upper social classes. The disorder was causing considerable incapacity, with 43% of patients unable to attend school or work. The conservative estimate from this study suggests a prevalence on June 30 1988 of 37.1 cases per 100,000 (95% confidence interval [CI], 26.8-50.2). Chronic fatigue syndrome is an

				important disorder in this Australian community that affects young individuals from all social classes and causes considerable ill health and disability.
Lloyd AR, Wakefield D, Boughton CR, Dwyer JM.	Department of Immunology, Prince Henry Hospital, Little Bay, NSW.	Immunological abnormalities in the chronic fatigue syndrome.	Med J Aust 1989 Aug 7;151(3):122-4 comment in: Med J Aust. 1990 Jan 1;152(1):50-2	The chronic fatigue syndrome is a disorder of unknown aetiology which is characterized by debilitating fatigue. Recent evidence has suggested that viruses may persist in the tissues of patients with chronic fatigue syndrome. A concurrent immunological disturbance is likely to be associated with the persistence of viral antigens. Therefore, the humoral and cellular immunity of 100 patients who were suffering from chronic fatigue syndrome and that of 100 healthy, age- and sex-matched control subjects were compared. This study documents the frequent occurrence of abnormalities within the cellular and humoral immune systems of patients with well-defined chronic fatigue syndrome. Disordered immunity may be central to the pathogenesis of chronic fatigue syndrome. In patients with chronic fatigue syndrome, a significant (P less than 0.01) reduction was found in the absolute number of peripheral blood lymphocytes in the total T-cell (CD2), the helper/inducer T-cell (CD4) and the suppressor/cytotoxic T-cell (CD8) subsets. A significant (P less than 0.001) reduction also was found in T-cell function, which was measured: in vivo by delayed-type hypersensitivity skin-testing (reduced responses were recorded in 50 [88%] of 57 patients); and in vitro by phytohaemagglutinin stimulation. Reduced immunoglobulin (Ig) levels were common (56% of patients), with the levels of serum IgG3- and IgG1-subclasses particularly (P less than 0.05) affected.
Lloyd AR.	Department of Infectious Diseases, Prince Henry Hospital, Little Bay, NSW.	Muscle versus brain: chronic fatigue syndrome.	Med J Aust 1990 Nov 5;153(9):530-4 comment in: Med J Aust. 1991 Feb 4;154(3):220	
Luka J, Okano M, Thiele G.	Department of Pathology and Microbiology, University of Nebraska Medical Center, Omaha.	Isolation of human herpesvirus-6 from clinical specimens using human fibroblast cultures.	J Clin Lab Anal 1990;4(6):483-6	The isolation and characterization of human herpesvirus-6 (HHV-6) has been hindered by the lack of cell lines useful for its rapid propagation. Recently, we have reported that the MRC-5 cell line (human diploid lung fibroblasts) was susceptible for HHV-6 infection. In this study, we report on the isolation of HHV-6 from the peripheral blood or buffy coat of three chronic fatigue syndrome patients, one post-liver transplant patient, and one severe chronic active Epstein-Barr virus syndrome patient using the MRC-5 cell line. Additionally, it was observed by Southern blot hybridization studies that four of five isolates had different restriction enzyme fragment patterns than the isolate obtained from the National Institutes of Health with Eco RI. These data suggest the usefulness of the MRC-5 cell line in the isolation and characterization of HHV-6 from various patients.
Manu P, Lane TJ, Matthews DA.	University of Connecticut School of	The frequency of the chronic fatigue	Ann Intern Med 1988 Oct 1;109(7):554-6	STUDY OBJECTIVE: To determine the frequency of the chronic fatigue syndrome among patients with symptoms of fatigue. DESIGN: Prospective, cohort study.

	Medicine, Farmington.	syndrome in patients with symptoms of persistent fatigue.	Erratum in: Ann Intern Med 1988 Dec 15;109(12):997	SETTING: Referral clinic, based in a primary care general internal medicine faculty practice of a university medical center. PATIENTS: Consecutive sample of 135 patients (53 men, 82 women) with 6 months or more of debilitating fatigue. INTERVENTIONS: All patients had a complete history taken, had a physical examination and a comprehensive battery of blood tests, and were given the Diagnostic Interview Schedule of the National Institute of Mental Health, a highly-structured 260-item instrument designed to enable accurate psychiatric diagnoses. Other diagnostic studies (for example, sleep studies and electroencephalography) were ordered if necessary for individual patients. MEASUREMENTS AND MAIN RESULTS: Six of the one hundred thirty-five patients met criteria for chronic fatigue syndrome (95% CI, 0 to 10). Ninety-one (67%) patients (CI, 56 to 78) had clinically active psychiatric disorders and 4 (3%) patients (CI, 0 to 8) had medical disorders that were considered a major cause of their fatigue. Thirty-four (25%) patients (CI, 14 to 36) had insufficient symptoms or objective findings of the chronic fatigue syndrome. CONCLUSION: The chronic fatigue syndrome is rare among patients with symptoms of persistent fatigue. Most of these patients have psychiatric disorders.

Moldofsky H, Saskin P, Lue FA.	Department of Psychiatry, University of Toronto, ON, Canada.	Sleep and symptoms in fibrositis syndrome after a febrile illness.	J Rheumatol 1988 Nov;15(11):1701-4	Sleep physiology and symptoms of 9 patients with fibrositis syndrome secondary to a febrile illness were compared to 9 patients with fibrositis syndrome who did not attribute their symptoms to a febrile illness and to 10 healthy controls. Both patient groups showed an alpha EEG (7.5 to 11 Hz) nonrapid eye movement sleep anomaly, had similar observed tender points, and self-ratings of musculoskeletal pain. These findings suggest that patients with postfebrile fibrositis have a nonrestorative sleep disorder characteristic of patients with fibrositis syndrome and share similar symptoms with patients who have a "chronic fatigue syndrome."
Montague TJ, Marrie TJ, Klassen GA, Bewick DJ, Horacek BM.	Department of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada.	Cardiac function at rest and with exercise in the chronic fatigue syndrome.	Chest 1989 Apr;95(4):779-84	To evaluate a possible cardiac pathophysiology of the chronic fatigue syndrome, we compared the resting cardiac function and exercise performance of 41 patients to those of an age-matched and sex-matched normal control group. Persistent fatigue following an acute apparently viral illness was the major complaint of all patients; none had specific cardiac symptoms nor abnormal physical findings. Electrocardiographic spatial patterns were normal in the patients, and there were no differences in the body surface sum of positive T-wave integrals between the patients (240 microV.x 10(2) +/- 107 microV.s x10(2))

				and control (244 microV.x 10(2) +/- 108 microV.s x 10(2) subjects. Twenty-four hour ambulatory ECGs revealed no differences in sinus rates and incidences of ventricular dysrhythmias in the two populations. Left ventricular dimensions and systolic fractional shortening values were also similar in both groups; moreover none of the patients had segmental wall motion abnormalities. On graded exercise testing, 20 of 32 normal subjects achieved target (85 percent of age-maximum) heart rates, compared to four of 31 patients (p less than 0.001). The duration of exercise averaged 12 +/- 4 minutes for the normal subjects and 9+/- 4 minutes for the patients (p less than 0.01). The temporal profile of exercise heart rates was dissimilar in the two groups, with patients' rates consistently and progressively less than those of normal subjects. Peak heart rate averaged 152 +/- 16 beats per minute for the normal group vs 124 +/- 19 beats per minute for the patients (p less than 0.0001); in age-related terms, respectively, 82 +/- 6 percent of the maximum heart rate vs 66 +/- 10 percent (p less than 0.0001). Thus, patients with chronic fatigue syndrome have normal resting cardiac function but a markedly abbreviated exercise capacity characterized by slow acceleration of heart rate and fatigue of exercising muscles long before peak heart rate is achieved.(ABSTRACT TRUNCATED AT 250 WORDS)

Nix WA.	Klinik und Poliklinik fur Neurologie, Johannes Gutenberg-Universitat, Mainz.	[Chronic fatigue syndrome--a new disease picture]?[article in German]	Nervenarzt 1990 Jul;61(7):390-6	The chronic fatigue syndrome has recently been more frequently diagnosed. Yet it is unknown if this syndrome represents a disease entity of its own or merely a diagnostic label for a miscellaneous group of disorders. Further investigations are needed to find out if the syndrome has an organic or psychosomatic aetiology, or a mixture of both. In the meantime it is the responsibility of the clinician to make this decision in each individual case.
Parras F, Salva F, Reina J, Gil J, Portela D, Alomar P.		[Chronic fatigue syndrome associated with Epstein-Barr virus infection].[article in Spanish]	Med Clin (Barc) 1989 Apr 29;92(16):619-22 comment in: Med Clin (Barc). 1990 Mar 3;94(8):315-6	Epstein-Barr virus (EBV) infection is ubiquitous and may result in multiple and widely different clinical features; the most common of these is infectious mononucleosis (IM). Recently, a group of patients has been included in the chronic EBV infection syndrome (EBVIS), with a sustained nonspecific syndrome consisting of asthenia, anorexia, low grade fever and changes in mood, associated with a viral infection not necessarily caused by EBV; this has been called chronic fatigue syndrome (CFS). We report a patient who fulfilled the

				criteria for CFS associated with EBV after an acute, well documented EBV infection. We discuss its etiological and pathophysiological implications, emphasizing the need for extreme caution in the diagnosis of CFS. A merely clinical diagnosis may hide severe mistakes.

Peterson PK, Shepard J, Macres M, Schenck C, Crosson J, Rechtman D, Lurie N.	Department of Medicine, Hennepin County Medical Center, Minneapolis, Minnesota 55415.	A controlled trial of intravenous immunoglobulin G in chronic fatigue syndrome.	Am J Med 1990 Nov;89(5):554-60 comment in: Am J Med. 1990 Nov;89(5):551-3	PURPOSE: Currently, there is no established therapy for chronic fatigue syndrome (CFS), a recently defined illness that has been associated with a variety of immunologic abnormalities. Based on the hypothesis that a chronic viral infection or an immunoregulatory defect is involved in the pathogenesis of CFS, the therapeutic benefit of intravenous immunoglobulin G (IV IgG) was evaluated in a group of patients with CFS. Additionally, serum immunoglobulin concentrations and peripheral blood lymphocyte subset numbers were measured at the outset of the study, and the effect of IV IgG therapy on IgG subclass levels was determined. PATIENTS AND METHODS: Thirty patients with CFS were enrolled in a double-blind, placebo-controlled trial of IV IgG. The treatment regimen consisted of IV IgG (1 g/kg) or intravenous placebo (1% albumin solution) administered every 30 days for 6 months. Participants completed a self-assessment form prior to each of the six treatments, which was used to measure severity of symptoms, functional status, and health perceptions. Patients were also asked to report adverse experiences defined as worsening of symptoms occurring within 48 hours of each treatment. RESULTS: Twenty-eight patients completed the trial. At baseline, all 28 patients complained of moderate to severe fatigue, and measures of social functioning and health perceptions showed marked impairment. Low levels of IgG1 were found in 12 (42.9%), and 18 (64.3%) had low levels of IgG3. At the end of the study, no significant therapeutic benefit could be detected in terms of symptom amelioration or improvement in functional status, despite restoration of IgG1 levels to a normal range. Major adverse experiences were observed in 20% of both the IV IgG and placebo groups. CONCLUSION: The results of this study indicate that IV IgG is unlikely to be of clinical benefit in CFS. In addition to the ongoing need for placebo-controlled trials of candidate therapies for CFS, an expanded research effort is needed to define the etiology and pathogenesis of this disorder.
Phillips H.		Chronic fatigue syndrome.	Med J Aust 1989 Mar 20;150(6):351-2	
Pinardi G, Scarlato G.	Istituto di Clinica neurologica, Universita, Ospedale maggiore Policlinico, Milano.	[The chronic fatigue syndrome. A multifactorial approach and the treatment	Recenti Prog Med 1990 Dec;81(12):773-7	The chronic fatigue syndrome is a poorly defined symptoms complex characterized primarily by chronic or recurrent debilitating fatigue and various combinations of other symptoms, including psychological symptoms, sore throat, lymph node pain, headache, myalgia, arthralgias. Psychological disturbances,

		possibilities].[article in Italian]		ranging from mild depression or anxiety to severe behavioral abnormalities, are always present. Chronic fatigue syndrome is the name that more accurately describes this symptom complex of unknown cause. A viral aetiology has long been hypothesized: many viruses are potential candidates, including any of the 23 Coxsackie A or 6 Coxsackie B viruses, herpes viruses, particularly Epstein-Barr virus and varicella. These studies, though interesting, remain unconvincing because of methodological flaws such as a poor case definition and inadequate control groups. This syndrome may represent an infection by a yet unidentified virus. It is more likely due to an abnormal immune response toward different intracellular pathogens. There is no treatment to ameliorate the chronic fatigue syndrome. Epidemiological studies are essential with explicit operational case definition before progress can be made in the management of this distressing disorder.

Portwood MF.		Chronic fatigue syndrome--a diagnosis for consideration.	Nurse Pract 1988 Feb;13(2):11-2, 15-8, 23	Chronic fatigue syndrome (CFS) is an illness which may be mild or completely disabling. Clients who return with recurring non-related symptoms and no specific diagnosis may suffer from CFS. The symptoms of CFS are numerous and varied, including fatigue, malaise, myalgias, difficulty concentrating, headaches and sore throat. Patient complaints seem out of proportion to the physical findings, which may be normal. There is no cure for this chronic disease. Therapy is primarily symptomatic. The role of the health care provider is to recognize this confusing disorder and help the patient and family cope with its many effects.

Powell R, Dolan R, Wessely S.	National Hospital For Nervous Diseases, Queen Square, London, U.K.	Attributions and self-esteem in depression and chronic fatigue syndromes.	J Psychosom Res 1990;34(6):665-73	There is considerable overlap in symptomatology between chronic fatigue syndrome (CFS) and affective disorder. We report a comparison of depressive phenomenology and attributional style between a group of CFS subjects seen in a specialized medical setting, which included a high proportion with depression diagnosed by Research Diagnostic Criteria (RDC), and depressed controls seen in a specialized psychiatric setting. Significant symptomatic differences between the depressed CFS group and depressed controls were observed for features such as self-esteem and guilt as well as attribution of illness. All the CFS groups tended to attribute their symptoms to external causes whereas the depressed controls experienced inward attribution. This may have resulted from differences in the severity of mood disorder between the samples, but it is also suggested that an outward style of attribution protects the depressed CFS patients from cognitive changes associated with low mood but at the expense of greater vulnerability

				towards somatic symptoms such as fatigue.
Prieto J, Subira ML, Castilla A, Serrano M.	Department of Internal Medicine, University Clinic, School of Medicine, Pamplona, Spain.	Naloxone-reversible monocyte dysfunction in patients with chronic fatigue syndrome.	Scand J Immunol 1989 Jul;30(1):13-20	We studied monocyte function in 35 consecutive patients with chronic fatigue syndrome (CFS) and 25 healthy controls. Eighty-five per cent of the patients showed monocyte dysfunction characterized by marked reduction in the number of monocytes displaying immunoreactive cytoskeletal vimentin filaments, a low phagocytosis index, and a reduced expression of HLA-DR antigens. These values increased dramatically after incubation of the patients' monocytes with the opioid antagonist naloxone. Other immunological abnormalities also noted in the patients were low lymphocyte blastogenesis and diminished numbers of monocytes displaying receptors for Fc of IgG (FcR) and C3b (CR1). These findings suggest that an increased opioid activity acting through a classical receptor mechanism is active on monocytes from a high proportion of patients with CFS and that this represents a novel example of immunomodulation by opioid peptides in human disease. We suggest that endogenous opioids are involved in the pathogenesis of the chronic fatigue syndrome.

Riley MS, O'Brien CJ, McCluskey DR, Bell NP, Nicholls DP.	Department of Medicine, Royal Victoria Hospital, Belfast.	Aerobic work capacity in patients with chronic fatigue syndrome.	BMJ 1990 Oct 27;301(6758):953-6 comment in: BMJ. 1990 Nov 24;301(6762):1217 BMJ. 1991 Jan 5;302(6767):50	OBJECTIVE--To determine the aerobic work capacity of patients with the chronic fatigue syndrome and compare it with that of two control groups, and to assess the patients' perception of their level of activity before and during illness. DESIGN--A symptom limited exercise treadmill test with on line gas analysis and blood sampling was used. Subjects were assessed by one investigator, who was blind to the group which they were in. SETTING--Department of medicine, Royal Victoria Hospital, Belfast. SUBJECTS--13 Patients (10 women, three men) who fulfilled the diagnostic criteria for chronic fatigue syndrome. Two control groups of similar age, sex, and body weight: 13 normal subjects (10 women, three men)

				and seven patients (five women, two men) with the irritable bowel syndrome. MAIN OUTCOME MEASURES--Aerobic work capacity as assessed by several variables such as length of time on treadmill, heart rate, and biochemical measurements; Borg score; and visual analogue scores of perceived level of physical activity. RESULTS--The patients with the chronic fatigue syndrome had a reduced exercise capacity compared with that of the other subjects, spending a significantly shorter time on the treadmill. They had a significantly higher heart rate at submaximal levels of exertion and at stage III exertion had significantly higher blood lactate concentrations. Using a Borg score, they showed a significantly altered perception of their degree of physical exertion with a mean score of 8.2 compared with 6.6 and 5.3 for the normal subjects and patients with the irritable bowel syndrome respectively. Using a visual analogue scale they indicated that they had a greater capacity for activity before illness than had the patients with the irritable bowel syndrome, but the scores were not significantly different between the two groups. Both groups of patients indicated reduced activity at the time of testing. Normal controls and patients with the irritable bowel syndrome aspired to a greater level of activity than their current level, but the patients with the chronic fatigue syndrome aspired to a level similar to that which they had had before their illness. CONCLUSIONS--Patients with the chronic fatigue syndrome have reduced aerobic work capacity compared with normal subjects and patients with the irritable bowel syndrome. They also have an altered perception of their degree of exertion and their premorbid level of physical activity.

Rosen SD, King JC, Wilkinson JB, Nixon PG.	Department of Cardiology, Charing Cross Hospital, London.	Is chronic fatigue syndrome synonymous with effort syndrome?	J R Soc Med 1990 Dec;83(12):761-4	Chronic fatigue syndrome (CFS), including myalgic encephalomyelitis (ME) and postviral syndrome (PVS), is a term used today to describe a condition of incapacity for making and sustaining effort, associated with a wide range of symptoms. None of the reviews of CFS has provided a proper consideration of the effort syndrome caused by chronic habitual hyperventilation. In 100 consecutive patients, whose CFS had been attributed to ME or PVS, the time course of their illness and the respiratory psychophysiological studies were characteristic of chronic habitual hyperventilation in 93. It is suggested that the labels 'CFS', 'ME' or 'PVS' should be withheld until chronic habitual hyperventilation - for which conventional rehabilitation is available - has been definitively excluded.

Sawyer MH, Webb DE, Balow JE, Straus SE.	Medical Virology Section, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland.	Acyclovir-induced renal failure. Clinical course and histology.	Am J Med 1988 Jun;84(6):1067-71	Four patients with a chronic fatigue syndrome experienced five episodes of acute renal insufficiency associated with high-dose (500 mg/m2) intravenous acyclovir administered intravenously as one-hour infusions. Nephrotoxicity developed despite precautions to avoid volume contraction. Examination of the urinary sediment of three patients by polarizing microscopy showed birefringent needle-shaped crystals within leukocytes. In the most severely affected patient, a serum creatinine concentration of 8.6 mg/dl developed and the patient underwent percutaneous renal biopsy that revealed foci of interstitial inflammation without tubular necrosis. Urine, blood, and renal tissue levels of acyclovir were high. One patient was rechallenged with low-dose intravenous acyclovir and the four patients later received oral acyclovir, all without adverse effect. The combined data from these patients support crystalluria and obstructive nephropathy as a mechanism of acyclovir-induced renal failure in humans. This experience emphasizes the importance of maintaining adequate hydration during high-dose acyclovir therapy.

Shahar E, Lederer J.	Department of Family Medicine, Sackler School of Medicine, Tel-Aviv University, Israel.	Asthenic symptoms in a rural family practice. Epidemiologic characteristics and a proposed classification.	J Fam Pract 1990 Sep;31(3):257-61; discussion 261-2 comment in: J Fam Pract. 1991 Jan;32(1):14	Asthenic symptoms (eg, fatigue, lassitude, weakness) are of major concern in family practice setting, yet relatively little research has addressed this issue. A retrospective chart review over a 10-year period was conducted to better characterize these symptoms in a rural family practice providing health care to 508 adult patients. Asthenic complaints were recorded at least once in the medical charts of 164 patients (32%) with a preponderance of female patients. Peak prevalence occurred in the third decade of age and during the summer months. Associated symptoms, mainly pain and dizziness, were reported in 75% of the cases. A cause or diagnosis was not identified by the practicing physician in nearly 50% of the encounters; nevertheless, most episodes resolved spontaneously. Patients could be subclassified into three categories according to the recurrence pattern of their asthenic symptoms during the study period. The largest category (64%) included patients who had a single or two episodes and was thus termed "episodic asthenia." Forty-five patients (27%) with recurrent

				episodes (mean 4.4, range 3 to 10) were classified as having "recurrent episodic asthenia." A third small group (14 patients, 9%) with persistent complaints over the years but no evidence of the chronic fatigue syndrome were classified as having "chronic persistent asthenia." The proposed classification may help future research of asthenic symptoms in the family practice setting.

Spracklen FH.	Department of Medicine, University of Cape Town.	The chronic fatigue syndrome (myalgic encephalomyelitis)--myth or mystery?	S Afr Med J 1988 Nov 5;74(9):448-52	The chronic fatigue syndrome (CFS) or myalgic encephalomyelitis has caused great confusion, misunderstanding and perhaps even mismanagement of many persons presenting with a variety of combinations of ill-defined complaints. The history, possible pathogenesis and clinical features, of what is probably in most instances a post-viral infection syndrome, are reviewed. The recent Centers for Disease Control case definition is summarised and simplified. The need for such uniformity of definition, acceptable to most workers in the field, is emphasised in order to facilitate further studies into the cause, diagnosis, course and treatment of CFS. The difficulty in treating this condition and the currently recommended management are described. Double-blind controlled studies are essential in assessing any proposed new treatment.

Straus SE, Dale JK, Tobi M, Lawley T, Preble O, Blaese RM, Hallahan C, Henle W.	Medical Virology Section, National Institute of Allergy and Infectious Diseases, Bethesda, Md 20892.	Acyclovir treatment of the chronic fatigue syndrome. Lack of efficacy in a placebo-controlled trial.	N Engl J Med 1988 Dec 29;319(26):1692-8	Twenty-seven adults with a diagnosis of the chronic fatigue syndrome were enrolled in a double-blind, placebo-controlled study of acyclovir therapy. The patients had had debilitating fatigue for an average of 6.8 years, accompanied by persisting antibodies to Epstein-Barr virus early antigens (titers greater than or equal to 1:40) or undetectable levels of antibodies to Epstein-Barr virus nuclear antigens (titers less than 1:2) or both. Each course of treatment consisted of intravenous placebo or acyclovir (500 mg per square meter of body-surface area) administered every eight hours for seven days. The same drug was then given orally for 30 days (acyclovir, 800 mg four times daily). There were six-week observation periods before, between, and after the treatments. Three patients had acyclovir-induced nephrotoxicity and were withdrawn from the study. Of the 24 patients who completed the trial, similar numbers improved with acyclovir therapy and with placebo (11 and 10, respectively). Neither acyclovir treatment nor clinical improvement correlated with alterations in laboratory findings, including titers of antibody to Epstein-Barr virus or levels of circulating immune complexes or of leukocyte 2',5'-oligoadenylate synthetase. Subjective

				improvement correlated with various measures of mood. We conclude that acyclovir, as used in this study, does not ameliorate the chronic fatigue syndrome. We believe that the clinical improvement observed in most patients reflected either spontaneous remission of the syndrome or a placebo effect.
Straus SE, Dale JK, Wright R, Metcalfe DD.	Medical Virology Section, National Institute of Allergy and Infectious Diseases, Bethesda, MD 20892.	Allergy and the chronic fatigue syndrome.	J Allergy Clin Immunol 1988 May;81(5 Pt 1):791-5	The chronic fatigue syndrome is a heterogeneous disorder characterized by easy fatigability, feverishness, diffuse pains, and depression. Many patients also report inhalant, food, or drug allergies. This article reviews the clinical features of the syndrome and hypotheses of its pathogenesis, especially those regarding the Epstein-Barr virus and cellular immune mechanisms. Also summarized are recent studies of the validity of atopic complaints in the syndrome. The results of epicutaneous skin testing demonstrated a high correlation with history in 24 patients. Atopy coexists with the chronic fatigue syndrome in greater than 50% of patients.

A model is outlined of an acute illness giving way to a chronic fatigue state in which symptoms are perpetuated by a cycle of inactivity, deterioration in exercise tolerance and further symptoms. This is compounded by the depressive illness that is often part of the syndrome. The result is a self-perpetuating cycle of exercise avoidance. Effective treatment depends upon an understanding of the interaction between physical and psychological factors. Cognitive behavioural therapy is suggested. Cognitive therapy helps the patient understand how genuine symptoms arise from the frequent combination of physical inactivity and depression, rather than continuing infection, while a behavioural approach enables the treatment of avoidance behaviour and a gradual return to normal physical activity.

Bell EJ, McCartney RA.		A study of Coxsackie B virus infections, 1972-1983.	J Hyg (Lond) 1984 Oct;93(2):197–203	The results of a twelve-year study of Coxsackie B virus (CBV) infections in patients with a variety of acute and chronic illnesses are reported. CBVs were isolated from only 123 patients most of whom were children with respiratory illness. Virus diagnosis in adults was based mainly on the detection of significant rising or static high neutralizing antibody titres. Between 1972 and 1979 most investigations centred on patients with suspected viral heart disease, 12% of whom were found to have diagnostically significant CBV titres. In studies on patients with definite myo-pericarditis the number positive increased to 33%. In 1980 clinical interest switched to the possible role of CBV in myalgic encephalomyelitis (ME), an illness of diverse symptomatology. Investigation of suspected cases of ME in 1983 showed that 16% were serologically positive compared to 4% of normal adults in the West of Scotland. In patients with well-documented ME this figure rose to 41%. The demand by clinicians for CBV neutralizing antibody tests has increased over the past twelve years and continues to escalate annually, especially in patients with chronic relapsing illness.

Buchwald D, Sullivan JL, Komaroff AL.		Frequency of 'chronic active Epstein-Barr virus infection' in a general medical practice.	JAMA 1987 May 1;257(17):2303–7	Twenty-one percent of 500 unselected patients, aged 17 to 50 years, seeking primary care for any reason were found to be suffering from a chronic fatigue syndrome consistent with "chronic active Epstein-Barr virus (EBV) infection," They had been experiencing "severe" fatigue, usually cyclic, for a median of 16 months (range, six to 458 months), associated with sore throat, myalgias, or headaches; 45% of the patients were periodically bedridden; and 25% to 73% reported recurrent cervical adenopathy, paresthesias, arthralgias, and difficulty in concentrating or sleeping. The patients had no recognized chronic "physical" illness and were not receiving psychiatric care. While antibody titers to several EBV-specific antigens were higher in patients than in age- and sex-matched controls subjects, the differences generally were not statistically significant. A chronic fatigue syndrome consistent with the chronic active EBV infection syndrome was prevalent in our primary care practice. However, our data offer no evidence that EBV is causally related to the syndrome. Indeed, we feel that among unselected patients seen in a general medical practice currently available EBV serologic test results must be interpreted with great caution.
Byrne E, Trounce I, Dennett X.		Chronic relapsing myalgia (?Post viral): clinical, histological, and biochemical studies.	Aust N Z J Med 1985 Jun;15(3):305–8	Two patients with persistent myalgia characterised by onset after an ill-defined systemic illness, marked fluctuations in the severity of the symptoms, and normal neuromuscular examination with the exception of variable muscle tenderness on deep palpation, may have a forme fruste of myalgic encephalomyelitis. Differentiation from psychogenic muscle pain is important in management. Muscle histology revealed non-specific Type II fibre atrophy. Mitochondrial respiration was assayed polarographically in intact organelles in vitro and revealed a mild depression of State 3 respiration rates with Site I and Site II substrates.
Caligiuri M, Murray C, Buchwald D, Levine H, Cheney P, Peterson D, Komaroff AL, Ritz J.	Division of Tumor Immunology, Dana-Farber Cancer Institute, Boston, MA, USA.	Phenotypic and functional deficiency of natural killer cells in patients with chronic fatigue syndrome.	J Immunol 1987 Nov 15;139(10):3306–13	Natural killer (NK)3 cells are large granular lymphocytes that appear to play a significant role in the host's defense against viral infection. We performed an extensive phenotypic and functional characterization of NK cells on 41 patients with the chronic fatigue syndrome (CFS), or "chronic active Epstein-Barr virus infection" syndrome, and on 23 age- and sex-matched asymptomatic control subjects in an attempt to further characterize this illness. These studies demonstrated that a majority of patients with CFS have low numbers of

				NKH1+T3- lymphocytes, a population that represents the great majority of NK cells in normal individuals. CFS patients had normal numbers of NKH1+T3+ lymphocytes, a population that represents a relatively small fraction of NK cells in normal individuals. When tested for cytotoxicity against a variety of different target cells, patients with CFS consistently demonstrated low levels of killing. After activation of cytolytic activity with recombinant interleukin 2, patients were able to display increased killing against K562 but most patients remained unable to lyse Epstein-Barr virus-infected B cell targets. Additional cytotoxicity experiments were carried out utilizing anti-T3 monoclonal antibody to block killing by NKH1+T3+ cells. These experiments indicated that the NK cell that appears to be responsible for much of the functional activity remaining in patients with CFS belongs to the NKH1+T3+ subset, which under normal circumstances represents only approximately 20% of the NK cell population.

Maurizi CP.		Raphe nucleus encephalopathy (myalgic encephalomyelitis, epidemic neuromyasthenia).	Med Hypotheses 1985 Apr;16(4):351–4	An injury to the dorsal raphe nucleus by Coxsackie B viruses is suggested as the cause of the disease sometimes called myalgic encephalomyelitis. The signs and symptoms are consistent with a serotonin deficiency in the dorsal raphe nucleus and the disease has a predisposition for women in nursing. Stress and underlying tryptophan deficiencies are considered as contributory factors.
May PG, Donnan SP, Ashton JR, Ogilvie MM, Rolles CJ.		Personality and medical perception in benign myalgic encephalomyelitis.	Lancet 1980 Nov 22;2(8204):1122–4	In an outbreak of benign myalgic encephalomyelitis in a girls' school all the residential pupils, both those affected and those unaffected, were investigated. Special virological tests were essentially negative, but it seemed that a few girls had had a viral infection. Psychological testing showed that among younger girls the patients were more neurotic than the others. Girls with various disorders were found to have been classified as having the same disorder, because of what has been called altered medical perception. The conclusions of an international symposium on this condition were not substantiated.
McCartney RA, Banatvala JE, Bell EJ.		Routine use of mu-antibody-capture ELISA for the serological diagnosis of Coxsackie B virus infections.	J Med Virol 1986 Jul;19(3):205–12	The role of coxsackie B viruses (CBV) in myo/pericarditis has been well documented; however, interpretation of static high neutralising antibody titres in individual patients has always been difficult. In introducing the mu-antibody capture ELISA test for the detection of CBV-specific IgM, we hoped to overcome this problem. A regimen for the routine serological diagnosis of CBV infections was introduced, using the CBV IgM ELISA as a screening test, followed by neutralisation tests (NT) to confirm the positive results. Seven hundred and sixty patients and 304 healthy adult controls were tested. The percentage CBV IgM positive in each of the clinical categories myo/pericarditis (33%) chest pain (22%), myalgic encephalomyelitis (31%), myalgia/Bornholm (19%) and controls (9%) was similar to those found in previous studies using NT alone. Cross-reactions with other enteroviruses, including hepatitis A (Enterovirus 72), were observed but did not prove to be a problem in the illness studied, since most involved adults. Both homotypic and heterotypic CBV IgM responses were found. Matching IgM and NT indicated a recent CBV infection. Positive IgM with negative NT titres suggested a recent infection with an enterovirus other than a CBV.

Pampiglione G, Harris R, Kennedy J.		Electro-encephalographic investigations in myalgic encephalomyelitis.	Postgrad Med J 1978 Nov;54(637):752–4	The main EEG features are described of thirty-six young adults who were examined at the Royal Free Hospital between 1960 and 1964 and twelve children seen at the Hospital for Sick Children, Great Ormond Street, London, between 1957 and 1977. It is important in the future, if a plan is considered for the study of a fresh epidemic, to include systematic EEG studies covering a period of 2 to 3 years. The EEG alterations found in this limited survey, though modest, would suggest that cerebral function was disturbed with somewhat variable distribution by an insidious illness which has not yet been identified.

Ramsay AM, Rundle A.		Clinical and biochemical findings in ten patients with benign myalgic encephalomyelitis.	Postgrad Med J 1979 Dec;55(654):856–7	Ten patients in whom the clinical findings were consistent with the syndrome variously described as ‘benign myalgic encephalomyelitis’, ‘epidemic neuromyasthenia’, ‘Royal Free disease’ and ‘Icelandic disease’ were investigated for blood levels of myoglobin and various enzymes. Although there is no clinical resemblance between the two diseases, the biochemical pattern bears a close similarity to that found in Duchenne muscular dystrophy (DMD) though differing sharply in that no rise in creatinine kinase levels was found. These findings are discussed with particular reference to recent suggestions that the permeability of cell membranes may be impaired by changes in intracellular energy mechanisms.

Rowlandson PH, Stephens JA.		Cutaneous reflex responses recorded in children with various neurological disorders.	Dev Med Child Neurol 1985 Aug;27(4):434–47	Cutaneous reflex responses were recorded from tibialis anterior or first dorsal interosseous muscles of children with hemiplegia, spinal-cord compression, necrotizing sacroid granulomatosis, acute encephalomyelitis, myalgic encephalomyelitis, and a group of children attending the Learning Difficulties Clinic. Abnormalities of response are reported and are compared with the different reports in the literature of abnormal reflex EMG responses recorded by various methods. It is concluded that cutaneo-muscular reflex testing may have a part to play in the diagnosis of difficult paediatric problems
Simpson LO, Shand BI, Olds RJ.		Blood rheology and myalgic encephalomyelitis: a pilot study.	Pathology 1986 Apr;18(2):190–2	The blood rheology of EDTA-anticoagulated blood samples from blood donors and subjects considered to have myalgic encephalomyelitis was assessed by multiple shear rate viscometry and by multiple-pressure filterability. Although average viscosities of the two groups were different, the differences did not reach statistical significance. In contrast, the data from multiple-pressure filtration of whole blood showed significant differences between females at the lowest (2.5 cm of water) filtration pressure. It appears that the acute phase of the disorder is associated with changes in blood rheology which could impair microcirculatory blood flow. In contrast, the chronic state does not appear to be associated with rheological abnormalities.

Taerk GS, Toner BB, Salit IE, Garfinkel PE, Ozersky S.		Depression in patients with neuromyasthenia (benign myalgic encephalomyelitis).	Int J Psychiatry Med 1987;17(1):49–56	Neuromyasthenia (benign myalgic encephalomyelitis) is a term used to describe a protracted and incomplete recovery phase following viral-like illnesses. There are few significant physical findings or abnormal laboratory determinations. Although depressive symptoms have been observed in individuals with neuromyasthenia, systematic psychological investigations based on a standardized interview technique have not been reported. This study was designed to investigate the prevalence of psychiatric disorders and psychiatric symptoms in a group of patients presenting with neuromyasthenia. The study consisted of three parts: a structured psychiatric interview (The National Institute of Mental Health Diagnostic Interview Schedule), a self-report measure (The Beck Depression Inventory) and Dexamethasone Suppression Test. Results indicated that relative to a matched comparison group of non-clinical volunteers, a significant percentage (67%) of neuromyasthenic patients met criteria for major depression. Even more striking was the observation that 50 percent of the sample had a

				major depressive episode prior to the development of neuromyasthenia. These findings suggest that sporadic neuromyasthenia may be the result of an organic illness in psychologically susceptible individuals.
